Learning Objectives/Aims

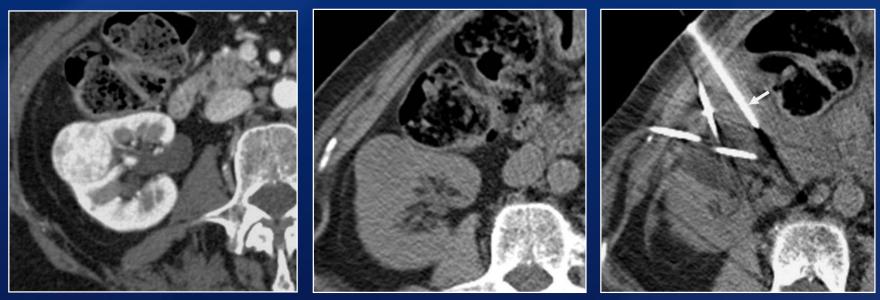

- Summarize key adjunctive imaging and procedural techniques available to assist radiologists when performing percutaneous ablations involving challenging gastrointestinal and genitourinary tumors.
- After reviewing this exhibit the participant should have increased confidence to utilize various adjunctive techniques to aid in performing percutaneous ablations.

Background

- Percutaneous tumor ablation gaining acceptance as a minimally invasive treatment for the management of liver, kidney, prostate and adrenal tumors.
- As the popularity of these procedures increases, so have the recognized challenges of treatment and complications.
- Over recent years, several techniques have been described to improve patient safety and outcomes.
- Tumor locations that were previously considered highrisk, in close proximity to vital structures, are now more accessible and amenable to ablation with satisfactory clinical outcomes.

Displacement - Fluid

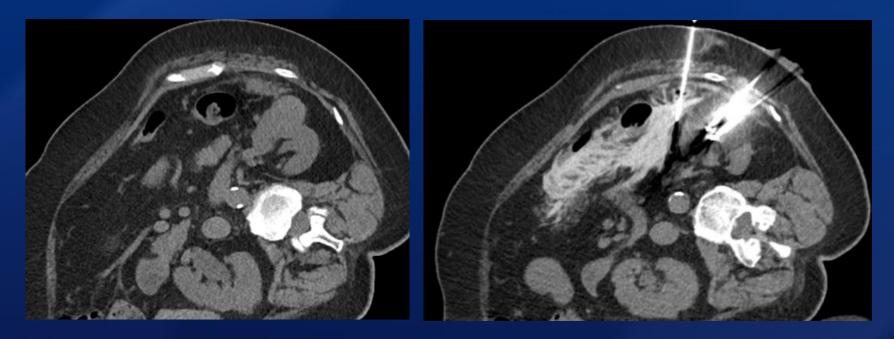

Key adjunctive technique in percutaneous ablation.

Hydro displacement is the single most important technique which can expand the number of tumors that can be safely treated.

Infusion of sterile fluid (saline or D5W) via needle or catheter in order to displace adjacent critical structure and prevent ablation of non target structures. In the case shown, sterile saline has been instilled to displace colon away from target renal tumor allowing safe growth of ice ball during freeze cycles.

Displacement - Fluid

Key adjunctive technique in percutaneous ablation.

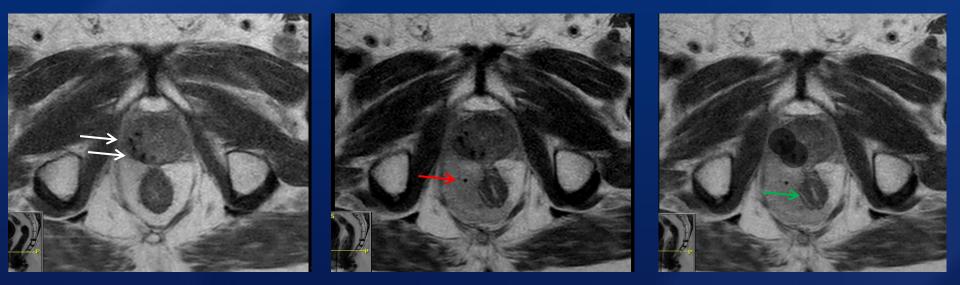

Contrast doped hydrodisplacement fluid :

TLINIC

Non-ionic or ionic contrast media can be added to the sterile infusion fluid prior to injection with suggested optimal ratio of 1:50 / 2 %. This can provided added visualization of adjacent bowel or solid organs.

Campbell c, et al. Contrast media-doped hydrodissection during thermal ablation: optimizing contrast media concentration for improved visibility on CT images. AJR 2012;199:677-82.

Displacement - Fluid

Key adjunctive technique in percutaneous ablation.

Hydrodisplacement fluid is also well visualized during MRI guided ablation procedures. In the case shown, after probe placement into right prostatic tumor (white arrows), a catheter was placed in the right perirectal space (red arrow) and sterile saline instilled to displace rectum (green arrow) prior to commencing freeze cycles.

Pre ablation tumor embolization

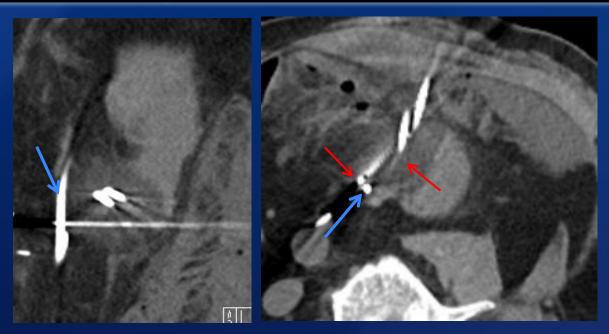

Decrease post ablation bleeding

- Performance of prophylactic trans-arterial embolization prior to cryoablation of large renal cell carcinomas (>5cm) decreases bleeding complications without a discernible effect on renal function or recurrence rate.
- Balance with underlying renal function, coronary artery disease, need for anticoagulation cessation / bridging.
- Typically performed 24 hours prior to ablation
- Coils preferred over particles, although combination of both is reasonable.

Retrograde pyeloperfusion

Case example: Localised RCC recurrence post partial nephrectomy, with two RCC nodules (red arrows) adjacent to PUJ and ureter (green arrows). Externalized ureteral stent (blue arrow).

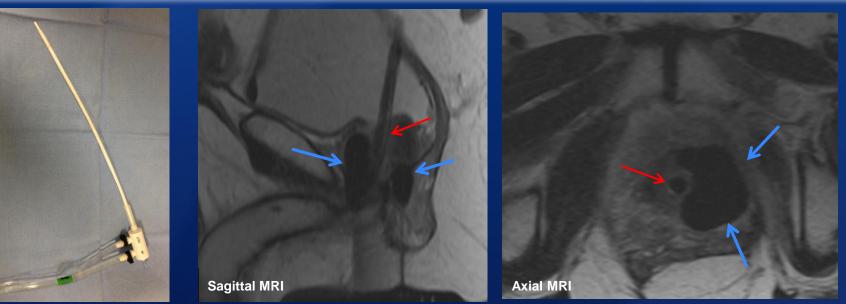

Ureteric / PUJ protection

MAYO CLINIC

- Ablation performed close to the ureter may result in ureteral injury and subsequent stricture formation
- Intraprocedural ureteric /PUJ protection Infuse sterile fluid retrogradely via an externalized ureteral stent.
- Stent internalization for 6 weeks if ice ball encases the ureter.
- Now >900 renal ablations with no ureteral strictures with this technique.

Cantwell, et al. Protecting the ureter during radiofrequency ablation of renal cancer: a pilot study of retrograde pyeloperfusion with cooled dextrose 5% in water. JVIR 2008;19:1034-40

Protective urethral warming catheter

Urethral protection

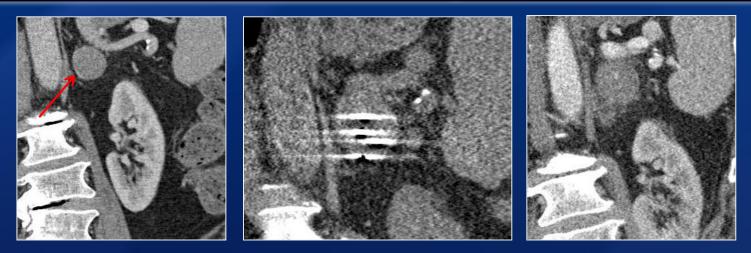

MAYO

- During prostate cryoablation a protective warming catheter (red arrows) is placed via the urethra into the bladder prior to commencing freeze cycles.
- Continuous warmed fluid circulates via the closed-loop continuous-flow temperature-controlled urethral catheter during cryoablation to minimize injury of urethral tissue from adjacent ice ball (blue arrows)
- Significantly decreases risk of secondary urethral injury related to epithelial sloughing.

Favazza CP, et al . An investigation of the effects from a urethral warming system on temperature distributions during cryoablation treatment of the prostate: A phantom study. *Cryobiology*. 2014;69(1):128-133.

Cohen JK, Miller RJ, Shuman BA. Urethral warming catheter for use during cryoablation of the prostate. Urology. 1995;45(5):861-864.

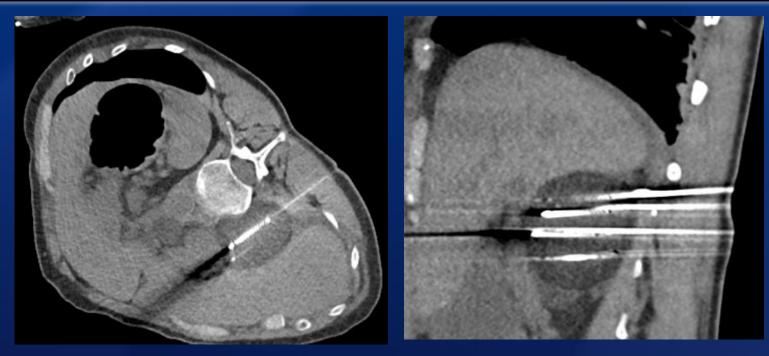

Adrenal - Adrenergic blockade

- Ablation of tumors involving the adrenal gland has been associated with profound blood pressure fluctuations including hypertensive crisis.
- Pre-ablation α-blockade can decrease the severity of the hypertensive episode, at the expense of higher need for vasopressors periprocedurally.
- Premedication with alpha-blockade should be considered in most patients.
- Phenoxybenzamine can be titrated 10 days prior to treatment. Doxazosin is an alternative medication that can be used with potential cost savings.

Adrenal – Blood pressure

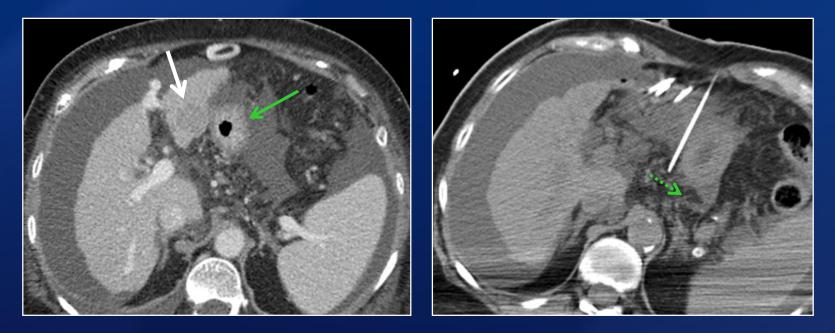

- Intra procedural hemodynamic changes can occur either from direct or indirect ablation of the adrenal gland, particularly during the thawing phase of any freeze cycle.
- Arterial lines are used to preemptively manage any severe hypertensive episode by aggressively monitoring the arterial blood pressure during ablation
- Close interaction with anesthesia colleagues during procedure is essential, as is rapid availability of relevant IV antihypertensive / pressor agents

MAYO CLINIC

Displacement – Lever Technique

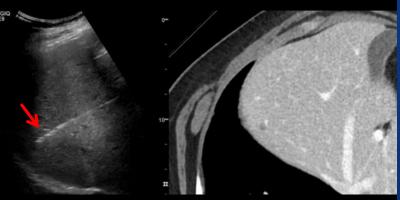

- Stomach can be difficult to displace using standard fluid hydro displacement
- Ablation probe can be used as a lever to displace stomach from liver tumor using site of skin entry as a fulcrum. After gently torqueing the handle medially, the stomach moves laterally, increasing distance from the ablation zone.

US Fusion

US/CT fused image – showing placement of MW antenna (red arrow) into small CRC liver metastasis

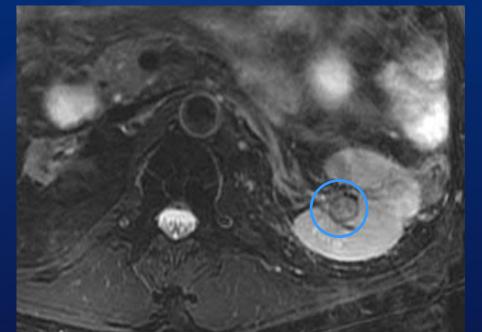

Advantages of Fusion Imaging

- Expansion of ablation cases
- Target tumors with poor US or CT visualization
- Real time imaging and probe placement
- Out of axial plane probe placement
- Treat tumors in difficult locations
- Improved operator confidence
- Improved accuracy of device placement

US Fusion Techniques

Treatment of tumors in difficult locations

Ax MRI T2 fat sat Ax MRI T1 contrast Case example : Central renal mass ablation—solitary kidney Preablation Creatinine = 2.9 mg/dL

US Fusion techniques

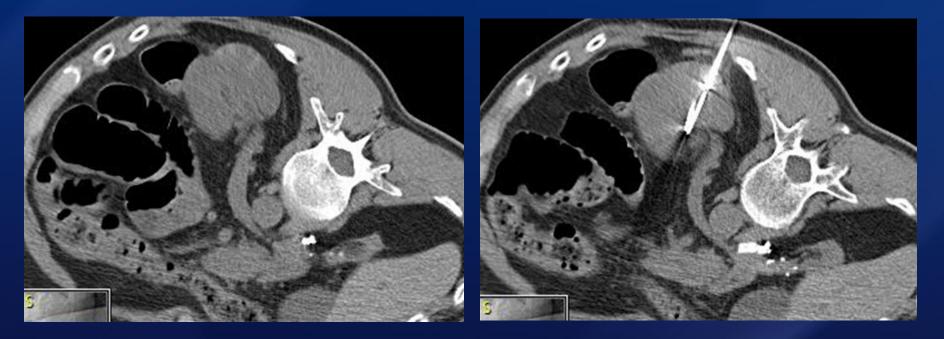

Central renal mass ablation—solitary kidney

- Confidence increased with US-MRI fusion
- Safe probe placement into mass under US fusion guidance

US Fusion Techniques

Central renal mass ablation—solitary kidney

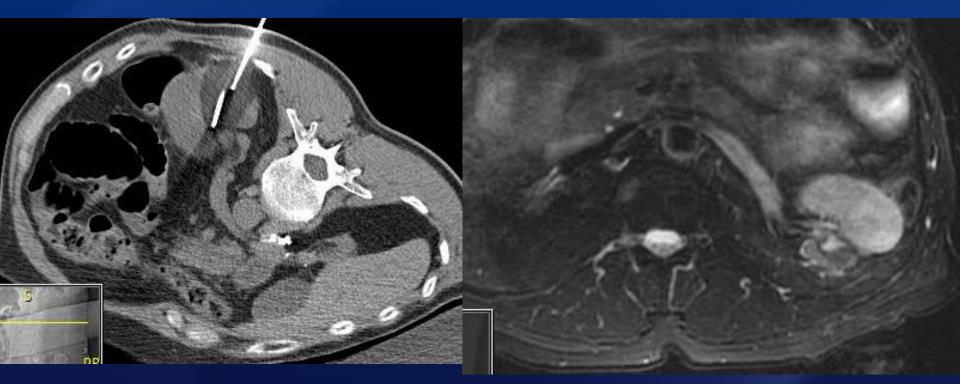

Pre ablation CT

Post probe placement

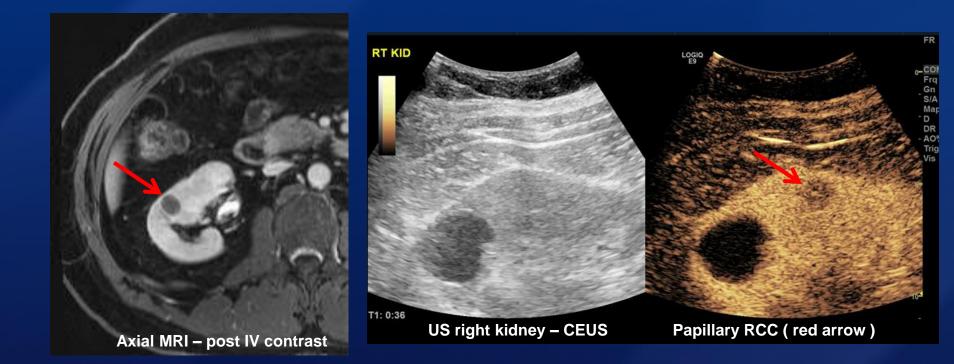

US Fusion Techniques

Central renal mass ablation—solitary kidney

CryoablationT2 MRI : local tumor controlCreatinine = $2.9 \rightarrow 3.1 \text{ mg/dL post ablation}$

Contrast-enhanced ultrasound

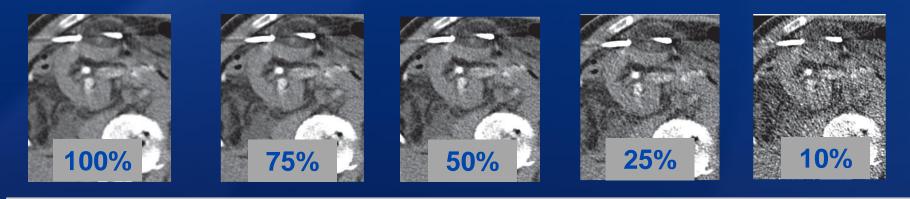

Technique can be performed for lesions that are poorly visualized on conventional US in order to guide ablation probe placement.

Contrast-enhanced ultrasound (CEUS) involves the administration of intravenous contrast agents containing microbubbles of perfluorocarbon or nitrogen gas. The bubbles affect ultrasound backscatter and increase vascular contrast in a similar manner to intravenous contrast agents used in CT and MRI.

CT – Tube current modulation

% Dose

- Cryoablation has been associated with considerable radiation exposure during treatment. This needs to be considered as the technique is incorporated into mainstream oncologic treatment algorithms.
- Without compromising the clinical outcome, the smallest radiation dose should be used to guide and monitor ablation.
- It has been shown that reduction of mAs by 25-50% results in image quality sufficient to effectively monitor cryoablation.

Summary

After reviewing this exhibit, the participant should be able to appreciate important adjunctive techniques related to tumor ablation:

Procedural techniques:

- hydrodisplacement and other mechanical displacement maneuvers
- ureteral stents to protect collecting system
- Urethral warming catheter to minimize urethral injury
- selective embolization to minimize bleeding
- alpha blockade for adrenal ablation

Imaging techniques:

- ultrasound-fusion imaging for lesion localization
- contrast-enhanced ultrasound to identify index lesion(s)
- manual dose reduction during CT monitoring
