Background

- In patients with advanced non-small-cell lung cancer (aNSCLC), accurate / accessible epidermal growth factor receptor (*EGFR*) mutation testing is important to guide treatment decisions^{1,2}
- Activating *EGFR* mutations in patients with NSCLC is associated with female gender, Asian ethnicity, never-smokers and tumours of adenocarcinoma (ADC) histology³
- Mutation testing is commonly performed using tumour biopsy or cytology samples; however, a proportion of patients do not have a suitable sample available for testing
- The large, multicentre, interventional, non-comparative IGNITE diagnostic study (NCT01788163) will assess the current status of *EGFR* mutation testing in patients with locally advanced or metastatic NSCLC of ADC / non-ADC histology in a real-world setting (Asia-Pacific [AsiaPac] and Russia)

¹NCCN 2012; ²NICE 2013; ³Dearden et al. 2013

Study design

Patients were enrolled from China (n=1458), Russia (n=972), Indonesia (n=302), Taiwan (n=271), Singapore (n=102), Thailand (n=94), Australia (n=71), South Korea (n=62) and Malaysia (n=50)

Patients

- Patients with newly diagnosed, locally advanced / metastatic chemotherapy-naïve NSCLC not suitable for curative treatment (including surgery and chemoradiotherapy) or
- Recurrent disease after surgical resection with / without adjuvant chemotherapy

Objectives

To determine:

- *EGFR* mutation frequency (ADC and non-ADC histology) [primary endpoint]
- Concordance between *EGFR* mutation status obtained via tissue / cytology and blood (plasma)-based testing
- Correlations between *EGFR* mutation status and demographic data / disease status
- *EGFR* mutation testing practices
- Treatment decisions following *EGFR* mutation testing

Statistical analysis

- Sample size: 2500 patients from AsiaPac / 1000 patients from Russia needed to be tested to give similar precision of ADC and non-ADC mutation frequency estimate
- Descriptive summary statistics described *EGFR* mutation frequency, sampling / mutation testing methodologies and treatment decisions
- Concordance rate of *EGFR* mutation status between matched tissue / cytology and plasma samples, pooled test sensitivity, specificity, PPV and NPV; exact 2-sided 95% CIs
- Correlation between *EGFR* mutation status and demographic / disease data analysed with multivariate logistic regression model of *EGFR* mutation status at baseline

CI, confidence interval; NPV, negative predictive value; PPV, positive predictive value; WHO, World Health Organization
Summary statistics collated for evaluable populations (all patients with known tumour [tissue / cytology] and / or plasma sample *EGFR* mutation status)

Correlations between *EGFR* mutation status and demographic / disease status

- Multivariate regression analyses indicated that:
 - ADC histology, never-smoking status, Asian ethnicity significantly correlated with *EGFR* mutation-positive tissue / cytology and plasma sample (all $p < 0.01$)
 - female gender significantly correlated with *EGFR* mutation-positive tissue / cytology sample ($p = 0.0075$)
 - an association was also seen between plasma *EGFR* mutation and increasing number of metastases ($p < 0.0001$) and being aged ≤ 65 years ($p = 0.0009$)

Conclusions

- IGNITE is the largest, multicentre real-world observational study of *EGFR* mutation frequency in patients with NSCLC of ADC and non-ADC histologies
- IGNITE further confirms that ADC histology, never-smoking status and Asian ethnicity are significantly correlated with *EGFR* mutation-positive status
- Plasma ctDNA may be used for patients whose tumour sample is not available / evaluable to determine *EGFR* mutation status for patients from AsiaPac
- Investigation of Russian concordance data is ongoing
- *EGFR* mutation status and histology data indicate that *EGFR* mutation testing should be considered in patients with NSCLC of ADC and non-ADC histology

Sampling methodologies

Tissue / cytology

The majority of tissue / cytology samples were:

- obtained during **current diagnosis** (AsiaPac 93.7%, Russia 74.1%)
- derived from the **primary tumour** (AsiaPac 67.1%, Russia 80.3%)
- sampled from the **lung / lymph nodes** (AsiaPac 68.3%, Russia 79.8% / AsiaPac 14.1%, Russia 10.2%)
- collected via **bronchoscopy** (AsiaPac 22.4%, Russia 44.9%)

Tissue / cytology samples were predominantly stored as **FFPE tissue blocks** (AsiaPac 74.6%, Russia 91.2%) and fixed with **10% neutral buffered formalin** (AsiaPac 74.4%, Russia 84.4%)

- Mutation tests not performed on the tissue / cytology samples of 262 patients
- Most common reason for not testing was insufficient material provided for the test (AsiaPac 84.0%, Russia 50.0%)

FFPE, formalin-fixed paraffin embedded
