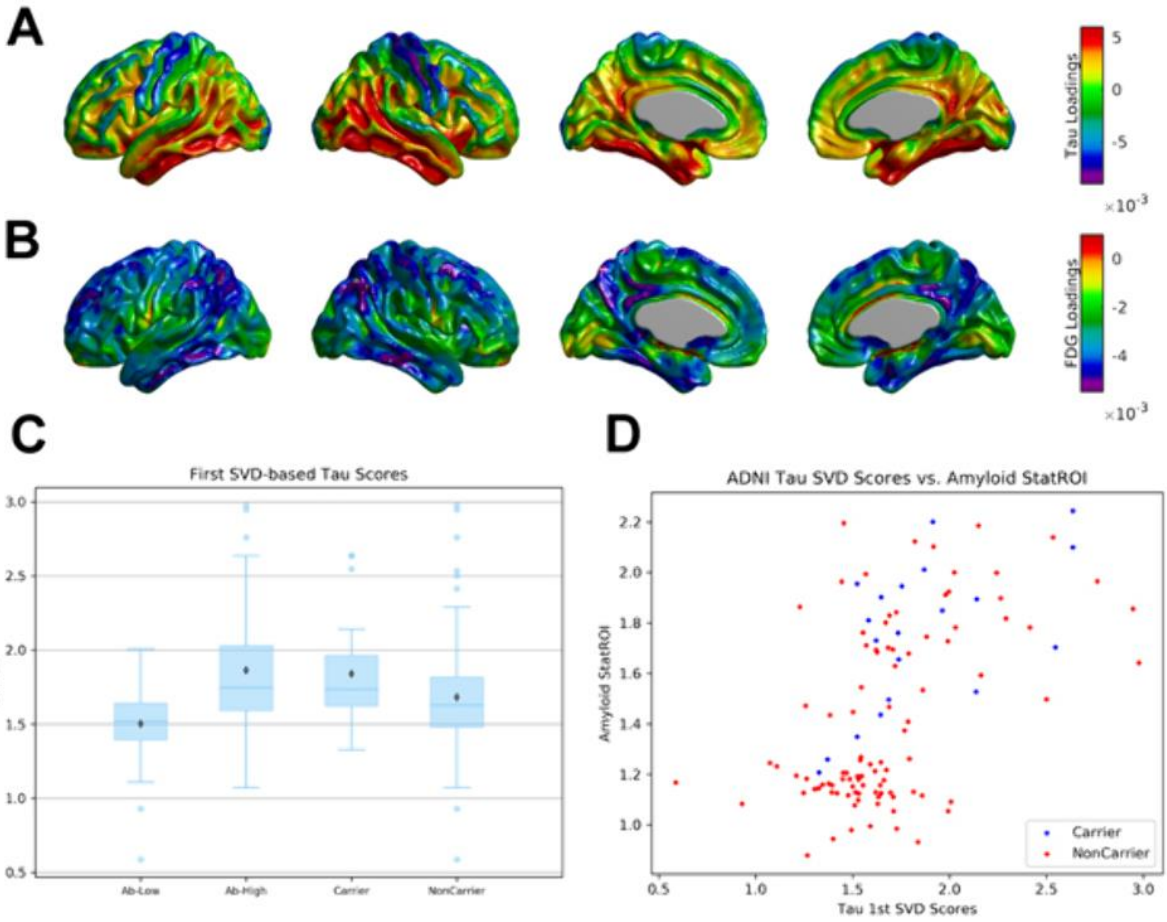
TAU IS ASSOCIATED WITH REDUCED CEREBRAL GLUCOSE METABOLISM IN MCI INDEPENDENTLY OF BETA-AMYLOID AND APOEE4 GENOTYPE

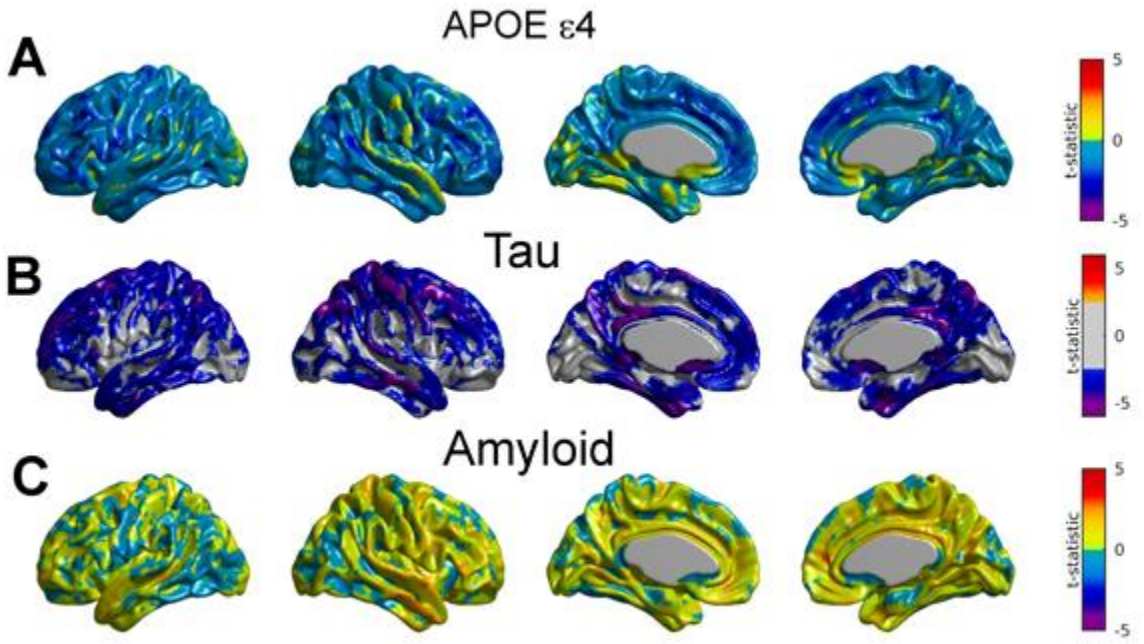
POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Felix Carbonell[1], Carolann Mcnicoll[1], Alex Zijdenbos[2], Barry Bedell[3]
[1]Biospective Inc., Clinical, Montreal, Canada, [2]Biospective Inc., Technology, Montreal, Canada, [3]Biospective Inc., Preclinical, Montreal, Canada

Aims: It has been shown that spatially distributed scores from Amyloid PET images are significantly correlated with glucose metabolism in MCI [1]. We hypothesize that analogous Tau PET scores are associated with a stronger reduction of glucose metabolism independently of the effects of beta-amyloid and APOE e4 genotype.
Methods: Our cross-sectional statistical analysis was applied to Tau, Amyloid, and FDG PET images from MCI subjects from the ADNI study. We employed a Singular Value Decomposition (SVD) approach to the cross-correlation matrix between Tau and the FDG images, as well as between Tau and Amyloid images [1]. The resulting SVD-based individual scores were used to fit voxelwise models for assessing the effect of the SVD-based tau, amyloid scores, and APOE ε4 status on the FDG images. [1] Carbonell *et al.*, *Journal of Alzheimer's Disease* **73**, 543–557, 2020.
Results: The first SVD component accounted for 21.49% of the total co-variability between FDG and Tau datasets. Figures 1A and 1B show a surface representation of the Tau and FDG spatial loadings, respectively. Figure 1C shows box plots of the Tau SVD-based scores, which are statistically different when segregated by amyloid status and significantly correlated with StatROI measurements of amyloid SUVR taken from an AD-signature ROI (Figure
1D).



Figures 2A, 2B, and 2C show the t-statistic maps for the APOE e4, tau, and amyloid effects on FDG PET.



Conclusions: We determined that only the distributed tau scores showed extended areas of statistical significance with FDG PET. More importantly, this relationship survives after controlling for the effects of distributed beta-amyloid and APOE ε4 genotype. Our results suggest that tau is associated with reduced glucose metabolism in MCI independently of beta-amyloid burden.

AMINO-TERMINALLY ELONGATED ABETA-3-X PEPTIDES CAN BE GENERATED BY THE SECRETED METALLOPROTEASE ADAMTS4 AND DEPOSITS IN THE BRAIN OF A SUBSET OF ALZHEIMER'S DISEASE PATIENTS

POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Merle Fricke[1], Christina Lehnen[1], Hans-Wolfgang Klafki[1], Barbara Morgado[1], Sandra Lehmann[2], Carolina Münch[2], Thomas Liepold[3], Jens Wiltfang[1], Olaf Jahn[3], Sascha Weggen[2], Oliver Wirths[1]

Aims: The aggregation and deposition of amyloid-β (Aβ) peptides in the brain is thought to be the initial driver in the pathogenesis of Alzheimer's disease (AD). In addition to full-length Aβ peptides starting with an aspartate residue in position 1, both N-terminally truncated and elongated Aβ peptides are produced by various proteases from the amyloid precursor protein (APP), and have been detected in brain tissues and/or body fluids. We had demonstrated recently that the particularly abundant N-terminally-truncated Aβ4-x peptides are generated by ADAMTS4, a secreted metalloprotease that in the brain is exclusively expressed in the oligodendrocyte cell population.
Methods: We employed a previously developed electrochemical sandwich immunoassay and immuno-precipitation (IP) followed by mass spectrometry to determine Aβ-3-40 levels in the supernatants of a variety of cell lines, in addition to a detailed immunohistochemical analysis of human brain samples.
Results: In this study, we describe another ADAMTS4 cleavage site in APP N-terminal to Asp(1) between residues Glu(-4) and Val(-3), resulting in the release of N-terminally elongated Aβ-3-40 peptides, which serve as a component in a promising Aβ-based plasma biomarker assay. These elongated Aβ-3-40 peptides were detected in supernatants of various cell lines, and ADAMTS4 enzyme activity promoted the release of Aβ-3-x peptides. In addition, extracellular and vascular localization of N-terminally elongated Aβ-3-x peptides was identified in a subset of AD patient cases with immunohistochemistry. The results indicated that ADAMTS4 facilitates the generation of N-terminally elongated Aβ-3-x peptides, which were also identified in parenchymal and vascular deposits in brain samples of a subset of AD patients.
Conclusions: These findings implicate ADAMTS4 in both the pathological process of Aβ aggregation and in the early detection of amyloid pathology in AD.

ADVERSE EFFECT OF AMYLOID BETA OLIGOMERIZATION IN THE BRAIN CLEARANCE MECHANISMS

POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Jorge Ghiso[1], Erwin Cabrera[1], Tammaryn Lashley[2], Agueda Rostagno[1]
[1]New York University Grossman School of Medicine, Pathology, New York, United States of America, [2]UCL Queen Square Institute of Neurology, Department Of Neurodegenerative Disease, London, United Kingdom

Aims: The mechanisms regulating the soluble-to-fibrillar conversion of amyloid beta (Abeta), the main component of parenchymal and vascular brain deposits in Alzheimer's disease (AD), remain a topic of intense scrutiny. Impaired brain clearance and abnormal Aβ degradation are considered key events for the formation and progressive accumulation of soluble neurotoxic oligomers and the development of synaptic pathology, one of the strongest correlates to cognitive impairment in AD. Our studies aimed to provide insight into the influence of Abeta oligomerization in brain elimination.
Methods: Stereotaxic cerebral injections in C57BL/6 mice were used to evaluate the brain clearance of well-defined radiolabeled monomeric and oligomeric assemblies of the main components of the AD brain deposits including full-length as well as N- and C-terminal truncated Abeta species. Proteomic approaches in combination with immunohistochemical studies using antibodies specifically recognizing different Abeta proteoforms were employed for identification and topographic localization in AD and transgenic models.
Results: Our data demonstrate that while soluble forms exhibited fast brain removal, oligomerization increased brain retention, a characteristic particularly evident in Abeta1-42 and enhanced in fragments truncated at Phe4. Consistent with these findings, the Abeta species with lower clearance propensity were found in the most insoluble parts of brain deposits, including plaque cores, as demonstrated by mass spectrometry, and immunohistochemical studies. On the contrary, Abeta species with low oligomerization proclivity, including C-terminally truncated derivatives, were easily eliminated from the brain consistent with their common presence in the interstitial and cerebrospinal fluids.
Conclusions: Overall, our data indicate that Abeta oligomerization negatively influences brain clearance mechanisms with the potential to exacerbate amyloid formation and self-perpetuate the amyloidogenic process, issues that should not be overlooked at the time of designing therapeutic strategies for AD.

MOLECULAR BASIS OF CLINICAL ONSET IN FAMILIAL ALZHEIMER'S DISEASE.

POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Sara Gutierrez[1], Lucía Chávez-Gutiérrez[1], Nick Fox[2], Natalie Ryan[3]
[1]VIB center for brain & disease research, Laboratory Of Proteolytic Mechanisms Mediating Neurodegeneration, Leuven, Belgium, [2]University College London, Dementia Research Centre, Queen Square Institute Of Neurology, London, United Kingdom, [3]Institute of Neurology, University College London, Dementia Research Centre, London, United Kingdom

Aims: Familial Alzheimer's disease (FAD), caused by mutations in Presenilin (PSEN1/2) and Amyloid Precursor Protein (APP) genes, is associated with an early age at onset (AAO) of symptoms of dementia. AAO is relatively consistent within families and between carriers of the same mutations, but differs markedly between individuals carrying different mutations. Gaining a mechanistic understanding of why certain mutations manifest several decades earlier than others is important in elucidating the foundations of pathogenesis and clinical onset. Pathogenic mutations affect the protease (PSEN/γ-secretase) and the substrate (APP) that generate amyloid β (Aβ) peptides. Altered Aβ metabolism has long been associated with AD pathogenesis. This study aims at understanding the molecular basis of pathogenicity and clinical onset. We hypothesize that Aβ profiles arising from the destabilizing nature of the FAD-linked mutations best reflect pathogenicity and define AAO.
Methods: We investigated this central aspect of AD pathophysiology via a comprehensive analysis of 25 PSEN1 and 25 PSEN2 mutations associated with a broad range of clinical onsets. We generated MEF cell lines stably expressing only wildtype or mutant PSEN1/2 γ-secretase complexes and infected these cell lines with APPC99. Secreted Aβ peptides where measured by ELISA.
Results: Our studies show that the Aβ (37 + 38 + 40) / (42 + 43) peptide ratio linearly correlates with AAO reported for carriers of PSEN1 and PSEN2 variants, and the correlative data offer predictive value in the assessment of variants of unclear pathogenicity in these genes.
Conclusions: This study delivers data and an experimental platform for AAO assessment valuable for fundamental, clinical and genetic research. Furthermore, it supports therapeutic interventions aimed at shifting Aβ profiles towards shorter Aβ peptides.

STUDYING THE CONFORMATIONAL INTERPLAY OF DIFFERENT AMYLOID BETA PEPTIDES WITH NATIVE ION MOBILITY – MASS SPECTROMETRY

POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Tanja Habeck, Silvana Zurmühl, Edvaldo Maciel, Frederik Lermyte
Technical University of Darmstadt, Clemens-schöpf-institute For Organic Chemistry And Biochemistry, Darmstadt, Germany

Aims: Amyloid beta (Aβ) peptides contribute to the formation of plaques and accordingly neurodegeneration. Due to variations in their biological production, different Aβ peptide isoforms exist. This study explores the distinct conformations of various Aβ species using native ion mobility combined with high-resolution mass spectrometry (IMMS). Additionally, we investigated how these peptides interact when mixed in solution. IMMS allows us to detect structural variability and examine the early stages of oligomerization.
Methods: A Waters Synapt XS with travelling wave ion mobility was used in this study. Prior to measurement stock solutions of all peptides were diluted to 30 µM in a 10 mM ammonium acetate solution. To investigate the influence of Aβ isoforms on each other, these peptides were mixed in equal proportions. Furthermore, we utilized non-pathogenic scrambled sequences and a less aggregation-prone rodent variant of Aβ42 as control samples.
Results: We observed clear distinctions in IMMS behaviour among the various Aβ monomers. Our high-resolution data revealed that a signal on the m/z axis, previously attributed to overlapping oligomeric species, actually originates from a conformationally diverse dimer, without contributions from higher-order oligomers. By studying the conformations of this dimer, we were able to differentiate between isoforms with different levels of toxicity associated with their aggregation. Furthermore, we identified hetero-oligomeric species, supporting the hypothesis that interactions between Aβ peptides influence the oligomerization processes.
Conclusions: To our knowledge this is the first study of the interplay between Aβ species on the conformational level with native IMMS. Additionally, the combination of different Aβ species gives new insights into early oligomerization processes. Considering hypotheses on Alzheimer's disease pathology that assign a key role to soluble oligomers, these insights potentially provide valuable information in better understanding the disease.

3D MAPPING DELIVERY AND PLAQUE CLEARING EFFICACY OF A BBB SHUTTLE-ENHANCED ADUCANUMAB BIOSIMILAR IN A MOUSE MODEL OF ALZHEIMER'S DISEASE

POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Jacob Hecksher-Sørensen[1], Marta Ramos Vega[2], Evi Alexiou[3], Allan Jensen[4], Camilla Stampe Jensen[4], Jacob Lercke Skytte[3], Casper Graversen Salinas[3], Sandra Vergo[4], Henrik H. Hansen[2]

Aims: Accumulation of amyloid β (Aβ) in the brain is a neuropathological hallmark of Alzheimer's disease (AD). Recently approved Aβ-directed antibodies, including aducanumab, have demonstrated modest efficacy in AD, which may potentially be explained by poor blood-brain barrier (BBB) penetration. Transferrin receptor (TfR) mediated enhanced brain delivery of monoclonal antibodies across the BBB is a promising concept in drug development for CNS disorders. Using sheet fluorescence microscopy (LSFM) coupled with deep learning computational analysis, the present study aimed to visualize, map and quantify compound distribution and amyloid plaque load following long-term therapy with a BBB shuttle-enhanced Aβ-directed antibody in a mouse model of AD
Methods: APP/PS1 transgenic mice (32 ± 3 weeks of age, n=6-10 per group) were treated with an aducanumab biosimilar (AduBS, 10 or 50 nmol/kg), aducanumab biosimilar fused with a mTfR binder as BBB-shuttle (AduBS-BBB, 10 nmol/kg), control hIgG (Contr, 50 nmol/kg), or saline for 12 weeks. Whole-brains were stained with an antibody against hIgG (compound labelling) and hAβ (plaque labelling), respectively, cleared and scanned on a LSFM. A deep-learning image analysis algorithm was developed and validated for automated whole-brain visualization, segmentation, anatomical mapping and quantification of compound distribution and Aβ plaques at micrometre resolution using a custom mouse brain atlas.
Results: Both Aβ-directed antibodies, but not control hIgG, accumulated in brain areas with high Aβ plaque load, notably in cortical layers. Compared to AduBS, similar brain distribution pattern, compound fluorescent signal and Abeta plaque clearing efficacy was achieved using a five times lower dose of AduBS-BBB.
Conclusions: AduBS-BBB shows enhanced CNS accessibility and significant plaque-clearing efficacy, supporting the applicability of the TfR-shuttle concept to improve BBB penetrance of therapeutic antibodies in AD and other neurodegenerative diseases.

INHIBITION OF CU/ZN-SOD BY AB-INDUCED CO-AGGREGATION CAN BE PARTIALLY MITIGATED BY TRANSTHYRETIN

POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Jan Homolak[1], Kristina Pavic[2], Melita Salkovic-Petrisic[3,4], Ana Babić Perhoč[4]
[1]University Of Zagreb School Of Medicine, Department Of Pharmacology And Croatian Institute For Brain Research, Zagreb, Croatia, [2]University of Zagreb, Faculty Of Pharmacy And Biochemistry, Zagreb, Croatia, [3]School of Medicine University of Zagreb, Department Of Pharmacology And Croatian Institute For Brain Research, Zagreb, Croatia, [4]University of Zagreb School of Medicine, Department Of Pharmacology And Croatian Institute For Brain Research, Zagreb, Croatia

Aims: Amyloid beta (Aβ) has been found to hinder the functioning of Cu/Zn-superoxide dismutase (Cu/Zn-SOD) through mechanisms that are not yet fully understood. This inhibitory effect of Aβ on Cu/Zn-SOD could be a crucial factor in the development of neurodegenerative conditions marked by the accumulation of protein aggregates, notably Alzheimer's disease (AD) and amyotrophic lateral sclerosis (ALS), where Aβ and Cu/Zn-SOD aggregation respectively play pivotal roles. Our primary goal was to clarify the mechanisms responsible for Aβ-induced inhibition of Cu/Zn-SOD in vitro. Furthermore, we sought to examine whether the presence of transthyretin (TTR), recognized for its ability to stabilize Aβ, could influence Aβ's inhibitory effects on Cu/Zn-SOD.
Methods: Cu/Zn-SOD activity was assessed using 1,2,3-trihydroxybenzene autoxidation. Aβ-Cu/Zn-SOD binding was studied through quantitative fluorescence adhesion assays and native polyacrylamide gel electrophoresis (PAGE) mobility shift assays using both standard and fluorescently labeled substrates. Co-aggregation was analyzed using Congo red spectral shift and binding-induced fluorescence.
Results: The inhibitory influence of Aβ on Cu/Zn-SOD is modulated by factors such as its aggregation status, the presence of Cu2+ and Zn2+, as well as the incubation conditions. A higher concentration of Cu/Zn-SOD within Aβ aggregates exhibits a negative correlation with the propensity for co-aggregation. Notably, TTR mitigates Aβ aggregation and its co-aggregation with Cu/Zn-SOD, thereby mitigating Aβ's inhibitory effect on Cu/Zn-SOD.
Conclusions: Aβ and Cu/Zn-SOD exhibit a propensity to co-aggregate, resulting in reduced total superoxide radical neutralization capacity. Enhanced Cu/Zn-SOD incorporation into Aβ aggregates represents a form of "suicide inhibition" halting further amyloid aggregation at the expense of the ability to neutralize free radicals, with potential implications for AD and ALS. The role of TTR in preventing Aβ-mediated inhibition of SOD in AD warrants further exploration.

INTRANASAL DELIVERY OF THE SMOOTHENED AGONIST (SAG) ALLEVIATES ALZHEIMER'S DISEASE DEFICITS IN APPSWE/PS1DE9 MOUSE MODEL

POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Yi-Heng Hsieh, Ding-I Yang
National Yang Ming Chiao Tung University, Institute Of Brain Science, Taipei City, Taiwan

Aims: We have reported that sonic hedgehog (SHH) expression is elevated in the Alzheimer's disease (AD) transgenic mouse brain (APPswe/PS1dE9; Hung et al., 2016). Further, we found that exogenous application of SHH exerts protective effects against transient focal cerebral ischemia (Huang et al., 2013). However, whether chronic activation of SHH signaling may affect AD phenotypes *in vivo* has been less well studied. The present work was therefore conducted to test whether the smoothened agonist (SAG), a SHH pathway activator, may recover the cognitive deficits and alleviate pathological aggression to exert beneficial effects in the animal model of AD.
Methods: Wild-type (WT) littermates and APPswe/PS1dE9 (AD) mice were intranasally given SAG for 12 weeks during 7-10 months of age. Three behavioral tests including novel object recognition test, Morris water maze, and fear conditioning were performed at the completion of drug delivery. Afterwards, cortical and hippocampal tissues were collected for biochemical analyses.
Results: We found that SAG restored the abilities of recognition and spatial memory in the AD mice based on the results of all three behavioral tests. Biochemical analyses revealed that SAG recovered synaptic plasticity, alleviated caspase-3-dependent apoptosis, decreased the formation of senile plaques and soluble Aβ1-42, mitigated the microgliosis, as well as alleviated oxidative stress in the AD mice.
Conclusions: We conclude that SAG can have beneficial effects in AD mice.

MEDIATION OF THE APOE ASSOCIATIONS WITH COGNITION THROUGH ALZHEIMER'S PATHOLOGY

POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Jae-Won Jang
Kangwon National University, School Of Medicine, Chuncheon, Korea, Republic of

Aims: The ApoE ε4 allele of the apolipoprotein E (APOE) gene is a strong genetic risk factor for aging-related cognitive decline. However, the causal connection between ApoE ε4 allele and cognition is not well understood. The objective of this study was to identify the roles of Amyloid/Tau (AD pathology) in associations of APOE with cognition.
Methods: We studied mild cognitive impairment individuals from the Alzheimer's Disease Neuroimaging Initiative database The multiple linear regression analyses were conducted on 397 subjects(mean age of 71.9 years; 58.9% of female; 48.3% of APOE ε +4 allele carriers) (Table1) Serial mediation model of biomarker cascade hypotheses were performed using ApoE ε4 as predictor, CSF amyloid beta, phospho-Tau as Mediators and Cognition represented by CDR-SB across 36months as outcome adjusted by age, gender, education. Causal mediation analyses with 5,000 bootstrapped iterations were conducted to explore the mediation effects. Process R package was used for mediation analysis
Results: In MCI, APOE e+4 allele was not directly correlated with cognitive decline across 36months The effect of the APOE genotype on cognition was partly mediated by amyloid beta ($p<0.001$) but not by phopho-Tau ($p=0.212$) (Fig1 & Table2).
Conclusions: AD biomarker partially mediates the potential links between APOE genotype and cognition. Overall, the APOE ε4 allele may lead to a dysregulation of the AD cascade, which in turn leads to cognitive impairment.

ZN-DEPENDENT AMYLOIDOSIS AND ITS REVERSAL

POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Vladimir Mitkevich
Engelhardt Institute of Molecular Biology, Laboratory Of Protein Conformational Polymorphism In Health And Disease, Moscow, Russian Federation

Aims: The pathogenesis of Alzheimer's disease (AD) is associated with the formation of cerebral amyloid plaques, the main components of which are the modified beta-amyloid (Abeta) molecules as well as the metal ions. Aβ isomerized at Asp7 residue (isoD7-Abeta) is the most abundant isoform in amyloid plaques. We hypothesized that the pathogenic effect of isoD7-Abeta is due to the formation of zinc-dependent oligomers, and that this interaction can be disrupted by the rationally designed short peptides.
Methods: We utilized Surface Plasmon Resonance, Isothermal Titration Calorimetry, Dynamic Light Scattering and Molecular Dynamic simulation to demonstrate Zn^{2+}-dependent oligomerization of isoD7-Abeta and the formation of a stable isoD7-Abeta:Zn^{2+}:short peptide complex incapable of forming the oligomers. To demonstrate the physiological importance of zinc-dependent isoD7-Abeta oligomerization and the ability of short peptides to interfere with this process at the organismal level, we employed transgenic nematodes overexpressing human Abeta.
Results: We show that the presence of isoD7-Aβ in the medium triggers extensive amyloidosis that occurs in a Zn^{2+}-dependent manner, enhances paralysis, and shortens the animals' lifespan. Exogenous short peptides completely reverses these pathological effects of isoD7-Abeta.
Conclusions: We conclude that the synergistic action of isoD7-Abeta and Zn^{2+} promotes Abeta aggregation and that the selected small molecules capable of interrupting this process can potentially serve as anti-amyloid therapeutics. Supported by the Russian Science Foundation, grant #19-74-30007

DECIPHERING THE PATHOLOGICAL SIGNIFICANCE OF SELF-PROPAGATING AB STRAINS IN DIFFERENT ANIMAL MODELS

POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Rodrigo Morales[1], Nazaret Gamez[1], Claudia Duran-Aniotz[2], Ines Moreno-Gonzalez[3], Ruben Gomez-Gonzales[1]
[1]The University of Texas Health Science Center at Houston, Neurology, Houston, United States of America, [2]Universidad Adolfo Ibanez, Psychology, Santiago, Chile, [3]Universidad de Málaga, Departamento De Biologia Celular, Genética Y Fisiologia, Malaga, Spain

Aims: Alzheimer's disease (AD) is an heterogenous disorder characterized by the accumulation of amyloid-beta (Aβ) and tau. One possible explanation for the clinical and pathological variation in AD lies in the presence of distinct conformational strains of Aβ. Numerous studies provide compelling evidence for the existence of such strains as well as their ability to template their conformations in a prion-like manner. However, the interaction of such Aβ strains with different hosts has yet to be thoroughly examined. Here, we examined the host-seed interaction of different human brain-derived and synthetic misfolded Aβ strains in two different mouse models of amyloid pathology. We specifically explored the potential differences in amyloid propagation and pathological manifestations considering Aβ strains and animal models as variables
Methods: 50-day-old Tg2576 mice were intra-cerebrally challenged with mouse or human brain-derived Aβ seeds, or synthetic Aβ strains. Age-matched APP/PS1 mice were intra-cerebrally challenged with the biological Aβ-seeds as well. Cerebral pathology was assessed in 300-day-old Tg2576 mice, and in 180-day-old APP/PS1 mice
Results: Two structurally-defined synthetic misfolded Aβ strains induced remarkably different pathological features in Tg2576, including different rates of aggregation, tropism to specific brain regions, and differential recruitment of Aβ40/Aβ42 peptides. Moreover, the administration of human brain homogenates derived from AD patients, displaying unique patterns of amyloidosis, seeded distinct phenotypes in challenged APP/PS1 mice, as evaluated by their seeding activity, vascular pathology, and reactivity to thioflavin-S. Finally, we observed that the same human brain homogenate induced a different cerebral Aβ pathology when inoculated into Tg2576 and APP/PS1 mice.
Conclusions: Our findings support the concept of Aβ strains and demonstrate that they may drive different clinical and pathological outcomes in humans. Our work highlights the contribution of the host in pathological characteristics.

MOLECULAR STRUCTURAL CHANGES IN BRAIN TISSUE OF AN ALZHEIMER'S MOUSE MODEL: IMPACT OF POSTMORTEM DELAY

POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Agnes Paulus[1], Sara Bachiller[2], Tomas Deierborg[3], Oxana Klementieva[1]
[1]Faculty of Medicine, Lund University, Experimental Medical Science, Lund, Sweden, [2]Institute of Biomedicine of Seville (IBiS), Virgen del Rocío University Hospital, Spanish Research Council (CSIC), University of Seville (US), Department Of Medical Biochemistry, Molecular Biology And Immunology, School Of Medicine, Sevilla, Spain, [3]Faculty of Medicine, Lund University, Experimental Medical Science,, Lund, Sweden

Aims: Understanding structural changes in brain tissue is a crucial pursuit for a deeper comprehension of molecular mechanisms during Alzheimer's disease (AD). The bedrock of such explorations rests upon human brain tissues, often acquired after a postmortem interval that can significantly vary from hours to days. Strikingly, the conceivable impact of postmortem delay (PMD) on molecular structures, including amyloids, remains to be unraveled. This study thus presents a question: Could PMD exert an influence on molecular structures? To address this, we employed Fourier-transform infrared (FTIR) spectroscopy, a label-free and non-destructive approach. Using FTIR we investigated changes in secondary structures of proteins and lipids in a mouse brain model of AD collected at different PMD.
Methods: Brains from 7-month-old APP^{NL-G-F} mice model of AD were collected at distinct time intervals: (I) immediately after sacrifice, (II) 6 hours, and (III) 24 hours post-sacrifice at room temperature. The brains were carefully extracted from the skulls and then preserved in paraformaldehyde, without undergoing perfusion. Subsequently, these brains were sectioned (15-micrometers thickness), and specifically employed for FTIR experiments.
Results: Our results indicate that PMD induces distinct modifications in the secondary structures of amyloid plaques and lipids. Specifically, we observed shifts in the characteristic beta-sheet structures of amyloid plaques, possibly contributing to changes in their aggregation patterns. Additionally, alterations in lipid composition and organization were detected, suggesting potential interactions between amyloid aggregates and lipid composition in the postmortem tissue of an animal model of AD.
Conclusions: In conclusion, our study highlights the impact of PMD on the protein structures within the amyloid plaques and lipid structures. These insights point to the refinement of experimental protocols and data interpretation for structural studies based on postmortem tissues.

CHARACTERIZATION OF SOLUBLE SYNTHETIC AMYLOID BETA AGGREGATES

POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Alejandro Iván Ruiz Riquelme
University of Santiago de Compostela, Center For Research In Molecular Medicine And Chronic Diseases (cimus), Santiago de Compostela, Spain

Aims: Objective 1 – Biochemical characterization of soluble synthetic Aβ aggregates. Objective 2 – Structural characterization of soluble synthetic Aβ aggregates. Objective 2 – Toxicity assessment of soluble synthetic Aβ aggregates.
Methods: 1) Generation of soluble synthetic Aβ aggregates in different states of aggregation. Different aggregation protocols (monomers, oligomers, protofibrils, fibrils). Ultracentrifugation (100000 G). 2) Biochemical analysis. Native and SDS-PAGE. 3) Structural analysis. Transmission electron microscopy. 4) *In vitro* assessment of toxicity. Aβ cellular assay developed by Aoyagi et al. [1].
Results: Aβ aggregates of different size were generated and characterized both biochemically and structurally. We observed the existence of short fibrillar aggregates soluble at 100000 G with features different from insoluble Aβ fibrils. By native PAGE, short fibrils appeared as oligomers whereas insoluble fibrils got stuck in the wells, not entering the gels. Similar results were observed by SDS-PAGE. By transmission electron microscopy, we saw clear differences between soluble and insoluble fibrils with soluble fibrils being shorter and with a sharp morphology. After adding the fibrils to biosensor cells expressing Aβ, differences in the toxicity (measured as seeding activity) were observed.
Conclusions: Since soluble Aβ fibrils are the target of AD therapies such as the antibody lecanemab [2], synthetic soluble Aβ fibrils, easier to obtain than human soluble Aβ fibrils, can be used as a model to study the mechanism of antibodies targeting the initial stages of Aβ aggregation.

THE AMYLOID BETA AGGREGATION MODULATOR GAL-201 IS UNDER DEVELOPMENT FOR ORAL AD TREATMENT: COGNITIVE IMPROVEMENT IN A TRANSGENIC AD MODEL

POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Hermann Russ[1], Katrin Riemann[2], Jeldrick Ahsen[2], Gerhard Rammes[2]
[1]Galimedix Therapeutics Inc., 3704 Calvend Lane, Kensington, United States of America, [2]Klinik für Anaesthesiologie und Intensivmedizin der Technischen Universität München, Klinikum Rechts Der Isar, Munich, Germany

Aims: The small molecule GAL-201 has recently been characterized as a promising development candidate for oral treatment of AD (https://doi.org/10.3390/ijms23105794). It binds with high affinity (Ki=2.9 nM) to the misfolded form of monomeric amyloid beta and prevents the aggregation to the neurotoxic amyloid beta oligomers and protofibrils. These amyloid species have been validated by recent positive Phase 3 studies with antibody drugs, such as lecanemab as AD drug target. Prior to beginning clinical development, GAL-201 should also be investigated in an established transgenic (tg) model of AD for its neuroprotective and symptomatic potential.
Methods: The tgArcSwe mouse model of AD has been chosen since it carries, besides the Swedish mutation (APPswe), the amyloid beta-associated Arctic mutation (ArcAb). Tg and wild type mice (12 months) were tested for their cognitive performance in the water-cross maze after administration of 80 mg/kg GAL-201 subcutaneously on the day before the experiment.
Results: GAL-201 significantly improved the cognition in the mutants compared to placebo. The escape latency, which is the duration the animals need to perform the test, was clearly shorter since the transgenic mice showed a cognitive improvement when treated with GAL-201 (n=9-10 per group, p=0.06). In the accuracy experiment, the improvement of the GAL-201-treated transgenic mice was even more pronounced (n=9-10 per group, p=0.02). In addition, new in vitro data about the duration of the biological activity of GAL-201 will be presented.
Conclusions: The available results of the animal study in the Arctic mutation AD model further strengthen the profile of GAL-201 as a promising development candidate for oral Alzheimer therapy. The next step is the initiation of the IND enabling program, before starting a classic Ph 1 SAD/MAD study.

ELUCIDATION OF AMYLOID-BETA'S GAMBIT IN OLIGOMERIZATION.

POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Adrien Schmid[1], Martin Zwahlen[1], Caroline Herron[2], Bea Gil[2]
[1]Arpeggio SA, Diagnostics & Therapeutics, Lausanne, Switzerland, [2]University College of Dublin, UCD, School Of Biomolecular And Biomedical Science, Dublin, Ireland

Aims: The modest therapeutic efficacy with some clinical antibodies as well as the ongoing, heated debate on viable, oligomeric amyloid-beta (Aβ) targets emphasizes the strong need for identifying specific Aβ «hotspots» for the improvement of next generation disease modifying-therapies for Alzheimer's disease (AD).
Methods: Targeted and quantitative mass spectrometry (MS), immuno-precipitation coupled with MS (IP-MS), SDS-PAGE and immunoblotting.
Results: Using advanced technologies in mass spectrometry, together with earlier developed antibody molecules against specific Aβ isoforms, we were able to shed light on an enigma associated with SDS-PAGE stable, low molecular weight (LMW) as well as large Aβ assemblies. Here we provide strong analytical proof of detection of specific Aβ isoforms (target hotspots) present in Aβ oligomers. This finding allows for an unprecedented, selective targeting of oligomeric assemblies, irrespective of the oligomer morphology. We show that the early appearance of specific Aβ isoforms rapidly seed the formation of small (≤17kDa), neurotoxic oligomers, which eventually leads to the formation of SDS-PAGE stable complexes of larger Aβ entities (>50kDa). We applied targeted and quantitative MS approaches to elucidate the composition of these meta-stable core Aβ structures and provide, for the first-time, quantitative data on the composition of Aβ oligomers.
Conclusions: We highlight here the strong need for identifying additional, molecular mechanisms associated with the early events of Aβ peptide aggregation during the long, insidious phase of AD. This in turn will allow the improvement of antibody-specific target engagement of early, pathological Aβ species present in the human AD brain and biofluids.

NATURAL ABETA OLIGOMERS THAT DIFFUSE OUT OF AD BRAIN IMPAIR HIPPOCAMPAL SYNAPSES AND ARE QUANTIFIED BY AN IMPROVED OLIGOMER IMMUNOASSAY

POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Dennis Selkoe
Brigham and Women's Hospital, Neurology, Boston, United States of America

Aims: Objective: The Abeta oligomer hypothesis is a corollary of the amyloid hypothesis of Alzheimer's disease (AD) which posits that Abeta assemblies smaller and more diffusible than ~8 nm compacted amyloid plaque fibrils are principal bioactive forms of Abeta and contribute importantly to neurotoxicity and inflammation. Several forms of Abeta oligomers have been described or postulated, some of which are putatively soluble in aqueous fluids and others of which (often termed protofibrils) have been characterized as either soluble or particulate.
Methods: Methods: We used gentle aqueous soaking of typical AD cortex for 30 min without homogenization to avoid breaking up plaques. The soaking extracts were characterized by immunochemical assays, electrophysiology, transmission electron microscopy, and an improved oligomer-preferring ELISA.
Results: Results: Aqueous soaking extracts from AD cortex impaired synaptic plasticity (long-term potentiation) in both the Schaeffer collateral-CA1 pathway and the mossy fiber-CA3 pathway in wild-type mouse hippocampal slices. Immunodepletion of Abeta from the extract or simply co-incubating the extract with oligomer-preferring monoclonal antibodies (mAb) prevented this. High g-force ultracentrifugation (≥250,000g) of the aqueous extracts pelleted virtually all of the oligomeric Abeta signal as measured by an oligomer-preferring ELISA. Immunogold EM of the extracts demonstrated the presence of short, dispersed amyloid fibrils labeled by clinical mAbs, including lecanemab and donanemab. An improved, plate-based, oligomer-preferring ELISA (71A1 capture/3D6 detector) specifically quantified oAbeta in human and AD mouse brain extracts and human CSF and plasma.
Conclusions: Conclusions: A substantial portion of Abeta oligomers diffuse readily from AD cortex, are particulate (fibrillar) by immuno-EM and ultracentrifugation, and impair two forms of hippocampal synaptic plasticity, but the latter functions are prevented by FDA-approved therapeutic antibodies that bind both diffusible and plaque-associated amyloid fibrils.

Aims: Beta-amyloid (Aβ) and α-synuclein fibrils are hallmarks of neurodegenerative diseases such as Alzheimer's and Parkinson's disease, respectively. Their presence in the brain leads to neurodegeneration and memory decline. Therefore, the search for new drugs that can decrease the formation of such deposits is of great interest. This study investigates two compounds: Octovespin, a peptide modified from Occidentalin-1202, which is a peptide isolated from *Polybia occidentalis* wasp venom, and fraternine-10, a peptide isolated from the venom of the social wasp *Parachartergus fraternus*. In *in vitro* assays, octovespin decreased the aggregation of Aβ. In *in vivo* trials, Octovespin reduced the cognitive deficits in Aβ-induced mice model. *In vitro* investigations of fraternine-10 are still ongoing. Here, we describe the computational approach for investigate the inhibitory activity of octovespin and fraternine-10 against Aβ fibrils (17-42 peptides) and α-synuclein fibrils (38-95 peptides).
Methods: We used molecular docking and molecular dynamics simulations (MD) with 100 ns to study the interactions.
Results: The results indicate that Octovespin and Fraternine-10 can interact with the fibrils for at least 100 ns, with the potential capacity to promote disaggregation.
Conclusions: Our findings can help us understand the characteristics and capabilities of these compounds, as well as their potential as derivatives of wasp venom for disrupting the fibril formation of Aβ and α-synuclein.

TMP21 REGULATES BACE1 MATURATION AND AMYLOIDOGENESIS

POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Xiaojie Zhang[1], Zhao Wang[2], Zhe Wang[3], Weihong Song[2]
[1]Central South University, Psychiatry, Changsha, China, [2]Wenzhou Medical University, Institute Of Aging, Wenzhou, China, [3]Xuanwu Hospital, The National Clinical Research Center For Geriatric Disease, Beijing, China

Aims: Amyloid β protein (Aβ) is derived from amyloid precursor protein (APP) by β- and γ-secretase cleavages. BACE1, the β-secretase, cleaves APP at Asp-1 and Glu-11 site to release amyloidogenic C99 and non-amyloidogenic C89, respectively. Transmembrane protein 21 (TMP21) is required for intracellular protein trafficking and maturation. This study aimed to examine the role of TMP21 in AD pathogenesis and its underlying mechanism.
Methods: APP processing was analyzed by Western blot and Aβ level was measured by ELISA. Adeno-associated virus and stereotactic injection were used to express or knockdown TMP21 gene. Behavioral tests were performed to examine the cognitive function of AD transgenic model mice.
Results: TMP21 overexpression increases Aβ generation. Mechanistically, TMP21 overexpression restricts BACE1 maturation by binding to immature BACE1 and retaining it in the endoplasmic reticulum or lipid raft, and then shifts the BACE1 cleavage preference towards Asp-1 to increase amyloidogenic C99 and subsequent Aβ production. Abnormal TMP21 expression lead to accumulation of immature BACE1, increased Aβ secretion and neuritic plaque formation, and exacerbates cognitive dysfunction in AD mice.
Conclusions: Our results demonstrate that TMP21 is a trafficking receptor regulating BACE1-mediated amyloidogenesis and dysregulation of its disorders contribute to AD pathogenesis through affecting BACE1 intracellular trafficking and maturation. Together, our findings reveal a novel mechanism of TMP21 in BACE1 maturation and APP processing, and highlight a close involvement of the lipid raft in AD pathogenesis.

QUANTITATIVE PROTEOMICS REVEALS NOVEL AMYLOID BETA 42 COLLABORATORS ORCHESTRATING AGGREGATION AND TOXICITY

POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Arun Upadhyay[1], Deepak Chhangani[2], Nalini Rao[1], Julia Kofler[3], Robert Vassar[1], Diego Rincon-Limas[2], Jeffrey Savas[1]
[1]Feinberg School of Medicine, Northwestern University, Neurology, Chicago, United States of America, [2]University of Florida, Neurology, Gainsville, United States of America, [3]University of Pittsburgh, Pathology, Pittsburgh, United States of America

Aims: Amyloid beta 42 (Aβ42) is the most-studied amyloid forming protein. Aβ42 aggregates are considered most outstanding factor instigating downstream changes in pathways leading to Alzheimer's disease (AD). Aβ42 aggregation primarily is a self-driving phenomenon. However, we do not understand how presence of other proteins affect the aggregation and toxicity of Aβ peptides. Our aim is to identify proteins interacting at very early stage of amyloid aggregation pathway.
Methods: We recently got breakthrough in developing a novel biochemical amyloid purification protocol from mouse or human brain tissues. We used highly pure amyloid fibril cores from multiple sources, including human, mouse, primary rat neurons, and Drosophila, for quantitative (MS3) mass spectrometry analyses followed by a battery of complimentary biochemical and proteomic studies.
Results: Our robust proteomics pipeline identified proteins present in amyloid fibrils obtained from multiple sources. Using different age groups of animal, we can delineate early interaction partners from late binding proteins. Using metabolically labelled (N15) tissue, we can also filter out non-specifically bound proteins as contaminants. To confirm our MS findings we utilized biochemical assays, immunoblots, immunohistochemistry, and ELISA, and immunogold labelling. Additionally, we subjected some of the most interesting protein partners to further investigation using in vitro studies. Many of the proteins can also modify amyloid aggregation and associated toxicity in Aβ42 overexpressing fly models.
Conclusions: Although Aβ peptides can readily aggregate in vitro, their oligomerization and aggregation in human brain is unquestionably influenced by several factors. Very early protein interaction partners collaborating with small Aβ peptides may affect the trajectory and profile of amyloid aggregation and thus the downstream AD-associated pathological changes.

DEAMIDATION PROTEINS AND AUTOANTIBODIES AGAINST THEM AS NOVEL AD BLOOD BIOMARKERS

POSTERS: A01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ABETA AGGREGATION, PROTEIN MISFOLDING

Roman Zubarev
Karolinska Institutet, Medical Biochemistry & Biophysics, Stockholm, Sweden

Aims: What causes aggregation of Aß and Ptau, the most prominent AD hallmarks? The underlying cause could be the disregulation of protein homeostasis, in particular, of the defence against accumulation of deamidation products. Deamidation is a spontaneous posttranslational modification, in which asparagine residues lose ammonia and attach a water molecule. In the majority of cases, this leads to the formation of the damaging isoaspartyl residue. In isoaspartyl, the backbone is extended by the CH2 group compared to normal amino acid, which destabilizes the native protein structure. This, in turn, decreases the protein solubility, and results in aggregation of long-lived molecules, such as albimin (lifetime in blood ca. 3 weeks). Human serum albumin (HSA) is the most abundant blood protein, and its a major carrier of Aß and Ptau from blood brain barrier to clearance centers (liver and kidneys). Accumulation of deamidated HSA should lead to a bottleneck in clearance, and contribute to aggregation of these damaging molecules in brain. Here we hypothesized that in AD the level of HSA deamidation is significantly higher than in normal blood, while the amount of antibodies against deamidated HSA is significantly lower.
Methods: We used proteomics analysis to measure the isoaspartate level in AD and normal blood. Then created a monoclonal antibody (mAb) sensitive to isoaspartyl in a key position in the HSA molecule, and designed an ELISA based on this mAb. We also artificially aged HSA, inducing extensive deamidation in it, and used this aged HSA (aHSA) as a bait to measure the level of antibodies in blood against it.
Results: Hypothesis was confirmed.
Conclusions: We produced a novel diagnostic tool for early detection of AD risk in form of two complementary ELISAs.

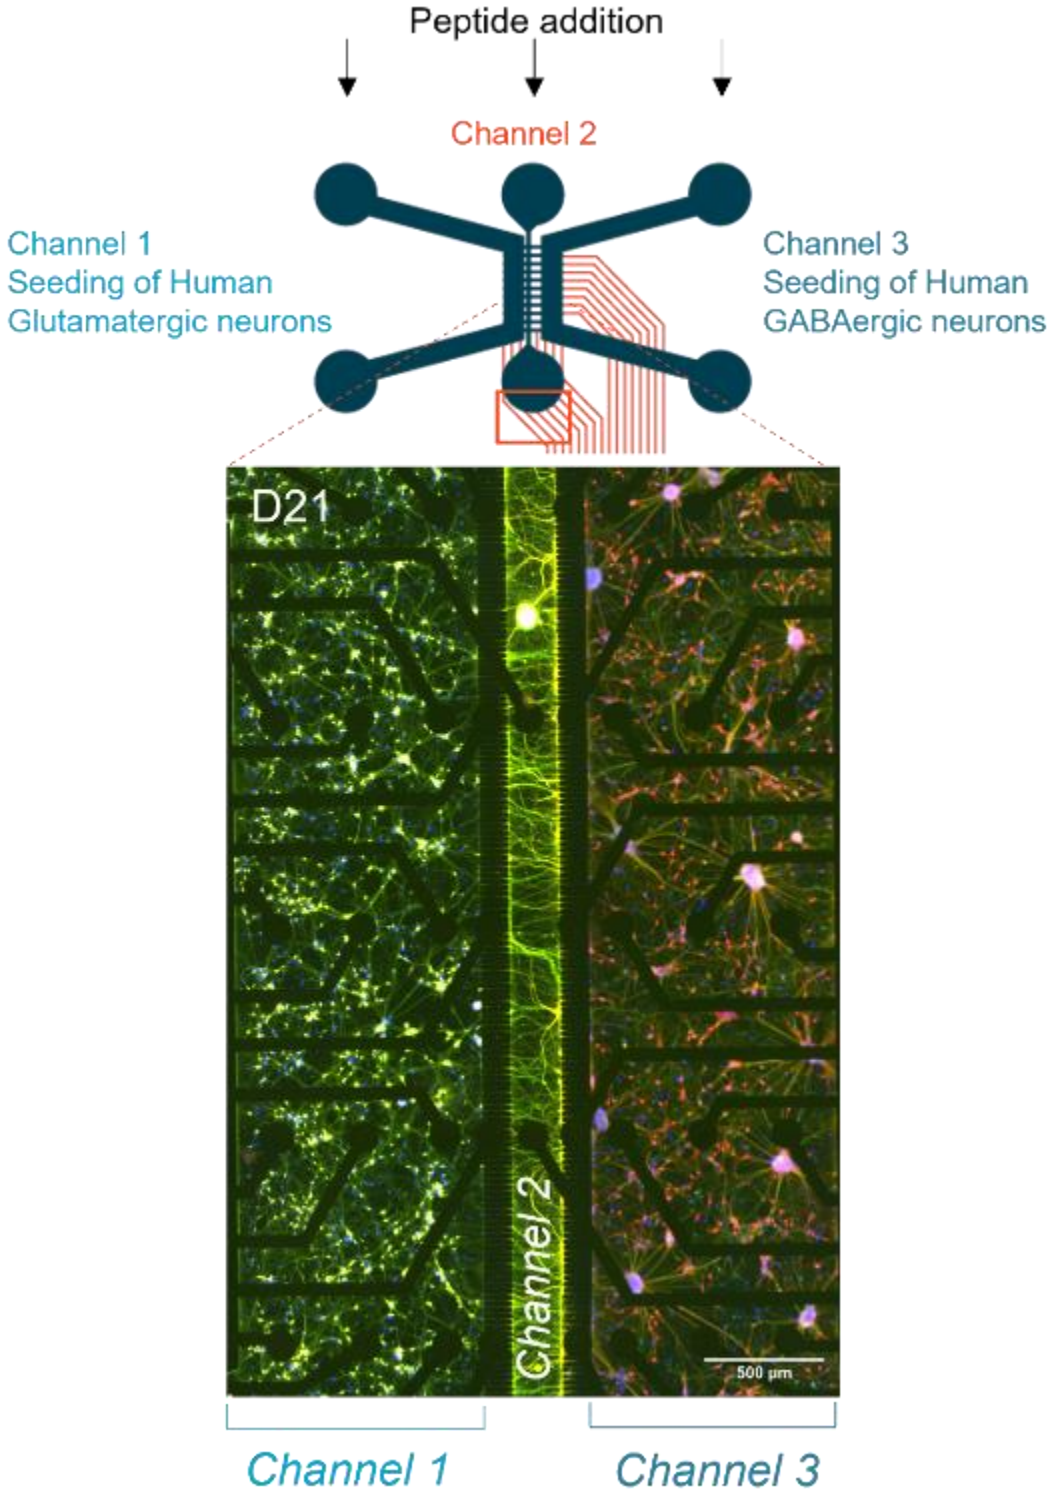
BIO-DIAMOND PROJECT: ADVANCING ALZHEIMER'S DISEASE MODELS FOR TARGET VALIDATION AND DRUG DISCOVERY

POSTERS: A01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELL TO CELL TRANSMISSION, SPREADING OF PATHOLOGY, PRION-LIKE

Ahmad Allouche[1], Louise Miny[2], Sonia Kridi[1], Jessica Rontard[2], Julie Colin[1], Benoît Maisonneuve[2], Nicolas Violle[1], Thibault Honegger[2]
[1]ETAP-Lab, Meurthe Et Moselle, Vandœuvre-lès-Nancy, France, [2]NETRI, Rhône, Lyon, France

Aims: Here, we present a full characterization of the reproducibility of a microfluidic-based hiPSC culture, an essential tool toward developing models of AD that are both physiologically relevant and up to the industry's standards.
Methods: We employed NETRI's DuaLink Shift microfluidic system for co-culture of hiPSC-derived glutamatergic and GABAergic neurons. This innovative device, depicted in the figure, features three compartments for precise isolation of soma, neurites, and synapses via microchannels. In collaboration with ETAP-Lab, we introduced AβO and TauO into a microfluidic co-culture of hiPSC-derived neurons. These oligomers, known for their neurotoxicity, were added at various concentrations and developmental stages. Our approach assesses their impact on different neuron types, replicating key aspects of Alzheimer's
pathology.



Results: We propose a comprehensive characterization of the neuronal populations maintained for several weeks in microfluidic devices, using a range of analytical methods, including immunoassays, immunostaining, and electrophysiological activity assessments. These preliminary data highlight the impacts of the addition of peptides on neuronal activity.

Conclusions: This represents a crucial step in the development of highly relevant, industry-standard models for AD. Such models can serve as indispensable resources for academic research teams and pharmaceutical industries alike, facilitating the elucidation of the pathological mechanisms of Alzheimer's disease and the screening of new effective treatments.

INFLUENCE OF THE APP-BCTF (C99) OLIGOMERIZATION AND EXOSOMAL SPREAD IN ALZHEIMER'S DISEASE

POSTERS: A01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELL TO CELL TRANSMISSION, SPREADING OF PATHOLOGY, PRION-LIKE

Céline Badot, Inger Lauritzen, Frédéric Checler
CNRS, Ipmc, Sophia Antipolis, Valbonne, France

Aims: The accumulation of C99 was found to cause early Aβ-independent lysosomal-autophagic pathology. Recently, our lab showed that exosomes, small endocytic extracellular vesicles, isolated from AD models are also enriched with both monomeric and oligomeric C99, but the role of C99 oligomerization remains unknown. Since exosomal secretion is known to increase when lysosomal-autophagic degradation is compromised, but also to participate to prion-like transmission of neurotoxic proteins, we hypothesize that particularly C99 oligomers spreading could be neurotoxic. Thus, my aim is to characterize the neo-oligomerization of C99, its toxicity and the exosomal spread of C99 oligomers.
Methods: The bimolecular fluorescence complementation (BiFC) method is a protein interaction assay based on the principle that a fluorescent protein (Venus) is reassembled from its two complementary non-fluorescent N-terminal (VN) or C-terminal (VC) fragments when an interaction occurs between two proteins (C99 tagged with VN or VC) thus giving rise to a yellow fluorescence.
Results: By using biochemical approaches and high-resolution microscopy, we validated inducible C99 BiFC constructs allowing the visualization of C99 neo-oligomerization. Oligomers were found to be formed in the trans-Golgi network and to be trafficked to the endolysosomal system, in which they accumulate in enlarged autophagic compartments reflecting clearance deficits. Moreover, C99 oligomers were less prone to γ-secretase cleavage, supporting a potentiation of Aβ-independent toxicity of oligomers.
Conclusions: Our new BiFC tool allowed us to specifically detect *de novo* C99 oligomerization and a link between oligomers trafficking into the late endosomal system and lysosomal-autophagic toxicity. These results support the perspective of visualizing the exosomal propagation of C99 fluorescent oligomers and their related neurotoxicity. Hopefully, the outcomes of this project will be a step forward in understanding the role of C99 in AD pathogenesis.

INDUCTION OF NEUROINFLAMMATION BY THE DISRUPTION OF GUT MICROBIOTA IN NEURODEGENERATIVE DISEASES.

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Benjamin Adebisi
Institute of Anatomy, Cell Biology, Brain and Neurodegeneration., Functional And Molecular Neurobiology, Osogbo, Nigeria

Aims: The research aims to link how the disruption of gut microbiota triggers proteinopathies in the brain. Impairment of protein metabolism in the brain, such as alpha synuclein and beta amyloid, is responsible for the aggregation. Aggregated proteins alter neuronal functions and such alterations have been indicted in neuronal cell loss in most patients with neurodegenerative diseases such as Parkinson's and Alzheirmer's diseases.
Methods: Literature reviews on the several pathological mechanisms elucidating on the aggregation of proteins were researched and one of such notable biological process is neuroinflammation, which is mediated by the microglia. Microglia are activated in response to immune triggers to foreign materials in the brain.
Results: The triggers responded to by the microglia are Lipopolysaccharides, LPS, a major components in the outer membrane of gram-negative bacteria. These bacteria are migrated from the mucosa of the gastrointestinal tract through the blood stream, endocrine pathways or vagal networks. The gut has several millions of bacteria, which activities maintain the physiological state of system; howbeit, disruption of the microorgasms results in leaky gut, giving allowance for the migration of several bacteria to the central nervous system, bacteria also crosses the blood-brain barrier, giving room for eliciting immune responses, which alter mitochondrial functions and invariably protein aggregation seen in many neurodegenerative diseases. Mitochondrial disruptions have been connected with impairment of lysosomal and proteasomal degradation pathways, causing accumulation of aged organelles and proteinopathies.
Conclusions: Since the culminative effects of neuroinflammation, mitochoindrial dysfunction and protein aggregation are pathological processes in neuodegenerative diseases linked to the microbial components and balance in the gut, it is imperative that management of these diseases are looked into through maintaining healthy microbial population in the gastrointestinal system by the use of probiotics.

EXTRACELLULAR ATP AS DETERMINANT OF MICROGLIA ACTIVATION AND NEUROINFLAMMATION IN ALZHEIMER'S DISEASE

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Nikita Arnst[1], Martina Bedetta[1], Simonetta Falzoni[2], Dorianna Sandonà[1], Nelly Redolfi[1], Annamaria Lia[1], Elisa Greotti[1,3,4], Francesco Di Virgilio[2], Paola Pizzo[1,3,5]
[1]University of Padova, Department Of Biomedical Sciences, Padua, Italy, [2]University of Ferrara, Department Of Medical Sciences, Ferrara, Italy, [3]Italian National Research Council (CNR), Neuroscience Institute, Padua, Italy, [4]University of Padova, Padova Neuroscience Center (pnc), Padua, Italy, [5]University of Padova, Centro Studi Per La Neurodegenerazione (cesne), Padua, Italy

Aims: Alzheimer's disease (AD) is a neurodegenerative disease that still lacks an effective cure. Recently, the presence of activated microglia in histological samples of AD brains supports the hypothesis that inflammation might play a central role as a trigger of neuronal damage. In this context, microglia are one of the main targets of extracellular ATP (eATP), a molecule involved in the activation and propagation of neuroinflammation. To establish the role of eATP as a determinant of microglia activation and neuroinflammation we started by characterizing both microglia reactivity and the inflammatory state of the PS2APP (line B6.152H) mouse model of AD.
Methods: We performed a morpho-functional analysis of microglia in the somatosensory cortex (SSCx) of WT and AD mice at 2-, 6-, and 9 months using confocal microscopy and Imaris software. We used Iba1 to stain microglia, coupled with Lamp2 and vGLUT1/2 staining to assess microglia pruning activity. We performed also a western blot analysis of NLRP3 to assess a possible early activation of the inflammasome.
Results: 3D images of microglia stained with Iba-1 showed less branching morphology in AD mice at all time points. Also, LAMP2-positive structures volume, as well as vGLUT1/2 volume in Iba-1 positive cells in AD mice, were increased, indicating higher microglia pruning activity during the early disease stages. We found a significant increase in NLRP3 levels in 2-month-old AD mice.
Conclusions: We reveal an early activation of microglia in the SSCx of PS2APP mice. Indeed, Iba-1 reactivity and microglia pruning activity are higher in AD mice at 2 months of age, thus well before the surge of both plaque deposition and cognitive deficits. We aim to measure eATP in the brain at the same time points.

Aims: We are investigating the human brain's adaptive response to Alzheimer's Disease (AD) progression by examining the dynamics of specific pathways and gene expressions, integrating RNA quantification and protein analyses across two distinct cohorts.
Methods: The first cohort comprises 30 fresh-frozen human post-mortem hippocampal samples, divided into age- and sex-matched groups of non-neurological controls (n=7), early AD (Braak 4, n=12), and advanced AD (Braak ≥5, n=11). We analyzed 770 RNA strands using a NanoString nCounter panel and explored neuroinflammation, neurotransmission, and myelin metabolism pathways. Western Blot analyses were conducted on hippocampal proteins from the same subjects. The confirmation cohort encompasses 30 FFPE human hippocampi (n=6/group, age- and sex-matched), with young controls, controls with and without Amyloid-β deposits, Braak 4, and Braak 6 subjects. Immunofluorescence on the confirmation cohort is being performed to investigate cross-pathway gene involvement.
Results: Comparing RNA levels of Braak 4 to Controls revealed 36 differentially expressed genes (11 up and 25 downregulated, with 4 overlapping with GWAS), whereas Braak 6 to Braak 4 showed 278 (54 up and 224 downregulated, 21 overlapping with GWAS) and Braak 6 to Controls revealed 349 (87 up and 262 downregulated, 24 overlapping with GWAS). Early AD showed an upregulation of inflammatory pathways and a downregulation of myelin synthesis pathways. These pathways were inversely altered in advanced AD without reverting to control levels. Neurotransmission pathways were consistently downregulated.
Conclusions: We show a strong inflammatory response in early AD stages that diminishes as the disease progresses, while the myelin metabolism pathways show the opposite pattern. It suggests an association between the two pathways, supported by GWAS data, and could shed light on damages of neuroinflammatory's peak response and diminution. [SNSF grant: 310030_212322]

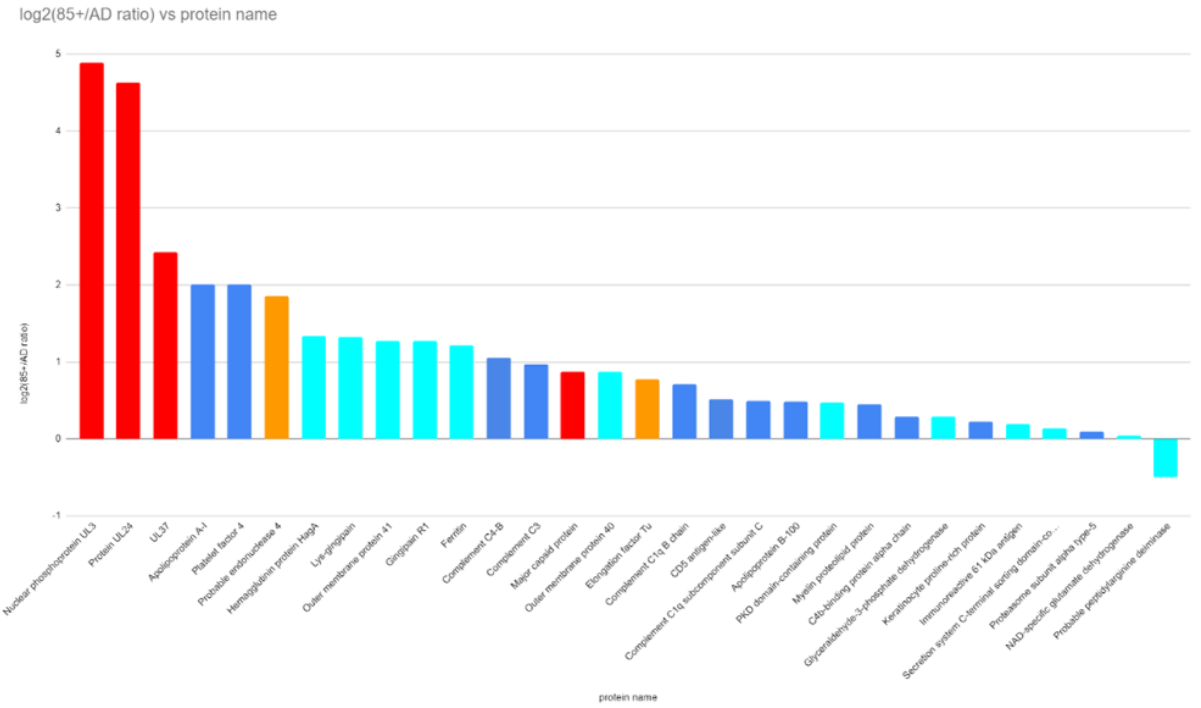
PROFILING IMMUNOLOGIC RESPONSE TO PATHOGENS IN POPULATIONS: ELDERLY POPULATION WITH OR WITHOUT ALZHEIMER'S DISEASE

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Omer Bender, Daniel Bar
Tel Aviv University, Faculty Of Medicine, Tel Aviv, Israel

Aims: Alzheimer's disease (AD) has been associated with several pathogens. Specifically, Herpes simplex 1 virus (HSV-1), Chlamydia Pneumoniae (CP) and the periopathogenic bacteria Porphyromonas gingivalis (PG) has been demonstrated in the brain of AD patients and causally linked to pathological cleavage of the APP to form the insoluble Aβ1–42 peptides, one of the pathological hallmarks in AD. While exposure to PG and HSV-1 are prevalent, only a portion of affected individuals will develop AD. We propose that specific immune responses modulate the risk of developing AD following exposure to CP, PG, HSV-1 or other AD-associated pathogens.
Methods: We will test this hypothesis by screening blood for antibodies against CP, PG, HSV-1 and brain tissue auto-antibodies. The immune response of No-AD, AD patients and younger controls to various pathogens will be measured. We will identify which pathogenic proteins are recognized by the immune system of each subject, using proteomics, and test for a differential immune response to surface markers and virulence proteins and build a predictive model of immune-dependent AD-avoidance.
Results: Among the proteins identified by the adaptive immune system are those found by previous studies to penetrate the blood brain barrier and novel proteins associated with AD (Figure1).



Conclusions: We had shown differential immune response virulence proteins preferentially bound by the AD group suggesting an immune protective role for antibodies to these pathogens' proteins. The low and ineffective antibody counts of the AD patients might enable the pathogens to colonise brain tissue and promote local inflammation.

THE INFLUENCE OF FORMYL PEPTIDE RECEPTORS ON AMYLOID BETA SENSING IN GLIA AND IMMUNE CELLS

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Lukas Busch, Bernd Bufe
University of Applied Sciences Kaiserslautern, Department Of Informatics And Microsystems Technology, Zweibrücken, Germany

Aims: Recent research on Alzheimer's Disease (AD) discovered over 100 structurally diverse Aβ peptides, of which so far only $Aβ_{1-42}$ and $Aβ_{1-40}$ are well characterized. We could recently identify $Aβ_{1-42}$, $Aβ_{1-40}$ but also $Aβ_{11-40}$ and $Aβ_{17-40}$ as sensitive activators of formyl peptide receptors (FPRs), a small gene family of immune receptors, comprising three members. In this study we investigated the biological effects and structural basis of Aβ interactions on FPRs in glia and primary human immune cells.
Methods: • Calcium imaging experiments • Chemotaxis assays • ERK phosphorylation assays
Results: FPR1 displayed over tenfold higher sensitivity to $Aβ_{11-40}$ and $Aβ_{17-40}$ than to $Aβ_{1-42}$. Glial U87 cells strongly responded to $Aβ_{11-40}$ and $Aβ_{17-40}$ in calcium imaging experiments, driven by FPR1 activation. In chemotaxis assays, only $Aβ_{11-40}$ but not $Aβ_{17-40}$ induced cell migration, indicating functional bias among Aβ peptides. In primary human neutrophils and mouse astrocytes $Aβ_{11-40}$ and $Aβ_{17-40}$ elicited FPR-dependent signaling, arguing for a physiological significance of FPRs in Aβ sensing. To investigate the structural basis of the biased Aβ signals, we systematically screened fragmented peptides spanning the complete Aβ sequence and identified two motifs that induced subtype-specific responses through FPR1 and FPR3. Both motifs prompted ERK-phosphorylation in U87 cells, but only the FPR1-specific agonist initiated chemotaxis, highlighting FPR-subtype dependent differences in signal transduction of glia responses.
Conclusions: We here identified $Aβ_{11-40,}$ and $Aβ_{17-40}$ as novel activators of FPR1 in glia and immune cells. We show that Aβ binding motifs differ between FPR-subtypes and trigger Aβ variant-selective effects. Given that the composition of Aβ variants can drastically differ in-between patients non-canonical Aβ sensing by FPRs may contribute to the complexity of glial cell responses and the strong variance in the pathological progression of AD between patients.

INVESTIGATING THE REGULATION OF THE NLRP3 INFLAMMASOME IN ASC-DEPENDENT AND ASC-INDEPENDENT PATHWAYS OF ALZHEIMER'S DISEASE

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Shilauni Dadwal[1,2], Michael Heneka[2]
[1]University of Luxembourg, Luxembourg Centre For Systems Biomedicine, Esch-Belval Esch-sur-Alzette, Luxembourg, [2]Université du Luxembourg, Lcsb, Belvaux, Luxembourg

Aims: The inflammasome is a protein complex that activates caspases, leading to inflammation in response to various stimuli, including microorganisms and protein aggregates of e.g. amyloid-β, and tau. Among the numerous studied inflammasomes, NLRP3 has been extensively investigated due to its well-described activation mechanism. To develop targeted therapies for inflammatory disorders, it is crucial to fully understand how various molecules and signaling pathways activate and regulate the assembly of NLRP3 inflammasomes. So far in literature kinases like NEK7, MARK4, GBP5, PKR, AKT, and BTK are known to regulate the NLRP3 inflammasomes. In our project, we are focusing on the interactions between these kinases and what are the other factors involved in the activation, inhibition, and regulation of NLRP3. We are also focusing on the potential interactions of these regulatory factors within ASC-dependent and ASC-independent pathways. So far, data shows the increased expression of NLRP3 upon external stimuli which is the very first step towards studying the regulation of NLRP3 inflammasome in murine and human models.
Methods: In our study, we assessed the expression of NLRP3, ASC, interleukins (IL-1beta and IL-18), and kinases (NEK7, MARK4, GBP5, PKR, AKT, BTK) in various models, like primary microglia, Raw macrophages 264.7, THP-1, BV2 cell lines, iPSCs and APP mouse models upon treatment with lipopolysaccharide (LPS) and nigericin. Subsequently, we employed immunocytochemistry, ELISA, and Western blot techniques for further analysis.
Results: Our investigations have so far demonstrated an increased expression of NLRP3 and ASC in samples subjected to LPS and nigericin treatments compared to controls across primary microglia, Raw macrophages, THP-1, and BV2 cell lines.
Conclusions: Our ongoing studies have revealed an upregulation of NLRP3 and ASC expression. Additionally, we are exploring the expression of interleukins and kinases after the treatment.

POLYUNSATURATED FATTY ACID METABOLISM IN THE ALZHEIMER'S BRAIN AND THE INFLUENCE OF APOE4

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Brandon Ebright[1], Dante Dikeman[1], Isaac Asante[1], Shaowei Wang[2], Stan Louie[1], Hussein Yassine[2]
[1]USC Alfred E. Mann School of Pharmacy and Pharmaceutical Sciences, Clinical And Experimental Therapeutics, Los Angeles, United States of America, [2]University of Southern California, Neurology, Los Angeles, United States of America

Aims: To determine how fatty acid metabolism in the brain changes with Alzheimer's disease (AD) progression, the influence of the APOE4 allele, and how it contributes to neuroinflammation.
Methods: In postmortem human brains from the Religious Order Study (n=198), polyunsaturated fatty acids (PUFA) and their eicosanoid metabolites were quantified using a targeted LC-MS/MS assay. The brain levels of bioactive lipids were compared between persons with no cognitive impairment (NCI), mild cognitive impairment (MCI) and AD dementia, and stratified by APOE genotype and sex.
Results: Lipidomic analysis of human cortex tissue revealed higher levels of n-6 arachidonic acid (AA) and lower levels of n-3 PUFAs such as eicosapentaenoic acid (EPA) and docosapentaenoic acid (DPA) in APOE4-carriers with AD (**Figure 1**). The endogenous precursors to n-3 PUFAs, α-linolenic acid (ALA) and stearidonic acid, were significantly higher in APOE4 non-carriers with AD but did not change in APOE4-carriers (**Figure 2**). Downstream AA metabolites formed through lipoxygenase (LOX) activity such as 5-HETE and 15-HETE were lowest in brains with AD and consistently lower in APOE4-carriers regardless of disease state (**Figure 3**). This downregulation in LOX-mediated metabolism also appeared to be influenced by sex, where males had the greatest reduction in LOX metabolites. Alternatively, the cyclooxygenase (COX) pathway was promoted with disease progression, evidenced by higher levels of the inflammatory mediator thromboxane B2 (TXB2) in brains with MCI and APOE4-carriers with AD. **Figure 1:**

Figure 2:

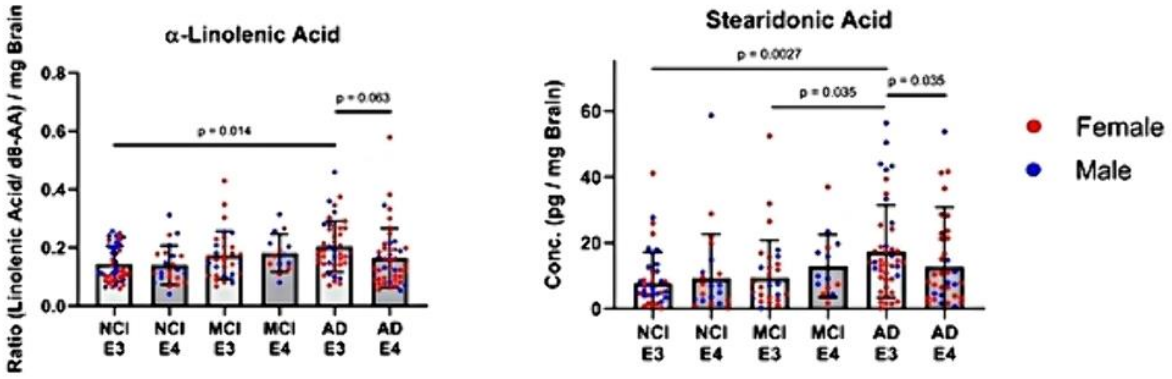

Figure 3:

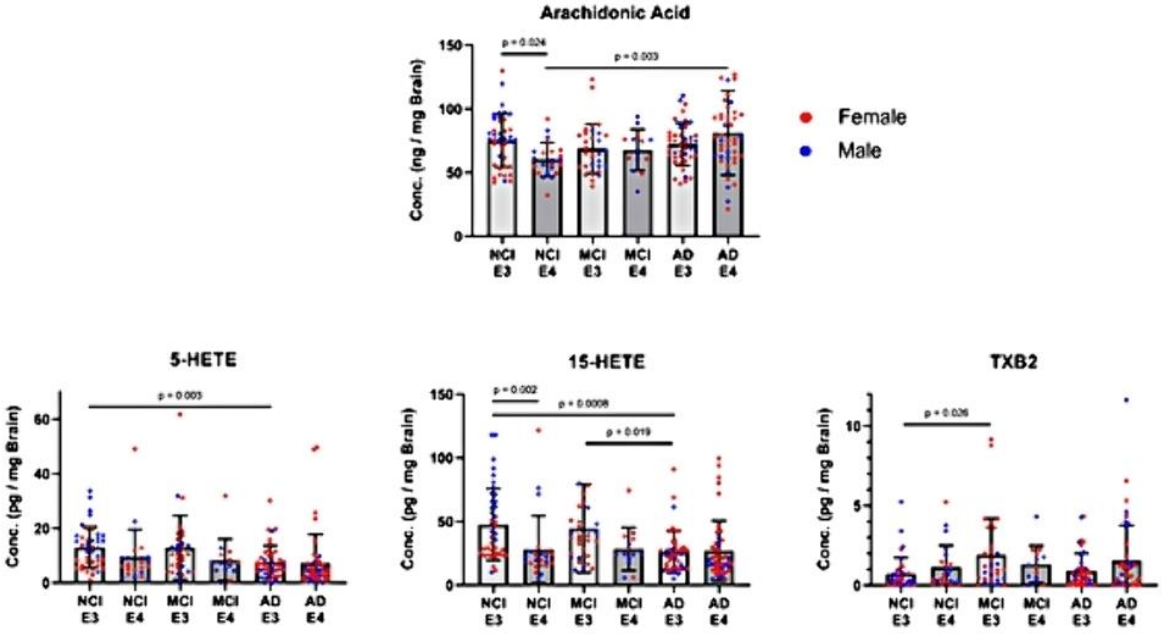

Conclusions: These findings suggest that brains with AD have increased calcium-dependent phospholipase A2 (cPLA2) activation, promoting higher levels of AA and inflammatory eicosanoids. Furthermore, the cPLA2 activation, suppression of endogenous n-3 PUFA production, and suppression of LOX activity are exacerbated in APOE4-carriers and appear to be influenced by sex.

TREM2 IS DOWN-REGULATED BY HSV1 IN MICROGLIA AND INVOLVED IN ANTIVIRAL DEFENSE IN THE BRAIN.

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Stefanie Fruhwürth[1], Line Reinert[2], Carl Öberg[1], Marcelina Sakr[1], Marcus Henricsson[3], Henrik Zetterberg[4], Sören Paludan[2]
[1]Sahlgrenska Academy, Institute of Neuroscience and Physiology, Department Of Psychiatry And Neurochemistry, Göteborg, Sweden, [2]Aarhus University, Department Of Biomedicine, Aarhus, Denmark, [3]AstraZeneca, Biomarker Discovery And Development, Mölndal, Sweden, [4]University of Gothenburg, Department Of Psychiatry And Neurochemistry, Molndal, Sweden

Aims: The aim of this study was to explore how herpes simplex virus type 1 (HSV1) modulates gene expression in human microglia and to determine the functional impact on control of HSV1 infection.
Methods: Here, we have used human induced pluripotent stem cell (hiPSC)-derived models of microglia and cortical neurons as well as Trem2-/- mice to study innate immune sensing of HSV1 by microglia, antiviral mechanisms, and control of HSV1 infection.
Results: Here, we report that HSV1 infection of hiPSC–derived microglia down-regulates expression of genes in the TREM2 pathway. TREM2 was found to be important for virus-induced *IFNB* induction through the DNA-sensing cGAS-STING pathway in microglia and for phagocytosis of HSV1-infected neurons. Consequently, TREM2 depletion increased susceptibility to HSV1 infection in human microglia–neuron cocultures and in the mouse brain. Thus, TREM2 is important for the antiviral immune response in microglia.
Conclusions: Our data further support the idea of the essential role for microglia in early antiviral defense and provide mechanistic insight into the virus-cell interactions that govern the outcome of HSV1 infection in the brain. Since *TREM2* loss-of-function mutations and HSV1 serological status are both linked to Alzheimer's disease, this work poses the question whether genetic or virus-induced alterations of TREM2 activity predispose to post-infection neurological pathologies.

DECIPHERING THE ROLE OF A BRAIN-SPECIFIC LNCRNA IN AD-RELATED NEUROINFLAMMATION

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Ulrike Fuchs[1], Sophie Schröder[1], André Fischer[2]
[1]German Center for Neurodegenerative Diseases, Epigenetics And Systems Medicine, Göttingen, Germany, [2]German Center for Neurodegenerative Diseases (DZNE), University Medical Center Göttingen, Psychiatry And Psychotherapy, Göttingen, Germany

Aims: Long non-coding RNAs (lncRNAs) are emerging as important regulators of neuronal plasticity and have recently been linked to the onset and progression of neurodegenerative diseases. However, our knowledge about the role of lncRNAs in neuronal and non-neuronal cells is still limited. The aim of this project was to identify cell type-specific expression changes of non-neuronal lncRNAs in the context of AD-related neuroinflammation and to characterize their function.
Methods: To this end, we performed an RNA sequencing-based screening of differentially expressed lncRNAs in primary astrocytes following their activation. We identified multiple candidate lncRNAs for further analysis and studied their role via loss of function approaches.
Results: Our data reveal that one brain-specific lncRNA candidate is de-regulated in amyloid-beta activated astrocytes and regulates inflammatory pathways and synapse homeostasis. Knockdown of this lncRNA was sufficient to induce a neuroinflammatory phenotype in primary astrocytes. Furthermore, we found that this lncRNA was also de-regulated in human AD data sets.
Conclusions: Since lncRNAs are often cell-type and tissue specific, they provide an optimal therapeutic target with less side effects, compared to other target structures. Thus, our lncRNA candidate could serve as a novel biomarker for AD-related neuroinflammation and a target for therapeutic interventions via RNA-based medicines.

AMYLOID-BETA EVASION BY NEUROTROPIC PATHOGENS BORRELIA BURGDORFERI AND STREPTOCOCCUS PNEUMONIAE

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Pavel Uvarov[1], Lilith Heiland[1], Alexander Moir[2,3], Anna Maaser-Hecker[2,3], Daan Cox[1], Taru Meri[4], Deepak Kumar[2,3], Rudolph Tanzi[2,3,5,6], Karita Haapasalo[1,2,3]
[1]University of Helsinki, Bacteriology And Immunology, Helsinki, Finland, [2]Mass General Institute for Neurodegenerative Disease, Massachusetts General Hospital, Genetics And Aging Research Unit, Department Of Neurology, Charlestown, United States of America, [3]Harvard Univeristy, Harvard Medical School, Boston, United States of America, [4]University of Helsinki, Faculty Of Biological And Environmental Sciences, Helsinki, Finland, [5]Massachusetts General Hospital, Mccance Center For Brain Health, Boston, United States of America, [6]Henry and Allison McCance Center for Brain Health, Department Of Neurology, Boston, United States of America

Aims: Amyloid-beta is toxic to neurons and, in excess, can trigger Alzheimer's disease. It has also been shown to protect the brain from infectious agents invading the central nervous system. Pathogenic microbes have, however, evolved to evade the innate immune system facilitating microbial spread in host tissues. While evasion of the complement system has been described to be a common trait on pathogens, little is known about microbial amyloid-beta evasion. The aim of this study is to determine whether microbes have evolved strategies to evade this emerging mechanism of innate immunity involving host defense peptides such as amyloid-beta.
Methods: Binding of synthetic and cell derived amyloid-beta to bacteria and several microbial molecules was assessed by ELISA, Western blotting, and electron microscopy. Bacterial culturing was used to study survival of *Borrelia* when challenged with amyloid-beta 1-42. 3D human neural cell cultures were used for modeling the effect of multiple interactions between amyloid-beta, bacteria and innate immune molecules in a pathological microenvironment.
Results: We identified novel putative amyloid-beta-binding proteins from multiple bacterial species. Binding of synthetic amyloid-beta 1-42 to *Borrelia hermsii* reduced its survival. However, *Borrelia burgdorferi,* responsible for Lyme neuroborreliosis, exhibited resistance to synthetic amyloid-beta and amyloid-beta in 3D cultures. Increases in cytokine levels and reduction of soluble amyloid-beta in 3D cultures were detected in the presence of several pathogens but not in cultures infected with neurotropic pathogens, *B. burgdorferi* and *Streptococcus pneumoniae*.
Conclusions: Results indicate amyloid-beta's target specificity in binding to microbial molecules and reducing their survival. The molecular mechanism by which some pathogens evade amyloid-beta entrapment and whether this trait, exploited by restricted species of bacteria, could be related to neuroinflammation and amyloid-beta plaque formation characteristic to Alzheimer's disease warrants further investigation.

APOE4 INDUCES AN ADAPTIVE IMMUNE RESPONSE IN MICE

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Sem Halters, Elga De Vries, Jan Van Den Bossche, Lynn Van Olst, Daniëlle Wessels, Willem Van De Zande, Carla Rodriguez-Mogeda, Juan Garcia-Vallejo
Amsterdam UMC, location VU, Medical Cell Biology And Immunology, Amsterdam, Netherlands

Aims: Recent studies indicated that the peripheral immune system is dysregulated in early stages of Alzheimer's disease (AD). APOE4 is the most important known genetic risk factor for developing late-onset AD. The role of APOE4 on the central immune system has been studied extensively, whereas we don't know its effect on the peripheral immune system yet. Therefore, we wanted to study the peripheral immune landscape of APOE3 and APOE4 targeted replacement mice.
Methods: We performed mass cytometry on the splenocytes of 6 month old APOE3 and APOE4 targeted replacement (TR) mice. By using immunohistochemistry, we checked for the presence of immune cells in the brain and changes on the brain vasculature of APOE3-TR and APOE4-TR mice.
Results: We observed an adaptive immune response in APOE4-TR mice, based on increased numbers of activated B cells and a shift from naïve and effector $CD8^+$ T cells towards memory CD8 T cells. On top of that, both regulatory $CD4^+$ T and regulatory B cell populations were enriched in APOE4-TR mice. Interestingly, memory $CD8^+$ T cells in APOE4-TR also expressed lower levels of the checkpoint inhibitors, PD-1, PD-L1, and LAG-3, and higher levels of the tissue-resident marker CD103. In APOE4-TR mice, $CD8^+$ T cells were also able to infiltrate the brain via the corpus callosum. Potentially mediated by a decrease in the tight junction molecule Claudin-5 on the brain vasculature.
Conclusions: Taken together, we discovered that human APOE4 induces an adaptive immune response in mice. APOE4 induced changes in memory $CD8^+$ T cells are mainly associated with tissue-residency and lower T cell exhaustion. It seems that changes on the brain vasculature in APOE4-TR mice allow $CD8^+$ T cells to accumulate in the corpus callosum.

DEVELOPMENT OF NEW HUMAN MODELS TO STUDY THE ROLE OF COMPLEMENT IN NEURODEGENERATION

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Ashley Comer[1], Fabrizio Pontarelli[1], Gregory Wirak[1], Soumya Nair[2], Vaishnavi Rajagopal[2], Dimitry Ofengeim[1], Timothy Hammond[1]
[1]Sanofi, Rare And Neurologic Diseases, Cambridge, United States of America, [2]Sanofi, Immunology And Inflammation, Cambridge, United States of America

Aims: Complement overactivation has emerged as a key mechanism in neurodegenerative disease, and in mouse models of Alzheimer's disease genetic or therapeutic inhibition of the complement pathway reduces synapse loss, prevents neuron death and improves cognition. Despite this data, the mechanisms driving complement-induced neural dysfunction in the human brain are not fully understood.
Methods: Complement proteins vary substantially between rodent and humans, so we have developed human *in vitro* iPSC models and humanized *in vivo* mouse models to bridge the gap.
Results: We show in a human iPSC-derived brain tri-culture system with motor neurons, microglia and astrocytes that complement deposition on neurons disrupts firing as measured by calcium imaging and MEA recordings, and that this effect is caused by complement sub-lytic activation of membrane attack complex (MAC) pores. In addition, complement activation increased human synaptosome engulfment by iPSC microglia, suggesting a dual role for the pathway in disrupting neural connectivity. We also developed a humanized complement mouse model in which human complement-preserved serum is injected into the mouse striatum. We show that serum injection into the mouse brain leads to human complement activation and deposition on mouse neurons. This model will be critical to test human-specific complement inhibitors in the mouse brain, where additional functional readouts can be measured.
Conclusions: Modulating complement components or their regulators holds promise for controlling neuroinflammation and preserving neuronal function in neurodegenerative disease, and these models will help pave the way for novel therapeutic development.

THE CHOROID PLEXUS IS AN IMMUNOLOGICAL RHEOSTAT FOR THE HUMAN CENTRAL NERVOUS SYSTEM

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Ryan Hobson, Samuel Levy, Andrew Teich, Neil Shneider, Elizabeth Bradshaw, Wassim Elyaman
Columbia University, Neurology, New York, United States of America

Aims: Analyze the phenotype of adaptive and innate immune cells and their dynamics at the brain's borders in directly modulating neuroinflammation in neurodegenerative diseases.
Methods: Here, we performed single-cell RNA and T cell receptor (TCR) sequencing on 142,521 immune cells isolated from fresh human postmortem choroid plexus and paired leptomeninges and brain parenchyma from several neurodegenerative conditions including late-onset Alzheimer's disease (LOAD), Parkinson's and amyotrophic lateral sclerosis (ALS) (n=67 sequenced samples).
Results: Comparing the TCR repertoires between meninges and choroid plexus from the same donor revealed completely independent resident T cell TCR sequences, suggesting that T cells in these two tissues respond to different antigen triggers and likely serve divergent functions. Indeed, comparing the RNA expression profiles of key immune populations across the meninges and choroid plexus revealed divergent roles and a preference for wound-healing and regulatory gene programs in the choroid plexus. Interestingly, we also found that choroid plexus CD8 T cells are a prominent source of IFNγ and likely contribute to choroid plexus barrier disruption and immune cell chemotaxis across the blood-CSF barrier. Importantly, we identified a population of tissue resident NK cells in the choroid plexus that may play a role in eliminating IFNγ-producing CD8 T cells and therefore maintaining barrier integrity.
Conclusions: These results suggest that unlike the meninges which supply T cells to the brain from a population of tissue resident T cells, the choroid plexus immune interface serves as a local rheostat for immune cell migration across the blood-CSF barrier. Work is currently underway to identify the factors that drive immune cell residency in the choroid plexus, especially tissue resident NK cells and CD8 T cells, which could reveal druggable targets for broadly controlling neuroinflammation.

USING SINGLE-MOLECULE AND SUPER-RESOLUTION METHODS TO INVESTIGATE THE LINK BETWEEN ASC AND AMYLOID-B IN A MOUSE MODEL OF ALZHEIMER'S DISEASE

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Beatrix Huissoon[1], Giulia Albertini[2], Emre Fertan[1], John Danial[1], Jeff Lam[1], Bart De Strooper[2], David Klenerman[1]
[1]University of Cambridge, Yusuf Hamied Department Of Chemistry, Cambridge, United Kingdom, [2]KU Leuven & VIB, Center For Brain & Disease Research, Leuven, Belgium

Aims: It is now believed that small, 'oligomeric' aggregates of amyloid β (Aβ) are the primary sources of toxicity and responsible for neuronal loss in Alzheimer's disease. Understanding of how these aggregates cause toxicity and how the brain responds to them is still limited. We investigated the effect of injected oligomers of human Aβ on inflammatory responses in mouse brains. This could provide further insight into the amyloid cascade and oligomeric toxicity.
Methods: The left ventricles of 2-month-old wild-type C57BL/6 mice were injected with human Aβ1-42 oligomers (oAβ) or scr, a scrambled form of Aβ. They were then sacrificed at 2, 6, 12, 24, 48, 72 and 96 hours (n≥3). Another set of mice were first fed a diet containing Pexidartinib (PLX3397) for 3 weeks to deplete their microglia, then injected as before and sacrificed at 6, 24, 72 and 96 hours. Single molecule imaging using SiMPull assays were performed, alongside super-resolution analysis with DNA-PAINT to assess differences in size and shape of aggregates.
Results: Single molecule imaging methods were able to show a microglia-dependent increase in ASC (inflammasome adapter) levels in response to injection of oAβ, with a subsequent increase in endogenous Aβ production. Also, evidence has been found that microglia are responsible for the clearance of oAβ. Using super-resolution techniques, a higher proportion of larger Aβ aggregates are seen with oAβ injection compared to the control, with differences in ASC size and shape also found.
Conclusions: These data provide evidence to support the idea that small, oligomeric aggregates of Aβ can trigger inflammatory responses in mouse brains, which is largely dependent on the presence of microglia. The associated increase in mouse Aβ production also provides some support for the amyloid cascade hypothesis.

LONGITUDINAL EFFECTS OF CAREGIVING BURDEN ON INFLAMMATORY BIOMARKERS IN SPOUSAL CAREGIVERS OF INDIVIDUALS WITH COGNITIVE IMPAIRMENTS

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

So Yeon Jeon[1,2]
[1]Chungnam National University College of Medicine, Psychiatry, Daejeon, Korea, Republic of, [2]Chungnam National University Hospital, Psychiatry, Daejeon, Korea, Republic of

Aims: Caring for spouses with cognitive impairments presents significant emotional and physiological challenges. This study longitudinally examined the correlation between neuropsychiatric symptoms, as assessed by the Neuropsychiatric Inventory (NPI), and the levels of the inflammatory biomarker Oxidized Low-Density-Lipoprotein Receptor-1(OLR1) in spousal caregivers.
Methods: From May 2020 to May 2023, patients visiting the Chungnam National University Hospital Geriatric Neuropsychiatric Clinic with their spouses underwent clinical evaluations and blood tests. The study involved twenty spousal caregivers of individuals with diagnosed cognitive impairments, who completed baseline and one-year follow-up assessments. NPI scores were utilized to evaluate neuropsychiatric symptoms at baseline and after 12 months. Correspondingly, blood samples were collected at both time points to measure OLR1 levels. Longitudinal analyses, adjusted for age, sex, and baseline cognitive status, were utilized to scrutinize the evolving relationship between NPI scores and OLR1 levels.
Results: Preliminary data indicate a significant positive correlation between baseline NPI scores and OLR1 levels (p=0.038). Moreover, over a year, alterations in NPI scores were positively correlated with fluctuations in OLR1 levels (p=0.017). Spousal caregivers who reported an escalated care-recipient burden demonstrated a consistent increase in OLR1 levels throughout the 12-month observation period.
Conclusions: The results indicate that the neuropsychiatric challenges associated with caregiving might be linked with heightened inflammatory responses, as reflected by OLR1 levels. This correlation provides a deeper understanding of the physiological pathways potentially influenced by the stressors associated with caregiving for spouses with cognitive impairments. The potential ramifications on caregivers' cognitive and cardiovascular health necessitate further investigation.

Aims: Neuroinflammation leads to the direct demise of neurons, reduced synaptic activity, and suppression of neurogenesis in the hippocampus— making inflammation a critical factor in the progression of Alzheimer's Disease (AD). ER176 is a 3rd generation, PET neuroinflammation radiotracer that may help identify suitable candidates for specialized treatment when adversely impacted by neuroinflammation. ER176 has advantages over other radiotracers with its increased specific binding, reduced variability between subjects, capability to image low-affinity binders, and low radio metabolites entering the brain. We assessed ER176 detection of neuroinflammation in selected participant groups.
Methods: Participants from the Mayo Clinic Study of Aging were recruited for this study. The study included four participant groups: cognitively unimpaired with normal amyloid (CU A-, n=19), cognitively unimpaired with high amyloid (CU A+, n=15), mild cognitive impairment with increased amyloid (MCI A+, n=8), and AD dementia (AD, n=6). We explored the variations in Neuroinflammation PET results among different groups.
Results: Neuroinflammation was more elevated in the MCI and AD patients compared to both CU groups. Group averages showed that inflammation locality (MCI in frontal lobe, thalamus, basal ganglia, temporal lobe, & the occipital lobe and AD in temporal lobe) levels varied between the different groups. A voxel-wise comparison using a two-sample t-test revealed that the MCI and AD groups exhibited greater neuroinflammation than the CU groups. No differences were seen between CU A- vs CU A+.
Conclusions: Our findings suggest that the progression of neuroinflammation corresponds with cognitive decline rather than amyloid deposition

alone.

SEX DIFFERENCES IN CSF IMMUNE ACTIVATION MARKERS IN PREDEMENTIA ALZHEIMER'S DISEASE

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Stephanie Knudtzon[1], Kaja Nordengen[2], Per Selnes[3], Lene Pålhaugen[3], Knut Waterloo[1], Berglind Gísladóttir[3], Tormod Fladby[3], Bjørn-Eivind Kirsebom[1]
[1]Department of Neurology, University Hospital of North Norway, Neurology, Tromsø, Norway, [2]Institute of Clinical Medicine, University of Oslo, Oslo, Norway, Institute Of Clinical Medicine, Oslo, Norway, [3]Akerhus University Hospital, Neurology, Oslo, Norway

Aims: Alzheimer's disease (AD) is more commonly seen among females than males. The innate immune system plays an important role in the development of AD, and different immunological responses may account for some of the sex differences observed in the development of AD. To elucidate possible sex differences in AD-linked innate immune activity, concentrations of five innate immune biomarkers in the cerebrospinal fluid (CSF) were compared between males and females in cognitively normal (CN) cases with normal AD biomarkers, as well as predementia AD cases as defined by the A/T/N classification.
Methods: A total of 251 participants were included in the study. CSF amyloid beta $_{42/40}$ ratio (A), phosphorylated-tau181 (T), and total tau (N) concentrations were used to define the A/T/N classification. The included groups were CN without AD pathology (A-/T-/N-, n=75, 49.3% female), and two predementia AD groups comprising A+/T-/N- (n=38, 65.8% female) and A+/T+ or N+ (n=136, 53.7% female). Sex differences in CSF monocyte chemoattractant protein 1 (MCP-1), interleukin (IL)-6, IL-18, clusterin and Interferon-γ (INF-γ) and their association with total-tau (t-tau) and neurofilament light chain (NfL) were assessed with linear regression. Adjustments for multiple comparisons were performed with false discovery rate.
Results:

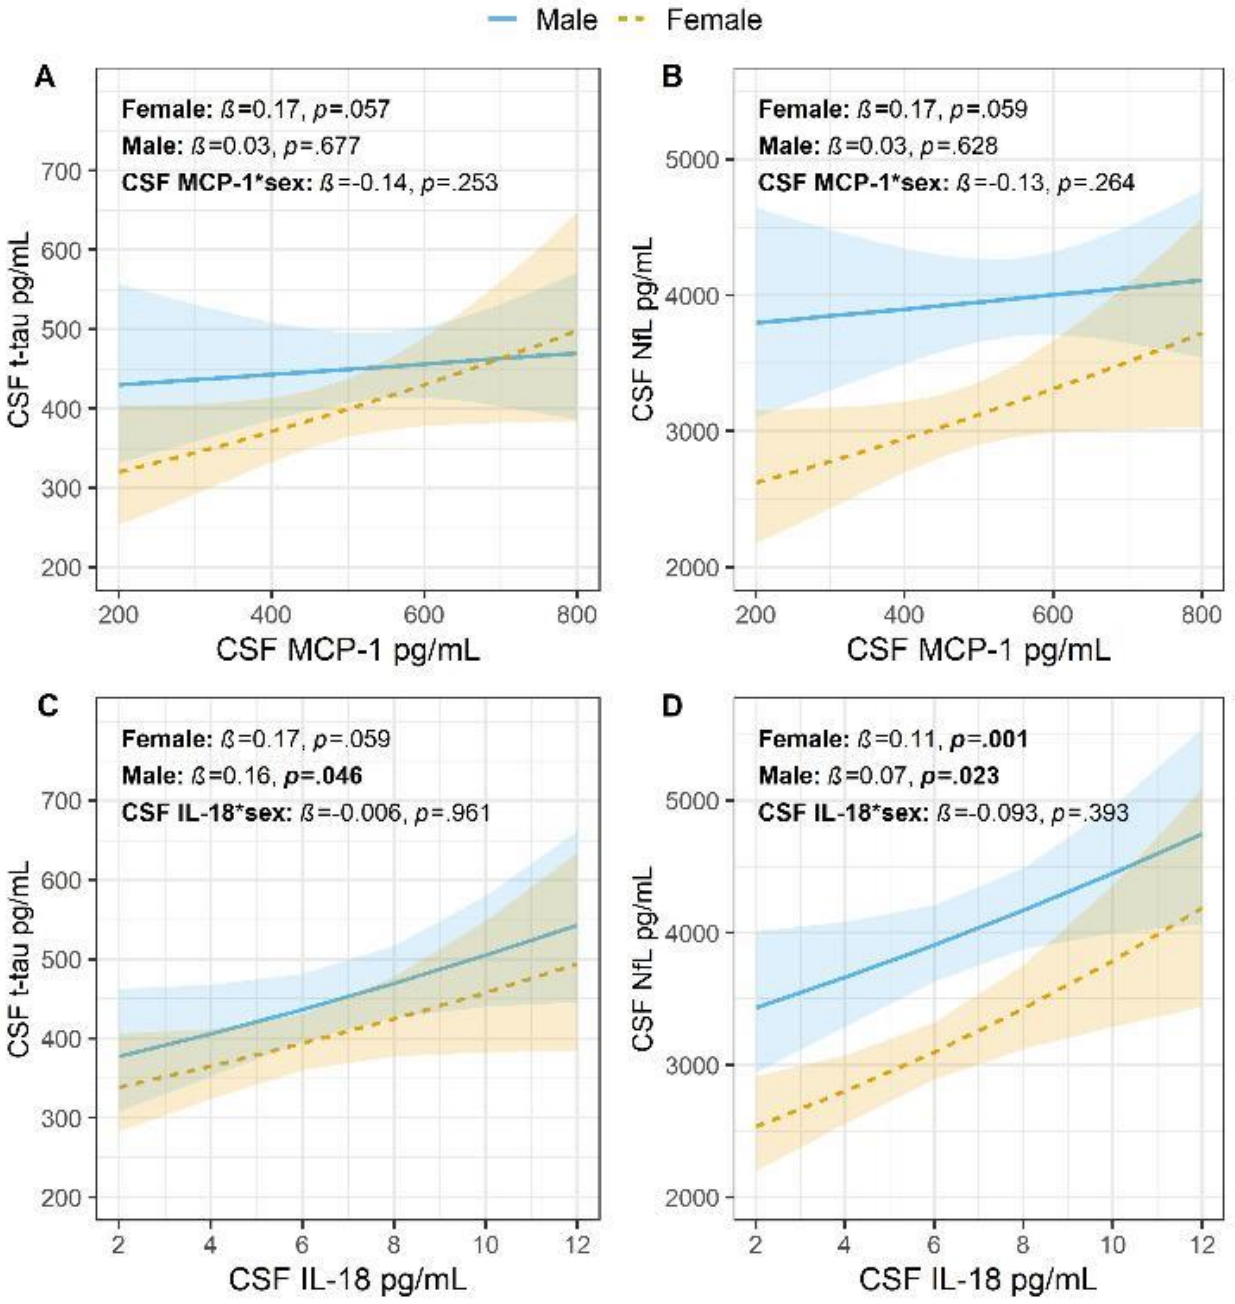
0
-3
A-/T-/N-
A+/T-/N-
A+/T+ or N+



CSF concentrations were higher in males than females for the following biomarkers: clusterin in the A-/T-/N- group (p.adjusted=.045), IL-18 in the A+/T-/N- group (p.adjusted=.015), and MCP-1 in the A+/T+ or N+ group (p.adjusted<.001). There were no significant sex differences in the associations between CSF neurodegeneration markers (t-tau or NfL) to MCP-1 or IL-18.

Conclusions: Higher concentrations of CSF immune biomarkers in males may indicate sex-related differential immune activation pattern across A/T/N stages. However, these differences seem not to relate to markers of neurodegeneration.

Gemelli Irccs, Rome, Italy, [3]National Research Council (CNR), Institute Of Translational Pharmacology, Rome, Italy, [4]Istituto Superiore di Sanità, Department Of Infectious Diseases, Rome, Italy, [5]Sapienza University of Rome, Department Of Public Health And Infectious Diseases, Laboratory Affiliated To Istituto Pasteur Italia - Cenci Bolognetti Foundation, Rome, Italy

Aims: In previous studies we demonstrated that when Herpes Simplex virus type 1 (HSV-1) reaches the CNS its replication triggers accumulation of Alzheimer's disease (AD) hallmarks leading to synaptic and memory deficits in C57/Bl6 mice. Here we investigated the contribution of interleukin-1β (IL-1β) to the HSV-1-induced AD-like phenotype after multiple cycles of viral reactivation.
Methods: Molecular, electrophysiological and behavioral analyses were performed in C57/Bl6, APP$^{-/-}$ and Tau$^{-/-}$ mice infected with HSV-1 and subjected to either two (2TS) or six (6TS) thermal stress-induced viral reactivations, along with or without treatment with the IL-1 receptor antagonist, anakinra (30 mg/kg, i.p.).
Results: After 2TS, HSV-1-infected C57/Bl6 mice exhibited increased levels of IL-1β negatively affecting synapse structure and function leading to memory deficits. This AD-like phenotype was fully rescued by mice treatment with anakinra, that also counteracted the hyperphosphorylation of glycogen synthase kinase 3β at Tyr216 and amyloid precursor protein (APP) at Thr668, we observed in infected mice. In HSV-1-infected APP-/- and Tau-/- mice undergone 2TS we also found upregulation of IL-1β mRNA (+1.8 and +1.7 folds vs. mock-infected mice, respectively, $p<0.05$) that correlated with deficits of long-term potentiation (74.9±6.7% vs. 102.3±10.2% in Tau-/- mice and 67.2±5.7% vs. 90.8±9.8% in APP -/- mice; $p<0.05$ vs mock-infected). After 6TS brain accumulation of amyloid-β (Aβ) and pTau was far greater than at 2TS and anakinra treatment failed to ameliorate the synaptic and memory deficits in HSV-1-infected mice.
Conclusions: Collectively, our findings suggest that IL-1β-mediated neuroinflammation is a major determinant of the AD-like phenotype that we observed at early stages of our mouse model of sporadic AD. At later stages Aβ and pTau accumulation makes our model no more responsive to pharmacological treatments blocking the molecular cascade downstream the IL receptor.

ACTIVATED CGAS-STING PATHWAYS COORDINATE NEUROINFLAMMATION AND MITOCHONDRIAL IMPAIRMENT IN THE APP KNOCK-IN MICE

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Sifang Liao[1], Makoto Shimozawa[2], Li-Peng Mao[3], Per Nilsson[4], Evandro Fang[1]
[1]University of Oslo and Akershus University Hospita, Department Of Clinical Molecular Biology, Lørenskog, Norway, [2]Karolinska Institutet, Department Of Neurobiology, Care Sciences And Society, SOLNA, Sweden, [3]Institute of Geriatric Immunology, School of Medicine, Jinan University, Department Of Microbiology And Immunology, School Of Medicine, Guangzhou, China, [4]Karolinska Institutet, Department Of Neurobiology, Care Sciences And Society, Solna, Sweden

Aims: Alzheimer's disease (AD) is the primary form of late-onset dementia with the hallmarks of amyloid-β plaques and tau aggregates deposition. Mitochondrial dysfunction and neuroinflammation play crucial roles in the development of AD. The cGAS enzyme detects cytosolic DNA, especially leaked mtDNA, leading to the activation of STING and the expression of genes that cause inflammation. TANK-binding kinase 1 (TBK1) is located downstream of the cGAS-STING pathway and is responsible for regulating the expression of type-I interferons and other cytokines; interestingly, TBK1 also plays a role in the autophagy/mitophagy to maintain mitochondrial quality. We aim to investigate how TBK1 coordinates its double-side roles in AD using a cross-species approach in the APP knock-in mice.
Methods: Hippocampus tissues were collected from 2, 6, and 12-month-old APP knock-in mice and their controls. Then RNA-seq, electron microscope, and Immunohistofluorecense were utilized to examine the changes in neuroinflammation and mitochondrial morphology in the APP knock-in mice and their controls.
Results: Our RNA-seq data suggest that signaling pathways related to neuroinflammation were elevated in the APP^{NL-G-F} AD mice in an age-dependent manner. Compared with WT mice, we observed altered mitochondrial homeostasis and a high accumulation of damaged mitochondria in the hippocampal tissue of the 12-month-old APP^{NL-G-F} mice paralleled by activation of the cGAS-STING signaling in this AD mouse. We then analyzed the genes related to lysosomal function and found that these genes are significantly affected in the APP^{NL-G-F} mice.
Conclusions: Our data suggest that APP KI mice displayed strong neuroinflammation, and it may be due to the accumulation of damaged mitochondria. We are now manipulating the expression and activity of TBK1 and monitoring the effects on neuroinflammation and mitophagy in AD animals of different ages.

NEUROINFLAMMATION IN ALZHEIMER'S DISEASE: EVIDENCE OF ELEVATED INFLAMMASOMES SIGNALLING CASCADE IN POSTMORTEM NEOCORTEX

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Frances Lim[1], Yuek Chai[1], Thiruma Arumugam[2], Michelle Tan[1,3], Mitchell Lai[1]
[1]National University of Singapore/Yong Loo Lin School of Medicine, Pharmacology, Singapore, Singapore, [2]La Trobe University, Microbiology, Anatomy, Physiology & Pharmacology, Melbourne, Australia, [3]Singapore General Hospital, Clinical Translational Research, Singapore, Singapore

Aims: Inflammasomes are cytosolic pattern recognition receptors that play a vital role in host innate immune response to pathogen infections and in tissue repair upon cellular damage. *In vitro* and animal experimentations showed that early build-up of Alzheimer's disease (AD)-associated proteins, namely β-amyloid plaques and neurofibrillary tangles, may trigger the activation of the inflammasomes. Upon activation, inflammasome forms a protein complex and elicits a signalling cascade involving the cleavage and activation of pro-inflammatory cytokines, leading to neuroinflammation, and contributing to AD pathophysiology. However to date, there is no comprehensive study of the inflammasomes-related pathway signalling cascade in human cases of AD. Hence, this study aims to investigate the key inflammasomes-related genes in postmortem AD brains.
Methods: Expression profiling of inflammasomes-related genes NLRP1, NLRP3, AIM2, PYCARD, CASP1, IL1B, IL18 and GSDMD were performed in two neocortical areas (Brodmann areas [BA] 9 and 21) in a cohort of 48 neuropathologically confirmed AD patients and 33 controls. Mann-Whitney U test and False Discovery Rate were used to compare the relative expression levels of each gene between AD and control groups.
Results: In both BA9 and BA21, CASP1, PYCARD and GSDMD relative gene expression levels were significantly increased in AD compared to controls. IL18 gene expression level was significantly increased in BA9 of AD compared to controls, while NLRP1, NLRP3, AIM2 and IL1B gene expression levels were significantly increased in BA21.
Conclusions: AD neocortex showed both region-specific and non-specific upregulation of genes related to inflammasome activation. Given that activated inflammasomes play an instrumental role in the instigation of neuroinflammation which may subsequently exacerbate the neurodegenerative process in conditions such as AD, inflammasomes may be considered as a potential treatment target in alleviating neuroinflammation in AD patients.

REGULATION OF ASTROCYTE REACTIVITY BY THE ALZHEIMER'S DISEASE RISK GENE CLU

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Alexandra Lish[1], Elyssa Grogan[1], Hyo Lee[2], Nancy Ashour[1], Seeley Fancher[1], Gwen Orme[1], Nicholas Seyfried[3,4,5], Courtney Benoit[1], Richard Pearse Ii[1], Tracy Young-Pearse[1]
[1]Brigham and Women's Hospital, Neurology, Boston, United States of America, [2]Icahn School of Medicine at Mount Sinai, Genetics And Genomic Sciences, New York City, United States of America, [3]Emory University School of Medicine, Center For Neurological Disorder, Atlanta, United States of America, [4]Emory University School of Medicine, Department Of Biochemistry, Atlanta, United States of America, [5]Emory University School of Medicine, Neurology, Atlanta, United States of America

Aims: Genetic studies have implicated CLU in the pathogenesis of Alzheimer's disease (AD). CLU is implicated in heterogeneous biological processes, but the precise molecular mechanisms by which CLU alters disease risk remain unclear. We aimed to interrogate the cell autonomous and non-autonomous consequences of CLU loss-of-function.
Methods: CRISPR/Cas9 editing was employed to generate CLU iPSC isogenic sets of lines (WT, HET, and KO). After differentiating these lines to neurons and astrocytes, we performed unbiased proteomic profiling to identify candidate cell-type specific mechanisms impacted by CLU loss. Top findings were validated using a combination of methods, including western blotting, ELISA measurements, and qPCR. Finally, astrocyte-neuron-microglia co-cultures were used to elucidate how astrocyte-derived CLU influences the homeostasis of other cell types.
Results: Based on our proteomics screen, we focused on an intriguing finding that the loss of CLU induces an inflammatory response in astrocytes in the absence of other AD-relevant stressors. This resulted in the upregulation of IL-6 and C3. We determined that NfkB signaling is strongly upregulated in CLU KO astrocytes. Activating NfkB signaling in astrocytes increases CLU expression, suggesting a compensatory feedback loop. Using microglia-astrocyte-neuron co-cultures, we found that astrocytic CLU affects neuronal synaptic vesicle release
Conclusions: Taken together, our data provide a mechanistic link between CLU expression in astrocytes and NfkB signaling, both of which are strongly implicated in AD pathogenesis. In AD, there is significant degeneration of neurons and microglial overactivation, and our unique experimental approach allows us to capture whether and how the loss of CLU in human astrocytes contributes to pathological changes in other brain cell types.

A MULTI-PRONGED RESPONSE OF XENOGRAFTED HUMAN MICROGLIA TO ALZHEIMER'S DISEASE AB PATHOLOGY

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Renzo Mancuso
VIB-University of Antwerp, Vib-center For Molecular Neurology, Antwerp, Belgium

Aims: Analyzing human microglia cell states relevant to Alzheimer's Disease (AD) in human brain samples is challenging due to genetic diversity, postmortem delay and admixture of pathologies.
Methods: We therefore collected 138,577 single cell expression profiles of human microglia derived from a well-controlled xenotransplantation model of AD.
Results: Human microglia adopt a disease-associated (DAM) profile similar to mouse microglia but display a more pronounced HLA state, likely related to antigen presentation in response to amyloid plaques. The human response is in addition characterized by a pro-inflammatorycytokine/chemokine CRM response raised to oligomeric Aβo. Expression of AD risk genes is distributed over this multi-pronged response to amyloid pathology. Genetic deletion of TREM2 or APOE, as well as APOE polymorphisms and TREM2R47H expression modulate these responses differentially.
Conclusions: Therapeutic strategies targeting microglia need to assess how they affect not only DAM responses but all different cell states, as this will define their therapeutic outcome.

Aims: The concept of hybrid molecules incorporating pharmacophores of herbal drugs and commercial ones is novel and promising that can effectively target multifactorial diseases . In the present work a hybrid molecule has been prepared containing the pharmacophores of L-Dopa and Curcumin, so that it serves dual purpose of release of Dopamine as well as protection of surviving neurons .
Methods: We have designed , synthesized and tested a hybrid molecule containing pharmacophores of L-Dopa , the commercial drug for Parkinson,s disease and Curcumin. . Curcumin protects neuronal mitochondria against oxidative/nitrosative stress, induces glutathione synthesis in cell and animal models of Parkinson's disorder. The composition was designed through in silico methods .The hybrid molecule has been synthesized in one step .In vitro tests on N27 Neuronal cell line and study conducted in neurotoxin 6-hydroxydopamine induced sporadic Parkinson's disease rat model show positive results.
Results: The synthetic hybrid molecule was obtained in quantitative yield .It was characterized by IR, H^1, ^{13} C NMR and Mass spectra. *In-silico* studies show that this modified Curcumin - L-DOPA drug can serve as a highly efficient inhibitor of both i.e. Parkin (c-Abl) as well as α-Synuclein, the two neuronal proteins implicated in Parkinson disease. In vitro tests on N27 Neuronal cell line and study conducted in neurotoxin 6-hydroxydopamine induced sporadic Parkinson's disease rat model show enhanced activity vis-a vis L-Dopa.
Conclusions: The Conjugate containing pharmacophores of L-Dopa and Curcumin is expected to serve dual purpose i.e. release Dopamine as well as offer protection to surviving neurons in case of Parkinson's disease. The hybrid approach has potential future in drug discovery, since it can combine the basic concept of Ayurveda with perspective of modern medicine . .

HERPES SIMPLEX VIRUS-1 INFECTION INDUCES COMPLEMENT PROTEINS UPREGULATION IN BRAIN CELLS: POSSIBLE ROLE IN SYNAPTIC DAMAGE

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Mariya Timotey Miteva[1], Virginia Protto[1,2], Maria Elena Marcocci[1], Roberto Piacentini[3], Domenica Donatella Li Puma[3], Anna Teresa Palamara[1,2], Giovanna De Chiara[4]
[1]Sapienza University of Rome, Department Of Infectious Diseases And Public Health, Rome, Italy, [2]Istituto Superiore di Sanità, Department Of Infectious Diseases, Rome, Italy, [3]Università Cattolica del Sacro Cuore, Department Of Neuroscience, Rome, Italy, [4]National Research Council (CNR), Institute Of Translational Pharmacology, Rome, Italy

Aims: Several pieces of evidence suggest that recurrent herpes simplex virus-1 (HSV-1) infection reaching the brain is one of the risk factors for Alzheimer's disease (AD). Numerous studies suggest that abnormal upregulation of the complement cascade, a key component of the innate immune system, is involved in the pathogenesis of AD, also concurring to synaptic elimination in the brain (Hong et al, 2016). This study aims to investigate if HSV-1 infection triggers complement protein activation in brain cells and to evaluate if this event leads to synaptic loss, a process recently demonstrated for other viral brain infections, but still unexplored for HSV-1.
Methods: We mock- and HSV-1 infected primary neuron-glia co-cultures isolated from rat brain embryos and analyzed cells 24h post-infection. Cells were assayed by Western Blot and RT-PCR for the expression of complement components C1q, C3, and C4 and synaptic markers PSD-95 and synaptophysin, postsynaptic and presynaptic markers, respectively. Immunofluorescence analyses (IF) were also carried out to detect specifically C3 and C1q expression. A Neutralisation Assay was performed infecting cells in the presence or absence of an anti-C3 antibody, or with Compstatin, an inhibitor of C3 convertase.
Results: HSV-1 infection in cultured rat brain cells induces a significant increase of C1q, C3, and C4 at both mRNA and protein levels. ELISA Assay shows a significant C3 increase in supernatants of HSV-1 infected cells. The C3 and C1q increase after HSV-1 infection was also confirmed by IF. Finally, neutralization of C3, in both strategies, leads to partial rescue of the HSV-1-induced decrease of PSD-95 and synaptophysin.
Conclusions: Overall, these results suggest a possible complement-dependent synaptic damage triggered by HSV-1 brain infection, thus strengthening the causal link between HSV-1 and neurodegeneration.

INHIBITION OF AN OXIDIZED CONFORMER OF MACROPHAGE MIGRATION INHIBITORY FACTOR (MIF) AS A STRATEGY AGAINST SPORADIC ALZHEIMER´S DISEASE

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Andreas Müller-Schiffmann[1], Felix Torres[2], Anatolly Kitaygorodskyy[3], Argyro Alatza[4], Sarah Tschirner[1], Annemieke Rozemuller[5], Selina Wray[4], Roland Riek[3], Vishwanath Lingappa[3], Carsten Korth[6]
[1]University of Düsseldorf, Neuropathology, Düsseldorf, Germany, [2]ETH Zurich, Physical Chemistry, Zurich, Switzerland, [3]Prosetta Biosciences, Chemistry, San Francisco, United States of America, [4]University College London, Neurodegenerative Diseases, London, United Kingdom, [5]VUMC Amsterdam, Neuropathology, Amsterdam, Netherlands, [6]Heinrich Heine University of Düsseldorf, Neuropathology, Düsseldorf, Germany

Aims: The molecular factors connecting epidemiologically established systemic risk factors such as subchronic inflammation, obesity, diabetes and others to sporadic Alzheimer's disease (AD) are unknown. Eventually, these risk factors converge on trigger proteins upstream of the amyloid beta cascade and tau phosphorylation.
Methods: We used small molecule compounds inhibiting cellular host factors necessary for herpes virus replication as a discovery tool to identify such molecular interfaces upstream of AD cellular pathology. The target of the lead compound was identified via drug affinity chromatography. Validation was done in cellular and animal models of AD-like pathology.
Results: Our lead compound inhibited the conversion of macrophage migration inhibitory factor (MIF) to the oxidized conformer (oxMIF) in the presence or absence of herpes virus infection. This led to decreased downstream Akt and GSK signaling, as well as decreased tau phosphorylation and aggregation *in vitro* and *in vivo* in the tgTau58/2 model. Novel monoclonal antibodies specific to oxMIF enabled improved characterization of its induction and conformational conversion.
Conclusions: oxMIF is a powerful molecular target in the pharmacotherapy of sporadic AD and apparently a converging point of external systemic factors triggering or accelerating AD-like neuropathology. Its inhibition is a highly promising avenue for sporadic AD pharmacotherapy.

Aims: The role of transactive response DNA binding protein-43 (TDP-43), immune response, and mitochondrial damage in the pathogenesis of Alzheimer's disease (AD) is under investigation. TDP-43 has been studied in amyotrophic lateral sclerosis (ALS) and frontotemporal lobar degeneration with ubiquitin-positive inclusions, but several data support its role in AD. Neurofilament light chain (NfL) is a well-established biomarker of neuroaxonal injury in neurodegenerative diseases. Growth differentiation factor-15 (GDF-15) represents a validated marker for mitochondrial dysfunction and has interesting associations with disability in AD. The aim of this study is to assess the CSF concentrations of NfL, GFAP, GDF-15, TDP-43, and 13 different cytokines in a cohort of AD patients, and to explore their association with clinical disability and pathological burden.
Methods: We used the commercially available immunoassay kits for NfL, GFAP, and TDP-43 run on the ultrasensitive SR-X Biomarker Detection System (Quanterix). Concentrations of selected cytokines were determined by multiplex bead-based flow cytometry assay (LEGENDplex, Biolegend, San Diego, CA). GDF-15 concentrations were assessed using Abcam's GDF-15 Human ELISA kit.
Results: 58 patients were enrolled in this study. Patient median age (IQR) was 75 years (71.75-78.25) and 35% were males. The median MMSE score (IQR) was 24 (21.15-26). MMSE was correlated with beta-amyloid CSF concentration (R 0.44;p<0.001), with GDF-15 CSF concentration (R =0.44;p<0.001), with IL-17A (R=0.37;p=0.006). TDP-43 CSF concentration correlated with IL-1beta (R=-0.32;p=0.015), with IL-6 (R=-0,27;p=0.041) and with IL-12p70 (R=-0.27;p=0.042). GDF-15 CSF concentration was also inversely correlated with beta-amyloid CSF concentration (R=-0.47;p<0.001). CSF NfL concentration was correlated with age (R=0.28;p=0.032), IP-10 (R=0.27;p=0.04), IL-1beta (R=0.27;p=0.041), TNF-alpha (R=0.29;p=0.02), IL-6 (R=0.35;p=0.007) and IL-8 (R=0.28;p=0.036).
Conclusions: The findings of this study, support the notion of a link between neuroinflammation, neurodegeneration, and mitochondrial dysfunction in the pathogenesis of cognitive decline in AD.

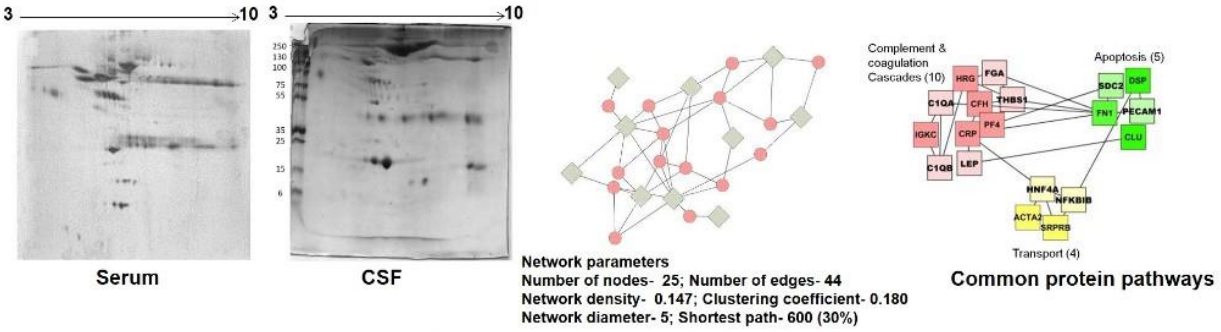
BIOLOGICAL PROTEIN INTERACTION STUDY OF AMYLOID BETA PEPTIDE INTERACTIONS WITH BLOOD AND CSF: ROLE IN ALZHEIMER'S DISEASE

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Pratibha Sharma[1,2], Alagiri Srinivasan[1], Rajinder Dhamija[3]
[1]All India Institute of Medical Sciences, Biophysics, New Delhi, India, [2]Institute of Human Behaviour and Allied Sciences, Human Behaviour Department, Delhi, India, [3]Institute of Human Behaviour and Allied Sciences, Director And Professor Neurology, Delhi, India

Aims: Background: Alzheimer's disease (AD) is a complex and age-dependent neurodegenerative disorder that results in dementia, causing cognitive impairment and memory decline. The pathology and etiology of this disease are quite complicated. Amyloid beta (1-42) is known to play a central role in the disease by forming fibrils. Plaque refers to the loose tangle of fibers deposited outside neurons. Many CSF and blood proteins interact with Aβ and plaques through the blood-brain barrier. An interactive analysis of their functions is necessary to describe the disease status. **Objective:** To identify the blood and CSF protein interactions specific to oligomer Aβ.
Methods: Aβ peptide monomer and oligomer forms were separated using gel-filtration chromatography. These were allowed to pull-down separately with blood serum and CSF proteins from Wister albino rat using affinity chromatography in proteins native form. Interacting proteins were digested in-gel and in-solution by trypsin and identified using Mass spectrometry. Gene ontology and pathway analysis were performed for classification and interactions of proteins with respect to AD pathways.
Results:



Proteomics analysis results of blood serum and CSF proteins from Wister Albino rat interacting with Amyloid beta (1-42) peptide

The results of the pathway analysis indicate that the complement pathway has an essential role to play in AD, depicted in below images.

Conclusions: The circulatory proteins play a crucial role in the transport and clearance of Aβ, which can trigger inflammation pathways and apoptosis pathways.

SPECIFIC SERUM AUTOANTIBODIES PREDICT THE DEVELOPMENT AND PROGRESSION OF ALZHEIMER'S DISEASE WITH HIGH ACCURACY

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Lu Shen[1], Liangjuan Fang[1], Bin Jiao[2]
[1]Xiangya Hospital, Central South University, Department Of Neurology, Changsha, China, [2]87 Xiangya Road Xiangya Hospital, Central South University, Department Of Neurology, Changsha, China

Aims: Autoimmunity plays a key role in the pathogenesis of Alzheimer's disease (AD). However, whether autoantibodies in peripheral blood can be used as biomarkers for AD has been elusive.
Methods: Serum samples were obtained from 1,686 participants, including 767 with AD, 146 with mild cognitive impairment (MCI), 255 with other neurodegenerative diseases, and 518 healthy controls. Specific autoantibodies were measured using a custom-made immunoassay. Multivariate support vector machine models were employed to investigate the correlation between serum autoantibody levels and disease states.
Results: Seven candidate AD-specific autoantibodies were identified, including MAPT, DNAJC8, KDM4D, SERF1A, CDKN1A, AGER, and ASXL1. A classification model with high accuracy (area under the curve (AUC) = 0.94) was established. Importantly, these autoantibodies could distinguish AD from other neurodegenerative diseases and out-performed amyloid and tau protein concentrations in cerebrospinal fluid in predicting cognitive decline ($P < 0.001$).
Conclusions: This study indicated that AD onset and progression are possibly accompanied by an unappreciated serum autoantibody response. Therefore, future studies could optimize its application as a convenient biomarker for the early detection of AD.

RATIONAL TARGETING OF NLRP3 INFLAMMASOME IN MICROGLIA: A CRSIPR TILING SCREEN BASED APPROACH FOR DEVISING A NOVEL NEURO-IMMUNOMODULATORY THERAPY FOR AD

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Falak Sher
Columbia University, Neurology, New York City, United States of America

Aims: The NLRP3 inflammasome is crucial in Alzheimer's disease (AD) inflammation and progression, with microglia playing a key role. Targeting NLRP3 can reduce AD-associated inflammatory markers and pathologies. Current NLRP3 inhibitors often lack specificity, leading to side effects. A more precise inhibitor would address these issues, making it a promising therapeutic avenue for AD. We are actively exploring this direction through following aims: 1). Investigate the role of the NLRP3 inflammasome in AD's pathogenesis and progression. 2). Identify the subunits of microglial inflammasome and importantly 3). Develop a rational NLRP3 inhibitor that offers increased specificity and reduced side effects.
Methods: 1. Utilization of pooled CRISPR-tiling to disrupt inflammasome protein-coding sequences in human microglial model systems. 2. Functional mapping of high-throughput CRISPR perturbations to identify critical protein interfaces. 3. Employing CRISPR-mediated homology-directed repair (HDR) for high-throughput variant classification, combined with a haploidization strategy, to assess over 500 variants for altered inflammasome activation.
Results: 1. Identified a crucial, non-redundant subcomplex of the NLRP3 protein family essential for inflammasome activation. 2. Revealed in-frame alleles causing inflammasome subunit loss-of-function due to destabilization or functional alteration. 3. Pinpointed specific amino acids in NLRP3 ideal for developing rational small molecules to regulate inflammasome activity.
Conclusions: 1. The NLRP3 inflammasome plays a significant role in AD's pathogenesis, and interventions targeting it can alleviate AD-related pathological hallmarks. 2. Many current NLRP3 inhibitors lack specificity and come with side effects, emphasizing the need for more targeted inhibitors. 3. The research introduces a robust methodology that illuminates specific amino acids in NLRP3 for intervention and advances the understanding of the inflammasome, offering potential therapeutic applications in AD.

RAB10 IN NEURO-IMMUNE CROSS-TALK ASSOCIATED WITH ALZHEIMER'S DISEASE

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Erzsebet Szatmari[1], Wyatt Bunner[1], Lauren Grodi[1], Alessandro Didonna[2], Jonathan Jacob Carver[2], Debajit Bhowmick[2]
[1]East Carolina University, Physical Therapy, Greenville, United States of America, [2]East Carolina University, Anatomy And Cell Biology, Greenville, United States of America

Aims: Objectives: Reduced activity of Rab10, a small Rab GTPase involved in vesicular trafficking was found to confer resilience against Alzheimer's disease (AD) even for high-risk individuals. To identify the mediators of Rab10-dependent neuroresilience, we developed heterozygous knockout mice for Rab10 ($Rab10^{+/-}$). The objective of this study was to elucidate the role of Rab10 in the AD-dependent activation of central and peripheral immune responses.
Methods: Methods: Immunofluorescence staining: for Iba1 and GFAP on coronal sections from 4-month-old $Rab10^{+/}$ and $Rab10^{+/+}$ mice. Flow cytometry: to evaluate the activation state and the immunophenotype of specific immune cells isolated from the spleen of 4-month-old $Rab10^{+/}$ and $Rab10^{+/+}$ mice. Treatment of $Rab10^{+/-}$ and $Rab10^{+/+}$ organotypic hippocampal slices with oligomeric amyloid (oAβ) or scrambled Aβ peptide as control, followed by measurement of pro-inflammatory cytokine release into the culture medium using a Luminex multiplex assay.
Results: Results: In the $Rab10^{+/-}$ hippocampus, the baseline activation status of the microglia (Iba1-immunoreactivity) was significantly reduced. Flow cytometry analysis of peripheral immune cells indicated reduction in natural killer (NK) cells in the spleen of $Rab10^{+/-}$ mice. There was no difference between genotypes in the total CD8 and CD4 lymphocytes. However CD8 effector cells % was significantly lower, while CD4 effector cells were higher in $Rab10^{+/-}$ mice. Treatment of $Rab10^{+/-}$ and $Rab10^{+/+}$ organotypic hippocampal slices with oAβ42 or scAβ followed by measurement of cytokine release indicated a significant reduction in the production of IL1-β, TNFα and IFNγ in $Rab10^{+/-}$ slices.
Conclusions: Conclusions: Our data suggest a role for Rab10 in innate immunity that has been shown to contribute to AD progression. Through attenuating neuroinflammation and modulating immune cell phenotypes, Rab10 reduction might offer a promising therapeutic avenue for prevention or treatment of AD.

BETA-AMYLOID IS A CYTOKINE AND ALZHEIMER'S IS AN INNATE AUTOIMMUNE DISEASE REGULATED BY AMINO ACID (TRYPTOPHAN, ARGININE, BETA-ALANINE, TAURINE) METABOLISM

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Autumn Meek, Yanfei Wang, Mark Reed, Christopher Barden, Donald Weaver
Krembil Brain Institute, Neurobiology, Toronto, Canada

Aims: There is a need for a model of AD that unifies current divergent theories into a harmonized mechanistic explanation. Incorporating protein aggregation processes into a broadly-encompassing immunopathic model of AD by repositioning Aβ as an immunopeptide (cytokine) achieves this goal. Our study comprehensively evaluates Aβ as a cytokine, conceptualizing AD as an innate autoimmune disease subject to endogenous homeostatic regulation by four amino acids (tryptophan, arginine, β-alanine, taurine).
Methods: We performed a comprehensive series of in silico, in vitro, and in vivo studies to rigorously analyze the molecular mechanisms of Aβ-mediated neurotoxicities in AD, comparing Aβ to known cytokines and AD to known autoimmune diseases.
Results: Triggered by diverse stimuli (infection [viral, bacterial], trauma, ischaemia, air pollution), Aβ is released as a cytokine initiating an innate immunity cascade in which Aβ demonstrates immunomodulatory and antimicrobial properties (whether or not bacteria are present), resulting in a misdirected attack upon host neurons. This mistaken attack occurs because of similar membrane electrotopologies between neurons and bacteria; *i.e*. Aβ cannot differentiate neurons (particularly the synaptic zone) from bacteria. This neuron-bacterium misidentification is a key aetiopathogenic step in AD. After the misdirected-attack, the resulting necrotic neuronal products (Aβ-GM1 aggregates) diffuse to nearby neurons causing ongoing release of Aβ, leading to a chronic innate autoimmune cycle. AD is therefore a brain-centric autoimmune disorder of innate immunity; a subsequent screening program identified four amino acids (tryptophan, arginine, β-alanine, taurine) and their metabolites as key homeostatic regulators on brain innate immunity capable of downregulating neuroinflammation.
Conclusions: Positioning Aβ as a cytokine, conceptualizing AD as an innate autoimmune disease, and identifying endogenous regulatory molecules (L-tryptophan, L-arginine, β-alanine, taurine) which homeostatically influence innate autoimmunity constitutes an innovative mechanistic and therapeutic approach to AD.

CXCL16-CXCR6 AXIS INVOLVEMENT IN ALZHEIMER'S DISEASE-SPECIFIC CD8+T-CELLS RECRUITMENT TO THE BRAIN

POSTERS: A01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Marco Zattoni[1], Sabine Bernegger[1], Sofia Weinbender[1], Rodolphe Poupardin[2], Barbara Altendorfer[1], Heike Mrowetz[1], Ludwig Aigner[1]
[1]Paracelsus Medical University Salzburg, Institute Of Molecular Regenerative Medicine, Salzburg, Austria, [2]Paracelsus Medical University Salzburg, Institute Of Experimental And Clinical Cell Therapy, Salzburg, Austria

Aims: Together with brain amyloid depositions, astrogliosis and microglia activation, Alzheimer´s disease (AD) progression has been recently associated with infiltration of $CD8^+$ T-cells into brain parenchyma. $CD8^+$ T-cells tightly associate with microglia and neurons in brain of AD-affected humans and APP/PS1 animals, a widely used AD mouse model. Although the mechanism involved in parenchymal $CD8^+$ T-cells accumulation remains unknown, recent studies suggested a potential role of the Cxcl16-Cxcr6 axis in their recruitment to the brain. Therefore, we aim to assess the interplay between $Cxcr6^+CD8^+$ T-cells and Cxcl16-producing cells in APP/PS1 brain.
Methods: Public available single cell RNA sequencing (scRNA seq) datasets helped us to identify the cellular source of Cxcl16 and its receptor. Quantitative PCR (qPCR) and immunohistochemical (IHC) analysis of brain tissue from microglia-depleted mice allowed us to investigate the role of Cxcl16-expressing cells in the recruitment of $Cxcr6^+CD8^+$ T-cells.
Results: scRNA seq datasets revealed that *Cxcr6* is mainly expressed by effector $CD8^+$ T-cells, while *Cxcl16* expression is characteristic of microglial cells. qPCR analysis indicated a significant overexpression of *Cxcl16* and *Cxcr6* in diseased-animals compared to controls. Furthermore, we observed slightly reduced *Cxcl16* and *Cxcr6* levels in microglia-depleted APP/PS1 mice compared to untreated animals, indicating microglia as the main source of Cxcl16 in AD-affected brains and a putative role of this chemokine in the recruitment of Cxcr6-expressing T-cells. Interestingly, IHC analysis of microglia-depleted APP/PS1 brain tissue showed an increased number of $Cxcr6^+CD8^+$ cells in close contact to remaining $Iba1^+$ cells.
Conclusions: Overall, these results suggested an involvement of Cxcl16-Cxcr6 axis in the recruitment of $CD8^+$ T-cells in APP/PS1 animals. Further functional analysis of microglia and T-lymphocytes cross talk may pave the way for novel therapies targeting Alzheimer´s and other related neurodegenerative diseases.

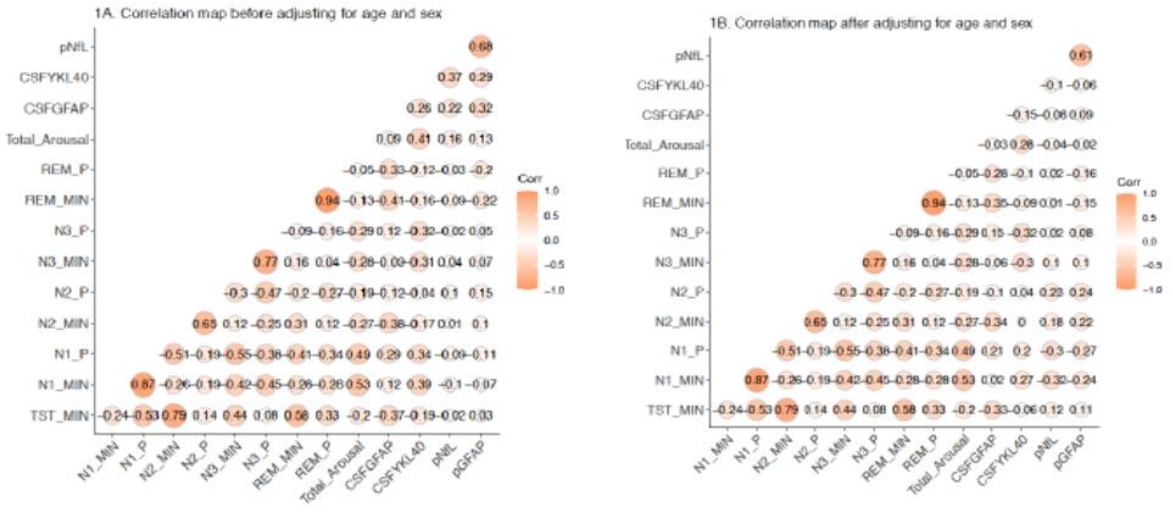
Aims: The relationship between neuroinflammation and sleep in cognitively unimpaired individuals has been scarcely studied. We aimed to explore the relationship between markers of neuroinflammation in cerebrospinal fluid (CSF) and plasma and sleep quantitative measures.
Methods: A total of 55 CU without sleep disorders underwent a nocturnal polysomnography (PSG) followed by morning blood collection. Additionally, 51 participants also underwent morning lumbar puncture to collect CSF. We assessed the concentrations of Glial Fibrillary Acidic Protein in CSF (CSFGFAP), in plasma (pGFAP), CSFYKL40 and plasma neurofilament (pNfL) for associations with PSG-derived quantitative sleep parameters using Spearman tests. Sleep parameters included total sleep time (TST), NREM (N1, N2, N3) and REM duration (MIN) and percentage (P), as well as total arousal events. Considering the influence of age and sex on biomarker concentrations, we also conducted analyses adjusted for these factors using linear regression models.
Results: Demographic, clinical and biomarker data are summarized in Table1. The mean age was 56 (13) years, with 32% being male. CSFGFAP showed significant negative correlation with TST, N2 duration; REM sleep duration, and percentage (all $p<0.05$). Similarly, CSFYKL40 positively correlated with N1 duration and percentage, and negatively correlated with N3 duration, percentage, and total arousal events (all $p<0.05$) (Figure 1.A). After adjusting for age and sex, we continued to observe negative correlation between CSFGFAP and TST, REM sleep ($p<0.05$), as well as between CSFYKL40, N3 sleep and total arousal events ($p<0.05$). Additionally, pNfL displayed an inverse correlation with N1 duration and percentage (both $p<0.05$) (Figure 1B).

Table 1. Sociodemographic, Clinical and fluid data from study Group (N=55)	
Age , Mean (SD), years	56 (13)
Male sex, n(%)	17 (31%)
APOE4+, n (%)	16 (32%)
MMSE, mean (SD)	29.4 (1)
TST, mean (SD), min	353 (65)
REM duration, mean (SD), min	63 (24)
N1 duration, mean (SD), min	39 (24)
N2 duration, mean (SD), min	175 (41)
N3 duration, mean (SD), min	73 (33)
Total arousal events, mean (SD)	17.5 (14)
CSFGFAP, median (IQR), pg/mL	6519 (4117)
CSFYKL40, median (IQR), pg/mL	191 (89)
pGFAP, median (IQR), pg/mL	108 (93)
pNfL, median (IQR), pg/mL	8 (4.7)

Figure1. Spearman Correlation Map between Sleep parameters and Inflammation Biomarkers



Conclusions: In CU individuals, the duration and quality of sleep associated with concentration of neuroinflammation and axonal damage biomarkers. This association is more pronounced in CSF neuroinflammation biomarkers. The nature and impact of these associations deserves further investigation.

SLEEP-DEPENDENT MODULATION OF BRAIN HOMEOSTASIS IN ALZHEIMER'S DISEASE

POSTERS: A01.D. DISEASE MECHANISMS, PATHOPHYSIOLOGY: SYNAPTIC PLASTCITY & SYNAPSE PATHOLOGY

Sara Calafate[1], Bart De Strooper[2], Tiago Gil Oliveira[3], Joris De Wit[2]
[1]Life and Health Sciences Research Institute (ICVS), School Of Medicine, Braga, Portugal, [2]KU Leuven & VIB, Center For Brain & Disease Research, Leuven, Belgium, [3]University of Minho, School Of Medicine, Braga, Portugal

Aims: In Alzheimer's disease (AD), early accumulation of amyloid-β (Aβ) causes deficits in episodic memory, leading to cognitive impairment. Moreover,hippocampal hyperactivity and increased susceptibility for seizure emerges, placing synapse dysfunction is at the basis of AD pathogenesis. Remarkably, neuronal hyperactivity is prominent during sleep and sleep disturbances are accompanied by silent epileptic-like discharges in individuals with AD during the prodromal phase. Moreover, early sleep disturbance coincides with aberrant neuronal activity and neuroinflammation, in patients and mouse models.
Methods: Recently, using spatial transcriptomics and bulk RNAsequencing, I found that the sleep-active Melanin Concentrating Hormone (MCH) decreases the expression of immediate early genes and restrains synaptic activity of hippocampal neurons (Calafate et al, 2023). MCH-neurons located in the lateral hypothalamic area (LHA), regulate duration of rapid-eye movement (REM) sleep and project to the hippocampus modulating hippocampal-dependent memory. Moreover, we took advantage of techniques such as EEG/EMG, electrophysiology and others.
Results: My work identified an early impairment of the MCH-system in AD patients and in the AppNL-G-F mice (a mouse model for early stages of AD) at the time point that aberrant hippocampal activity, impaired REM sleep and higher susceptibility for seizures emerge. Moreover, my work showed that MCH peptide is sufficient to rescue increased hippocampal excitatory synaptic transmission in the AppNL-G-F mice. This suggests that MCH, released during sleep, protects neurons from aberrant excitation placing the MCH-system as a key modulator of neuronal activity and homeostasis. However, brain homeostasis depends on complex interaction between cell-types. My preliminary data identifies that MCH-system has the capacity to modulate microglia response and therefore has the potential to orchestrate microglia-neuron communication.
Conclusions: I hypothesize that the failure of the sleep-related MCH-system contributes to loss of neuronal homeostasis by different but complementary mechanisms.

LICOCHALCONE A PREVENTS ALZHEIMER'S DISEASE DEVELOPMENT IN APPSWE/PS1DE9 MICE

POSTERS: A01.D. DISEASE MECHANISMS, PATHOPHYSIOLOGY: SYNAPTIC PLASTCITY & SYNAPSE PATHOLOGY

Marina Carrasco[1], Jordi Olloquequi[2], Ester Verdaguer[3], Carme Auladell[3], Jesus Ureña[3], Antoni Camins[1], Miren Ettcheto[4]
[1]universitat de Barcelona, Pharmacology, Toxicology And Therapeutic Chemistry, Barcelona, Spain, [2]university of Barcelona, Biochemistry And Physiology, barcelona, Spain, [3]universitat de Barcelona, Cellular Biology, Physiology And Immunology, Barcelona, Spain, [4]University of Barcelona, Pharmacology, Toxicology And Therapeutic Chemistry, barcelona, Spain

Aims: Alzheimer's Disease (AD) is the main form of dementia with no effective treatment available. Multiple studies have demonstrated the multifactorial character of the disease, suggesting that multi-target drugs could be a potential therapeutical treatment. Licochalcone A (LCA), a chalcone that comes from *Glycyrrhiza glabra,* has shown an anti-inflammatory and anti-diabetic effect among others, positioning as a promising drug to stop AD. Accordingly, the aim of this study was to evaluate the neuroprotective role of LCA to prevent AD development.
Methods: To perform this study, six-month-old C57BL/6J and double transgenic APPswe/PS1dE9 (APP/PS1) male mice were used. At five-month-old, animals were treated with LCA at a dose of 15 mg/kg/day or saline intraperitoneally three times per week/4 weeks, dividing them into 4 different groups; WT Saline, WT LCA, APP/PS1 Saline and APP/PS1 LCA. Afterwards, Novel Object Recognition Test (NORT) and Morris Water Maze (MWM) were performed to evaluate memory loss. Finally, several hallmarks of AD such as dendritic spine loss, β-amyloid (βA) plaques and chronic neuroinflammation, among others were evaluated.
Results: Our study demonstrated a protection against memory loss after LCA treatment in APP/PS1 mice in NORT and MWM behavioural tests. Additionally, these results correlate with the preservation of dendritic spine number in the animals previously treated with LCA comparing to the saline-treated transgenic mice. Altogether, the biochemical assays demonstrate a synaptic deterioration and βA plaques deposition in APP/PS1, which is significantly ameliorated due to LCA administration, enhancing synapsis and βA plaques clearance. Finally, LCA reported an amelioration of neuroinflammatory processes such us a reduction of microglial activation.
Conclusions: In conclusion,our results demonstrated that LCA ameliorates memory loss in APP/PS1 mice by the maintenance of dendritic spines, the reduction of βA plaques deposition and neuroinflammation.

ALTERED ACTIVITY-DEPENDENT NEURONAL GENE EXPRESSION IN ALZHEIMER'S DISEASE

POSTERS: A01.D. DISEASE MECHANISMS, PATHOPHYSIOLOGY: SYNAPTIC PLASTCITY & SYNAPSE PATHOLOGY

Xavier Fernandez-Olalla, Carles Vendrell-Tornero, Arnaldo Parra-Damas, Carlos A. Saura
Institut de Neurociencies, Departament De Bioquímica I Biologia Molecular, Bellaterra, Spain

Aims: Changes in gene expression programs in memory-related neural circuits are associated with cognitive decline in normal and pathological aging, including Alzheimer's disease (AD). However, the specific genes and the transcriptional regulatory mechanisms underlying synapse and cognitive dysfunction during AD progression are largely unknown. Our previous studies have revealed impairment of activity-induced CREB/CRTC1-regulated transcription at early and intermediate AD pathological stages. The aim of this study is to examine the mechanisms of activity-dependent gene changes during AD pathological progression.
Methods: We identified potential activity-regulated genes by analyzing published RNA-seq and CREB/CRTC1 ChIP-seq datasets obtained from depolarized mouse cultured neurons. We applied biochemical and molecular biology approaches to assess the differential expression of gene transcripts and proteins induced by neuronal activity and potentially altered in human hippocampus of AD. Furthermore, we used lentiviral transduction to modulate CREB signaling in mouse neuronal cultures.
Results: Our results revealed that specific activity-dependent immediate-early-genes (IEGs) as well as synaptic function and plasticity-related genes were transcriptionally regulated by CREB/CRTC1 signaling. Accordingly, pharmacological and lentiviral modulation of the CREB/CRTC1 signaling pathway confirmed differential modulation of these activity-dependent genes in primary neurons. Importantly, some of these genes were deregulated in the human hippocampus at distinct AD pathological stages.
Conclusions: These results indicate that altered expression of activity-dependent neuronal genes regulated by CREB/CRTC1 in memory-related neural circuits may contribute to early cognitive dysfunction in AD.

Aims: Pathological protein aggregation and synaptic dysfunction are major contributors to neurodegenerative disorders. However, understanding disease-relevant protein aggregation, such as Beta-amyloid, Alpha-synuclein and Tau aggregation within synapses, remains limited. To address this, we present a novel method for visualizing protein aggregates in individual synaptosomes.
Methods: We combined Single-molecule Pull Down (SiMPull) and direct Stochastic Optical Reconstruction Microscopy (dSTORM), to immobilize individual synaptosomes and characterize single aggregates within them with ~20nm spatial resolution.
Results: We validated the method with mouse models of neurodegenerative diseases and post-mortem human brain tissues.
Conclusions: Our method offers a valuable tool for decoding molecular triggers underlying neurodegeneration at an early stage and provides new insights into developing earlier therapeutic strategies.

Aims: Phospholipase D1, a multimodal signaling element is aberrantly modulated in neurodegenerative states. Using multidisciplinary functional and morphological assessments, we have attempted a thorough approach and provide some key observations that highlight the importance of PLD1 signaling mechanisms as very viable and tolerated therapeutic target in different neurodegenerative states**.** Recently we have optimized the mechanistic action of PLD in both temporal and spatial manner to provide a clear insight into developing targeted therapeutics that will have minimal side-effects. We provide our recent advances in this presentation.
Methods: Human clinical samples of postmortem brains from Alzheimer's Disease (AD) patients, behavioral variant frontotemporal dementia (bvFTD or FTD) patients, and age-matched controls (CTRL) were used to study co-localization of PLD1 with various markers in the autophagy, neuroinflammation, microglial and synaptic neurotransmission pathway to outline the clinical relevance of the disease. These studies were replicated in the 3xTg-AD, hTau, P301S and adeno-associated viral vector (AAV)-based human PLD1 overexpression (hPLD1OXP) or PLD1 inhibition (PLD1 shRNA) in wildtype and transgenic mouse models at 6-months, 12-months or 18-months of age to understand whether the signaling mechanism underlying human clinical condition was faithfully replicated in our functional models. Lastly, RNAseq and protoemics study were conducted to refine the therapeutic approaches. Preliminary studies were conducted to understand the targeted delivery of our lead compound.
Results: Behavioral, electrophysiological, biochemical results of PLD1 expression in healthy and diseased states will be discussed along with an emphasis on how the cellular expression differs. Signaling partners will be discussed with respect to synaptic neurotransmission and aberrant cellular processes in astrocytes and microglia.
Conclusions: Targeted therapies against aberrant PLD1 in distinct cellular milieu will be critical in promoting the resilience to cognitive decline

Aims: Cognitive dysfunction and dementia are critical symptoms in Lewy Body dementias (LBD). Specifically, alpha-synuclein (αSyn) accumulation in the hippocampus leading to synaptic dysfunction was linked to cognitive deficits in LBD. Here, we investigated the cellular and molecular impact of αSyn on hippocampal neurons by focusing on cofilin pathology and dendritic spine impairment, aiming at defining a novel therapeutic target for synaptic and cognitive deficits in LBD.
Methods: Cofilin pathology and the underlying molecular mechanisms were assessed *in vitro* by analyzing hippocampal neurons either overexpressing αSyn or subjected to the exogenous addition of αSyn pre-formed fibrils (PFFs). We have validated our findings in a mouse model of human αSyn neuronal overexpression, the Thy1αSyn mice, in an additional one of brain injection of αSyn PFFs, and in post-mortem brain samples from LBD patients.
Results: We observed that either αSyn overexpression or αSyn PFFs treatment triggered the formation of cofilin-actin rods, synapse disruptors, in cultured hippocampal neurons and in the hippocampus of synucleinopathy mouse models and of LBD patients. *In vivo*, cofilin pathology was present concomitantly with synaptic impairment and cognitive dysfunction. Rods generation prompted by αSyn involved the co-action of the cellular prion protein (PrP^C) and the chemokine receptor 5 (CCR5). Importantly, we showed that CCR5 inhibition, with a clinically relevant peptide antagonist, reverts dendritic spine impairment promoted by αSyn.
Conclusions: Our findings show that αSyn disrupts hippocampal synaptic structure by inducing the formation of cofilin-actin rods via PrP^C and CCR5. Importantly, we identify CCR5 as a novel therapeutic target to prevent synaptic impairment and cognitive dysfunction in LBD.

M1 MELANOPSIN GANGLION CELL DEGENERATION IN THE 3XTG MOUSE MODEL

POSTERS: A01.D. DISEASE MECHANISMS, PATHOPHYSIOLOGY: SYNAPTIC PLASTCITY & SYNAPSE PATHOLOGY

Luis Perez De Sevilla Muller, Brandy Recio, Amirreza Toloei, Nicholas Brecha
UCLA, Neurobiology, Los Angeles, United States of America

Aims: Objectives: This study aimed to investigate M1 melanopsin ganglion cell degeneration in the 3xTg mouse retina using specific melanopsin antibodies and morphological analysis. With circadian rhythm disruption observed in Alzheimer's disease (AD), our objectives were to test if melanopsin ganglion cell-related cellular changes, which are known to contribute to sleep disorders and circadian dysfunction, occurs in this mouse model of AD.
Methods: Methods: We examined M1 melanopsin ganglion cell degeneration in 3xTg mouse retinas using specific antibodies and a morphological analysis of wholemount retinas. Analysis focused on quantifying cell loss, and dendritic morphology. A range of ages of 6- to 12-month-old were studied to establish the temporal progression of degeneration.
Results: Results: Immunohistochemistry revealed progressive melanopsin ganglion cell degeneration in 3xTg mice. Morphological analysis demonstrated significant cell loss, and dendritic retraction. Notably, the degenerative process was more pronounced with increasing age, suggesting an age-dependent pattern.
Conclusions: Conclusions: Our study shows a degeneration of M1 melanopsin ganglion cells in the 3xTg mouse retinas, suggesting a link between circadian rhythm disruption and AD. The observed morphological changes underscore the connection between retinal degeneration and the circadian rhythm disturbances and sleep disorders seen in AD. Understanding the cellular basis of these changes may guide future therapeutic strategies aimed at mitigating circadian rhythm dysfunction and sleep disturbances associated with AD.

Aims: Aim of the study was to evaluate the correlation between subtle inflammatory alterations and synaptic dysfunction in Alzheimer's disease.
Methods: : sixty AD patients and 20 age-matched controls underwent CSF analyses for neurogranin, Tau, P-tau and Abeta amyloid, NfL, GFAP, and inflammatory markers as well as an extensive cognitive, behavioral and motor assessment. Correlations between CSF biomarkers were evaluated using partial correlation adjusted for the effect of age, sex and disease duration.
Results: AD patients exhibited higher levels of neurogranin and inflammatory CSF markers compared to controls. Neurogranin showed a strong correlation with inflammatory markers in CSF, independently from the relationship with neuronal and amyloid related.
Conclusions: this study suggested a shared mechanism linking synaptic dysfunction and subtle inflammatory alterations in early Alzheimer disease that need to be confirmed in on going longitudinal studies.

Aims: Alzheimer's disease is characterized by amyloid beta accumulation, leading to synaptic dysfunction. Although oligomeric amyloid beta is implicated in synaptic impairment and neurodegeneration, the underlying mechanisms remain a topic of debate. Our current research project focuses on elucidating the specific effects of amyloid beta on glutamate exocytosis in induced pluripotent stem cell (iPSC)-derived cortical neurons.
Methods: Mature human iPSC-derived neurons were exposed to either 100 nM recombinant monomeric amyloid beta or a combination of 100 nM monomers and 1 nM mature amyloid fibrils for 10 minutes to promote the formation of oligomeric species. To assess synaptotoxicity at the neurites, we employed ultrafast amperometric glutamate biosensors. Exocytotic release of glutamate from discrete synaptic vesicles at the neurites was stimulated by the application of a high-concentration potassium chloride solution. Glutamate release was then recorded electrochemically with a high sampling rate of 100 kHz in both treated and non-treated neurons.
Results: In this ongoing project, our observations to date indicate that a brief 10-minute incubation of iPSC-derived neurons with a solution containing 100 nM amyloid beta monomers and 1 nM mature fibrils led to a dramatic reduction in glutamate exocytosis. Conversely, incubation with 100 nM amyloid beta monomers alone for 10 minutes did not result in impaired glutamate release. However, a 1-hour incubation with the same solution resulted in a noticeable reduction in glutamate exocytosis.
Conclusions: Preliminary data suggests that iPSC-derived neurons are highly sensitive to the synaptotoxic effects of amyloid beta aggregates. Even a brief exposure time can affect glutamate release, as evidenced by electrochemical detection.

Aims: Blood biomarkers related to neurodegeneration have shown association with cognitive decline and brain atrophy. Recently, the detection of synaptic pathology in blood may offer additional value to a blood-based relationship of neurodegeneration. In this study, we investigated the additional value of blood SNAP25 to blood GFAP and NfL.
Methods: We examined 110 participants (54 AD and 56 healthy controls) from the Swedish BioFINDER pilot study. The mean age of patients was 75.9 years (7.1 SD) and there was an even distribution of sex. We examined group differences by the Wilcoxon rank sum test and associations between the blood markers and MRI and MMSE were determined by linear regression, adjusting for age and sex, and in combination with each other. GFAP and NFL were measured by commercial Simoa assays 4-Plex E kit and SNAP25 with a prototype Simoa assay, developed from a previously validated in-house CSF assay.
Results: All blood biomarkers were significantly increased in patients with AD as compared to controls. These three biomarkers significantly correlated with each other (R=0.42-0.56; p=<0.001). SNAP-25 and GFAP associated with cortical thickness (β=-0.05, p=0.009; β=-0.09, p=<0.001) but not NFL. The biomarkers associated with MMSE (SNAP-25 β=-6.69, p=0.001; GFAP β=-2.46, p=<0.001; NFL β=-1.52, p=0.007). Only GFAP associated with cortical thickness and MMSE in the AD group alone (β=-0.08, p=0.002; β=-1.99, p=<0.015). GFAP is the only marker contributing to the model when combining the markers to predict cortical atrophy and MMSE.
Conclusions: In this pilot study, blood SNAP25, NfL, and GFAP were significantly associated with cognition and brain atrophy. Yet only GFAP was associated with these measures in the symptomatic group. In a multivariate model, SNAP25 did not add additional value in the association of blood biomarkers and neurodegeneration.

ASTROCYTIC-TO-MICROGLIAL ENDOZEPINE SIGNALING REGULATES SYNAPTIC PRUNING IN ALZHEIMER'S DISEASE

POSTERS: A01.D. DISEASE MECHANISMS, PATHOPHYSIOLOGY: SYNAPTIC PLASTCITY & SYNAPSE PATHOLOGY

Yuan Shi[1,2,3], Mochen Cui[1,2,4], Juan Zu[1,2,4], Viktoria Ruf[1], Qiang Huang[1,2], Jochen Herms[1,2,3]
[1]Ludwig-Maximilians-Universität München, Center For Neuropathology, Munich, Germany, [2]German Center for Neurodegenerative Diseases (DZNE), Department Of Translational Brain Research, Munich, Germany, [3]Ludwig-Maximilians-Universität München, Munich Cluster For Systems Neurology (synergy), Munich, Germany, [4]Ludwig-Maximilians-Universität München, Munich Medical Research School, Munich, Germany

Aims: Astrocytes and microglia have been demonstrated to independently engulf synapses in Alzheimer's disease (AD), employing various mechanisms. However, whether they communicate with each other and jointly modulate synapses is less well defined. Endozepine diazepam binding inhibitor (DBI) is primarily produced and released by astrocytes and prominently binds to microglia which is pivotal in engulfing synapses. Here, we aimed to investigate whether the synaptic loss in AD is dependent on DBI-mediated astrocyte-microglia communication.
Methods: Synaptic plasticity of eGFP-labeled apical dendrites in *APPswe/PS1dE9* mice are monitored using longitudinal 2-photon *in vivo* imaging. DBI expression is acquired and analyzed using super-resolution confocal microscopy coupled with 3D reconstruction. Furthermore, spatial transcriptomic and single-cell RNA sequencing are employed to determine the astrocytic subpopulations based on their relative locations to plaques. Besides animal models, we assessed alterations of plaque-surrounding astrocytes and microglia in human postmortem brain tissues from patients with AD.
Results: We observed a gradually decreased synaptic density in *APPswe/PS1dE9* mice around amyloid plaques, coupled with heightened astrocytic DBI as well as their transmission into microglia. Moreover, microglia in *APPswe/PS1dE9* mice show promoted synaptic engulfment. These effects were mitigated by interfering with DBI signaling using shRNA or genetic depletion. Similar to *APPswe/PS1dE9* mice, we observed elevated astrocytic DBI and microglial synaptic engulfment in postmortem brain tissues from AD patients, compared to healthy controls.
Conclusions: These results collectively reveal that the astrocyte-microglia communication is dysregulated in AD via aberrantly activated DBI signaling, leading to excessive synaptic loss that can be ameliorated by DBI suppression. Our finding supports endozepine DBI as a potential therapeutic target for rescuing AD-related synaptic loss, and glial communication as an intriguing aspect for developing new strategies for treating neurodegenerative diseases.

COMPLEXINS AND THE DEVELOPMENT OF EARLY AD PATHOLOGIES IN PARVALBUMIN INTERNEURONS

POSTERS: A01.D. DISEASE MECHANISMS, PATHOPHYSIOLOGY: SYNAPTIC PLASTCITY & SYNAPSE PATHOLOGY

Kelly South Pham[1], Sneha Malepati[1], Matthew Rowan[2]
[1]Emory University, Department Of Cell Biology, Atlanta, United States of America, [2]Emory University School of Medicine, Cell Biology, Atlanta, United States of America

Aims: The cellular and proteomic complexity of the mammalian brain contributes to differential vulnerabilities to pathology development during preclinical Alzheimer's disease (AD). The group of presynaptic proteins called complexins (Cplx) have been identified as "pro-resilient" against cognitive decline in human tissues. Cplx also appears to be preferentially expressed in inhibitory cells, with our group recently identifying that Cplx proteins are extremely enriched in the parvalbumin interneuron-specific proteome with respect to excitatory neurons. Here we investigate the distribution of complexin-positive parvalbumin interneurons across multiple brain regions and how modifying the abundance of complexins contributes to the emergence of AD pathologies.
Methods: We stereotaxically injected a parvalbumin interneuron-specific fluorescent marker into the primary somatosensory (SS) cortex and lateral entorhinal cortex (LEC) and performed immunohistochemistry (IHC) to characterize the quantity of co-localization of parvalbumin interneurons and complexins in different brain regions. We then used an adult-onset, region-specific AAV approach in conjunction with a CRISPR/Cas9 construct to knockdown complexins in parvalbumin interneurons in a cell-type- and region-specific manner. We then performed IHC to characterize any pathological amyloid and tau species produced as a result of the complexin knockdown.
Results: We quantified the amount of complexin-positive parvalbumin interneurons in the LEC, a highly vulnerable region in AD. We further quantified the extent of amyloid and tau pathologies which occur in response to the knockdown of complexins in parvalbumin interneurons in the LEC compared to controls.
Conclusions: These results confirm some of the "pro-resilient" qualities of complexins in protecting a highly vulnerable neuron and brain region, revealing a potential therapeutic genetic intervention for preclinical AD.

SIGNALING MECHANISMS OF GLUTAMATERGIC SYNAPSE MAINTENANCE AND DEGENERATION

POSTERS: A01.D. DISEASE MECHANISMS, PATHOPHYSIOLOGY: SYNAPTIC PLASTCITY & SYNAPSE PATHOLOGY

Yimin Zou
University of California, San Diego, Neurobiology, La Jolla, United States of America

Aims: The synapses are the computational unit of neural circuits. Reduction of synaptic numbers and decline of synaptic functions, which occur early in Alzheimer's disease and Parkinson's disease, are closely correlated with and may be a key underlying mechanism of the decline of brain function.
Methods: Work from our lab showed that the planar cell polarity (PCP) signaling pathway plays an essential and direct role in glutamatergic synapses formation in development and glutamatergic synapse maintenance in adulthood (Thakar et al., 2017) (Zou, 2020) (Ban et al., 2021) (Feng et al., 2021). The PCP proteins are localized in the developing and adult synapses and interact with synaptic scaffold proteins and glutamate receptors and are responsible for the formation and stability of the vast majority of glutamatergic synapses in the brain.
Results: Our lab found that planar cell polarity is the key signaling mechanism for synapse maintenance and the direct target for amyloid β induced synapse degeneration (Feng et al., 2021). Oligomeric Aβ binds to Celsr3 and weakens the interaction between Celsr3 and Frizzled3 and assists Vangl2 in disassembling synapses. A regulator of PCP signaling, Ryk, is also required for Aβ-induced synapse loss functioning together with Vangl2. In the 5XFAD mouse model of Alzheimer's disease, Ryk conditional knockout in neurons or intracerebroventricular infusion of a function-blocking monoclonal Ryk antibody protected synapses and preserved cognitive function (Feng et al., 2021).
Conclusions: Therefore, the PCP pathway has emerged as a key regulatory mechanism for synapse degeneration and provides novel target to understand and intervene with neurodegeneration. I will present new progress in understanding how oligomeric Aβ and phosphorylated tau lead to glutamatergic synapse degeneration.

EXERCISE DAMPENS MICROGLIAL SYNAPTIC ENGULFMENT IN A MOUSE MODEL OF ALZHEIMER'S DISEASE

POSTERS: A01.D. DISEASE MECHANISMS, PATHOPHYSIOLOGY: SYNAPTIC PLASTCITY & SYNAPSE PATHOLOGY

Juan Zu[1,2,3], Mochen Cui[1,2,3], Fang Zhang[2], Gerda Mitteregger[1], Yuan Shi[1,2,4], Jochen Herms[1,2,4]
[1]Ludwig-Maximilians-Universität München, Center For Neuropathology, Munich, Germany, [2]German Center for Neurodegenerative Diseases (DZNE), Department Of Translational Brain Research, Munich, Germany, [3]Ludwig-Maximilians-Universität München, Munich Medical Research School, Munich, Germany, [4]Ludwig-Maximilians-Universität München, Munich Cluster For Systems Neurology (synergy), Munich, Germany

Aims: Emerging evidence substantiates the effects of exercise in ameliorating cognitive impairment in Alzheimer's disease (AD). However, the precise mechanisms engendered by exercise in AD remain elusive. Microglia play a central role in AD-associated dementia via eliminating synapses. Here we aim to investigate whether and how long-term voluntary exercise affects microglial synaptic engulfment in the AD context.
Methods: We utilized three-month-old *APPswe/PS1dE9* (*ΔE9*) mice that emulate the amyloid plaque profile of AD and housed them individually with either operational or blocked running wheels. After three months of voluntary exercise, the brains from both cohorts were harvested. We conducted multiplex immunostaining, super-resolution microscopy, and 3D-reconstruction-based analysis to measure the engulfed synaptic materials spatially localized in microglial lysosomes.
Results: We ascertained that exercise reduces microglial lysosomal content (CD68) and their phagocytosis of synaptic materials (PSD95). With this altered functionality, we uncovered a notable elevation in microglial α7 nicotinic acetylcholine receptors (nAchRα7) – the principal microglial acetylcholine receptors, generally reduces in the AD context – following long-term exercise in *ΔE9* mice. Furthermore, under the stimulation of *ΔE9* mice brain extraction, we observed that primary microglia exposed to acetylcholine chloride revealed heightened nAchRα7 expression and significantly reduced synaptosomes phagocytosis, both of which were blocked by a nAchRα7 antagonist – methyllycaconitine citrate.
Conclusions: In summary, our results furnish evidence that long-term exercise mitigates excessive microglial phagocytosis of synaptic materials through nAchRα7 modulation, providing a prospective therapeutic target for the modification of AD pathophysiology.

CAMKIIALPHA IS OXIDIZED AND ACTIVATED BY OLIGOMERIC AMYLOID-BETA

POSTERS: A01.E. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELLULAR SIGNALLING, KINASES, PHOSPHATASES, CALCIUM

Hugo Fanlo-Ucar[1], Pol Picón-Pagès[2], Víctor Herrera-Fernández[2], Sira Ausellé-Bosch[2], Lorena Galera-López[2], Daniela Gutiérrez[3], Andrés Ozaita[2], Alejandra Álvarez[3], Baldomero Oliva[2], Francisco J. Muñoz[2]
[1]UPF-MELIS (PRBB), Department Of Medicine And Life Sciences, Barcelona, Spain, [2]Universitat Pompeu Fabra, Melis, Barcelona, Spain, [3]Pontificia Universidad Católica de Chile, Centro Uc De Envejecimiento Y Regeneración (care), Santiago, Chile

Aims: Memory function relies on hippocampal formation through long-term potentiation (LTP), which involves NMDA receptors activation, the subsequent autophosphorylation of CaMKIIα and the nuclear translocation of the transcription factor CREB. In addition, it is known that amyloid beta-peptide oligomers (oAβ) lead to synaptic loss, dramatically affecting memory. Nonetheless, how this pathological mechanism occurs is not well understood. Therefore, we examined the impact of oAβ on CaMKIIα.
Methods: i) *In vitro* biochemical kinase assays, ii) molecular/cellular biology studies with SH-SY5Y cells, murine hippocampal neurons, brain samples from control and AD individuals and control and AD transgenic mice and iii) modelling by bioinformatic analysis.
Results: Our findings show that oAβ generates reactive oxygen species (ROS), which significantly oxidize CaMKIIα (ox-CaMKIIα), which is also significantly present in AD brain samples. Additionally, we demonstrated that oxidation induces a conformational change in the structure that hinders the recovery of the native conformation, promoting an activated state of CaMKIIα. We also discovered that its phosphorylation is mutually exclusive with oxidation. In both AD transgenic mouse brains and primary cultures of murine hippocampal neurons, we demonstrated that the oxidation of CaMKIIα leads to the phosphorylation of CREB and its translocation to the nucleus. We also found that oAβ induces an increase in the transcription of the pro-survival CREB target genes ARC and BDNF.
Conclusions: Our data suggest that CaMKIIα oxidation may work as a protective mechanism triggered when neurons are exposed to oAβ, but it can have deleterious effects at long term. APOE4 IS INSTRUMENTAL IN AUGMENTING RHOA KINASE PHOSPHORYLATION AND CONTRIBUTES THEREBY TO CLASSICAL ALZHEIMER'S DISEASE NEURON PHENOTYPES

POSTERS: A01.E. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELLULAR SIGNALLING, KINASES, PHOSPHATASES, CALCIUM

Kristine Freude, Ruixin Tao
University Of Copenhagen, Health Sciences, Frederiksberg, Denmark

Aims: Validation that the APOE4 allele is linked to increased RhoA phosphorylation in neurons. Mechanistic insights into how APOE4 affects the RhoA phosphorylation level in neurons in spradic AD.
Methods: In vitro differentiation of iPSC to glutamatergic neurons, assessment of RhoA activitiy via G-Lisa and western blot. GC-MS and HPLC to measure cholesterol and geranylgeranyl pyrophosphate. Immunocytochemistry, transmission electron microscopy, Multielectrode assays to invesigate synaptic deficits.
Results: Succesful differentiation of glutamatergic neurons from iPSCs carrying various APOE genotypes. The level of normalized RhoA activation level was significantly higher in neurons carrying APOE 4/4 than those carrying APOE 2/2 and APOE 3/3. Even though APOE protein are mainly produced by astrocytes in the brain, it could also be detected in in-vitro differentiated glutamatergic neurons. Moreover, a slight decrease in APOE protein generation in APOE4/4 neurons could be observed. The gene expression level of geranylgeranyl pyrophosphate synthase did not demonstrate significant differences among each cell line. However, the content of geranylgeranyl pyrophosphate was assessed by HPLC and showed an increased trend in APOE4/4 neurons. The increased phosphorylation Tau and secretion of Abeta, as well as dysfunction of synapes observed in neurons carrying the APOE4/4 was reversible via RhoA inhibition.
Conclusions: Our reserach shows that the allelic status of APOE is linked to the phosphorylation of RhoA. An increased level of phosphorylated RhoA was observed in APOE4/4 neurons, leading to AD-specific neuronal pathologies and can be rescued via RhoA inhibition.

RELATIONSHIPS BETWEEN SIGNAL TRANSDUCTION DISRUPTIONS CAUSED BY MAP KINASES IN ALZHEIMER'S DISEASE

POSTERS: A01.E. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELLULAR SIGNALLING, KINASES, PHOSPHATASES, CALCIUM

Stephen Keegan[1], Gregory Cary[1], Jesse Wiley[2], Gregory Carter[1]
[1]The Jackson Laboratory, The Jackson Laboratory, Bar Harbor, United States of America, [2]Sage Bionetworks, Sage Bionetworks, Seattle, United States of America

Aims: The TaRget Enablement to Accelerate Therapy Development for Alzheimer's Disease (TREAT-AD) consortium is missioned to provide tools to the Alzheimer's research community for the development of novel therapeutics. Here we bioinformatically establish the cascading effects of therapeutically targeting MAPK-14.
Methods: The grouping of Alzheimer's disease (AD) candidate proteins into distinct biological domains provides the framework for a biologically interpretable bioinformatic analysis. Exploring the interaction networks assembled from AD biological domains using a weighted key driver analysis yields insight into the potential causality of genes annotated to the domains. Genes in the network are weighted by their TREAT-AD Target Risk Score derived from a meta-analysis of genetic and multi-omics studies pertaining to AD, including ADSP and AMP-AD. Local subgraphs of genes surrounding key drivers implicate genes hypothesized to be impacted by a disease-related change in a driver gene.
Results: We found MAPK-14, annotated to the oxidative stress biological domain, to be a top key driver gene. The subgraph comprised of genes that are neighbors to MAPK-14 comprise the genes most likely to be impacted by changes in the mRNA or protein expression of MAPK-14. We found that changes in MAPK-14 expression are predicted to alter signaling pathways corresponding to cellular responses to lipopolysaccharide stimulus. Within the subnetwork driven by MAPK-14 are the EP300 and PRKCE genes which are involved in the regulation of apoptotic signaling pathway and Fc receptor signaling pathway respectively.
Conclusions: Using the biological domain annotations and weighted key driver analysis, the causality of genes in an interaction network can be inferred. We predict that the modulation of MAPK-14 will stabilize other signal transduction changes in AD brains.

RNF10 IS A NOVEL SYNAPSE-TO-NUCLEUS MESSENGER OF AMYLOID SYNAPTOTOXICITY

POSTERS: A01.E. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELLULAR SIGNALLING, KINASES, PHOSPHATASES, CALCIUM

Elena Marcello[1], Laura D'Andrea[1], Stefano Musardo[1], Ramona Stringhi[1], Filippo La Greca[1], Silvia Pelucchi[1], Nicolò Carrano[1], Ana Ribeiro[1], Bahar Aksan[2], Matteo Audano[1], Francesca Genova[1], Daniela Mauceri[2], Nico Mitro[1], Diego Scheggia[1], Fabrizio Gardoni[1], Monica Di Luca[1]

Aims: Synaptonuclear messengers translate synaptic signaling into changes in gene transcription, thus modulating long-term functional modifications of the synapto-dendritic input. Alterations of such proteins lead to synaptic failure, suggesting a contribution to synaptopathies such as Alzheimer's Disease (AD). During AD early stages, the amyloid-β peptide (Aβ) oligomers trigger the disruption of mechanisms of neuronal plasticity, eventually resulting in synapse loss and in cognitive deficits. In this frame, the synaptonuclear messenger RING Finger Protein 10 (RNF10) operates as a mobile hub that docks NMDA receptor-derived signalosomes to nuclear target sites, regulating genes involved in spine morphology and AD pathogenesis. We aimed at investigating potential involvement in AD-synaptic dysfunction.
Methods: We used several imaging and biochemical approaches to investigate RNF10 pathway in AD in vitro and in vivo models.
Results: RNF10 expression and localization are altered in the hippocampus but not in the cortex of AD patients. To investigate the RNF10-triggered neuronal pathways in AD, we exposed primary hippocampal cultures to Aβ oligomers. Aβ triggers a calcium-dependent NMDA receptor-induced RNF10 nuclear translocation. RNASeq data show that RNF10 silencing prevents the Aβ oligomers-driven changes in the expression of genes implicated in mitochondrial function and synaptic plasticity, such as neurogranin. In the hippocampus of APP/PS1 mice we detected an upregulation of RNF10 signaling in the initial stages of the pathology. The RNF10 downregulation in the hippocampus of APP/PS1 mice before the onset of the pathology can upregulate the levels of neurogranin and ATP synthase in mitochondria and, thereby, restores cognitive function.
Conclusions: Our findings suggest that RNF10 can play a key role in translating Aβ-induced signaling into synaptic and mitochondrial dysfunction, thus contributing to AD cognitive deficits.

Aims: Hippocampal neuronal activity generates dendritic and somatic Ca^{2+} signals, which depending on stimulus intensity, rapidly propagate to the nucleus and induce the expression of transcription factors and genes with crucial roles in cognitive functions. Soluble Amyloid-beta Oligomers (AβOs), the main synaptotoxins engaged in the pathogenesis of Alzheimer's disease, generate aberrant Ca^{2+} signals in hippocampal neurons, increase their oxidative tone and disrupt structural plasticity. Here, we explored the effects of sub-lethal AβOs concentrations on activity-generated nuclear Ca^{2+} signals and on the Ca^{2+}-dependent expression of neuroprotective genes.
Methods: To induce neuronal activity, neuron-enriched primary hippocampal cultures were treated with the $GABA_A$ receptor blocker gabazine (GBZ), and and nuclear Ca^{2+} signals were measured in AβOs-treated or control neurons transfected with a genetically encoded nuclear Ca^{2+} sensor. Cytoplasmic Ca^{2+} signals were detected in neurons transfected with the genetically encoded cytoplasmic Ca^{2+} sensor, or loaded with Fluo-4 or FURA-2 indicators. To evaluate whether AβOs interrupt the GBZ-induced increase in CREB phosphorylation, we used immunofluorescece (Ser-133 p-CREB). The mRNA levels of Neuronal Per Arnt Sim domain protein 4 (Npas4), Brain-derived Neurotrophic Factor (Bdnf), Ryanodine Receptor type-2 (RyR2), and the antioxidant enzyme NADPH-Quinone-Oxidoreductase (Nqo1) were determined by qPCR. Statistical analysis was performed with One-way ANOVA followed by Bonferroni test or two-tailed Student's t-test.
Results: Incubation (6 h) with AβOs significantly reduced the nuclear Ca^{2+} signals and the enhanced phosphorylation of CREB induced by GBZ. Likewise, incubation (6 h) with AβOs significantly reduced the GBZ-induced increases in the mRNA Npas4, Bdnf, RyR2 and the antioxidant enzyme Nqo1.
Conclusions: Based on these findings we propose that AβOs, by inhibiting the generation of activity induced nuclear Ca^{2+} signals, disrupt key neuroprotective gene expression pathways required for hippocampal-dependent learning and memory processes.

BETA-AMYLOID:NA,K-ATPASE:SRC KINASE SIGNALING PATHWAY IN ALZHEIMER'S DISEASE

POSTERS: A01.E. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELLULAR SIGNALLING, KINASES, PHOSPHATASES, CALCIUM

Maria Strelkova[1], Anna Tolstova[1], Alexei Adzhubei[1,2], Evgeny Barykin[1], Vladimir Mitkevich[1], Alexander Makarov[1], Irina Petrushanko[1]

Aims: Src-kinase plays an important role in neurogenesis, metabolism and receptor sensitivity. This work is aimed at investigation of the putative role of beta-amyloid in Src-kinase hyperactivation in Alzheimer's disease and characterisation of their interaction with Na,K-ATPase that mediates this process.
Methods: Src-kinase autophosphorylation was performed *in vitro*. The autophosphorylated Src-kinase levels were measured as phospho-Y416 Src/Src Western blot signals ratio. The dissociation constants were measured with the Microscale Thermophoresis using His-tag labeling. The full-length Src-kinase conformations were obtained with REHTMD using GROMACS software. Open source servers were used for global docking. The results were analyzed with QASDOM server.
Results: We have shown for the first time that beta-amyloid acts as a specific ligand of Na,K-ATPase, triggering the activating autophosphorylation of Src-kinase bound to Na,K-ATPase.

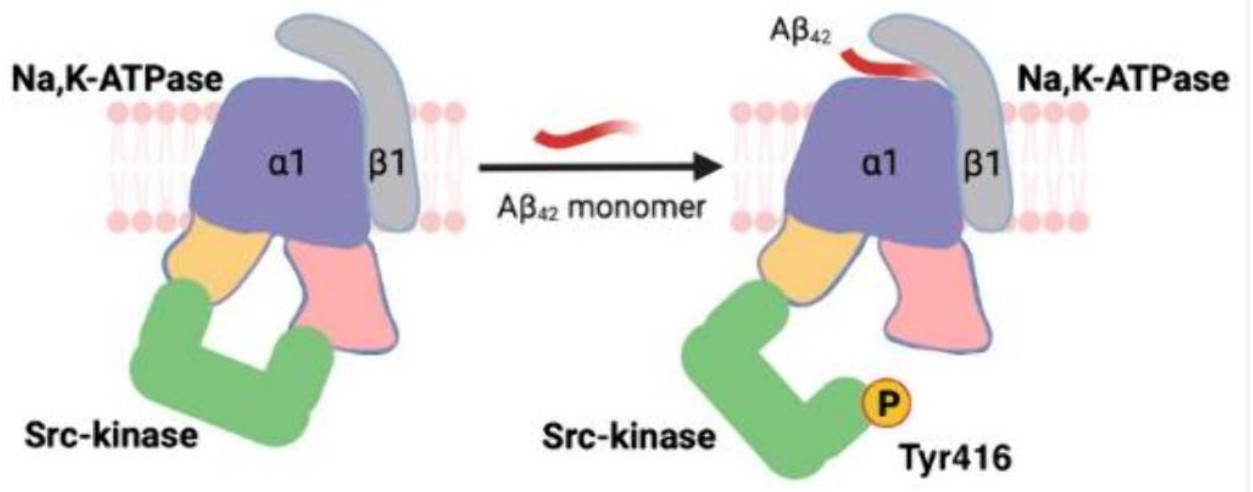

Fig.1. The presumptive scheme of Src-kinase activation by beta-amyloid (Petrushanko et al., *Cells*, 2022). By now we have looked further into Src:Na,K-ATPase interaction. The similarity of dissociation constants obtained for dephosphorylated Src:Na,K-ATPase complex and for autophosphorylated Src:Na,K-ATPase revealed that interaction between Src SH2-domain and Na,K-ATPase is essential for the whole complex stability. Semi-stable conformations of full-length Src-kinase including N-terminal domain were obtained and consequently used in global docking with Na,K-ATPase structure. The comparison between predicted interaction interfaces of Na,K-ATPase with full-length Src-kinase structures and structures of crystalline Src-kinase without N-terminal domain demonstrates the crucial

role of Src-kinase N-terminus in its interaction to Na,K-ATPase.

Conclusions: The neurotoxic effects of beta-amyloid in Alzheimer's disease may be associated with the long-term activation of Src-kinase through Na,K-ATPase:beta-amyloid interaction, thus making the complex the potential therapeutic target. To impair its stability, the competitive inhibitors to the SH2- or N-terminal domain of Src-kinase can be developed. This research was funded by Russian Science Foundation (Grant#19-74-30007).

Aims: In this study, we investigated the impact of amyloid burden on astrocyte calcium signaling and stimulation-evoked vasoactivity in fully awake mice to characterize direct associations between stimulation-evoked neurovascular coupling and endfoot calcium signals.
Methods: 5XFAD and littermate control mice were aged to 6 months before they were injected with AAV2/5-Gfa104-jGCaMP8f into barrel cortex followed by cranial window installation. Fully awake mice were imaged 3 weeks later using two-photon microscopy. Cerebral architecture in barrel cortex was illuminated using 500kD rhodamine dextran. Functional hyperemia was assessed during timed air puff stimulation of the contralateral whiskers. Calcium signals were recorded from reactive astrocytes before, during, and after whisker stimulation. Transients were analyzed by change in fluorescence ΔF/F over different cellular compartments by custom Matlab algorithms. Using a modeling algorithm, vascular tone in response to stimulation was measured, along with attached endfoot calcium levels.
Results: Astrocytes from 5XFAD mice showed a significant reduction in endfoot calcium signaling amplitudes and delayed rise time compared to wild type controls. Signaling properties such as amplitude, kinetics, and connectivity within networks were also characterized between the 5XFAD and control mice. Astrocyte calcium signaling was initiated after the onset of neurovascular coupling, and 5XFAD mice exhibited a significant increase in latency between neurovascular tone changes, and peak endfoot calcium transience.
Conclusions: Astrocytes from 5XFAD mice showed a significant reduction in endfoot calcium signaling amplitudes and rise time compared to wild type controls. Signaling properties such as amplitude, kinetics, and connectivity within networks were also characterized between the 5XFAD and control mice. Astrocyte calcium signaling was initiated after the onset of neurovascular coupling, and 5XFAD mice exhibited a significant increase in latency between neurovascular tone changes, and peak endfoot calcium transience.

THE ROLE OF THE "UNFOLDED PROTEIN RESPONSE" AND THE PERK PATHWAY IN PARKINSON'S DISEASE: STUDY OF GENETIC POLYMORPHISMS

POSTERS: A01.F. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LYSOSOMES, UBIQUITIN, PROTEASOME, ER STRESS, CHAPERONES

Marika Alborghetti[1], Nicole Piera Palomba[2], Edoardo Bianchini[1], Domiziana Rinaldi[1], Claudia Strafella[3], Valerio Caputo[3], Emiliano Giardina[3], Ferdinando Nicoletti[2], Teresa Esposito[4], Francesco Pontieri[1]
[1]Sapienza, University of Rome, Department Of Neuroscience, Mental Health And Sensory Organs (nesmos), Rome, Italy, [2]IRCSS Neuromed, Pozzilli, Is, Isernia, Italy, [3]IRCCS Fondazione Santa Lucia, Rome, Rome, Italy, [4]Institute of Genetics and Biophysics CNR, Biomedicine, Napoli, Italy

Aims: Background: The accumulation of α-synuclein in Parkinson's disease (PD) leads to the stress of endoplasmic reticulum (ER). The resulting cellular response is called "Unfolded Protein Responce" (UPR), and is activated with the aim of reducing protein synthesis and stimulating the expression of chaperone proteins to prevent protein aggregation and the degradation of already aggregated proteins. UPR is controlled by several sensor proteins, including PERK (PKR-like ER kinase). Aim of the study: To study a possible association between the development of PD and the presence of polymorphisms of the genes coding for proteins involved in the UPR and in particular in the PERK pathway.
Methods: This analysis focused on the study and analysis of 180 genetic variants (SNV) in a cohort of 800 PD patients and 600 healthy controls. Of these, 27 concern genes coding for proteins involved in the UPR (EIF2AK3, LRRK2, ATF4, ATF6, XBP1, BCL2, EIF2A, ERN1). The DNA
was extracted from the blood samples and the Open Array ™ technology allowed a massive and simultaneous genotyping of all the samples under examination.
Results: The analysis made it possible to find 51 SNVs with a statistically significant association with susceptibility to PD. Some of these concern EIF2AK3 coding for PERK. One missense genetic variant of EIF2AK3 resulted protective towards PD development.
Conclusions: Our study confirms the involvement of UPR and in particular of the PERK pathway in the development of PD. Further analyzes will be necessary to correlate these polymorphisms not only with the pathophysiological mechanisms, but also with the clinical course of PD. The PERK pathway represents a potential target for the development of new therapeutic strategies for both neuroprotective and symptomatological purposes.

PROTEOMIC CHARACTERIZATION OF SPPL2B-DEFICIENT MICE REVEALS UP-REGULATION OF THE SYNAPTIC TRANSPORTER KINESIN-LIKE PROTEIN KIF1A ACCOMPANIED BY INCREASED LOCOMOTOR ACTIVITY

POSTERS: A01.F. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LYSOSOMES, UBIQUITIN, PROTEASOME, ER STRESS, CHAPERONES

Cristina Contini[1], Greca Lai[1], Alessandra Schirru[1], Jack Badman[2], Per Nilsson[2], Tiziana Cabras[1], Simone Tambaro[2]
[1]University of Cagliari, Dep. Life And Environmental Sciences Biomedical Section, Proteomics Unit University Of Cagliari, Monserrato, Italy, [2]Karolinska Institute, Department Of Neurobiology, Care Sciences And Society, stockholm, Sweden

Aims: Signal Peptide-Peptidase like 2b (SPPL2b) is an intramembrane brain-specific peptidase, part of the GxGD-type aspartyl proteases family, similar to the enzymatically related presenilin proteins. SPPL2b is involved in the cleavage of several Alzhimer´s disease (AD)-related type II substrates, such as BRI2, TNF-alpha, Clec7a, and Neuregulin-1. The SPPL2b cleavage releases intracellular fragments, which are either degraded or act as signaling molecules. The physiophatological role of SPPL2b remains elusive. This study aims to investigate the effect of SPPL2b genetic deletion to identify alterations in the brain proteome and their impact on mice behavior.
Methods: We evaluated cortex and hippocampus proteome in SPPL2b-deficient and wild-type mice at 3 and 12 months of age. The brain tissues were analyzed using a shot-gun proteomic approach based on high-resolution mass spectrometry. The observed up-regulation of the Kinesin-like protein KIF1A was investigated through Western Blot and Immunofluorescence analysis. Furthermore, SPPL2b mouse behavior was characterized using open field and Elevated plus maze tests.
Results: The proteomics from SPPL2b mice showed qualitative and quantitative differences between WT and KO mice and in relation to the age, as well as different protein interaction networks, were identified. Notably, the Kinesin-like protein KIF1A was consistently up-regulated in both cortex and hippocampus in 3 and 12-month-old mice. Further Western blot and immunofluorescence validation confirmed a significant up-regulation of KIF1A. Behavioral analysis showed significantly higher motility and a higher frequency in open arms in SPPL2b-deficeint mice.
Conclusions: These studies identified several proteins that may underlie distinct aspects of the physiological and pathological roles of SPPL2b, such as KIF1A, which mutagenesis or downregulation has been shown to be involved in neurodegeneration and AD. Furthermore, these data could hepl to identify candidate proteins for further development as biomarkers.

CHIP-SEQ DATA ANALYSIS REVEALED T CELL INVOLVED AUTOIMMUNITY IN THREE BRAIN REGIONS OF AD PATIENTS

POSTERS: A01.F. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LYSOSOMES, UBIQUITIN, PROTEASOME, ER STRESS, CHAPERONES

Kun Han, Lin Wang, Zheng Yin, Stephen Wong
Houston Methodist Research Institute, Systems Medicine And Bioengineering, Houston, United States of America

Aims: Alzheimer disease (AD) is biologically characterized by the formation of pathologic β-amyloid-containing plaques and tau-containing neurofibrillary tangles. However, the causes have not been completely elucidated. In this study, our hypothesis is that autoinflammation might accumulate within the central nervous system, contributing to the pathogenesis of AD. The objective thus was to analyze publicly available Chip-seq datasets on the frontal cortex, hippocampus, and temporal cortex of healthy volunteers and AD patients to validate the hypothesis.
Methods: Chip-seq data analysis was performed on brain tissue samples from both healthy individuals and AD patients across a wide age range from 20 to over 100 years old.
Results: We identified age-irrelevant genes in all the three brain regions that significantly up- or down-regulated in AD patients compared to healthy individuals. Note that proinflammatory genes were overexpressed in AD patients, while anti-inflammatory genes were downregulated compared to healthy population. There are multiple human leukocyte antigen (HLA) members among the differentially expressed genes, suggesting a potential autoimmune response involving T cells targeting the central nervous system. Meanwhile, in the AD frontal cortexes, we identified age-relevant features that exhibited opposite expression patterns compared to healthy counterparts. Through pathway analysis, they can be classified into four major categories, with one category related to Neddylation, which is involved in proteasomal protein degradation to maintain homeostasis and has implications for antigen presentation, T cells activation, and AD.
Conclusions: In summary, we identified both age-irrelevant and relevant genes in three different brain regions of AD patients, suggesting a significant involvement of proinflammatory genes and potential T-cell mediated autoimmunity against the central nervous system in AD patients. We also highlighted the role of HLA genes and Neddylation-related pathways in AD pathogenesis.

CATHEPSIN B GENE DELETION IMPROVES BEHAVIORAL DEFICITS AND REDUCES PATHOLOGY IN MODELS OF ALZHEIMER'S DISEASE AND NEUROLOGICAL DISORDERS

POSTERS: A01.F. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LYSOSOMES, UBIQUITIN, PROTEASOME, ER STRESS, CHAPERONES

Vivian Hook[1], Thomas Reinheckel[2], Junjun Ni[3], Zhou Wu[4], Mark Kindy[5], Christoph Peters[2], Gregory Hook[6]
[1]University of California, San Diego, Pharmaceutical Sciences, And Neurosciences, La Jolla, United States of America, [2]Albert Ludwigs University, Molecular Medicine, Freiburg, Germany, [3]Beijing Institute of Technology, Molecular Medicine, Beijing, China, [4]Kyushu University, Pharmacology, Fukuoka, Japan, [5]University of South Florida, Pharmaceutical Sciences, Tampa, United States of America, [6]American Life Science Pharmaceuticals, Neuroscience, La Jolla, United States of America

Aims: Cathepsin B is a powerful lysosomal protease. The goal of this research was to evaluate cathepsin B gene knockout outcomes for amelioration of brain behavioral dysfunctions and neuropathology in neurological disease animal models of Alzheimer's disease, traumatic brain injury, and related.
Methods: Several neurological disease mouse models of Alzheimer's disease (AD), traumatic brain injury (TBI), and others were subjected to cathepsin B gene knockout and evaluated for improvements in behavioral dysfunctions including memory deficit and compromised motor function. Brain neuropathology in AD models was assessed for Abeta peptides and amyloid load, and a TBI model was assessed for brain lesions and neuronal loss. These efforts assessed cathepsin B mediation of neurodegenerative disease conditions.
Results: Deletion of the cathepsin B gene resulted in significant improvements in behavioral deficits and provided amelioration of neuropathology of Alzheimer's disease (AD), traumatic brain injury (TBI), and related models of brain disorders. In AD models expressing amyloid precursor protein (APP) mimicking common sporadic AD, cathepsin B knockout improved memory deficit, ameliorated neuropathology, and reversed Abeta peptide biomarkers.
Conclusions: Overall, the extensive data provides strong evidence that deletion of the cathepsin B gene improves behavioral dysfunction and reduces brain neuropathology in Alzheimer's disease, traumatic brain injury, and related neurological disease models. These findings support cathepsin B as a drug target for inhibitors to block its upregulation and thereby ameliorate cognitive deficit in Alzheimer's disease and improve behavioral dysfunctions in TBI-related brain injuiry and related neurological diseases.

APOE4 ALTERS EARLY ENDOSOMAL DYNAMICS IN PRIMARY NEURONS

POSTERS: A01.F. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LYSOSOMES, UBIQUITIN, PROTEASOME, ER STRESS, CHAPERONES

Emma Nyberg[1], Sabine Konings[1], Nils Lindblom[1], Oxana Klementieva[1], Isak Martinsson[2], Gunnar Gouras[1]
[1]Faculty of Medicine, Lund University, Experimental Medical Science, Lund, Sweden, [2]Norwegian University of Science and Technology, Kavli Insitute For Systems Neuroscience And Center For Neural Computation, Trondheim, Norway

Aims: APOE4 genotype is the most important genetic risk factor for developing AD. Accumulating evidence suggests that ApoE4 affects the endosomal system; however, our understanding how ApoE4 affects the endolysosomal pathway in neurons is incomplete. We aim to explore how ApoE isoforms affect the endolysosomal system in primary mouse neurons and if it changes with time in culture (modelling ageing) and prolonged neuronal activity.
Methods: To study cellular changes in neurons, we use primary hippocampal/cortical brain cultures, harvested from ApoE KO mice and ApoE3 or ApoE4 targeted replacement mice. We analyse the neurons after 18 and 25 days in vitro (DIV18 and DIV25). To explore how ApoE isoforms adapt to elevated activity DIV18 primary cultures are treated for 48 h with bicuculline.
Results: We found that mature (DIV18) ApoE4 neurons present less prominent early endosomes in distal dendrites compared to ApoE3. With time in culture early endosomes seem to accumulate in distal dendrites of both ApoE4 and ApoE KO neurons. Regions with high default network activity are vulnerable to AD pathology. By treating the culture with bicuculline for 48 h we increase neuronal excitability, and we hypothesized that the endosomal system is affected differently between the ApoE isoforms. Preliminary data show that 48 h of bicuculline reduces the number of early endosomes in the cell soma in ApoE4 neurons compared to its baseline (untreated control). In contrast, ApoE3 and ApoE KO neurons have either increased, or similar numbers of early endosomes as their baseline.
Conclusions: The endolysosomal pathway is a highly dynamic and important system for neurons, and is increasingly linked to AD. Our preliminary findings point toward ApoE4 initially altering early endosomal dynamics in neurons. These alterations change depending on the cellular context.

Aims: This study aims to regulate Nrf2-ERK1/2 signaling pathway through hypericin, inhibit oxidative stress, and finally achieve the purpose of treating PD.
Methods: Male C57BL/6 mice were divided into normal group, MPTP group, hypericin low, medium and high dose groups. In addition to the normal group, the remaining mice were intraperitoneally injected MPTP to establish Parkinson's disease model, once a day for 7 days. Since the first day of MPTP injection, hypericin low, medium and high dose groups were intragastricated with hypericin solution of 25 mg/kg, 50mg/kg and 100mg/kg, 0.2ml each, for 2 consecutive weeks. The expressions of tyrosine hydroxylase (TH), Nrf2 and p-ERK1/2 proteins in brain tissues of rats in each group were detected by Western Blot. The number of TH positive neurons in the substantia nigra was detected by immunofluorescence technique.
Results: Compared with the normal group, the gait frequency of each paw in MPTP group increased ((P<0.001); Compared with MPTP group, hypericin low-dose, medium-dose and high-dose groups reduced the footfrequency of each paw ((P<0.01). Western Blot results showed that compared with the normal group, the expressions of TH, Nrf2 and p-ERK1/2 proteins in MPTP group decreased ((P<0.01); Compared with MPTP group, TH, Nrf2 and p-ERK1/2 protein levels were increased in hypericin low, medium and high dose groups. Immunofluorescence results showed that the number of TH positive cells in MPTP group decreased compared with normal group, and the number of TH positive cells in hypericin low, medium and high dose groups increased compared with MPTP group.
Conclusions: Hypericin can effectively improve the motor dysfunction of PD mice, and has a protective effect on Daergic neurons of PD mice, which may be related to inhibiting oxidative stress.

Aims: Exposure to chronic stress or elevated glucocorticoid hormone levels has been associated with cognitive deficits and increased risk for Alzheimer's disease (AD), potentially due to negative impacts on mitophagy processes. However, the full extent of its impact on mitochondrial function balance in the AD brain cell system has not fully been understood. Here, we investigate the intracellular mechanisms of how elevated glucocorticoids induce BNIP3L/NIX-mediated mitophagy impairment in neurons and glial cells, contributing to AD.
Methods: This study uses a 9-week-long human mini-brain on a chip to delve into how glucocorticoids heighten AD markers by altering mitophagy activities, considering cortisol hypersecretion common in AD patients. Focusing on AD specifics and broader aging brain responses, we scrutinized the dysfunction of NIX-mediated mitophagy and the consequential aggregation of damaged mitochondria, fostering brain degradation.
Results: Our primary findings demonstrate that glucocorticoids induce the accumulation of damaged mitochondria in neurons by inhibiting NIX-driven mitophagy, subsequently causing a decrease in ATP production and synaptic density, along with the onset of tau pathology. Secondly, Prolonged co-culturing of astrocytes and neurons with high glucocorticoids leads to a dip in NIX-regulated mitophagy and a drop in mitochondrial genesis, likely influenced by the enhanced neuroinflammation evident with GFAP and MAO-B's activity. Finally, Glucocorticoids inflict mitochondrial damage in microglia but curtail proinflammatory markers (CD86, iNOS), weakening phagocytic action and resulting in Aβ accumulation.
Conclusions: In summary, sustained elevated levels of glucocorticoids obstruct mitophagy in neuronal and glial cells by inhibiting NIX, culminating in tau accumulation. This research highlights the critical need for research on developing therapies targeting mitochondrial efficacy in healthy aging.

STUDY OF MITOCHONDRIAL TRANSFER IN APP(NL-G-F) MICE PRIMARY NEURONAL CELLS

POSTERS: A01.G. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

Romain Giraud[1], Luana Naia[1], Liesbeth Voorbraeck[2], Shubin Guo[3], Maria Ankarcrona[2]
[1]Karolinska Institutet, Neurobiology, Care Sciences And Society, STOCKHOLM, Sweden, [2]Karolinska Institutet, Neurobiology, Care Sciences And Society, Stockholm, Sweden, [3]Westlake University, Westlake University, Hangzhou, China

Aims: Mitochondrial function and degradation (mitophagy) show early impairments in Alzheimer´s disease (AD), which can contribute to neurodegeneration. In neurodegenerative models, recent evidence showed bilateral mitochondrial transfer between astrocytes and neurons. Astrocytic mitochondria are transferred to neurons, thus restoring mitochondrial function and neuronal viability, while neuronal mitochondria are transferred to astrocytes to undergo mitophagy. The first objective is to study for the first time this mitochondrial transfer in clinically relevant AD models. Mitochondrial transfer involves extracellular vesicles (EVs) containing mitochondrial fragments, named mitovesicles. However, this EVs subtype is still poorly studied. Therefore, the second objective is to isolate and characterize mitovesicles in an AD mouse model.
Methods: The studies are performed using primary cultures from the APP^{NL-G-F} mouse, a clinically relevant AD model. The study of mitochondrial transfer is done using micro-fluidic and Boyden culture chambers, which allow co-culturing of astrocytes and neurons in which mitochondria are differentially fluorescently labeled. The isolation of mitovesicles is done using Tangential Flow Filtration and ultracentrifugation, and the characterization of their protein content is done by Western Blot and proteomics.
Results: Mitochondrial transfer has been successfully observed. While WT neuron-derived mitovesicles mainly integrate the host astrocytic mitochondrial network, APP^{NL-G-F}-derived mitovesicles show reduced engulfment and integration and induce higher number of mitophagy events in APP^{NL-G-F} astrocytes. EVs are enriched in both membrane (e.g., Atp5a) and matrix proteins (e.g., pyruvate dehydrogenase), however, mitovesicles were not fractioned from the global EVs pool. Therefore, protocol optimization is required to get better purity prior to proteomic analysis.
Conclusions: Mitochondria transfer have been observed in APP^{NL-G-F} neuronal cells. Further optimization of protocols is required to quantify this transfer and purify mitovesicles from general EVs pool.

Aims: The present study explored the potential neuroprotective role of NAR in PQ-induced Parkinsonism in Wistar rats. This aimed to study the effect of Naringenin against paraquat-induced oxidative, mitochondrial dysfunction, neuroinflammation and neurodegeneration in a rat model of PD.
Methods: Oxidative damage, mitochondrial dysfunction, neuroinflammation and neurodegeneration were determined by performing western blot analysis and Immunohistochemistry.
Results: Naringenin treatment significantly reduced paraquat-induced oxidative stress by modulating the paraquat-induced aberrant levels of antioxidant enzymes, mitochondrial dysfunction by increasing the mitochondrial complex activities, neuroinflammation by decreasing the protein expressions of GFAP and IBA-1, and neurodegeneration by increasing the protein expressions of MAP2 and NeuN in PQ-intoxicated rats.
Conclusions: Naringenin exhibited promising neuroprotective properties in the current study against paraquat-intoxicated rats, indicating its potential therapeutic properties against Parkinson's pathology. So, NAR shows neuroprotection against PQ-induced neurotoxicity and neurodegeneration, indicating its therapeutic potential against Parkinson's disease.

Aims: Olfactory dysfunction has been linked to the early phases of Alzheimer's disease (AD). The olfactory mucosa (OM), located in the upper nasal cavity, is accessible from living individuals via biopsy or swab sampling for molecular inspection. Previously, we and others have reported AD-related alterations, including amyloid-beta secretion, in the cells of the OM, and proven the safety of the OM sampling. However, the proteomic alterations occurring in the OM in individuals with AD have not previously been studied.
Methods: We have recruited and collected OM biopsies and swab samples from individuals with AD or mild cognitive impairment (MCI) and cognitively healthy controls for a discovery-phase proteomics study. The OM biopsy and swab samples (N=6 individuals/group) were obtained from different nostrils of the same individual during a single visit in the clinic and further processed for non-targeted proteomics with LC-ESI-MS/MS. All the participants of the study (> 50-year-old; males and females) underwent a careful diagnostic examination.
Results: With the preliminary LC-ESI-MS/MS run a total of 6821 different proteins were initially identified and quantified with a data independent acquisition method in OM biopsy samples, and 6593 proteins in OM swab samples. A total of 5429 of the identified proteins were found in both sample types. A large fraction of the proteins that were found differentially expressed in AD and MCI when compared to controls were mitochondrial. This is in line with our previously reported scRNA-seq experiments with primary cultures of AD OM cells.
Conclusions: The results of this study provide novel information on the utility of OM biopsies and swabs to study the early molecular alterations occurring in AD and suggest mitochondrial impairment as an early pathological feature in these samples.

MITOCHONDRIAL DEFECTS IN DOWN SYNDROME BRAIN OCCURS EARLY IN LIFE: IMPLICATION FOR NEURODEGENERATION.

POSTERS: A01.G. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

Chiara Lanzillotta[1], Antonella Tramutola[1], Daniel Esteve[2], Fabio Di Domenico[1], Marzia Perluigi[1], Eugenio Barone[1]

Aims: The impairment of mitochondrial function and increased levels of oxidative stress are two important factors contributing to the cognitive impairment associated with Down syndrome (DS). One potential source for mitochondrial defect could be an imbalance in mitochondrial proteostasis. In this regard several studies indicate that a specialized mitochondrial Unfolded Protein response (UPRmt) is activated upon aberrant accumulation of damaged or unfolded proteins in the mitochondrial matrix, resulting in the up regulation of key genes involved in the mitochondrial response. Therefore, the main goal of this project is to identify potential links between UPRmt activation and AD-related neurodegeneration in DS.
Methods: We evaluated the levels of specific protein implicated in the UPRmt (ATF5, GRP75, ATF4, CHOP, SIRT3, HSP60) in the hippocampus of Ts2Cje (DS model) and euploid (n=6/group) at different ages (0, 1, 6 months). Furthermore, we analyzed whether changes of the UPRmt were associated with: (i) proteins regulating brain energy metabolism and mitochondrial biogenesis (mitochondrial complexes, AMPK and PGC1A, TFAM, mitofusin and OPA1); (ii) oxidative stress (HNE and 3-NT); (iii) proteins mediating synaptic plasticity (PSD95, Syntaxin and BDNF).
Results: Ts2Cje showed an early activation of the UPRmt at P0 demonstrated by the early significant increase of GRP75. The protective activation of the UPRmt activation is lost at 1 month of age in Ts2Cje mice, during brain maturation, resulting in reduced levels of mitochondrial complexes, energy metabolism as well as increased levels of oxidative stress.
Conclusions: We propose that a close link exists among UPRmt, mitochondrial defects and oxidative stress drives the impairment of energy metabolism early in life before consistent AB deposition and neurofibrillary pathology in DS, thus contributing to early onset AD.

KEY SEQUENCE MOTIF IN REDOX CHEMISTRY OF METAL-AMYLOID BETA COMPLEXES STUDIED WITH NATIVE MASS SPECTROMETRY

POSTERS: A01.G. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

Frederik Lermyte, Sarah Brandner, Tanja Habeck
Technical University of Darmstadt, Clemens-schöpf-institute For Organic Chemistry And Biochemistry, Darmstadt, Germany

Aims: High concentrations of transition metals are found within plaques in Alzheimer's disease patients' brains. Chemical reduction of these metals is associated with production of neurotoxic reactive oxygen species (ROS). The underlying mechanism of this reduction is not fully understood. The goal of this study was to use native mass spectrometry to understand which amino acid residues are critical for this chemistry.
Methods: Measurements were carried out using a Synapt XS ion mobility – mass spectrometer (Waters Corporation) equipped with electrospray ionisation. Full-length and truncated amyloid beta sequences were studied, followed by customised sequences for in-depth investigation. Metal-free and metal-bound peptides were activated with varying energies; even-electron and radical fragments were subsequently quantitated.
Results: Activation energy series of different amyloid beta(1-16) variants (which contain the metal-binding domain) showed similar gas-phase behaviour concerning even-electron and radical-directed fragmentation. However, when bound to Cu(II), the human peptide showed threefold higher abundance of certain radical-directed fragmentation pathways. By careful analysis of fragmentation energetics and products, we ruled out both a known non-specific radical-directed mechanism, and secondary even-electron fragmentation. Instead, our results indicate a previously unreported, yet specific radical-directed origin. To identify the key amino acid residues in this mechanism, customized peptides were used, designed to resemble either the human or rodent sequence with one residue being replaced at a time. We were thus able to establish the key sequence motif that is essential for the mechanism, and rationalized our observations based on the known coordination spheres of Cu(II) and Cu(I) in solution.
Conclusions: A unique gas-phase reaction for Cu(II)-bound human amyloid beta was observed. Unravelling this mechanism could lead to a better understanding of ROS-induced damage to neurons and potentially support the development of treatments for Alzheimer's disease.

APOE4-MEDIATED CHANGES IN MITOCHONDRIAL MORPHOLOGY AND EXPRESSION OF NUCLEAR-ENCODED GENES IN CELL MODELS

POSTERS: A01.G. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

Daniela Marinho, Mariana Pires, Ildete L. Ferreira, A. Cristina Rego
University of Coimbra, Cnc-center For Neuroscience And Cell Biology, Coimbra, Portugal

Aims: ApoE4 is the primary genetic risk factor for sporadic Alzheimer's disease (AD), found in 40-65% of all AD patients. ApoE4 has been associated to several pathological processes linked to cognitive impairment. ApoE4 can interact with mitochondria and translocate to the nucleus, regulating the expression of genes involved in aging, amyloid beta (Abeta) production, inflammation and apoptosis, potentially linked to AD pathogenesis. Thus, in this study we aimed to investigate ApoE4-mediated alterations in mitochondrial morphology, function and nuclear translocation, as well as its impact on nuclear-encoded mitochondrial gene expression.
Methods: Different AD cell models were used, namely Wistar rat primary cortical neurons exposed to Abeta1-42 oligomers (AbetaO), primary cortical neurons from APP/PS1 transgenic versus WT mouse embryos, and mouse Neuro2a (N2a)-APPSwe versus N2a-WT cell lines. Cells were transfected with plasmid-encoded ApoE4-GFP or ApoE3- GFP. Mitochondrial function, morphology and mRNA levels of nuclear-encoded mitochondrial proteins were measured.
Results: Data show that ApoE4 is present in the nucleus and mitochondria in AD and WT cell models. Comparing to ApoE3, both rat and mouse WT neurons presented increased nuclear ApoE4 levels. Increased mitochondrial ApoE4 was also observed in Wistar rat primary neurons. In contrast, N2a-APPSwe cells revealed decreased ApoE4 levels in both organelles. Interestingly, decreased mRNA levels of sirtuin 3 in both N2a-WT and N2a-APPSwe cells, and PGC-1alpha in N2a-WT cells were also associated to ApoE4. ApoE4 expression also induced significant changes in mitochondrial morphology in WT rat neurons, APP/PS1 mouse neurons and N2a-WT cells. However, ApoE4 expression did not affect mitochondrial membrane potential or mitochondrial calcium levels in AD cells.
Conclusions: This study evidence ApoE4-mediated changes in mitochondrial morphology and gene expression in both non-AD and AD cell models.

MITOCHONDRIAL IMPAIRMENT IN A FAMILIAL AZHEIMERS' DISEASE IN VITRO MODEL

POSTERS: A01.G. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

Zahra Motamed[1,2], Daniel Heutschi[1], Carine Gaiser[1], Laura Suter-Dick[1,3]
[1]University of Applied Sciences Northwestern Switzerland, Institute For Chemistry And Bioanalytics, Muttenz, Switzerland, [2]University of Basel, Department Of Biomedicine, Basel, Switzerland, [3]Swiss Centre for Applied Human Toxicology (SCAHT), Toxicology, Basel, Switzerland

Aims: Alzheimer's disease (AD) is a neurodegenerative disorder characterized by the accumulation of extracellular amyloid beta (Abeta) plaques, intracellular neurofibrillary tangles and neuroinflammation, resulting in neuronal and synaptic loss. Mitochondrial dysfunction has been described as an early feature of AD. However, the precise mechanisms regarding its role in AD progression remain unclear. The goal of this work is to evaluate how mitochondria are affected in differentiated neurons and glial cells carrying familial AD (FAD) genotypes.
Methods: We modified the ReN-VM progenitor cell line to express FAD mutations: human amyloid beta precursor protein alone (ReN-GFP-APP) or in combination with a mutation in human presenilin 1 (ReN-GFP-APP-PSEN). Cells were differentiated in Matrigel for up to 9 weeks. Neuro-astroglia differentiation, expression of Abeta and phospho-Tau (p-Tau) were evaluated using immunofluorescence staining, Abeta production via ELISA. Mitochondrial localization was assessed through confocal microscopy and mitochondrial function by evaluating mitochondrial membrane potential (TMRE-staining).
Results: ReN-GFP-APP and ReN-GFP-APP-PSEN differentiated into neurons and astrocytes that produced Abeta 42. Moreover, FAD cells displayed axonal damage. ReN-GFP-APP-PSEN cells showed increased Abeta deposition and p-Tau after 6 and 9 weeks of differentiation, respectively. Additionally, after 6 weeks, fewer TMRE-positive mitochondria were detected in the axons, they appeared densely packed in the neuronal soma of ReN-GFP-APP and ReN-GFP-APP-PSEN cells.
Conclusions: ReN-GFP-APP-PSEN and ReN-GFP-APP cells displayed increased axonal damage at 6 weeks, accompanied by reduced mitochondrial activity compared to 2-week-old cultures**.** Our results show an association between mitochondrial dysfunction and neurodegeneration in an FAD model. Further investigation is required to elucidate the link between mitochondrial dysfunction and AD progression.

STUDYING MITOCHONDRIAL DYNAMICS IN THE LOCUS COERULEUS NORADRENERGIC SYSTEM WITH IN VIVO ACOUSTO-OPTIC TWO PHOTON IMAGING IN TAUOPATHIES

POSTERS: A01.G. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

Theresa Niedermeier, Paul Feyen, Katharina Ochs, Lars Paeger, Jochen Herms
German Center for Neurodegenerative Diseases, Translational Brain Research, Munich, Germany

Aims: The Locus coeruleus (LC), a small nucleus in the brainstem, is of special interest in the context of neurodegeneration such as in Alzheimer's disease (AD), where it is one of the first regions to show hyperphosphorylated 'pretangle' tau. Mitochondria have been proposed to be linked to this pathology due to the bioenergetic needs of the tonically active LC neurons with their extensive unmyelinated axonal projections. In this work mice expressing GFP in the outer mitochondrial membrane confined to LC neurons in a Cre-dependent manner are utilized to study the dynamics of these organelles in vivo in a model of tauopathy.
Methods: The study of mitochondria is often restricted to immunohisto- or cytochemical analysis, limiting conclusions about temporal aspects. Here we present a novel *in vivo* two-photon imaging method utilizing acousto-optics to study mitochondrial dynamics. Mice with region specific mitochondrial GFP expression were stereotactically injected with Cre-dependent AAVs carrying either human Tau-P301S-mKate2 or mKate2 and chronically imaged at four, five and six months of age.
Results: Moving mitochondria were successfully imaged and analysed, showing a significant reduction in mitochondrial transport in the tauopathy model. This reduction increased over the three recorded timepoints, while average velocity remained constant in controls. Importantly, decreased mitochondrial velocity correlated with a progressive loss of axonal projections in the cortex.
Conclusions: The presence of a significant number of moving mitochondria in adult mammals has been discussed controversially. Here we show not only the abundance of mitochondrial dynamics post neonatal stages, but also the importance of further *in vivo* studies of mitochondria in tauopathies and other diseases. For the first time, to our knowledge, we correlate mitochondrial dysfunction with the "dying-back" hypothesis in the LC *in vivo*.

NEUROPROTECTIVE EFFECT OF XMU-MP-1, A NOVEL HIPPO SIGNALING INHIBITOR, AGAINST STREPTOZOTOCIN-INDUCED CELLULAR MODEL OF ALZHEIMER'S DISEASE: INSIGHTS INTO MITOCHONDRIAL DYSFUNCTION

POSTERS: A01.G. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

Manas Sahu, Amal Mondal
Jawaharlal Nehru University, School Of Life Sciences, New Delhi, India

Aims: Alzheimer's Disease (AD), the most common form of dementia, is a growing global health concern with unmet clinical therapeutics to date. Apoptosis is one of the mainstream mechanisms driving neuronal death. The Hippo signaling pathway has recently emerged as a key pathway influencing cell survival, proliferation, and apoptotic-related pathophysiological conditions. Previous studies have highlighted the contributions of a hyper-activated Hippo signaling pathway in executing cellular death in various neurodegenerative disorders, including AD. However, it remains unknown whether suppressing the Hippo pathway can rescue neuronal death in AD and its possible mechanism. In this study, we investigated the beneficial role of the novel Hippo signaling inhibitor, Xmu-mp-1, in a cellular AD model.
Methods: Human neuroblastoma cell line SH-SY5Y was cultured and differentiated into mature neuronal types. Streptozotocin (STZ) treatment induced AD-like features via cellular metabolic changes. For Hippo signaling inhibition in the cells, a pharmacological antagonist, Xmu-mp-1, was used. Cell viability assay, immunocytochemistry, live/dead assay, DCF-DA assay, JC-1 assay, MitoSOX, and MitoTracker staining were performed to evaluate the potential of Xmu-mp-1 in rescuing the toxic effects of STZ treatment.
Results: Xmu-mp-1 protects the cells from cytotoxicity induced by STZ treatment. As evident in the live/dead assay, pre-treatment of differentiated SH-SY5Y cells with Xmu-mp-1 at a dose of 2μM reduced STZ-induced apoptosis. In addition, pre-treatment with Xmu-mp-1 also reduced oxidative stress, mitochondrial depolarization, and associated mitochondrial dysfunction triggered by STZ administration.
Conclusions: Xmu-mp-1 exhibits a neuroprotective role against AD as it improves the reduction in cell viability induced by STZ. Further mechanistic investigations into the neuroprotective role of Xmu-mp-1 revealed that Xmu-mp-1 exhibits neuronal protection by alleviating mitochondrial dysfunction. Future studies are needed to understand the therapeutic potential of Hippo signaling inhibition against AD in detail.

PROTECTIVE ROLE OF ANTIOXIDANTS AND NRF2 ACTIVATORS FROM OXIDATIVE DAMAGE INDUCED BY SPORADIC AND FAMILIAR FORMS OF AMYLOID BETA

POSTERS: A01.G. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

Maria Luisa Valle, Bitseat Getaneh, Jorge Ghiso, Agueda Rostagno
New York University Grossman School of Medicine, Pathology, New York, United States of America

Aims: Over 90% of Alzheimer patients manifest cerebral amyloid angiopathy (CAA), condition that deeply affects brain function by oxidative stress production, vascular cell death, blood brain barrier disruption and, frequently, cerebral hemorrhage. The extent of vascular compromise is exacerbated by the presence of genetic variants, particularly those located at positions 21-23 of amyloid beta. Among them, the E22Q Dutch mutation is associated with early onset very aggressive CAA, and cerebral hemorrhages. Studies from our and other groups indicated mitochondria-mediated pathways dysregulation as a contributing factor to the pathogenesis of CAA. As key providers of brain energy demands, mitochondria are the major consumers of oxygen and the most important generators of reactive oxygen species (ROS). In the current work, we aimed to provide insight into the amyloid beta compromised molecular pathways in microvascular endothelial cells and identify potential new targets for therapeutic intervention.
Methods: Human brain microvascular endothelial cells were challenged with well-defined oligomeric assemblies of both wild type amyloid beta 1-42 and E22Q variant. Using immunofluorescence microscopy and biochemical assays, we evaluated ROS formation and concomitant production of lipid and protein oxidation derivatives.
Results: Our findings demonstrate the formation of oligomeric assemblies of both amyloid beta peptides and induction of dose-dependent ROS formation that, in turn, causes lipid peroxidation and generation of protein carbonylation derivatives. Treatment with antioxidants and activators of Nrf2, a central regulator of the antioxidative response, significantly attenuated ROS production and concomitant ROS-induced damage.
Conclusions: Our data highlights the detrimental role of amyloid beta oligomeric assemblies for microvascular endothelial cells suggesting that modulation of oxidative stress is a complementary therapeutic strategy with the potential to preserve the neurovascular unit integrity.

PINOCEMBRIN REGULATED GSK-3B/WNT/B-CATENIN SIGNALING PATHWAY: A NOVEL MECHANISM FOR AB-MEDIATED NEURONAL APOPTOSIS

POSTERS: A01.G. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

Kumju Youn[1,2], Jeong-Hyun Yoon[3], Mira Jun[1,2,3]
[1]Dong-A University, Department Of Food Science And Nutrition, Busan, Korea, Republic of, [2]Dong-A University, Center For Food & Bio Innovation, Busan, Korea, Republic of, [3]The graduate School of Dong-A University, Department Of Health Sciences, Busan, Korea, Republic of

Aims: The deposition of amyloid-β (Aβ) peptides has been implicated as a one of pathological hallmark of Alzheimer's disease (AD). Increasing evidence indicates that Aβ initiates oxidative stress and a vicious cycle of mitochondrial damage, leading to apoptotic neuronal death. Pinocembrin (5,7-dihydroxyflavone), a major flavonoid found in honey and propolis, has shown significant neuroprotective property by suppressing Aβ cleaving enzyme in our previous study. The present study investigated a novel anti-AD effect of pinocembrin on mitochondrial dysfunction and apoptosis against Aβ injury.
Methods: Neurotoxicity and apoptosis by Aβ were assessed and the underlying mechanism by which pinocembrin suppressed cell death, mitochondria dysfunction, caspase cascade and GSK-3β/Wnt/β-catenin signaling pathway related protein markers were evaluated in $A\beta_{1-42}$-mediated PC12 cells.
Results: Pinocembrin significantly reversed Aβ-induced cell death, especially pinocembrin at 50 μM a similar neuroprotective effect to that of resveratrol, a well-known positive control. In addition, the compound counteracted Aβ-induced mitochondrial dysfunction, which was supported by maintaining mitochondrial membrane potential, decreasing BAX protein, and increasing BCL-2 protein within the mitochondria as well as upregulating TrxR1 mitochondrial antioxidant enzyme. Mitochondrial dysfunction by Aβ triggered the caspase cascade, whereas pinocembrin suppressed expression of caspase-9, -8 and -3. Interestingly, pinocembrin exerted neuroprotective effects against Aβ by inhibiting GSK-3β activation, which in turn promoted Wnt signaling via nuclear translocation of β-catenin.
Conclusions: Taken together, the present results demonstrated that pinocembrin prevented the Aβ-stimulated mitochondrial apoptosis via GSK-3β/Wnt/β-catenin signaling pathway, providing a useful approach for potential natural agent for AD prevention.

APOE GENOTYPE AFFECTS ENDOLYSOSOMAL CHOLESTEROL LOCALIZATION IN THE BRAIN

POSTERS: A01.H. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LIPIDS, LIPOPROTEINS AND MEMBRANE TRAFFICKING

Sherida De Leeuw, Ilana Samsonov, Tal Nuriel
Columbia University Irvine Medical Center, Taub Institute, New York, United States of America

Aims: Aberrant cholesterol processing may be the missing link in the biology of AD. Major genetic risk factor *APOE4* is a key player in cholesterol metabolism in the brain, and previous research from our group has shown that *APOE4* is related to lysosomal cholesterol accumulation in human iPSC-astrocytes, as well as altered endolysosomal morphology in the entorhinal cortex (EC) of aged *APOE4* mice. Therefore, we aim to elucidate the role of *APOE4* genotype in cholesterol mislocalization within the endolysosomal system of the brain.
Methods: We studied endolysosomal cholesterol accumulation in humanized *APOE2*, *E3*, and *E4* mouse brain sections. Cholesterol was labeled using the novel and highly specific D4H* probe, combined with immunohistochemical labeling of late endosomes/lysosomes, also called endolysosomes (CD63). Fluorescence was quantified and colocalized using Imaris.
Results: Quantification of total D4H*-cholesterol spots showed decreasing levels of cholesterol with genotype (*APOE2>E3>E4*), while cholesterol spots were generally decreased in female compared to male brain tissue. Interestingly, cholesterol spots specifically colocalized with endolysosomes showed opposite genotype dependent levels (*APOE2<E3<E4*), meanwhile small differences were detected in the females compared to males. Similar findings were detected in neuron-specific cholesterol and endolysosomal-cholesterol, indicating that neurons play a role in the *APOE*-dependent cholesterol differences detected.
Conclusions: In conclusion, cholesterol was disproportionately colocalized with endolysosomes in *APOE4* brain sections, compared to *APOE3>E2*. Importantly, we found that biological sex affects cholesterol levels, interacting with *APOE* genotype, which may help us understand the biology of sex-based difference in AD risk. We will further characterize cholesterol in early endosomes and lysosomes, determining the implications of *APOE4*-related endolysosomal-cholesterol buildup. Elucidating the biology of *APOE4* will improve our understanding of cellular mechanisms underlying AD.

BEHAVIORAL AND MOLECULAR PHENOTYPING OF TWO APP KNOCK-IN MOUSE MODELS OF ALZHEIMER'S DISEASE WITH CYP46A1 UPREGULATION

POSTERS: A01.H. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LIPIDS, LIPOPROTEINS AND MEMBRANE TRAFFICKING

Ljerka Delac[1], Francesca Eroli[1], Maria Latorre Leal[1], Gabriela Da Cruz Meda[1], Ines Da Costa Morreira[1], Per Nilsson[1], Ivan Nalvarte[2], Ingemar Björkhem[3], Silvia Maioli[1]
[1]Karolinska Institutet, Division Of Neurogeriatrics, Department Of Neurobiology, Care Sciences And Society, Solna, Sweden, [2]Karolinska Institutet, Biosciences And Nutrition, Flemingsberg, Sweden, [3]Karolinska Institutet, Department Of Laboratory Medicine, Flemingsberg, Sweden

Aims: To investigate whether the beneficial effects of CYP46A1 upregulation on memory and learning can counteract Alzheimer's disease (AD) pathology in a sex-specific manner, we have developed a novel mouse model of Alzheimer's disease with CYP46A1 overexpression.
Methods: We employed single *App* knock-in mice carrying Swedish and Beyreuther/Iberian (App^{NL-F}), and Arctic mutation (App^{NL-G-F}) crossed with mice overexpressing the human CYP46A1 transgene (Cyp46 Tg). Female and male cohorts were aged to 6, 12, and 18 months of age. A battery of cognitive and anxiety-like behavioral tests was conducted, followed by cholesterol and oxysterol measurements and immunohistochemical stainings for AD pathology markers.
Results: The results of our study demonstrate mild effects of CYP46A1 overexpression in spatial working memory at 12 months. At six months of age, only male App^{NL-G-F} mice exhibit anxiolytic behavior, whereas females do not. Interestingly, in the 6-month-old Cyp46 Tg x App^{NL-G-F} cohort, increased serum levels of 24-hydroxycholesterol (24-OH) and 27-hydroxycholesterol were not reflected in the brain, the main site of 24-OH production, as seen previously in Cyp46 Tg mice. Furthermore, quantification of microglia and amyloid-beta deposits at different age points has been carried out to elucidate impact of CYP46A1 overexpression dependent on the age and sex.
Conclusions: These results suggest alterations in cerebral oxysterol metabolism in the presence of triple *App* knock-in mutation and propose Cyp46 Tg x APP knock-in model as a novel platform to investigate cholesterol perturbations in AD.

ZDHHC7 PROMOTES AD-LIKE PHENOTYPE BY INDUCING HYPERPALMITOYLATION OF PROTEINS REGULATING SYNAPTIC PLASTICITY AND BETA AMYLOID METABOLISM

POSTERS: A01.H. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LIPIDS, LIPOPROTEINS AND MEMBRANE TRAFFICKING

Salvatore Fusco[1,2], Francesca Natale[1,2], Matteo Spinelli[1,2], Marco Rinaudo[1,2], Walter Gulisano[3], Ida Nifo Sarrapochiello[2], Daniela Puzzo[3], Claudio Grassi[1,2]

Aims: Alzheimer's disease (AD) is a growing problem for aging populations worldwide and it represents one of the most demanding challenges for biomedical and pharmacological research. More importantly, all therapeutic attempts made so far based on current knowledge have proven scarcely effective, probably because the molecular mechanisms underlying the onset and progression of the disease still remain poorly understood. An increasing number of studies has also shown the role of palmitoylated proteins in the regulation of synaptic plasticity and neuronal functions. The aim of our study was to investigate the role of zDHHCs and aberrant protein S-palmitoylation in AD.
Methods: S-palmitoylation is a protein post-translational modification regulated by zinc finger DHHC domain containing (zDHHC) S-acyltransferases that modulates both localization and activity of proteins controlling synaptic plasticity and beta amyloid (Aβ) metabolism. We previously discovered that aberrant protein S-palmitoylation plays a pivotal role in the brain insulin resistance (BIR)-dependent cognitive decline.
Results: Here, we demonstrated that hippocampal insulin resistance induced the FoxO1-mediated epigenetic overexpression of zDHHC7 in 3×Tg-AD mice. We also found increase of both zDHHC7 expression and S-palmitoylation levels of synaptic proteins and Beta-Secretase 1 (BACE1) in hippocampi of both 3×Tg-AD mice and AD patients. Hippocampal knockdown of zDHHC7 reduced the hippocampal Aβ deposition and prevented the onset of cognitive deficits in 3×Tg-AD mice. Accordingly, intranasal administration of protein S-palmitoylation inhibitor 2-bromopalmitate ameliorated the synaptic plasticity and cognitive deficits in mice. Finally, we found a direct correlation between BACE1 S-palmitoylation and Aβ 1-42 levels in human hippocampi.
Conclusions: Our data reveal a key role of zDHHC7-driven aberrant S-palmitoylation in the onset and progression of AD-related cognitive impairment and provide new potential targets for the development of therapeutic tools against AD.

UNDERSTANDING AB PLAQUE ASSOCIATED LIPID CO-AGGREGATION USING PULSE-CHASE SPATIAL MULTIOMICS

POSTERS: A01.H. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LIPIDS, LIPOPROTEINS AND MEMBRANE TRAFFICKING

Junyue Ge, Jörg Hanrieder
University of Gothenburg, Department Of Psychiatry And Neurochemistry, Gothenburg, Sweden

Aims: The primary goal is therefore to employ stable isotope labelling together with advanced novel mass spectrometry imaging to probe Aβ plaque pathology associated lipid dynamics in AD model systems.
Methods: Here, male APP knock-in mice (APPNL-G-F) carrying humanized Aβ sequence, along with Swedish mutation (KM670/671NL) on exon 16, as well as Arctic (E693G) and the Beyreuther/Iberian mutations (I716F) on exon 17, were used in the study. To study spatiotemporal Aβ plaque metabolism, mice were fed MouseExpress (15N, 98%) mouse feed (PULSE) based on ^{15}N following the labelling scheme: PULSE, 10 weeks (weeks 7 to 17), no CHASE (n = 3). Changes in isotope incorporation in Aβ peptides and lipids can spatially be delineated with mass spectrometry imaging (SILK imaging, iSILK). MALDI-MSI under negative-ion mode lipid analysis and subsequent peptide/protein ion imaging were performed at 10 µm spatial resolution on the same brain section from knock-in mice.
Results: By MALDI-MSI lipid analysis, heterogenous distribution of lipids were revealed in the frontal cortex in knock-in mouse brain. GM2 and GM3 showed aggregation only in the plaque, while GM1 showed enrichment in the plaque compared to the region outside of the plaque. ^{15}N enrichment was observed in PS and gangliosides. It was associated with the progressive increase in abundance of an envelope of high mass isotopologues (M1 to M6). There are mainly Aβ1-42 along with Aβ1-38 in the plaques, and ^{15}N-labeled amino acids were incorporated into Aβ peptides. MALDI-MSI detected solely labelled ^{15}N–Aβ1-42, but no unlabelled ^{14}N–Aβ1-42.
Conclusions: Pulse-chase spatial multiomics sheds light on what, where, when and how neuronal lipid species are involved in pathogenioc plaque formation.

ALTERATIONS IN PLASMA AND CEREBROSPINAL FLUID FATTY ACIDS IN ALZHEIMER'S DISEASE

POSTERS: A01.H. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LIPIDS, LIPOPROTEINS AND MEMBRANE TRAFFICKING

Ricard Lopez-Ortega[1], Farida Dakterzada[2], Mariona Jove[3], Jose Luis Cantero[4], Reinald Pamplona[3], Gerard Piñol-Ripoll[2]
[1]Hospital Universitari Arnau de Vilanova, Clinical Laboratory, Lleida, Spain, [2]Hospital de Santa Maria - IRBLleida, Cognitive Disorders Unit. Cognition And Behaviour Study Group, Lleida, Spain, [3]University of Lleida-IRBLleida, Department Of Experimental Medicine, Lleida, Spain, [4]University Pablo de Olavide, Department Of Physiology, Anatomy And Cellular Biology, Sevilla, Spain

Aims: Objectives: to assess the association of both cerebrospinal fluid (CSF) and plasma fatty acids (FAs) with Alzheimer's disease (AD) diagnosis and mild cognitive impairment (MCI) to AD progression. In addition, we evaluated the relation of FAs with the rate of MCI to AD progression.
Methods: Methods: FA composition of plasma and CSF samples from 289 participants (103 AD, 92 MCI, and 94 control) was determined by gas chromatography flame ionization detector method (GC-FID). The MCI subjects were followed up for a median of 58 (±12.5) months. We controlled our data for age, sex, MMSE, and APOE ε4.
Results: Results: In CSF, higher levels of anti-inflammatory index were associated with decreased risk of AD diagnosis vs MCI (p = 0.005) and higher levels of docosahexaenoic acid (DHA) were associated with reduced risk of MCI to AD progression (p = 0.021). In plasma, higher levels of oleic acid (OA) were associated with reduced risk of AD (p = 0.013) and MCI (p = 0.001) vs control, while higher levels of vaccenic acid were associated with an increased risk of AD vs control (p <0.001) and AD vs MCI (p = 0.006). Higher plasma levels of OA were also associated with reduced risk of MCI to AD progression (p = 0.016). Finally, higher plasma levels of DHA were associated with a higher rate of MCI to AD progression (p = 0.01).
Conclusions: Conclusions: Our results suggest that FA dysregulations at both central (CSF) and systemic (plasma) levels are involved in pathogenesis and progression of AD.

PERIPHERAL BLOOD BIOMARKERS IN PATIENTS WITH ALZHEIMER'S DISEASE AND THE DEVELOPMENT OF PERSONALISED TREATMENTS.

POSTERS: A01.H. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LIPIDS, LIPOPROTEINS AND MEMBRANE TRAFFICKING

Carmela Matrone[1], Alfonso Di Costanzo[2]
[1]University of Naples "Federico II", Neuroscience, Naples, Italy, [2]University of Molise, Medicina E Di Scienze Della Salute, Campobasso, Italy

Aims: Recently, peripheral biomarkers in the plasma of patients with Alzheimer's disease (AD) have gained considerable clinical attention. Several studies have identified potential blood signatures that could aid the development of new diagnostic and therapeutic strategies. We analysed the differences in plasma metabolites, Aβ42, and TNFα levels to identify changes that occur simultaneously in patients with AD.
Methods: We used ELISA to measure Aβ42 and TNFα levels, which are indicators of AD progression and systemic inflammatory processes, respectively. Additionally, we conducted metabolomic analysis to evaluate the changes in the vascular components that contribute to the disease. These factors were interpreted with respect to the Mini-Mental State Examination (MMSE) score, which allows measurement of the extent of cognitive decline.
Results: We evaluated the plasma levels of Aβ42 and TNFα in 38 patients with AD and 34 HE subjects. We observed that C26:1- and C28:1- lyso-PC levels increased in AD patients with lower MMSE scores and decreased in patients with higher Aβ42 levels. Additionally, we found that no plasma metabolites were correlated with MMSE scores or Aβ42 levels in patients with high TNFα levels. However, changes in several metabolites in the triacylglyceride pathway were observed in AD patients with higher TNFα, but not in those with higher Aβ42 or lower MMSE scores, suggesting that changes in TNFα might be independent of cognitive deterioration in AD patients.
Conclusions: This study highlights the potential of using a combination of different plasma signatures to define specific clinical phenotypes of patient subgroups, which could lead to the classification of patients with AD and the development of individualized treatment plans.

UNCOVERING THE ROLE OF AN AFRICAN-SPECIFIC ABCA7 FRAMESHIFT DELETION ON LIPID METABOLISM AND ALZHEIMER'S DISEASE

POSTERS: A01.H. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LIPIDS, LIPOPROTEINS AND MEMBRANE TRAFFICKING

Younji Nam
University of Miami, Genetics, MIAMI, United States of America

Aims: SA1: Assess the impact of the 44-bp deleted *ABCA7* on lipid metabolism and AD pathology. SA2. Evaluate the effect of neuron-microglia crosstalk on lipid homeostasis.
Methods: A) We studied the impact of an ancestry-specific deletion in *ABCA7* on lipid metabolism using patient-derived isogenic iPSC lines. Since cholesterol plays a critical role in Aβ aggregation in neurons and Aβ phagocytosis in microglia, evaluating defects in the lipid metabolism in these lines will provide insight into the role of *ABCA7* in AD pathology. B) We examined how the ABCA7 variant differentially or synergistically impacts lipid metabolism in neurons and microglia in monoculture and co-culture.
Results: Most ABCA7 non-synonymous coding changes associated with AD do not reach the plasma membrane, but we have discovered that the truncated p.Arg578Alafs ABCA7 protein is stable and in fact does localize in the plasma membrane similar to the wild-type protein. We have also demonstrated that the truncated ABCA7 protein has altered cholesterol distribution in the plasma membrane, suggesting a dysfunctional ABCA7 in spite of its membrane localization.
Conclusions: Genetic ancestry plays an important role in AD pathology with AAs having double the incidence of AD compared to non-Hispanic whites (NHW). However, the impact of AA-specific genetic variants on AD development has been understudied. ABCA7 is one of the leading genetic risk factors for African Americans and has a similar risk for African Americans as ApoE4 does in this population. This study will generate valuable phenotypic data in patient-derived neurons and microglia relating to both pathologic and cellular hallmarks of AD, including valuable insights into the role of ABCA7, a gene that has been implicated across populations, in lipid metabolism and AD development.

EXTRACELLULAR VESICLES BIOGENESIS AND RELEASE ARE AFFECTED BY ABETA PEPTIDE

POSTERS: A01.H. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LIPIDS, LIPOPROTEINS AND MEMBRANE TRAFFICKING

Margarida Vaz, Tânia Martins, Odete Da Cruz E Silva, Ana Gabriela Henriques
University of Aveiro, Departement Of Medical Sciences, Aveiro, Portugal

Aims: Alzheimer's disease (AD) represents an important healthcare challenge due to its intricate etiology and increasing prevalence. A main hallmark of AD is the presence of senile plaques, mainly composed of Aβ peptide aggregates. This peptide is extremely toxic, triggering several pathological events, that ultimately lead to neuronal death. Extracellular vesicles (EVs) are nanovesicles secreted by all cell types and recognized as key intercellular communication mediators. In AD, it has been reported that these EVs can carry Aβ, among other proteins relevant in disease pathogenesis as APP or tau, hence contributing to the seeding potential of the toxic proteins. However, Aβ effects in EVs biogenesis and release are not completely understood. Therefore, this work aimed to evaluate the effect of Aβ in this process.
Methods: N2a neuroblastoma cells were treated with Aβ peptide and EVs were then isolated from cells conditioned medium by ultracentrifugation. EVs were characterized by TEM and WB analysis was employed to evaluate the levels of proteins involved in EVs biogenesis and secretion. Additional proteomic studies were also carried out.
Results: A significant increase was observed in the levels of Flotilin, involved in EVs biogenesis, and in two Rab proteins, implicated in EVs secretion. The proteomic analysis also revealed alterations in proteins related to EVs.
Conclusions: These results support that Aβ peptide can alter EVs biogenesis and release. As EVs can be involved in cell communication and signaling events, data suggest that Aβ may have an impact at this level, potentially contributing to the abnormal mechanisms underlying AD pathogenesis. This work was funded by iBiMED under Grant UIDB/04501/2020 and UIDP/04501/2020; MV is supported by the individual PhD grant UI/BD/151354/2021 and TMS by the individual PhD grant SFRH/BD/145979/2019.

Aims: Recent studies demonstrated that factors circulating in the blood can have profound effects on synaptic plasticity and neurogenesis thereby shaping brain aging and neurodegenerative diseases. Here, we investigated the effect of blood serum of Alzheimer's disease (AD) patients and individuals experiencing later cognitive decline on microglia function *in vitro*.
Methods: The University Hospital Graz provided us with serum samples from AD patients and age-matched controls (n=30/group). We also obtained baseline blood serum from elderly participants of the Three-City (3C) cohort (n=418), who were cognitively healthy at baseline and divided into controls and cognitively declining over 12 years of follow-up. To assess phagocytosis, the uptake of fluorescent particles was measured by flow cytometry in a human microglia cell line after exposure to human serum.
Results: AD serum-treated microglia showed higher particle uptake compared to controls, which was associated with cognitive impairment in AD patients. Gene expression analysis of serum-treated microglia revealed that AD serum downregulated the transcription factor EB (*Tfeb*), a master regulator of lysosomal biogenesis. Testing the prognostic value of the phagocytosis assay in the 3C cohort, we found no difference between controls and cognitive declined individuals. However, correlations with their serum metabolome revealed an inverse correlation between particle uptake and the omega-3 fatty acid eicosapentaenoic acid (EPA). A similar correlation with EPA was found in the previously analysed AD cohort. *In vitro* EPA treatment reduced phagocytosis in microglia and upregulated levels of *beclin1*, a gene under *Tfeb* control that is important for autophagosome formation.
Conclusions: AD blood increased microglial phagocytic uptake, which inversely correlated with serum EPA levels, while causing lysosomal deficiency. *In vitro* experiments confirmed the EPA-dependent reduction in particle uptake and suggested increased autophagosome formation upon EPA exposure.

FOCAL POINT MICROGLIA RESPONSE: SPATIAL PROFILING OF THE INNATE IMMUNE SYSTEM IN DEMENTIAS WITH PURE AND MIXED PROTEIN PATHOLOGIES

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Tim Bathe[1], Gabriela Hery[2], Jonathan Villareal[1], Eric Cohen[3], Jennifer Phillips[1], Rohan Sharma[1], Wangchen Tsering[1], Stefan Prokop[1]
[1]University of Florida, Pathology, Gainesville, United States of America, [2]University of Florida, Small Animal Clinical Sciences, Gainesville, United States of America, [3]University of Florida, Biomedical Engineering, Gainesville, United States of America

Aims: Despite the identification of a multitude of genetic risk factors for neurodegenerative diseases (ND) in immune associated genes, the precise role of immune processes in disease pathogenesis and progression is far from understood. To better understand the complex interplay between different extracellular and intracellular protein pathologies and the brain's intrinsic immune system in neurodegenerative diseases, the aim of this study is to investigate the role of the immune system, more specifically microglia, in human postmortem brain tissue. Cases without significant pathological changes (Control), pure AD and LBD cases, and cases with mixed protein pathology will be examined and compared. The focus is on changes in the phenotype of microglia in disease-relevant brain regions (hippocampus, frontal cortex, occipital cortex and midbrain).
Methods: To better understand the complex interplay between different extracellular and intracellular protein pathologies and the brain's intrinsic immune system in neurodegenerative diseases, we set out to comprehensively profile immune response profiles in postmortem brain samples of patients with "pure" Alzheimer's disease neuropathological changes (ADNC) (AD), "pure" alpha-Synuclein pathology in Lewy body disease (LBD) and Dementias with "mixed" pathology (MIX). We are combining immunohistochemical profiling of microglia and digital image analysis with deep immunophenotyping using gene expression profiling on the Nanostring nCounter platform and digital spatial profiling on the Nanostring GeoMx platform.
Results: We identified a robust immune activation signature around ADNC. This signature is maintained in MIX patients, irrespective of co-existence of AD pathology and Lewy body (LB) pathology, while LBD patient samples with "pure" LB pathology exhibit a distinct immune signature.
Conclusions: Our studies highlight disease and brain region specific immune response profiles in response to intracellular and extracellular protein pathologies and further underscore the complexity of neuroimmune interactions in neurodegenerative diseases.

DETERMINE THE ROLE OF CLEC7A+ MGND-MICROGLIA IN NEURODEGENERATIVE DISEASES

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Wesley Brandao, Ana Carolina Durao, Jen-Li Barry, Gabryell Thiengo, Zhuoran Yin, Oleg Butovsky
Brigham and Women's Hospital - Harvard Medical School, Neurology, Boston, United States of America

Aims: Microglia play a pivotal role in maintaining brain homeostasis but lose key functions during the course of neurodegenerative diseases. Recently, our group has characterized two major microglia phenotypes: homeostatic microglia (M0) and microglia associated with neurodegenerative disease (MGnD), also known as disease-associated microglia (DAM). The pivotal question in neuroinflammation-targeted therapeutic approaches is whether the MGnD phenotype is beneficial or detrimental in neurodegenerative disease. Aim**:** Define the contribution of Clec7a^{+} MGnD microglia to the progression of neurodegenerative diseases using our novel mouse model, which allows specific targeting of the MGnD-microglia subset.
Methods: Methods: We generated Clec7a-Cre^{ERT2} transgenic mice, which were crossed with ROSA26^{TdTomato} and DTR^{Flox} mice to map MGnD microglia fate and role. In a disease context, these mice were crossed with APP/PS1 and 5xFAD mice or subjected to MOG immunization to induce experimental autoimmune encephalomyelitis (EAE).
Results: Results: We found that MGnD (Clec7a^{+}/ TdTomato^{+}) microglia are present at sites of demyelination, and their numbers correlate with EAE disease scores. Additionally, we demonstrated the specific ablation of MGnD-microglia during EAE development in ROSA26^{DTR} mice. In AD mouse models, Clec7a^{+} microglia were exclusively associated with amyloid beta (Ab) plaques, exhibiting elevated expression levels of MHC-II, GMCSF, and TNFα, while LAP expression was suppressed. Interestingly, we observed decreased expression of Clec7a MGnD microglia in 4-month-old male mice compared to females, which correlated with reduced Ab-plaque load and dystrophic neurons. Fate-mapping analysis indicated a turnover of approximately three months post-activation for Clec7a-TdTomato^{+} microglia, and its deletion leads to an increase in the dystrophic neurons.
Conclusions: Conclusion: Our Clec7a-Cre^{ERT2} mouse model provides a novel platform for studying the MGnD microglia subset in neurodegeneration.

DIFFERENTIAL EFFECT OF HEXOKINASE 2 GENE DOSAGE ON MICROGLIAL ACTIVATION AND ALZHEIMER'S DISEASE PROGRESSION.

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Juan Codocedo, Claudia Mera Reina, Peter Lin, Shweta Puntambekar, Brad Casali, Nur Jury Garfe, Pablo Martinez, Israel Coronel, Paul Fallen, Cristian Lasagna-Reeves, Gary Landreth

Aims: Hexokinase 2 (HK2) is a mitochondrial protein that performs the first step in glycolysis through the phosphorylation of glucose. Previous studies have proposed HK2 as a critical determinant of microglial response in various pathological processes. However, these studies reported conflicting data with respect to the effect of the complete deletion of HK2 on microglial metabolism and disease progression. Thus, the role of microglial HK2 in neuroinflammation remains poorly understood. **Objectives: 1.** Investigate the effect of HK2 gene dosage in the regulation of microglial phenotypes and Alzheimer's progression in the 5xFAD mice. **2.** Explore the molecular mechanisms associated to the inflammatory role of HK2 antagonism in AD.
Methods: Methods: We generated mice with a conditional deletion of one or two copies of HK2 in microglia of the 5xFAD mice. HK2 deletion was induced at 2 months of age and AD pathogenesis was evaluated at 5 months**.** We also investigated the effects of its inhibitor Lonidamine. *In vitro*, we investigated the mechanisms by which HK2 regulates microglial responses to Aβ.
Results: Results: The complete loss of HK2 exacerbates inflammation, by inducing mitochondrial activation of the inflammasome. Conversely, the partial antagonism of HK2, displays reduced pathology in the 5XFAD mice. Decreased activity of HK2 increase the levels of its cytosolic target IKBα, an NFKβ inhibitor, that prevents expression of inflammatory genes including several elements of the inflammasome.
Conclusions: Conclusions: HK2 partial antagonism prevents inflammation through a non-metabolic mechanism associated to the modulation of NFKβ signaling. The complete loss of HK2 affects an alternative inflammatory pathway, associated to mitochondrial dysfunction and activation of the inflammasome, demonstrating that HK2 regulates inflammation through different mechanisms and the result of its therapeutic targeting will depend of it molecular context.

STUDYING THE IMPACT OF ALZHEIMER'S DISEASE POLYGENIC RISK SCORES ON MICROGLIAL FUNCTION IN VITRO

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Wannes Dejonckheere[1], Sofie Carmans[1], Annerieke Sierksma[2], An Snellinx[2], Sarah Borrie[2], Yasmina Abakkouy[3], Isabelle Cleynen[3], Stephanie Humblet-Baron[4], Bart De Strooper[5], Rik Vandenberghe[6], Tom Cornelissen[1]

Aims: The risk of developing Alzheimer's disease (AD) is strongly affected by an individual's genetic make-up, even for non-familial AD cases. This genetic predisposition can be quantified by determining the presence of an individual's genetic risk loci. The combined weight of these risk loci can then be displayed as the polygenic risk score (PRS). Currently a prediction accuracy of up to 84% between AD cases and healthy controls is achieved. Interestingly, the majority of these risk genes are highly, if not only, expressed in microglia rather than in other brain cells. Therefore we set out to investigate how this PRS contributes to microglial function in vitro.
Methods: iPSC's from APOE3/E3 positive subjects with a high, low and intermediate PRS for developing AD and 4 APOE4/E4 carriers (high PRS, mainly driven by the presence of APOE4) were differentiated into microglia. Microglial morphology and motility were assessed after LPS stimulation while microglial phagocytosis was studied by detecting the uptake of bioparticles or Abeta42 oligomers/fibrils.
Results: iPSC's successfully differentiated into microglia as indicated by the presence of high levels of microglial mRNA markers. After LPS stimulation, microglia tend to adapt a rod like morphology while treatment with bioparticles or Abeta42 oligomers/fibrils leads to a more swollen spherical shape. Bioparticles and Abeta42 oligomers and sonicated fibrils were also rapidly phagocytosed while fibrillar Abeta42 was taken up slower. The contribution of the PRS on microglial function is currently being investigated.
Conclusions: How PRS affects microglial function and microglial contribution to AD development is currently unknown. Here we try to resolve this gap by studying microglial function in iPSC derived microglia from subjects with divergent PRS.

RG5942 A MIR-155 PHARMACOLOGICAL BLOCKER, MODULATES MICROGLIA RESPONSE AND MITIGATES COGNITIVE IMPAIRMENT IN ALZHEIMER'S DISEASE

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Ana Carolina Durao[1], Wesley Brandao[1], Zhuoran Yin[1], Madison Carpenter[1], Morgan Carlson[2], Oleg Butovsky[1]
[1]Brigham and Women's Hospital - Harvard Medical School, Neurology, Boston, United States of America, [2]Regulus Therapeutics Inc., Biology, San Diego, United States of America

Aims: Background: Microglia, the brain's resident immune cells, play a crucial role in maintaining brain homeostasis and influencing the progression of Alzheimer's disease (AD). In neurodegenerative conditions, microglia transform into a neurodegenerative phenotype known as MGnD, the functional mechanisms of which remain poorly understood. MicroRNA-155 (miR-155), previously linked to pro-inflammatory activation in microglia and monocytes through TREM2-APOE signaling, has shown increased expression in various neurodegenerative diseases, including AD, amyotrophic lateral sclerosis and multiple sclerosis. **Objectives:** To investigate the role of miR-155 in AD mouse models.
Methods: Methods: We generated miR-155$^{fl/fl}$ mice crossed with Cx3cr1Cre^{ERT2} mice on an APP/PS1 background. We employed RNAseq and immunohistochemistry to analyze gene expression profiles and AD pathology, while cognitive function was assessed through spontaneous alternation and forced alternation tests. Additionally, in collaboration with Regulus Therapeutics, we developed novel compounds capable of suppressing miR-155 in microglia, both in vitro and in an acute neurodegenerative mouse model.
Results: Results: Our findings reveal that microglial deletion of miR-155 induces a pre-MGnD activation state via interferon-g (IFN-γ) signaling, leading to enhanced compaction of amyloid plaques, reduced dystrophic neurites, alleviated synaptic degradation associated with plaques, and improved cognitive performance. Furthermore, preliminary tests have demonstrated the efficacy of the RG5942 compound in suppressing miR-155 expression in the N9 microglial cell line after LPS stimulation and in an acute neurodegenerative mouse model.
Conclusions: Conclusion: Our study unveils a novel miR-155-mediated regulatory mechanism in MGnD microglia and suggests that targeting miR-155 could be a promising therapeutic strategy for AD. Blocking miR-155 holds the potential to limit neurodegenerative pathology and preserve cognitive function in AD.

EFFECT OF AGING, AMYLOID PATHOLOGY AND APOE ISOFORM ON MICROGLIA PHENOTYPE AND GENE EXPRESSION.

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Nicholas Fitz, Iliya Lefterov, Radosveta Koldamova
University of Pittsburgh, Eoh, Pittsburgh, United States of America

Aims: Alzheimer's disease (AD) is a multifactorial disease with aging as the major risk factor and APOE representing the major genetic risk factor for late-onset AD. Microglia play an essential role in response to amyloid pathology and AD associated neuroinflammation. Less is known about the impact of major AD risk factors on normal microglial response. The current study aim is to profile the age-dependent microglial transcriptomic and proteomics changes in response to amyloid pathology and expressed APOE isoforms in an Alzheimer's disease mouse model.
Methods: Brain samples from Alzheimer's disease model mice expressing human APOE isoforms at different ages were used to isolate microglia and perform transcriptomic and proteomic analysis.
Results: To gain further insight in the correlation between amyloid pathology, APOE isoform and aging in the microglial transcriptome, we performed RNA-seq using isolated microglia. We identified phenotype-correlated networks using Weighted Gene Co-Expression Network Analysis (WGCNA) and identified that aging is the strongest factor that affects microglial transcriptome in both WT and APP mice. We also defined that APOE isoform-specific effect on microglial transcriptome significantly correlated to amyloid pathology and genes affected by both amyloid pathology and aging. The identified targets were validated using FISH. Finally, we performed proteomics analysis on the microglia isolated from the same groups of mice.
Conclusions: These findings demonstrate the importance of microglia in the pathogenesis of AD. APOE genotype and aging, the main risk factors for AD, affect microglial responses which may further aggravate neurodegeneration. Targeting microglia may be a preventive intervention to delay the progression of AD.

INFLAMMATORY MICROENVIRONMENT IN A BETA-AMYLOID MOUSE MODEL OF ALZHEIMER'S DISEASE

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Robin Guay-Lord, Laurent Potvin-Trottier, Lionel Breuillaud, Elodie Brison, Barry Bedell
Biospective Inc, Technology, Montreal, Canada

Aims: Beta-amyloid (Aβ) accumulation in Alzheimer's disease (AD) activates microglia and astrocytes. It is vital to improve our understanding of the spatial relationships between Aβ pathology and neuroinflammation. As such, the objective of this work is to provide quantitative measures of activated microglial and reactive astrocytes in the microenvironment of Aβ pathology in an APP/PS1 mouse model of AD.
Methods: We have developed a fully-automated method to identify, count, spatially localize, and characterize microglia, astrocytes, and Aβ plaques in multiplex immunofluorescent sections in APP/PS1 (ARTE10) transgenic mice [1]. We used a novel machine learning-based morphometric analysis to identify activated microglia. We quantified the microgliosis and astrogliosis both in the local microenvironment of the plaques (Fig. 1A) and distant to the plaques as a function of disease progression.
Results: We found that microglia identified as activated (Fig. 1B) by our machine learning model are denser, have more highly branched processes, and have less circular soma compared to non-activated microglia (Fig. 1C). ARTE10 mice demonstrated an age-dependent increase in Aβ plaques, microgliosis, and astrogliosis (Fig. 2). Analysis of the Aβ plaque microenvironment showed microgliosis primarily located less than 10 µm away from the plaques, with higher Iba-1 stain density (Fig. 3A), microglia density (Fig. 3B), and activated microglia density (Fig. 3C) compared to wild-type (WT) mice (dashed line). Interestingly, the astrogliosis also showed an increase with proximity to the plaques, but was also increased outside of the local plaque microenvironment (Fig. 3D). **Figure**

UNRAVELING THE RELATIONSHIP BETWEEN MICROGLIA AND NEUROFILAMENT LIGHT CHAIN

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Christina Heiss[1], Stefanie Fruhwürth[1], Lana Grötschel[2], Maria Olsson[3], Henrik Zetterberg[2,3,4]
[1]Sahlgrenska Academy, Institute of Neuroscience and Physiology, Department Of Psychiatry And Neurochemistry, Göteborg, Sweden, [2]Department of Psychiatry and Neurochemistry, Institute Of Neuroscience And Physiology, The Sahlgrenska Academy, University Of Gothenburg, Mölndal, Sweden, [3]Sahlgrenska University Hospital, Clinical Neurochemistry Laboratory, Mölndal, Sweden, [4]University of Gothenburg, Department Of Psychiatry And Neurochemistry, Molndal, Sweden

Aims: Alzheimer's disease (AD) is a neurodegenerative disease leading to elevated levels of neurofilament light chain in both cerebrospinal fluid and blood. Microglial activation plays a pivotal role in the progression of AD and various hallmark pathologies have been associated with microglial activation. However, it remains unknown how increased NfL levels affect microglia and how microglia in different states respond to NfL. Here we aim to elucidate the relationship between microglia and elevated levels of NfL as observed in AD.
Methods: We use human induced-pluripotent stem cell (hiPSC) derived microglia and neurons to study the mode of uptake of NfL. Labelled NfL is added to hiPSC-derived microglial cultures and uptake is assessed by fluorescence. Additionally, NfL, released by neurons, is measured in media of neuronal cultures and neurons co-cultured with microglia.
Results: Utilizing two different labeling methods, our results show a clear uptake of labelled NfL-proteins into microglia. The use of a pH-dependent dye indicates that the observed uptake happens via phagocytosis or endocytosis pathways. We further show a reduction in NfL levels in cultures of neurons when microglia are added.
Conclusions: In summary, our data convincingly illustrates the active uptake of NfL by microglia in response to neuronal degeneration. To strengthen its clinical and Alzheimer's disease (AD) research implications, further investigations are needed to elucidate the precise mechanism of this uptake.

INHALED XENON MODULATES MICROGLIA AND AMELIORATES DISEASE IN MOUSE MODELS OF AMYLOIDOSIS AND TAUOPATHY

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Ilya Ilin[1], Wesley Brandao[2], Nimansha Jain[3], Zhuoran Yin[2], Kilian Kleemann[2], Madison Carpenter[2], Mathew Blurton-Jones[4], Howard Weiner[5], David Holtzman[6], Oleg Butovsky[2]
[1]General Biophysics LLC, Neurology, Wayland, United States of America, [2]Brigham and Women's Hospital, Harvard Medical School, Neurology, Boston, United States of America, [3]Washington University School of Medicine, Neurology, St. Louis, United States of America, [4]University of California Irvine, Department Of Neurobiology And Behavior, Irvine, United States of America, [5]BWH, Neurology, Brookline, United States of America, [6]Washington University in St. Louis, Neurology, St. Louis, United States of America

Aims: Background: Alzheimer's disease (AD) is the most prevalent neurodegenerative disorder. Currently, anti-amyloid antibody treatments modestly slow disease progression in mild dementia due to AD. Emerging evidence shows that homeostatic dysregulation of the brain immune system, especially that orchestrated by microglia, plays a significant role in the onset and progression of the disease, including an increase in neuroinflammation and oxidative stress. Thus, a major question is how to modulate the phenotype and function of microglia to treat AD. Xenon gas (Xe) is a noble gas used in human patients as an anesthetic and neuroprotectant in treating brain injuries. Xe penetrates the blood-brain barrier, which can make it an effective therapeutic. **Objectives:** evaluate if Xe-gas treatment has a protective immunomodulatory role to ameliorate AD.
Methods: Methods: APP/PS1, humanized 5xFAD and P301S (tau) mice were treated with Xe 50% once a week for 2-3 months. After this period microglia and peripheral immune cells were evaluated by Immunohistochemistry, flow cytometry and scRNA-seq.
Results: Results: we identified that Xe inhalation polarizes mouse and human microglia towards an intermediate state of activation that we have termed as 'pre-MGnD' in an acute neurodegeneration model and mouse models with AD-like pathology, i.e., 5xFAD (amyloid) and P301S (tau). This microglial phenotypic transition enhanced amyloid plaque compaction and reduced dystrophic neurites. Moreover, Xe inhalation reduced brain atrophy, and neuroinflammation and improved nest-building behavior in APOE4:P301S mice. Mechanistically, Xe inhalation polarizes homeostatic microglia toward a pre-MGnD state via IFNg signaling that maintains the microglial phagocytic response while suppressing its pro-inflammatory properties.
Conclusions: Conclusion: these results support the translation of Xe inhalation as a novel approach to treating AD.

INNATE IMMUNITY PROTEIN IFITM3 REGULATES ALZHEIMER'S DISEASE-ASSOCIATED MICROGLIAL RESPONSE

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Tanya Jain[1], Georgia Frost[1], Yue-Ming Li[2]
[1]Weill Cornell Medicine, Neuroscience, New York, United States of America, [2]Memorial Sloan Kettering, Chemical Biology Program, New York City, United States of America

Aims: Amyloid plaques consist Aβ peptides, which are sequentially cleaved by α or β-secretase and then γ-secretase (GS) from amyloid precursor protein (APP). Our lab has previously identified interferon response protein IFITM3 as a γ-secretase (GS) modulatory protein that is upregulated in the human AD brain as well as in the 5xFAD mouse brain, particularly in glia. We have shown that IFITM3 regulates GS activity in neurons, and a deficit in IFITM3 results in decreased GS cleavage of APP, leading to reduced amyloid plaque deposition in the 5xFAD mouse. With our new studies, we want to: 1. Investigate the consequence of IFITM3 deficit on cognitive decline and neuronal loss in AD 2. Investigate whether IFITM3 plays a role in amyloid clearance by microglia
Methods: We have generated 5xFAD;IFITM3$^{-/-}$;TREM2$^{-/-}$ mice and have established human stem cell-derived IFITM3-/- microglial cells. We have used a panel of mouse behavioural, immunohistochemical and transcriptomic studies and *in vitro* microglial assays to investigate the function of IFITM3 in the phagocytic clearance of Aβ by microglia, its interplay with TREM2 and downstream signaling in the context of neuroinflammation.
Results: We have found that IFITM3 is highly expressed and inducible in microglial cells. We have shown that 5xFAD;IFITM3$^{-/-}$ mice have rescued cognition and neuronal loss compared to 5xFAD mice, and have an upregulation of several microglial DAM genes. In our *in vitro* microglial model, we have found that IFITM3$^{-/-}$ microglia display enhanced uptake of Aβ peptide, enhanced lysosomal degradation, and enhanced TREM2 expression and signaling.
Conclusions: With these studies, we have determined a novel role of IFITM3 in microglia. We have also found evidence of an interplay of IFITM3 with TREM2. These studies confirm IFITM3 is a viable therapeutic target AD treatment.

THE ROLE OF PURINERGIC RECEPTOR P2Y12 FOR MICROGLIA FUNCTION IN THE ALZHEIMER BRAIN: FROM ZEBRAFISH TO HUMANS

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Sofia Wüstenhagen[1], Kazi Tanzina Rahman[1], Sarra Zenagui[1], Yasmin Abdul Jabbar[1], Anders Wallin[1,2], Francesco Locatelli[1,2], Petronella Kettunen[1,2]
[1]University of Gothenburg, Neuroscience And Physiology, Gothenburg, Sweden, [2]Sahlgrenska University Hospital, Psychiatry, Cognition And Old-age Psychiatry, Mölndal, Sweden

Aims: The purinergic receptor P2Y12 is expressed by microglia and has been proposed to be involved in neuroinflammation related to neurodegenerative disorders, including Alzheimer's disease (AD). In this study, we used a newly developed p2y12 CRISPR zebrafish line in combination with human biofluid samples to better understand the role of P2Y12 in AD.
Methods: To explore the role of P2y12 in microglia function, we crossed the p2y12 mutants with transgenic ApoE:GFP fish marking microglia. We investigated microglia phagocytosis and lysosomal function in detail in vivo using confocal microscopy. Moreover, we measured the levels of P2Y12 in CSF samples from AD patients and controls from the Gothenburg Mild Cognitive Impairment study.
Results: Our experiments show that lack of P2y12 impairs microglia function, including microglia morphology, phagocytosis, as well as lysosomal function. Moreover, P2Y12 was measured in human CSF and data were correlated to other patient variables, such as the core AD CSF biomarkers indicating disease progression.
Conclusions: Taken together, our findings suggest that P2y12 is critical for cellular functions of microglia, which could underlie the pathological process in AD.

Aims: Human iPSC-based Alzheimer's Disease (AD) models have great potential for mechanistic and translational studies, as they enable investigation of pathomechanisms in human brain cells. However, current iPSC-AD models show low reproducibility and cell type diversity, lack physiological cell-cell interactions, or show only earliest disease phenotypes. Therefore, we aim to develop more reproducible and controllable iPSC-AD models that combine multiple brain cell types and enable analysis of pathomechanisms in a human, 3D cortical tissue-like environment.
Methods: We optimized protocols to differentiate iPSCs into cortical neurons, astrocytes, and microglia. We combined these differentiated cells into 3D co-cultures and characterized them using stainings, mass spectrometry analysis and functional assays. Using CRISPR/Cas9, we introduced AD-causing mutations to study AD pathogenesis in an isogenic system.
Results: By 3D co-culturing all cell types we established modular, human cortical tissue models that display dense networks of neuritic processes that are stable for >6 months without formation of a necrotic core. Added microglia migrate into and tile the cultures, surveil the environment and react to tissue damage. We further confirmed maturation of the cultures, e.g., by formation of synapses and deposition of a brain-like extracellular matrix. In AD cultures, we observed typical phenotypes such as increased Aβ secretion and age-dependent accumulation of extracellular and insoluble Aβ, increased levels of phospho-tau and microglial activation. Upon addition of exogenous Aβ42, we found aggregation into plaque-like structures with surrounding axonal dystrophies.
Conclusions: We developed a reproducible and controllable, human cortical tissue model to study cell states, crosstalk, and functionality in health and disease. Currently, we expand the model by including additional cell types such as oligodendrocytes and test approaches to elicit endogenous formation of plaque pathology.

TARGETING HEXOKINASE 2 TO MODULATE INFLAMMATORY RESPONSE OF MICROGLIAL CELLS AFTER TRAUMATIC BRAIN INJURY AND ITS IMPACT ON AD-LIKE DEMENTIA

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Claudia Mera Reina, Juan Codocedo, Peter Lin, Anushay Ansari, Paul Fallen, Cristian Lasagna-Reeves, Gary Landreth
Stark Neurosciences Research Institute, Indiana University, School of Medicine, Anatomy, Cell Biology And Physiology, Indianapolis, United States of America

Aims: Traumatic brain injury (TBI) and Alzheimer's disease (AD) are devastating neurological disorders, whose complex relationship is not completely understood. Persistent activation of microglia represents a mechanistic link between the development of a secondary injury after TBI, Aβ deposition and dementia. Activated microglia undergo a shift to aerobic glycolysis, to power the various energy intensive activities that subserve the change in microglia phenotype. Hexokinase 2 (HK2), an enzyme that catalyzes the first step in glycolysis, it is an important driver of microglial activation in various pathological processes. **Objective:** We propose that targeting HK2 could be of therapeutic utility for limiting inflammation-induced secondary injury and acceleration of AD pathogenesis in an amyloid mouse model subjected to mild TBI (mTBI).
Methods: To determine the role of HK2-driven microglial activation in the mTBI-induced AD pathology acceleration, we performed controlled cortical impact (CCI) in 5xFAD mice with inducible inactivation of microglial HK2. Additionally, we tested the therapeutic potential of HK2 antagonism using its pharmacological inhibitor, Lonidamine, inmediatly after CCI. Microglial gene expression was evaluated by qPCR. Cortical cytokine levels were measured by Elisa and Aβ species were evaluated by western blot. Cognitive dysfunction was tested in a Y-maze.
Results: HK2 expression was significantly up regulated at 7 days post CCI and its levels remained high after 30 days post injury. In 5xFAD mice, mTBI increased the expression of inflammatory cytokynes as well as the abundance of Aβ oligomeric forms. Importantly, HK2 antagonism attenuated these effects. Additionally, there was a reduction in the expression of several genes associated with microglial activation.
Conclusions: The antagonism of HK2 during the recovery phase post-TBI, had a potent anti-inflammatory effect, limiting the secondary injury associated with microglial dysfunction and progression to AD-like pathology.

TOTAL PLCG2 DEPLETION IMPAIRS MICROGLIAL RESPONSES AND CONFERS DIVERSE TRANSCRIPTIONAL ALTERATIONS IN A MURINE MODEL OF ALZHEIMER'S DISEASE

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Evan Messenger[1], Andy Tsai[2], Peter Lin[1], Adrian Oblak[1,3], Miguel Moutinho[1,4], Guixiang Xu[1], Anushay Ansari[1], Bruce Lamb[1,4], Gary Landreth[1,4], Stephanie Bissel[1,4]
[1]Indiana University School of Medicine, Stark Neuroscience, Indianapolis, United States of America, [2]Stanford University School of Medicine, Wu Tsai Neurosciences Institute, Stanford, United States of America, [3]Stark Neurosciences Research Institute, Indiana University, School of Medicine, Department Of Radiology & Imaging Sciences, Indianapolis, United States of America, [4]Indiana University School of Medicine, Anatomy, Cell Biology And Physiology, Indianapolis, United States of America

Aims: Many of the genes associated with altered risk for Alzheimer's disease (AD) are predominantly expressed in microglia and affect innate immune responses. Among these genes is PLCG2, a mediator of transmembrane signaling that acts downstream of many immune receptors on microglia, including TREM2. Recent RNA-Seq studies suggest a vital role for PLCG2 in many aspects of AD pathology, including the immune response. Reduction in PLCG2 activity is associated with exacerbated AD pathology, but the mechanisms underlying these effects remain unclear.
Methods: We explored the impact of *Plcg2* ablation or haploinsufficiency in the amyloidogenic 5xFAD murine model of AD and compared this to 5xFAD mice deficient in *Trem2.*
Results: While *Plcg2* haploinsufficiency increased X34+ and 6E10+ amyloid plaque pathology, loss of *Plcg2* exhibited similar pathology as wildtype and *Trem2*-deficient mice. Additionally, *Plcg2* deficiency significantly impaired microglial interactions with plaques and showed reduced immunoreactivity of microglia activation marker CD68 when compared to *Plcg2*$^{+/-}$ mice. Gene expression analysis of bulk RNA-Seq data revealed several biological processes altered by loss of *Plcg2*, including pathways associated with the microglial response, metabolism, synapses, and cell signaling. WGCNA produced many significant modules of co-expressed genes such as those associated with immunity, metabolism, and neuronal processes. Importantly, one module was differentially expressed between each genotype and contained predominantly immune-related genes, including DAM genes.
Conclusions: PLCG2 depletion impairs the ability of microglia to effectively transduce surface receptor signals in response to amyloid plaques, leading to a stunted immune response. Additionally, the WGCNA reveals a role for PLCG2 in metabolism, neuronal functioning, and mitochondrial health in AD. Overall, this study highlights the importance of PLCG2 in the innate immune response to amyloid pathology and reveals several novel pathways which may be regulated by PLCG2.

PHENOTYPIC CHARACTERIZATION OF A NOVEL SPI1*RS1377416 MOUSE MODEL OF ALZHEIMER'S DISEASE

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Giedre Milinkeviciute[1], Celia Da Cunha[1], Katelynn Tran[1], Adrian Mendoza-Arvilla[1], Shimako Kawauchi[1], Jonathan Neumann[2], Amber Walker[2], Andrea Tenner[1,3,4], Frank Laferla[1,5], Grant Macgregor[2,6], Kim Green[1,4]
[1]University of California Irvine, Institute For Memory Impairments And Neurological Disorders, Irvine, United States of America, [2]University of California Irvine, Transgenic Mouse Facility, Irvine, United States of America, [3]University of California Irvine, Molecular Biology And Biochemistry, Irvine, United States of America, [4]University of California Irvine, Neurobiology And Behavior, Irvine, United States of America, [5]University of California, Irvine, Neurobiology And Behavior, Irvine, United States of America, [6]University of California Irvine, Developmental And Cell Biology, Irvine, United States of America

Aims: Genome-Wide Association Studies (GWAS) implicate SPI1 as a risk factor for late-onset Alzheimer's Disease (LOAD). Within the brain, *SPI1* encodes a microglia-specific transcription factor, PU.1, necessary for microglial proliferation and activation. *SPI1* rs1377416 has been identified as a non-coding GWAS risk variant for AD. Here, we introduced the *Spi1* rs1377416 variant into the mouse genome to explore its impacts on AD pathogenesis.
Methods: By using CRISPR/Cas9, we generated *Spi1*rs1377416* mice that carry a non-coding mutation corresponding to the rs1377416 SNP found in human *SPI1*. We crossed the *Spi1* mice with the 5xFAD mouse model of amyloidosis and aged them to 4 and 12 months of age. Coronal brain sections were then obtained and immunolabeled with several markers to visualize amyloid plaques, glial cells and assess axonal and neuritic damage. Confocal images were then obtained and quantified in subiculum and cortex.
Results: We found an age-related increase in dense core plaque number and size in the subiculum of 5xFAD;*Spi1* mice. Despite this, microglial volume as well as astrocytic activation were reduced in 5xFAD;*Spi1* compared to 5xFAD mice at 12 months. Correspondingly, neuritic dystrophy and axonal damage were diminished. Notably, significant sex differences were observed in different analyses with males being affected less than females (with the exception of plaque deposition).
Conclusions: Our results indicate that the rs1377416 variant of *Spi1* induces an age-dependent increase in amyloid deposition in the 5xFAD model of amyloidosis. Moreover, this *Spi1* variant exerts a protective effect by suppressing astrocytic response and preventing neuritic and axonal damage. There is a strong sex difference observed between males and females when the variant is present and requires further investigation.

MICROGLIA: SENSORS AND MODULATORS OF ALZHEIMER'S DISEASE-RELATED NETWORK HYPEREXCITABILITY

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Lennart Mucke[1,2], Kaitlyn Ho[1], Gui-Qiu Yu[1], Cathrine Petersen[1,2], Victor Huang[1,2], Sara Knowles[1,2], Melanie Das[1,2]
[1]Gladstone Institute of Neurological Disease, Gladstone Institutes, San Francisco, United States of America, [2]Department of Neurology and Weill Institute for Neurosciences, University Of California San Francisco, San Francisco, United States of America

Aims: Neural network and immune dysfunctions may engage in a vicious circle promoting cognitive decline in Alzheimer's disease (AD) [*iScience* 24: 103245 (2021), *Neurobiol. Dis.* 186: 106263 (2023)]. To further test this hypothesis, we modulated the expression or amino acid sequence of the triggering receptor expressed on myeloid cells 2 (TREM2) or its adapter protein TYROBP and examined how these manipulations affect network hyperexcitability in AD-relevant models.
Methods: Mice lacking one or both *Trem2* or *Tyrobp* alleles and knockin mice expressing the common variant (CV) or R47H variant of human TREM2 were challenged with an excitotoxin or crossed with knockin mice bearing amyloidogenic variants of the amyloid precursor protein. Epileptiform activity ("hyperexcitability") was measured by video-EEG recording. Learning and memory were assessed by behavioral assays, neuropathological alterations by immunohistochemistry and confocal microscopy, and gene expression changes by RT-qPCR or RNA-seq.
Results: Reduced expression of TREM2 or TYROBP exacerbated hyperexcitability in excitotoxin-challenged mice. Expression of human TREM2-R47H, but not TREM2-CV, had similar effects. TREM2-R47H also worsened the age-dependent development of spontaneous hyperexcitability in mice with amyloid plaques. Reducing mouse TREM2 or expressing human TREM2-R47H, but not TREM2-CV, caused aberrant increases in the density of excitatory synapses in some but not other brain regions, compared to controls, potentially increasing excitation/inhibition ratios. Preliminary quantifications of synapses and behaviors suggest that expression of human TREM2-R47H may cause more marked effects than ablation of one mouse *Trem2* allele.
Conclusions: These results suggest that microglia/macrophages can suppress hyperexcitability of different causes and that this function depends on both TREM2 and TYROBP. Variants of these proteins may increase the risk of AD or other dementias, at least in part, by promoting network hyperexcitability.

INTRAVENTRICULAR INJECTION OF NOX2 BLOCKATOR PREVENTS THE APPEARANCE OF PATHOLOGICAL FEATURES IN MICE MODEL OF THE EARLY STAGES ALZHEIMER'S DISEASE

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Kristina Mukhina[1], Alexander Makarov[1], Irina Popova[1,2]
[1]Engelhardt Institute of Molecular Biology, Russian Academy of Sciences, Laboratory Of Protein Conformational Polymorphism In Health And Disease, Moscow, Russian Federation, [2]Institute of Theoretical and Experimental Biophysics Russian Academy of Sciences, Laboratory Of Systemic Organization Of Neurons Named After O. S. Vinogradova, Pushchino, Russian Federation

Aims: Alzheimer's disease (AD) is the most common neurodegenerative pathology with a poorly understood etiology. Recent data point out that ROSs may play a principal role in the initiation of AD. The main source of ROS in the brain is NADPH oxidase 2 (NOX2), located on the membrane of microglial cells. The study examined the effect of NOX2 blockade using the selective inhibitor GSK2795039 (GSK) on the manifestation of early markers of AD in mice with beta amyloid (Ab)-induced pathology.
Methods: To create an acute model of AD BALB/c mice were neurosurgically operated by injecting Abeta into the brain ventricle. GSK was administered i.c.v. within 3 days after surgery. Animal behavior was evaluated in Open Field and Social Interaction tests on days 7 and 14 after Abeta injection. Immunohistochemistry was performed on slices stained with antibodies to Iba-1 and the area and the number of microglial cells in areas CA1 and DG were counted. Brain homogenate was separated into fractions and analyzed for biochemical markers of oxidative stress.
Results: It was found that NOX2 blockade reduces aggression and enhances pro-social interaction in animals without worsening the general condition; prevents activation of microglia in the hippocampus, reducing cell area and number of processes; significantly reduces the level of the markers of oxidative stress - ROS and lipid peroxides and increases the level of reduced glutathione in the membrane, cytoplasmic and mitochondrial fractions of the brain homogenate.
Conclusions: GSK prevents the development of pathological changes associated with the initial stage of Abeta pathology at the behavioral, cellular and subcellular levels. Supported by the Russian Science Foundation (grant #19-74-30007)

Aims: Majority of the models of human neuronal disorders are presented by rodents, yet human neuronal functions have been reported to be significantly different from their rodent counterparts. Human induced pluripotent stem cell (hiPSC) -derived brain organoids offer an ample opportunity to investigate neuronal operational properties in a human context. Here we describe the electrophysiological properties of hiPSC-derived cortical-like brain organoids grown in air-liquid interphase.
Methods: By using the whole-cell patch clamp technique in current and voltage clamp modes, we recorded the basic neuronal operational properties in organoids matured with or without microglia for 4,5,6 and 7 months *in vitro*.
Results: Our data show that the presence of microglia significantly enhanced the frequency of spontaneous excitatory postsynaptic currents in the recorded neurons. Moreover, electrical stimulation of the slice during a positive current pulse led to a cessation of action potential firing suggesting inhibitory synaptic GABA release. Reconstruction of patch-clamped, biocytin-filled neurons revealed the presence of apical dendrite, axon, and different types of spines in the recorded neurons.
Conclusions: Our data suggest that the air-liquid interphase culture of human cortical-like organoids has the characteristics of functional neuronal network with excitatory and inhibitory system and could be used as a potential model for microglia-neuron interaction.

FUNCTIONAL ANALYSIS OF BIOMARKER CANDIDATES FOR MICROGLIAL ACTIVATION

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Ida Pesämaa, Stefanie Fruhwürth, Henrik Zetterberg
Institute of Neuroscience and Physiology, Gothenburg University, Department Of Psychiatry And Neurochemistry, Mölndal, Sweden

Aims: With the emergence of anti-amyloid therapies and microglia-modulating therapies, biomarkers for microglial activation are urgently needed. Recently, we identified six proteins (FABP3, MDH1, GDI1, CAPG, CD44, GPNMB) in models of microglial activation, with increased levels in the CSF of individuals with neurodegeneration and/or amyloid abnormalities. The levels of these proteins increase in a microglial activation-dependent manner, with FABP3, MDH1, and GDI1 as the most promising of the six candidates. Here, we aim to link the current biomarker candidates with functional information, such as biological pathways and characteristics crucial for microglial activation.
Methods: To identify functions related to the reported biomarker candidates, we revised our data, as well as additional proteomics datasets as published by others. We investigated correlations within these proteomic datasets, with a special focus on correlations between the levels of proteins related to microglial activation and neuroinflammation. Furthermore, we made use of in vitro models (iPSC-derived microglia) to study the functions of FABP3, MDH1, and GDI1 in the context of microglial activation.
Results: Our preliminary results confirm the previously reported positive and statistically significant correlation between CSF levels of FABP3, MDH1, GDI1, and CHI3L1. Furthermore, we have identified additional proteins that show a correlation with these four proteins, including LDHB and MPI. Finally, pathway analysis suggests that the majority of these proteins are involved in metabolic pathways including glycan degradation and pyruvate metabolism.
Conclusions: Taken together, our results further support the involvement of the reported biomarker candidates in the process of microglial activation. Moreover, our findings emphasize the importance of metabolic pathways in the context of microglial activation. Information regarding the biological function of a biomarker is likely to improve its application and it may even contribute to a more personalized treatment.

ABCA7 DEFICIENCY IMPAIRS THE RESPONSE OF MICROGLIA TO AMYLOID PATHOLOGY IN A HUMANIZED MODEL OF AD

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Jessie Premereur[1,2], Paula Miquel[1,2], Bob Asselbergh[2], Alma Mohebiany[1,2], Lena Duchateau[2,3], Kristel Sleegers[2,3], Renzo Mancuso[1,2]
[1]VIB Center for Molecular Neurology, Microglia And Inflammation In Neurological Disorders (mind) Lab, Antwerpen, Belgium, [2]University of Antwerp, Biomedical Sciences, Antwerpen, Belgium, [3]VIB Center for Molecular Neurology, Complex Genetics Of Alzheimer's Disease Group, Antwerpen, Belgium

Aims: The ATP-binding cassette transporter, subfamily A member 7 (ABCA7) is one of the most important AD risk genes identified, wherein loss of function (LOF) variants are linked to several microglial pathways, including lipid metabolism and endocytosis. However, the contribution of ABCA7 to microglial biology and AD remains largely unknown. Our main objective is to define the role of ABCA7 dysfunction in microglial homeostasis and AD pathology.
Methods: We generated two ABCA7-KO ESC lines and one patient-derived iPSC line (E709fs), together with their isogenic controls, and differentiated all lines into ESC/iPSC-derived microglia (ESC/iPSC-MG) using our MIGRATE protocol. To understand the effect of microglial ABCA7 dysfunction on AD pathology *in vivo*, we transplanted them into the brains of AD (AppNL-G-F) and control mice. At 6 months, we investigated the differences in the microglia transcriptome and cellular surface proteins using CITE-sequencing (Cellular Indexing of Transcriptomes and Epitopes), and their response to amyloid pathology with histopathology.
Results: ABCA7 LOF microglia display an altered internalization of amyloid β particles *in vitro*, indicating either enhanced phagocytic capacity or diminished degradation. Grafted ABCA7-KO cells displayed a reduced activation in response to amyloid pathology, both at the level of transcriptomic and histopathology. In contrast to TREM2 variants, ABCA7-KO microglia do cluster around plaques similarly to controls but do not engage into a disease associated program, suggesting correct recognition of the AD protein aggregates but failure to engage their endo-lysosomal system and process phagocytic material appropriately.
Conclusions: Our data suggests that distinct molecular mechanisms operate in microglia to contribute to the risk of AD, where ABCA7 LOF microglia fail to engage in an activated response profile.

DISTINCT GLYCOSYLATION CHANGES IN ALZHEIMER'S AB OLIGOMER- AND LIPOPOLYSACCHARIDE-ACTIVATED HUMAN MICROGLIA

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Xinyu Tang[1], Ryan Schindler[2], Jacopo Lucente[3], Armin Oloumi[2], Danielle Harvey[4], Carlito Lebrilla[2], Angela Zivkovic[1], Lee-Way Jin[3], Izumi Maezawa[3]
[1]University of California Davis, Nutrition, Davis, United States of America, [2]University of California Davis, Chemistry, Davis, United States of America, [3]University of California Davis, Pathology And Laboratory Medicine And M.i.n.d. Institute, Sacramento, United States of America, [4]University of California Davis, Public Health, Davis, United States of America

Aims: Glycosylation and complex carbohydrates have been reported to play critical roles in the early pathogenesis and progression of Alzheimer's disease (AD). However, the potential of these molecules to serve as biomarkers and targets for disease intervention remains largely unexplored. Microglia, the brain-resident immune cells, are key players in AD pathogenesis; however, their glycosylation changes in AD-relevant conditions are poorly understood.
Methods: We examined glycosylation and gene expression changes following the activation of human-induced pluripotent stem cell-derived microglia (hiMG) by amyloid-β oligomers (AβO). For comparison, we also examined responses to lipopolysaccharides (LPS). The glycosylation and glycosphingolipid profile of hiMG were measured using a mass spectrometry (MS)-based glycomic and glycosphingolipidomic approach. The changes in glycosyltransferase gene expression were measured using RNA-seq.
Results: AβO and LPS induced highly distinct glycosylation changes. AβO induced a decrease in bisecting GlcNAc N-glycans, aligning with downregulation of the MGAT3 (N-acetylglucosaminyltransferase 3) gene, and an increase in sialylation, with congruent upregulation of ST3GAL (α2,3-sialyltransferase 2, 4, and 6) genes. These changes were not induced by LPS; instead, LPS induced a decrease in complex N-glycans, aligning with the downregulation of mannosidase genes (MAN1A1, MAN2A2, MAN1C1), and an increase in terminal fucosylation, accompanied by upregulation of the fucosyltransferase 4 (FUT4) gene and downregulation of the α-L-fucosidase 1 (FUCA1) gene. However, glycosphingolipids did not reveal significant changes induced by AβO or LPS.
Conclusions: Distinct glycosylation pathways induced by AβO may contribute to microglial impairments in the early stages of AD. Further investigations of players within these pathways may uncover therapeutic targets for AD.

XBD173 ALTERS MICROGLIAL SYNAPTIC ENGULFMENT VIA 18 KDA TRANSLOCATOR PROTEIN (TSPO)

POSTERS: A01.I. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Zhishen Zhang[1,2], Mochen Cui[1,2,3], Juan Zu[1,2,3], Yuan Shi[1,2,4], Jochen Herms[1,2,4]
[1]Center for Neuropathology, Ludwig-maximilians-universität München, münchen, Germany, [2]German Center for Neurodegenerative Diseases, (dzne), München, Germany, [3]München Medical Research School, Ludwig-maximilians-universität München, Munich, Germany, [4]Ludwig-Maximilians-Universität München, Munich Cluster For Systems Neurology (synergy), Munich, Germany

Aims: 18 kDa translocator protein (TSPO) is an ancestral protein with multifaceted functions in the central nervous system (CNS). Previous studies have demonstrated distinct effects of selected TSPO ligands on cognition but with elusive mechanisms. In the CNS, microglia substantially impact cognition by constantly regulating synapses. Recently, we observed that modulating TSPO altered microglial morphology and their phagocytic activity towards synaptic materials. Here, we aim to investigate further the TSPO-mediated microglia-synapse interactions and microglial synaptic engulfment using a widely applied TSPO ligand.
Methods: We chose XBD173, a selected TSPO ligand of the phenylpurine class. We employed long-term *in vivo* 2-photon microscopy to monitor the interactions between eGFP-labelled microglia and eYFP-labelled dendritic spines in transgenic mice. We also employed multiplex immunostaining, coupled with super-resolution confocal microscopy and post hoc 3D reconstruction to evaluate the microglial phagocytic activity of synaptic materials and their TSPO expression in XBD173/vehicle-fed wild-type (WT) mice.
Results: After 21 days of XBD173/vehicle administration, we observed significant morphological alterations of cortical microglia in XBD173-fed WT mice with lowered TSPO expression. Furthermore, we observed that the microglia of XBD173-fed mice contained reduced lysosomes (CD68) containing less synaptic materials (PSD95). In addition, in XBD173-fed mice, we observed an altered pattern of microglia-synapse interactions compared to the vehicle-fed ones. Both effects were suppressed upon genetic depletion of TSPO, supporting the dependency of these microglial alterations on TSPO.
Conclusions: We report microglial engulfment of synaptic materials can be modulated by XBD173 via TSPO in mice. Our findings fill the gap by yielding evidence on how XBD173 affects microglial functionality and synaptic plasticity in the CNS.

Aims: To evaluate the association between longitudinal changes in plasma GFAP levels and AD pathophysiology and test its utility to monitor drug effects on AD clinical trials.
Methods: We assessed 107 individuals across the AD spectrum[Cognitively unimpaired(CU) n=71, mean age (SD) = 71.5(6.48); CU Aβ+,n=26, mean age (SD) =73.3(5.29); CI Aβ+,n=28, mean age (SD) =70.44(7.01)] from TRIAD cohort. All individuals had Aβ PET measurements at baseline.Sample size estimation was for a hypothesized 25% drug effect on plasma GFAP reduction. Linear regressions were used to test associations between plasma GFAP with cognition (MMSE),and plasma p-tau217, adjusted for age, sex, and education.
Results: We found a significant increase in the percentage of change of plasma GFAP in all groups, with the highest annual rate of progression in CU Aβ+ individuals(Fig.1A).The effect size was relatively similar across all groups, with CU Aβ+ individuals presenting the highest numerical value (0.48) (Fig.1B).When including only CU Aβ+ individuals, the sample size required for a trial would be 1067 individuals per arm(a reduction of 12% when compared to the entire CU population)(Fig 1C).A significant correlation was found between the rate of change of plasma GFAP and baseline plasma GFAP in the CU population(Fig 2A).In CI Aβ+,rate of change of plasma GFAP negatively correlated with rate of change of MMSE(Fig 2B) and positively correlated with baseline and longitudinal plasma p-tau217(Fig 2C & 2D).

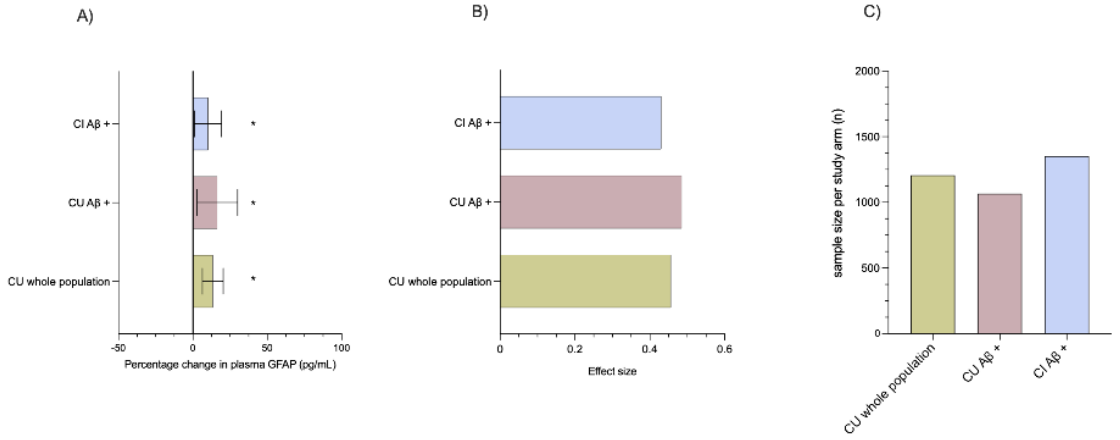

***Figure1*. Percentage of change and effect size of plasma GFAP levels in individuals across the AD continuum; sample sizes required for AD clinical trials powered to use changes in plasma GFAP as a surrogate.** A) Horizontal bars show the mean percentage change with a 95% confidence interval in individuals stratified by amyloid-β status and clinical diagnosis. [CU (mean =13.4% , SD= 29.38), CU Aβ + (mean=16.39%, SD=33.78), and CI Aβ + (mean=10.16%, SD= 23.58)], * indicates that the 95% confidence interval did not cross the zero line. B) The bars represent the effect sizes, calculated as the ratio between the mean and SD of the percentage of change over time points. [CU=0.45, CU Aβ += 0.48, CI Aβ + =0.43]. C) Vertical bars show sample size per arm required for hypothesized clinical trials in [CU (n=1206), CU Aβ + (n=1067), CI Aβ + (n=1353)].

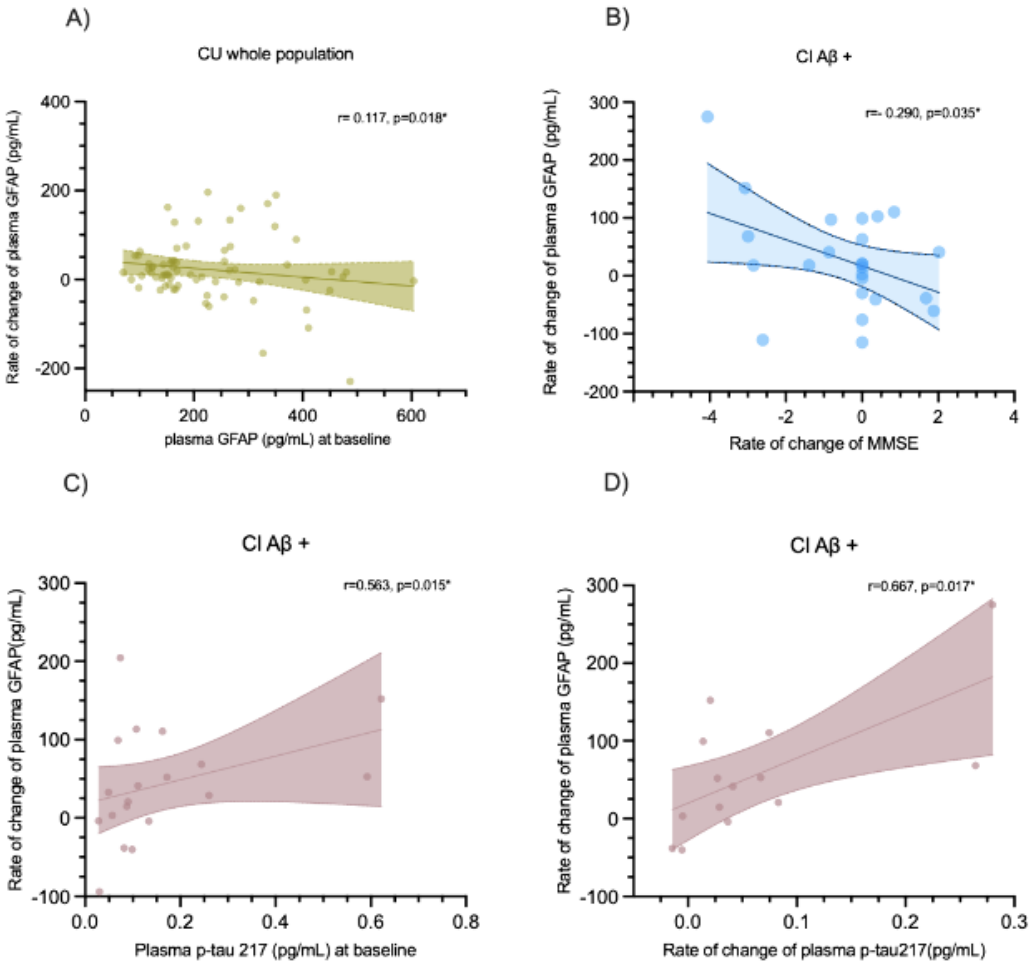

Figure2. **Association among rate of change of plasma GFAP in CU whole population, and MMSE and plasma p-tau217 in CI Aβ+ individuals.** Linear regressions showing the associations between the rate of change of plasma GFAP levels and A) Baseline plasma GFAP in CU whole population, B) Rate of change of MMSE in CI Aβ+ individuals, (C and D) Baseline and rate of change of plasma p-tau217 in CI Aβ + individuals.

Conclusions: Changes in GFAP in CU depended on baseline CU levels whereas changes in GFAP in CI Aβ+ associated with parallel cognitive decline and tau phosphorylation.Our findings suggest Plasma GFAP is a robust biomarker for tracking AD progression and may potentially be used as a secondary endpoint in AD clinical trials with CU Aβ+ individuals requiring a relatively smaller sample size.

[1]University Hospital, LMU Munich, Institute For Stroke And Dementia Research, Munich, Germany, [2]LMU Munich, Graduate School For Systemic Neurosciences, Planegg-Martinsried, Germany, [3]Ludwig-Maximilians-Universität München & Deutsches Zentrum für Neurodegenerative Erkrankungen (DZNE), Biochemistry, Munich, Germany, [4]Munich Cluster for Systems Neurology, Synergy, Munich, Germany

Aims: Astrocytes, microglia and oligodendrocytes are critical players in the maintenance of nervous system homeostasis and response to injury. Dysfunction of these cell types and their crosstalk can therefore enhance neuroinflammation and is thought to play an important role in neurodegenerative diseases such as Alzheimer's Disease (AD). However, the components and mechanisms that mediate neuron-glia and glia-glia crosstalk and how this becomes dysfunctional in AD is poorly understood. A major challenge of studying glial crosstalk in AD in a human context comes from the current lack of experimental human models recapitulating late-stage AD phenotype and containing major glial cell types in a physiological 3D environment.
Methods: We generated a reproducible and modular human induced pluripotent stem cell (hiPSC-) based 3D tissue model containing neurons, astrocytes, microglia and oligodendrocytes to study the interactions between the different cell types in physiological and disease contexts. Using CRISPR/Cas9, we introduced AD-causing mutations as well as alterations in AD risk factors such as ApoE and Clusterin to promote AD phenotypes. Our modular co-culture approach allows us to assess the effect of cell-type-specific genotypes in an AD environment, providing a unique asset to investigate glial crosstalk.
Results: We are incorporating astrocytes and microglia with ApoE-, Clusterin- or double-knockout genotypes to our 3D-AD model and evaluate the role of these AD-related proteins in Aβ accumulation, p-Tau and disease progression. By incorporating oligodendrocytes, we achieved myelination which allow us to study alterations in myelin production and maintenance as well as oligodendrocyte effect in an AD context.
Conclusions: Our cultures enable new research opportunities not only in the AD field to study the effect of different mutations on a specific cell type, but also in the future to investigate other diseases.

3.5D QUANTITATIVE IFISH FOR INVESTIGATING THE SPATIAL DISTRIBUTION OF ASTROCYTIC MRNA AND PROTEIN IN ALZHEIMER'S DISEASE

POSTERS: A01.J. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ASTROGLIA

Mochen Cui[1,2,3], Juan Zu[1,2,3], Qiang Huang[1,2], Yuan Shi[1,2,4], Jochen Herms[1,2,4]
[1]Ludwig-Maximilians-Universität München, Center For Neuropathology, Munich, Germany, [2]German Center for Neurodegenerative Diseases (DZNE), Department Of Translational Brain Research, Munich, Germany, [3]Ludwig-Maximilians-Universität München, Munich Medical Research School, Munich, Germany, [4]Ludwig-Maximilians-Universität München, Munich Cluster For Systems Neurology (synergy), Munich, Germany

Aims: Considerable efforts have been dedicated to elucidating the involvement of astrocytes in Alzheimer's disease (AD). While conventional techniques such as *in situ* hybridization and immunostaining have enabled the examination of astrocytic mRNA and proteins, they prove insufficient in capturing the subcellular heterogeneity of these components within astrocytes due to their intricate morphology and the occurrence of local translation in distant processes. Consequently, we aim to devise a method that permits simultaneous investigation of astrocytic mRNA and proteins at subcellular precision in AD.
Methods: We introduce a methodology referred to as "3.5D iFISH," a fusion of multiplex immunofluorescent staining (i) and modified mRNA *in situ* hybridization (FISH). It facilitates the simultaneous detection of protein and mRNA targets within astrocytes, making use of commercially available probes on free-floating murine brain sections. Additionally, our methodology is optimized for subsequent super-resolution confocal scanning and analysis via Imaris, enabling spatial examination of specific protein and mRNA within 3D reconstructed astrocytes (3.5D).
Results: We employed the *APPPS1dE9* mice and selected mRNAs encoding diazepam binding inhibitor (DBI), an astrocytic protein elevated in AD, as a proof of concept. We visualized the DBI protein, mRNA, and the intricate astrocytic architecture. Notably, we observed a significant upregulation of DBI protein and mRNA in processes of plaque-surrounding astrocytes. While in astrocytes distant from plaques, DBI protein and mRNA exhibit majorly somatic expression.
Conclusions: The 3.5D iFISH method offers a practical way to simultaneously characterize the expression of protein and mRNA in astrocytes in the AD context. It also facilitates the subsequent quantification of their subcellular distribution. Importantly, our approach is adaptable for various targets and can be extended to other cell types, e.g., microglia.

ASTROCYTIC INSULIN RECEPTOR ABLATION PRECIPITATES ALZHEIMER'S DISEASE ONSET

POSTERS: A01.J. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ASTROGLIA

Amaia Ezkurdia[1,2], María Javier Ramírez[1,2], Maite Solas[1,2]
[1]IdISNA, Navarra Institute For Health Research, Pamplona, Spain, [2]University of Navarra, Pharmacology And Toxicology, Pamplona, Spain

Aims: Insulin is an important regulator of glucose homeostasis and metabolism. However, its role in the central nervous system is not yet fully understood. The role of insulin and its receptor (i.e. the insulin receptor, IR) in neurons has been widely studied. However, the role of insulin action in astrocytes remains unknown. Astrocytes provide structural, energetic and metabolic support to neurons, and also form the blood-brain barrier, being indispensable for adequate brain homeostasis. Interruption of astrocytic insulin signalling could change those astrocytic functions and thus, alter neuronal activity leading to cognitive deficiencies. In this line, this study aims to evaluate the impact of astrocytic IR deletion on Alzheimer's disease (AD).
Methods: In vitro, cellular metabolism was examined using an extracellular flux analyzer (Seahorse). In vivo, astrocyte-specific gene ablation was performed using tamoxifen-inducible Cre/LoxP approaches. Once IR deletion is obtained those mice were crossed with APP/PS1 AD mouse model. Brain glucose metabolism was evaluated by 18F-FDG PET. Peripheral metabolic characterization was performed by glucose tolerance and insulin tolerance tests. Memory was assessed using the Fear conditioning and Morris Water Maze tasks. Beta-amyloid accumulation was assessed by immunohistochemistry and ELISA.
Results: IR-ablated astrocytes featured reduced glucose uptake and glycolysis, upon amyloid-beta treatment. In our hands astrocytic IR deletion precipitates AD pathology in APP/PS1 mice inducing cognitive deficiencies. This cognitive perturbances are accompanied by lower brain glucose uptake. Interestingly, IR deletion in astrocytes induced an increase in amyloid-beta burden in AD mice.
Conclusions: Astrocytic IR ablation drives brain and systemic metabolism towards a less efficient glucose-handling phenotype and accelerates AD features inducing cognitive deficiencies and elevated amyloid burden.

SPATIAL TRANSCRIPTOMICS ANALYSIS IDENTIFIES GLIAL STATES ASSOCIATED WITH HUMAN AMYLOID PLAQUE MICROENVIRONMENT

POSTERS: A01.J. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ASTROGLIA

Berke Karaahmet, Laurine Duquesne, Ya Zhang, Alina Sigalov, Christina Yung, Alexandra Kroshilina, Mariko Taga, Hans-Ulrich Klein
Columbia University Irving Medical Center, Neurology, New York, United States of America

Aims: Advances in transcriptomics have led to the identification of many molecular regulators involved in Alzheimer's disease (AD) pathology. While sophisticated single-cell based methods have revealed heterogeneous glial states in the AD brain, the histological localization of these signatures in relation to AD pathology has not been fully characterized due to the loss of spatial information. In this study, we aim to elucidate the glial states identified within the vicinity of amyloid-beta (Aβ) plaques.
Methods: For spatial transcriptomics, we optimized 10X Genomics' Visium pipeline (55-um spots) for immunohistochemistry on fresh frozen dorsolateral prefrontal cortex tissue of 17 donors acquired from Religious Orders Study/Memory and Aging Project (ROSMAP). We performed immunostaining for astrocytes using anti-GFAP and Aβ using Thioflavin S (ThioS) prior to following manufacturer's instructions for library preparation. We deconvolved our spatial dataset to identify localization of cellular states using Cell2location. To construct single nucleus reference transcription profiles containing cell state annotation, we used an unpublished dataset that consists of over 450 samples from ROSMAP. We then performed correlation analyses on the distance from plaque and deconvolution estimates within the 350-um radius around ThioS$^+$ plaques.
Results: We found a cluster of *SERPINA3* expressing astrocytes to be correlated with ThioS$^+$ plaque. This astrocyte state resembles previously discovered Disease-Associated Astrocytes in mouse models of AD. In contrast, we found several microglial states, thought to be involved in redox homeostasis, that were significantly underrepresented at the plaque niche.
Conclusions: Here, we demonstrate the heterogeneity in glial communities within the AB microenvironment. We show evidence that Serpina3$^+$ astrocytes seem to be more strongly associated with plaques, whereas several microglial clusters are found away from plaques. The role of these glial states in pathophysiology remains to be elucidated.

DETERMINING A TIME COURSE OF GLIAL CHANGES ASSOCIATED WITH CEREBRAL AMYLOID ANGIOPATHY

POSTERS: A01.J. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ASTROGLIA

Katelynn Krick[1], Sherika Johnson[1], Colin Rogers[2], Tiffany Sudduth[2], Erica Weekman[1], Donna Wilcock[1]
[1]Indiana University School of Medicine, Stark Neurosciences Research Institute, INDIANAPOLIS, United States of America, [2]University of Kentucky, Sanders Brown Center On Aging, Lexington, United States of America

Aims: Cerebral Amyloid Angiopathy (CAA) is a condition found at the intersection of Alzheimer's disease and vascular contributions to cognitive impairment and dementia (VCID). In the human brain it is observed when amyloid beta (Ab) accumulates in small/medium-sized cerebral blood vessels, altering vascular function and contributing to hypoperfusion and cognitive decline. The current study seeks to track the progression of CAA and associated neuroinflammation and glial cell changes in Tg2576 mice.
Methods: Mice were aged to 8-, 14-, 20-, and 27-months and assessed for CAA pathology via histology. Gene expression was evaluated in hippocampal tissue by qPCR, comparing 8- and 20-month APP and wildtype groups. Protein expression was evaluated via digital spatial profiling in the same APP mice, grouped by age or CAA presence compared to wildtype controls. CAA presence was defined as Ab surrounding lectin-positive vessels. Regions of interest were categorized as either positive or negative for CAA based on this criterion.
Results: Congophillic plaque deposition along the vasculature increased in width, length, and area in a time dependent manner in both the frontal cortex and hippocampus. Astrocyte marker GFAP and proinflammatory receptor TNFR1 gene expression both increased at 20 months compared to 8 months in the APP group. Of the protein profile assessed (Mouse Neural Cell Profiling and Mouse Glial Cell Subtyping), the most consistent changes were found in astrocyte markers. Both Aldh1l1 and S100B were increased at 20 months compared to 8 months of age in both APP and WT mice. GFAP protein expression was found to increase with both age and CAA.
Conclusions: This study showed increased vascular amyloid deposition and astrocyte gene and protein expression over time, further supporting a role for astrocytes in etiology and/or reaction to CAA.

PTDP-43 INCLUSIONS IN ASTROCYTIC ENDFEET: A POTENTIAL MECHANISM FOR BBB AND GLYMPHATIC SYSTEM DYSFUNCTION IN ALZHEIMER'S DISEASE

POSTERS: A01.J. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ASTROGLIA

Jessica Santiago[1], Dovile Poceviciute[2], Shorena Janelidze[3], Oskar Hansson[4], Malin Wennström[5]
[1]Lund University, Clinical Sciences, Malmö, Sweden, [2]Lund University, Department Of Clinical Sciences, Malmö, Malmö, Sweden, [3]Lund University, Department Of Clinical Sciences, Lund, Sweden, [4]Skåne University Hospital, Clinical Sciences, Malmo, Sweden, [5]Lund University, Department Of Clinical Sciences, Malmö, Sweden

Aims: Since functional astrocytic endfeet are crucial for the maintenance of the blood-brain barrier (BBB) and the glymphatic system and play an important role in Amyloid beta (Aβ) clearance, we hypothesize that the accumulation of toxic phosphorylated TDP-43 (pTDP43) can accelerate Alzheimer's Disease (AD) pathology by damaging these astrocytic structures. The main objectives of this study were to investigate the presence of pTDP-43 inside astrocytic endfeet, and its potential association with signs of BBB and glymphatic system dysfunction, as well as its connection to Alzheimer's Disease, specifically regarding the accumulation of Aβ in AD brains.
Methods: Using immunostaining against pTDP-43 and markers for astrocytes (GFAP), astrocytic endfeet (AQP4), and BBB leakage (CD146), we investigated the presence of astrocytic pTDP-43 in hippocampi of AD cases and non-demented-controls, as well as in cultured astrocytes exposed to Aβ40. Localization was determined by confocal microscopy and the stained area fraction was analyzed using Image J.
Results: We found pTDP-43 inclusions within astrocytic endfeet. These perivascular inclusions were more prominent in AD than in controls and correlated with the disease severity and loss of CD146 and AQP4. Exposure to Aβ40 led to the translocation of astrocytic pTDP-43 from the nuclei to the cytoplasm, a known sign of TDP-43 pathology.
Conclusions: The findings support our hypothesis that pTDP-43 in astrocytic endfeet contributes to AD pathology by impairing brain clearance mechanisms and highlight pTDP-43 potential as a therapeutic target in AD.

Aims: Investigate the association of plasma glial fibrillary acidic protein (GFAP) with white matter hyperintensity (WMH) in the Alzheimer's disease (AD) continuum.
Methods: We assessed 941 individuals from a research (TRIAD, n = 150) and a clinical cohort (BICWALZ, n = 791). Linear regressions accounting for age and sex were used to estimate the associations. In the BICWALZ cohort, levels of plasma GFAP were compared between individuals across the Fazekas scale (a clinical scale used to quantify the amount of white matter hyperintense lesions). Between-group differences were verified using ANCOVA followed by the Tukey Test.
Results: In TRIAD, an increase in GFAP levels was associated with WMH levels. When we stratified these individuals by diagnosis and corrected the model for Aβ burden, we observed that this association is independent of Aβ (β =0.000008299, Z score= 0.22062, p=0.00382; **Fig.1A**). GFAP levels present significant interaction within the Fazekas stage (F1, F2, F3) in the BICWALZ cohort. GFAP levels are higher in individuals in F2 and F3 compared to F1 (**Fig.1B**). Among these individuals, females present higher levels of GFAP in F1 [mean (F=174.31|M=139.04); p< 0.0001] and F2 (p< 0.0001; **Fig.1C**). No sex differences in the association between GFAP and WMH were observed in the TRIAD cohort.

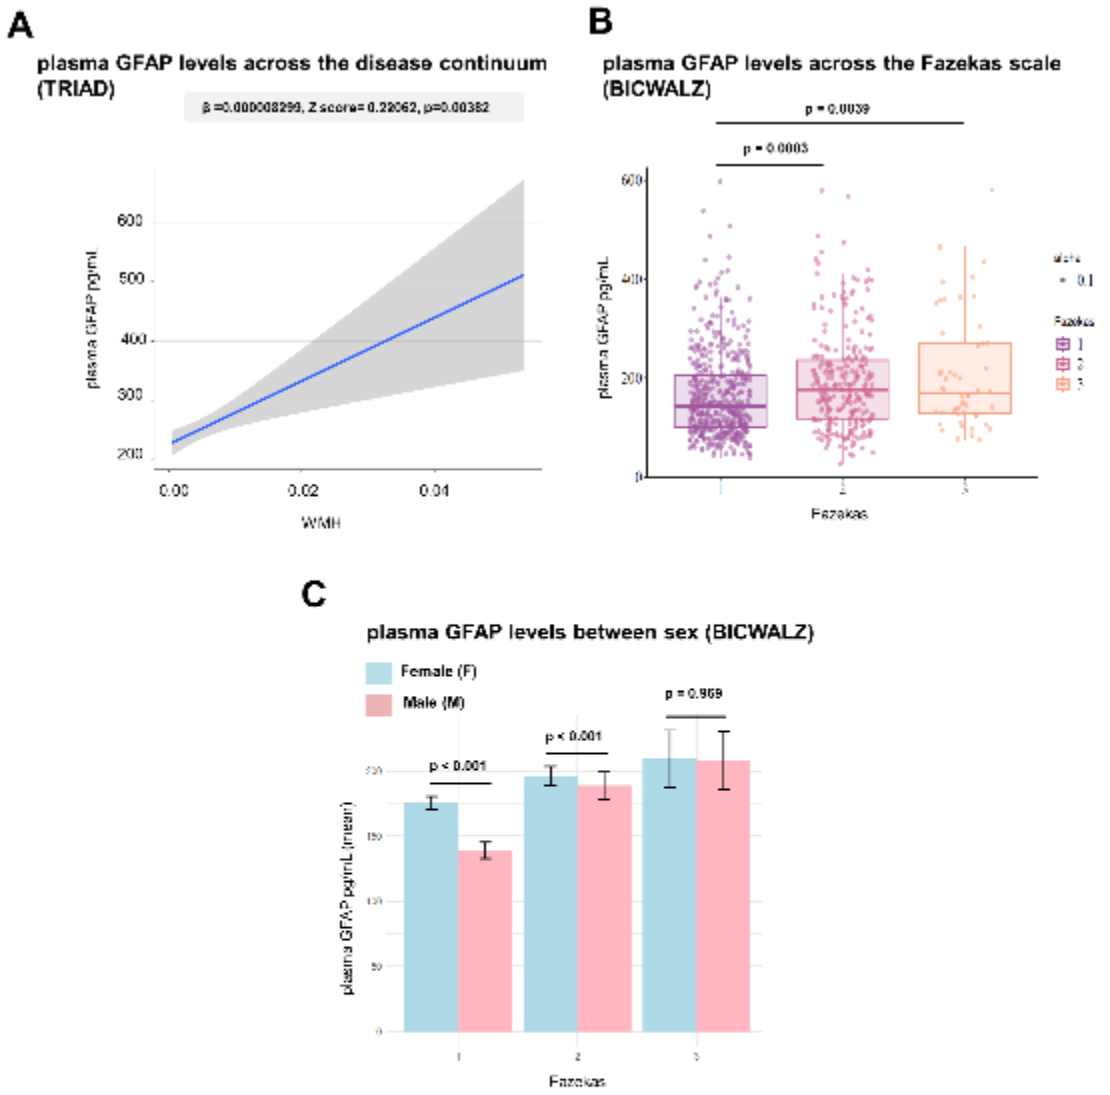

Figure 1. Plasma GFAP levels are associated with WMH in the disease continuum. (A) Linear regression shows the association between plasma GFAP levels as independent of Aβ burden. (B) Plasma GFAP levels increase within the Fazekas scale, and (C) females show greater plasma GFAP levels than males in F1 and F2 stages.

Conclusions: These findings highlight that GFAP levels are linked to cerebrovascular disease stages independent of AD pathology. The studies testing the association between GFAP levels and AD pathophysiology should consider the burden of cerebrovascular disease.

CHEMOGENICALLY ACTIVATED ASTROCYTES IN THE HIPPOCAMPUS REVEAL ASTROCYTE DYSFUNCTION IN ALZHEIMER'S DISEASE.

POSTERS: A01.J. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ASTROGLIA

Benjamin Tournier[1], Kelly Ceyzériat[1], Aurélien Badina[1], Yesica Gloria[1], Aida Fall[1], Quentin Amossé[2], Stergios Tsartsalis[2], Philippe Millet[2]
[1]University of Geneva, Psychiatry, Geneva, Switzerland, [2]University Hospitals of Geneva, Psychiatry, Geneva, Switzerland

Aims: The major goal of this study is to determine whether astrocytic control of hippocampal cellular functions is modified in Alzheimer's disease. *In vivo* measurements of connectivity between the hippocampus and the striatum, behavioral and *postmortem* measurements of neuroinflammation and pathological markers were performed after acute or chronic stimulation of astrocytes to reveal pathological alterations in astrocytic function.
Methods: We injected astrocyte-specific designer receptors exclusively activated by designer drugs (DREADD) delivered by adeno-associated virus (AAV) vectors or AAV controls in the hippocampus of 6 month-old WT or TgF344-AD rats. Simultaneous SPECT imaging for striatal dopamine release, brain activity and locomotor recordings were then performed after acute (3mg/kg, single i.p. injection) or chronic treatment (0.015mg/ml in drinking water, 3weeks) with clozapine N-oxide to activate astrocytes. After euthanasia, dopamine receptor D2 (D2R) and different aggregated forms of beta-amyloid (Aβ) were measured by ELISA. Double immunofluorescence made it possible to measure the activation of glial cells.
Results: In WT animals, acute and chronic activation of hippocampal astrocytes induce alteration of brain activity in dopaminergic areas and dopamine release in the striatum. This release results in a greater locomotor activity after acute but not chronic activation, which could originate from the downregulation of the D2R in the striatum that we observed. All these effects (dopamine release, brain activity and locomotor stimulation) are absent in TgF344-AD animals following astrocytes stimulation. However, chronic astrocyte stimulation induced a decreased in the highly aggregated forms of Aβ-40 and Aβ-42, which may be explained by the greater microglial phagocytic activity towards Aβ that we observed.
Conclusions: This study clearly shows an early astrocytic control deficit of hippocampal cellular functions and of Aβ accumulation in Alzheimer's disease. [supported by the SNSF grant: 310030_212322]

AMYLOID-BETA-DEPENDENT ASTROCYTE MICRODOMAIN HYPERACTIVATION IS MEDIATED BY GLUTAMATE ACCUMULATION

POSTERS: A01.J. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ASTROGLIA

Felix Unger[1,2], Benedikt Zott[1,2]
[1]Technical University of Munich, Institute Of Neuroscience, Munich, Germany, [2]Technical University of Munich, Department Of Neuroradiology, Munich, Germany

Aims: Accumulating evidence from mouse models of Alzheimer's Disease (AD) reports aberrant astrocytic calcium signaling at early disease stages. However, the mechanisms are still unclear. In neurons, the main driver of neuronal hyperactivity is an amyloid β (Aβ)-dependent disruption of the reuptake of synaptically released glutamate. Because Aβ blocks glutamate reuptake transporters mainly on astrocytic membranes and astrocytes possess functional glutamate receptors mediating intracellular calcium transients, we ask whether glutamate accumulation may cause Aβ-dependent astrocytic hyperactivity.
Methods: In our study, we combine two-photon calcium and glutamate imaging in astrocytes and neurons to decipher the mechanisms of the increased synaptically evoked calcium signals in vivo and in acute brain slices in the hippocampus. We model early AD by the acute application of synthetic and human brain-derived soluble Aβ oligomers and investigate their mechanisms of action using pharmacology.
Results: We found that the acute application of Aβ dimers increases the number and amplitude of calcium signals in astrocytes in the hippocampal CA1 region of wildtype mice in vivo via a metabotropic glutamate receptor (mGluR)-dependent mechanism. Second, in acute hippocampal slices, we established that synaptically released glutamate binds to astrocytic mGluRs and induces calcium signals in the microdomains of astrocytes. The application of oligomers leads to increased levels of glutamate at astrocytic membranes and potentiation of microdomain calcium signals. These effects can be mimicked by applying the glutamate reuptake blocker DHK and depend on mGluR activation.
Conclusions: Together, our data demonstrate that Aβ-dependent glutamate accumulation is a critical mechanism of astrocytic hyperactivity. This provides a mechanistic link between astrocytic and neuronal hyperactivity in early AD.

CHARACTERIZATION OF ASTROCYTIC EXTRACELLULAR VESICLES IN A MODEL OF ALZHEIMER'S DISEASE

POSTERS: A01.J. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ASTROGLIA

Liesbeth Voorbraeck[1], Romain Giraud[1], Maria Ankarcrona[1], Luana Naia[2]
[1]Karolinska Institutet, Neurobiology, Care Sciences And Society, Stockholm, Sweden, [2]Karolinska Institutet, Neurobiology Care Science And Society, Stockholm, Sweden

Aims: Mitochondrial dysfunction is an early feature in Alzheimer's disease (AD) as both amyloid beta peptide and hyperphosphorylated tau interfere with proper mitochondrial function and clearance of damaged mitochondria, which is especially detrimental at the level of the synapses, as it may impede neuronal transmission and contribute to neurodegeneration. We hypothesize that mitochondrial transfer is triggered by stress conditions and propose a feedback-loop in which healthy mitochondria are transferred from astrocytes to neurons, while neurons can transfer their damaged mitochondria to surrounding astrocytes to aid in mitophagy through extracellular vesicles (EVs). Furthermore, we believe this process is affected in AD, therefore, we set out to characterize astrocytic EVs in a disease relevant context.
Methods: EVs were isolated from conditioned media of primary cortico-hippocampal astrocytes derived from *App*$^{NL-G-F}$ and wildtype (WT) mice with a C57BL/6-J background through tangential flow filtration (TFF) followed by size-exclusion chromatography (SEC). After separation, the different fractions were kept separately for characterization, using nanoparticle tracking analysis (NTA), immunoblotting and proteomic analysis.
Results: We found that astrocytic EVs have an average size of 165 nm, which was constant across all fractions. The number of EVs produced per million astrocytes ranges between 10^9 and 10^{10} and no significant difference in EV number or size was found between WT and *App*$^{NL-G-F}$ cultures. Immunoblot and proteomics confirmed the presence of classic EV markers, including ALIX and Flotilin-1, as well as a variety of mitochondrial markers including proteins found in the mitochondrial matrix (PDH), mitochondrial membrane (VDAC1 and TOM20), and proteins involved in fission and fusion processes (OPA1).
Conclusions: Through characterization of astrocytic EVs, we hope to gain a better understanding of the transfer mechanism of mitochondria and its implications in neuronal health and future therapeutic applications.

ASTROCYTIC HEMOGLOBIN IS A H2O2-DECOMPOSING PEROXIDASE AND THERAPEUTIC TARGET FOR ALZHEIMER'S DISEASE

POSTERS: A01.J. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ASTROGLIA

Woojin Won[1], Elijah Lee[2], Ki Duk Park[3,4], C. Justin Lee[1]
[1]Institute for Basic Science (IBS), Center For Cognition And Sociality, Daejeon, Korea, Republic of, [2]Korea Institute of Science and Technology (KIST), 2center For Brain Disorders, Brain Science Institute, Seoul, Korea, Republic of, [3]Korea Institute of Science and Technology, Center For Brain Disorders, Seoul, Korea, Republic of, [4]University of Science and Technology, Daejeon,, Division Of Bio-medical Science & Technology, Daejeon, Korea, Republic of

Aims: Urgent need for innovative treatments for Alzheimer's disease (AD). Astrocytic hydrogen peroxide produced by reactive astrocytes is highlighted as a cause of AD pathogenesis. However, effective antioxidant drugs either lack or require high doses for a significant effect. Our goal is to evaluate "KDS12025," a catalyst targeting astrocytic H2O2, to enhance memory and astrocyte function in Alzheimer's disease.
Methods: In vitro H2O2 Assay, Chemical Libraries Synthesis, Binding Affinity and Computational Modeling, Off-Target Selectivity Assay, PAMPA for BBB Permeability, Cultured Primary Astrocyte Preparation, Intracellular H2O2 Detection, Cell Viability, and Electrophysiology Methods, with a focus on Hbb shRNA Vector and RT-PCR for Gene Silencing.
Results: we have developed and tested a recently synthesized potent, blood-brain barrier permeable H_2O_2-decomposing catalyst, KDS12025 (IC50 = 60 nM; 1,666-fold selectivity over sodium pyruvate) in cultured astrocytes and animal models of AD. Unlike conventional H_2O_2 scavengers, we found that KDS12025 acts as a catalyst for peroxidase enzymes, such as brain hemoglobin (Hb), which have a potent function of decomposing H_2O_2 into harmless water. Computational modeling and binding assay elucidate the mechanistic interaction of KDS12025 with Hb, highlighting its pivotal role. KDS12025 effectively aided in the decomposition of excessive H_2O_2 in amyloid beta 42-incubated cultured astrocytes. Moreover, devastating memory impairment in AD model was rescued by KDS12025. Interestingly, regardless of whether administered through intraperitoneal injection or ad libitum consumption, a consistent positive effect was observed. Finally, Hbβ-small hairpin RNA experiments *in vitro* and *in vivo* validated the requirement Hbβ in the action of KDS12025.
Conclusions: KDS12025 is a novel, blood-brain barrier permeable catalyst that promotes the decomposition of neurotoxic hydrogen peroxide in Alzheimer's disease by enhancing the peroxidase activity of brain hemoglobin, showing significant therapeutic potential in both cellular and animal models.

Aims: Alzheimer's disease (AD) is the most common and severe age-associated neurodegenerative dementia. While aging is the most significant risk factor for AD, disruption of synapses by oligomers of both amyloid beta (Aβ) and tau, via converging synergistic mechanisms, is one of the earliest events leading to memory dysfunctions. We previously found that exosomes secreted by hippocampal neural stem cells (NSCexo) act via specific miRNAs to provide synaptic protection against amyloid oligomers. Here we aimed to investigate how NSCexo, in comparison to mature neurons-derived exosomes (MNexo), modulate microglia in the hippocampus by performing immunofluorescence and transcriptomic analyses.
Methods: Male and female adult wild-type mice were injected ICV with PKH-26-labelled NSCexo or MNexo and the mice were euthanized 24h later. For the analysis of microglia activation, the brains were post-fixed in 4% PF and processed for immunofluorescence analysis using specific antibodies against Iba1 and CD68 (a marker of activation). For transcriptomic analysis, the hippocampus was dissected, snap frozen and processed for single nuclei RNA sequencing (snRNA seq) and for bulk RNA sequencing (RNA seq) on total homogenates and synaptosome fractions.
Results: Both NSCexo and MN-exo were taken up by microglia in the hippocampus. However, only NSCexo treatment led to elevated levels of microglial activation, as evidenced by increased CD68 immunostaining. RNA-seq and snRNA seq data further showed that immune response pathways were selectively activated by NSCexo in the hippocampus.
Conclusions: Our findings indicate that NSCexo have a significant impact on microglial activation, which could underlie their protective mechanism against AD pathology. These interactions result in specific gene expression changes in the hippocampal microglia, reinforcing the idea that increased levels of hippocampal stem cells could contribute to synaptic resilience against AD.

Aims: Decrease in adult neurogenesis has been described to correlate with Alzheimer's disease (AD) progression, but defects in this process at early stage of AD have not been explored yet. We have previously demonstrated that SVZ neurogenesis is reduced in Tg2576 mice at a presymptomatic stage due to intracellular Amyloid-beta oligomers (AβOs) accumulation in adult neural stem cells (aNSCs). We investigated if AβOs targeting in the dentate gyrus of young Tg2576 can rescue adult hippocampal neurogenesis (AHN) and recover AD-related memory deficits.
Methods: We analyzed the proliferative and differentiative features of resident and hippocampal-derived aNSCs of Tg2576 at a presymptomatic age, in relationship with the amount of Aβ and AβOs, measured by Western blot and Dot blot approaches. Upon intrabody conformational targeting of intracellular AβOs in vivo, based on viral-mediated delivery of the anti-AßOs scFvA13-KDEL intrabody, ER retained, we performed behavioural tests to evaluate cognitive improvement linked to AHN rescue.
Results: We observed proliferation and differentiation deficit of AD hippocampal progenitors, which are due to AβOs accumulation, as both defects can be rescued by the expression of scFvA13-KDEL intrabody, that interferes with the intracellular formation of AβOs in hippocampal aNSCs. Lentiviral delivery of scFvA13-KDEL in the dentate gyrus of young Tg2576 mice increased AHN and rescued Fear Conditioning, Pattern Separation and Social Novelty deficits. Moreover, intrabody treatment at symptomatic stage also ameliorated memory dysfunction in older mice.
Conclusions: We demonstrated a causal link between AβOs accumulation and reduced AHN in AD at presymptomatic stage. We also provided an innovative disease modifying gene-therapy approach to neutralize intracellular natural-occurring AβOs in the dentate gyrus, able to rescue hippocampal-dependent memory deficits, exploitable as an early therapeutic intervention to counteract disease onset and progression (funded by NGEU-MUR, PNRR-Mnesys-PE0000006).

Aims: To investigate the moderating effects of fitness on the relationship between arterial [aortic] stiffness and cerebral hemodynamics indexed by blood flow (Q), pulsatility index (PI) and resistive index (RI).
Methods: Cognitively unimpaired adults (n=77; Mean age=63.7) from the Wisconsin Registry for Alzheimer's Prevention and the Wisconsin Alzheimer's Disease Research Center participated in this study. Fitness was measured via VO_{2MAX} and participants were subsequently classified into fitness percentiles based on reference standards for age and sex established through normative data. Extremes of high and low fitness groups were defined as falling above or below the 75th or 25th fitness percentile, respectively. Aortic stiffness (aoPWV) and cerebral hemodynamics were measured by 2D phase contrast MRI in the ascending and abdominal aorta and 4D Flow cerebrovascular MRI, respectively. Covariate-adjusted (age, waist-to-hip ratio, and history of hypertension and cardiovascular disease) multivariable regression examined relationships between aoPWV and cerebral hemodynamics (Q, PI, and RI), as a function of fitness, for total blood flow (Q_{Total}) and for the left$_{(L)}$, right$_{(R)}$ and average$_{(avg)}$ internal carotid artery (ICA), middle cerebral artery (MCA) and anterior cerebral artery (ACA). Analyses focused on the extremes of high and low fitness (N=52, Mean age = 64.4).
Results: There were significant interactions between fitness and aoPWV on **cerebral Q** (ICA_R: p=0.028), **PI** (ICA_R: p=0.005; MCA_L: p=0.039; MCA_R: p=0.022; MCA_{AVG}: p=0.010) and **RI** (ICA_R: p=0.04; MCA_R: p=0.013; MCA_{AVG}: p=0.012; ACA_{AVG}: p=0.044), indicating that those with extremely high fitness demonstrated improved hemodynamics compared to the low fitness group even within the context of increasing aoPWV (Figs 1-3).

Figure 1. Blood Flow (Q)

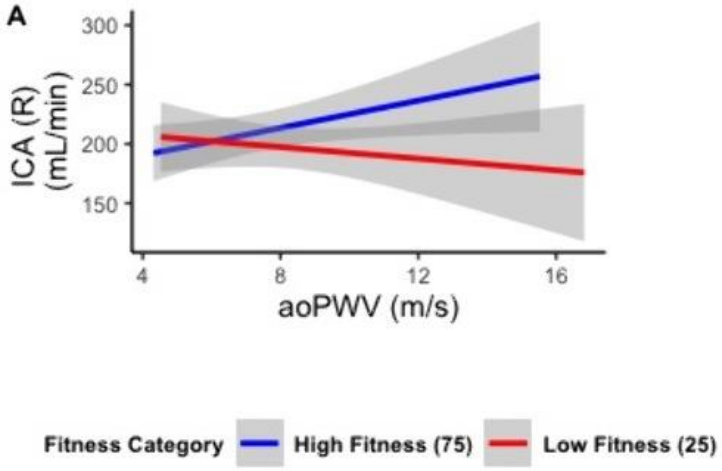

Figure 2. Pulsatility Index (PI)

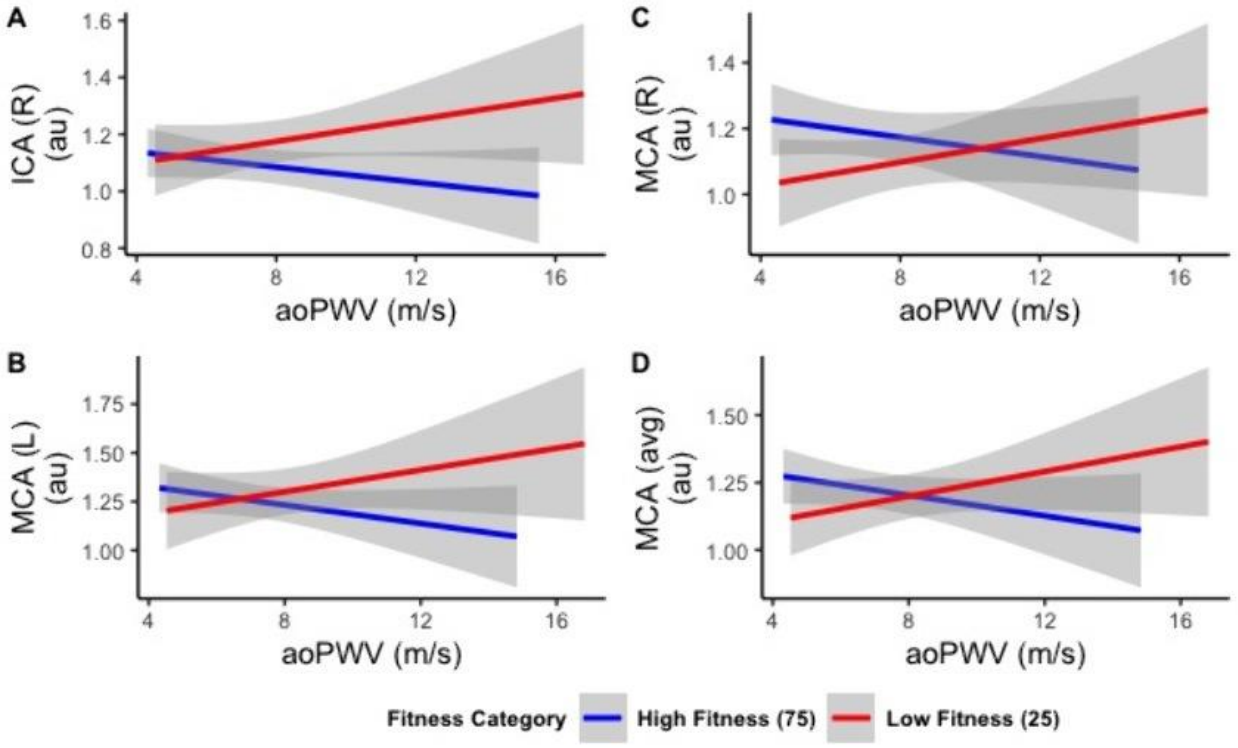

Figure 3. Resistive Index (RI)

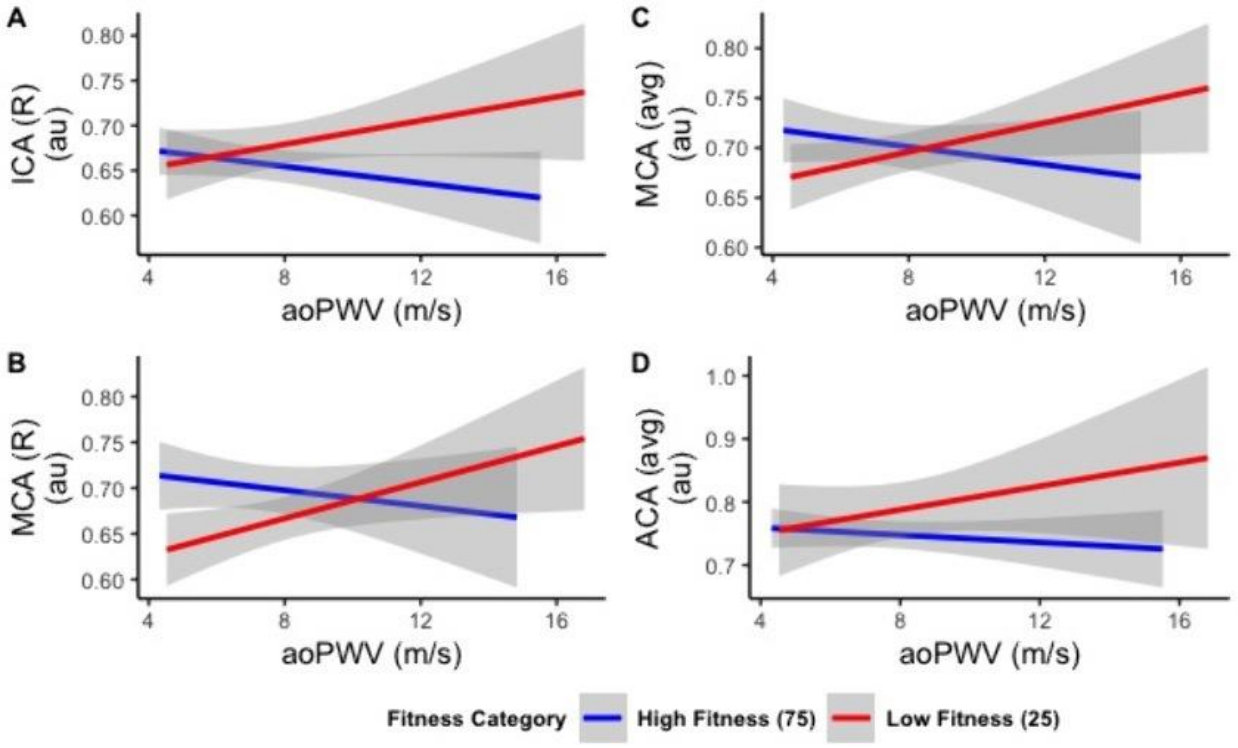

Conclusions: Our results suggest that high fitness (>75th percentile) seems to be protective against the expected negative effects of arterial stiffness on cerebral hemodynamics

University Hospital Düsseldorf, Heinrich-Heine University, Department Of Vascular- And Endovascular Surgery, Duesseldorf, Germany

Aims: Deposits of Aβ in the brain parenchyma and cerebral vessels (known as cerebral amyloid angiopathy, CAA) are the pathological hallmarks of Alzheimer's disease (AD). Recently, we demonstrated that aged AD transgenic mice APP23, which develop amyloid-β deposits in the brain parenchyma and cerebral vessels, have pre-activated platelets in blood and enhanced integrin activation. Moreover, platelets adhere to vascular amyloid-β deposits and cause vessel occlusion in aged APP23 mice. A comprehensive analysis of these AD transgenic mice revealed that activated platelets directly contribute to vascular amyloid plaques by promoting the formation of Aβ aggregates. To investigate whether platelets play a role in influencing Aβ deposition in the brain parenchyma and neuroinflammation, AD transgenic mice APP23 were crossed with $Mpl^{-/-}$ mice to generate thrombocytopenic APP23 mice.
Methods: Histological analysis of AD pathology in 24-month-old male APP23/$Mpl^{-/-}$ mice compared to male age-matched controls
Results: APP23/$Mpl^{-/-}$ mice showed a slight trend towards a lower amyloid plaque burden in the brain parenchyma, but the reduction was not statistically significant. In line with our prior findings, we found significantly reduced CAA formation in APP23/$Mpl^{-/-}$ mice compared to APP23 mice. Moreover, thrombocytopenia had no impact on neuronal loss in the CA1 region. However, by evaluating neuroinflammation, immunofluorescence staining showed a significant reduction of activated microglia and reactive astrocytes in APP23/$Mpl^{-/-}$ mice compared to APP23 mice.
Conclusions: Thrombocytopenia does not have a significant impact on plaque formation in the brain parenchyma in male APP23 mice. However, a low platelet count significantly reduces the formation of CAA.

Aims: Background: Cerebral small vessel disease(CSVD), including cerebral amyloid angiopathy(CAA) and arteriolosclerosis, commonly co-occur with Alzheimer's disease and related dementias(AD/ADRD). The medial temporal lobe(MTL) is prone to harboring multiple pathologies, such as neurofibrillary tangles(NFTs), amyloid-β-plaques, TDP-43[1], and CSVD. Whether a causal relationship between these pathologies exists remains largely unknown, but one possible linking mechanism is the dysfunction of perivascular clearance. We aimed to analyze the burden of CSVD in the MTL of a pathological AD cohort and to determine the relationship between CSVD and enlarged perivascular spaces (EPVS), a marker of clearance dysfunction.
Methods: 156 subjects(79.4±10.9y, 90F), part of the pathological cohort of the Massachusetts Alzheimer's Disease Research Center(MADRC) were included in the study. One hemisphere was formalin-fixed, and samples from predefined regions of the hippocampal body and entorhinal cortex were cut in 5 mm thick sections, which were then stained for luxol fast blue with hematoxylin&eosin(LHE), amyloid-b, hyperphosphorylated tau(At8), and phosphorylated TDP-43, following standard histological protocols(Figure 1). Deep-learning models(Aiforiaâ) enabled the calculation of the burden of CAA, amyloid-β-plaques, NFTs, and pTDP-43 inclusions(Figure 2). Additionally, severity of arteriolosclerosis[2] and EPVS area[3] were assessed on the LHE sections.
Results: In linear mixed effects models CAA predicted the density of neurofibrillary tangles in the entorhinal cortex, and amyloid-β-plaques burden in all regions. The role of arteriolosclerosis remains unclear. CAA and arteriolosclerosis were both predictors of PVS-enlargement.
Conclusions: These results point towards an association between microvascular pathology and AD-related pathology, possibly mediated by clearance dysfunction.

Aims: Sporadic Alzheimer's disease (sAD), familial AD with duplication of the Amyloid Precursor Protein gene (APPdup), and Down Syndrome (DS), the latter two with three copies of *APP*, share common hallmarks including amyloid and tau pathologies. However, the amount of Aβ peptides deposited in the wall of cerebral blood vessels leading to cerebral amyloid angiopathy (CAA) varies with higher CAA in APPdup compared to DS. Our aim was to characterize and understand the role of endothelial cells (ECs) forming the blood brain barrier (BBB) in CAA severity using human iPSC-derived-ECs (hiPSC-EC) from patients with APPdup and DS.
Methods: We analyzed the transcriptome of multiple independent hiPSC-ECs differentiations from APPdup and DS using RNAseq, measured Aβ using Multiplex ELISA and proteins from the tight- and adherent-junctions by immunocytochemistry, and measured the permeability of a monolayer of iPSC-ECs cultivated on Transwells.
Results: hiPSC-ECs with APPdup and DS had bigger size and secreted higher levels of Aβ compared to their isogenic controls. RNAseq analyses revealed dysregulated genes with a subset positively and negatively correlated with CAA in APPdup and DS respectively. We also identified opposite effects of APPdup and DS on the permeability of hiPSC-ECs (increase in APPdup and decrease in DS) highlighting the role of chromosome 21 genes to counterbalance the effects of APP overexpression on CAA.
Conclusions: These results could partly explain differences in CAA observed between postmortem brain tissue from APPdup and DS. Indeed, an increase of permeability of the blood brain barrier (BBB) in APPdup could favor the passage of peripheral Aβ species, soluble or aggregated, leading to vascular deposits thanks to the production of Aβ by the cerebrovascular unit. Individuals with DS would be protected by having a less permeable BBB.

Aims: Vascular dysfunction is increasingly recognized as an important early event in sporadic Alzheimer's disease. Multiple lines of evidence associate medin amyloid, a fragment of MFG-E8, with vascular ageing and dysfunction and thus suggest that medin may be a vascular risk factor for dementia. This study aims to investigate the impact of medin amyloid on vascular amyloid-β deposition and explore its potential use as a biomarker and novel therapeutic target.
Methods: Using immunohistochemical and biochemical analyses of the brain and isolated cerebral blood vessels of APP transgenic mice, we examined whether genetic depletion of medin could modify amyloid-β aggregation *in vivo*. Additionally, we studied the effects of human medin (over-) expression on the vasculature both *in vivo* and *in vitro* using newly generated mouse lines of human medin pathology.
Results: Our data unveils a mechanistic link between vascular amyloid-β and medin amyloid pathology. Both MFG-E8 and medin are highly enriched in the vasculature, and their levels increase with the severity of vascular amyloid-β burden. Furthermore, we present the first mouse models for studying human medin pathology and reveal the functional consequences of MFG-E8 overexpression.
Conclusions: Our data strongly support medin amyloid as a driver of cerebral amyloid angiopathy. These findings highlight medin as a potential biomarker and novel therapeutic target for vascular dysfunction and cerebral amyloid angiopathy, warranting further evaluation in our newly generated model system.

Aims: Medin, a fragment of the protein MFG-E8, is known to aggregate in arteries of almost everybody over 50 years of age. Recently, medin was found in the vasculature of Alzheimer's disease (AD) patients but its role in AD pathogenesis remained unclear. In this study, we therefore investigated how medin may affect Amyloid-β (Aβ) pathology.
Methods: Building upon our previous research demonstrating that medin forms aggregates in the aorta and cerebral arteries of ageing wildtype mice, leading to arterial stiffening and consequential vascular dysfunction, we explored medin deposition in the brains of APP transgenic (tg) mice. We employed immunohistochemical and biochemical techniques to examine its influence on Aβ deposition and aggregate morphotype. To understand the underlying disease mechanism, we studied the interaction between medin and Aβ through genetic knockout of the medin-containing domain of MFG-E8 as well as seeding assays. Moreover, we assessed transcriptional and protein changes in human brain tissue.
Results: Our study provides evidence of a direct amyloid-amyloid interaction between medin and Aβ. Notably, we found that medin does not only co-localize with cerebral Aβ deposits but also alters onset and plaque morphotype in APP tg mice upon genetic deletion or exogenous addition. Interestingly, in line with its primary vascular localization in humans, elevated levels of MFG-E8 and medin correlate strongly

with CAA severity in both humans and mice. Furthermore, genetic medin deficiency reduces CAA and vascular damage by more than half in APP23 mice. Current work now focusses on proteomic and cellular alterations in isolated human and mouse cerebral vessels.

Conclusions: Our findings unveil a novel mechanism underlying age-associated vascular disease and amyloid deposition, highlighting medin as a potential therapeutic target and candidate for CAA biomarker development.

ELUCIDATING THE ROLE OF PLACENTAL GROWTH FACTOR IN HYPERHOMOCYSTEINEMIA INDUCED VCID

POSTERS: A01.L. DISEASE MECHANISMS, PATHOPHYSIOLOGY: VASCULATURE, MICROBLEEDS, HYPERTENSION, ANGIOGENESIS

Erica Weekman[1], Katelynn Krick[1], Colin Rogers[2], Tiffany Sudduth[2], Sherika Johnson[1], Teodoro Bottiglieri[3], Donna Wilcock[4]
[1]Indiana University School of Medicine, Stark Neurosciences Research Institute, INDIANAPOLIS, United States of America, [2]University of Kentucky, Sanders Brown Center On Aging, Lexington, United States of America, [3]Baylor Scott and White Research Institute, Institute Of Metabolic Disease, Dallas, United States of America, [4]Indiana University School of Medicine, Stark Neurosciences Institute, Indianapolis, United States of America

Aims: Vascular contributions to cognitive impairment and dementia (VCID) are the leading cause of dementia amongst the oldest old, making it critical to understand the mechanisms underlying VCID. We have identified placental growth factor (PlGF), an angiogenic mediator, to be associated with diffuse white matter disease in humans, which is a common manifestation of cerebral small-vessel disease (cSVD). PlGF is also upregulated in our mouse model of hyperhomocysteinemia (HHcy)-induced cSVD, which recapitulates many of the same pathologies as human cSVD, collectively suggesting a key role for PlGF in cSVD.
Methods: Using a novel mouse model with an inactive variant of PlGF (PlGF-KI), we induced HHcy for 8 weeks in 6-month-old mice. We determined levels of homocysteine-related metabolites in plasma, neuroinflammatory gene changes in brain tissue using qPCR, and microhemorrhage occurrence using Prussian blue staining.
Results: Interestingly, there were significant sex differences due to the loss of PlGF in HHcy induced VCID. The loss of PlGF increased weight loss in females, but less so in males, and there were significant sex effects in the homocysteine metabolism pathway with HHcy PlGF-KI females having decreased methionine, and increased HHcy, SAM and SAH compared to males. Male PlGF-KI mice also had reduced pro-inflammatory gene changes relative to females. However, these sex specific changes did not result in differences in microhemorrhages as the HHcy diet increased microhemorrhages in the PlGF-KI mice, regardless of sex.
Conclusions: In summary, it appears that PlGF impacts response to diet induction of HHcy in a sex-dependent manner. PlGF appears to have a significant impact on the neuroinflammatory response and cerebrovascular consequences of HHcy. Data from these studies continues to be assessed to further elucidate the role(s) of PlGF in cSVD.

HYPERTENSION AND NEUROPSYCHIATRIC SYMPTOMS IN PATIENTS WITH DRUG-NAÏVE ALZHEIMER'S DISEASE

POSTERS: A01.L. DISEASE MECHANISMS, PATHOPHYSIOLOGY: VASCULATURE, MICROBLEEDS, HYPERTENSION, ANGIOGENESIS

Young Soon Yang
Soonchunhyang University College of Medicine, Cheonan Hospital, Neurology, SEOUL, Korea, Republic of

Aims: Neuropsychiatric symptoms (NPS) such as anxiety, depression, and delusions affect up to 90% of all patients with Alzheimer's disease (AD). NPS is associated with significant caregiver burden and patient distress. Given the severe burden of NPS in AD, it is critical to know potential modifiable risk factors of NPS in AD. This study explores the association between hypertension and NPS in patients with drug-naïve AD.
Methods: We reviewed medical records of 149 patients with AD with (n=80) and without (n=69) hypertension. NPS were assessed using the Korean version of Neuropsychiatric Inventory (K-NPI). Affective, psychotic, and behavior symptom clusters were assessed separately.
Results: The total score of K-NPI was not significantly different between patients with AD with and without hypertension. Among K-NPI domains, scores of depression/dysphoria (p=0.045), anxiety (p=0.022), and apathy/indifference (p=0.037) were significantly higher in patients with AD with hypertension. Systolic blood pressure (BP) was associated with higher total K-NPI and affective symptom cluster scores. Diastolic BP was associated with affective symptom cluster scores.
Conclusions: Results suggest that hypertension increases risk of specific NPS in patients with AD. Among NPS, hypertension was associated with affective symptom cluster.

HUMAN SERUM EXACERBATES AD PATHOLOGY IN CORTICAL ORGANOIDS: INSIGHTS INTO BLOOD-BRAIN BARRIER DYSFUNCTION

POSTERS: A01.M. DISEASE MECHANISMS, PATHOPHYSIOLOGY: BLOOD-BRAIN BARRIER

Declan Brennan[1], Haakon Nygaard[2]
[1]University of British Columbia, Neuroscience, Vancouver, Canada, [2]University of British Columbia, Neurology, Vancouver, Canada

Aims: In Alzheimer's disease (AD) patients, increased blood-brain barrier permeability is correlated with declining cognitive function. Previous studies have shown that human serum increases insoluble Amyloid-β (Aβ) and phosphorylated tau (pTau) in cortical organoids. It is possible that either a component in the blood exacerbates AD pathology or that AD patients are more susceptible to this insult. We sought to confirm that human serum exacerbates AD pathology in cortical organoids while also investigating the underlying mechanisms of this important effect.
Methods: Cortical organoids were generated from induced-pluripotent stem cells carrying either the APP London mutation (v717l) or its CRISPR-corrected isogenic line. Organoids were sliced every 30-40 days at 500 µm thickness before treatment with human serum at day 110. Human serum from young, elderly, and AD donors were either company bought or collected at the Clinic for Alzheimer's and Related Disorders. Aβ isoforms and pTau were measured using ELISA-based assays. Bulk RNA sequencing was done for each condition to analyze differentially expressed genes.
Results: Both mutant and control organoids exhibited increased Aβ deposits and reduced soluble Aβ after serum treatment, though mutant organoids had a greater number of large Aβ aggregates and higher pTau/Tau. This effect was consistent across donor demographics. APP mRNA levels remained unchanged, suggesting altered cleavage rather than increased expression. Reactive astrocyte markers were highly elevated, while APP cleavage proteins showed no significant changes in mRNA counts. This indicates that either altered APP cleavage occurs through signaling perturbations alone or that neurons and reactive astrocytes have an inverse change in expression in response to serum.
Conclusions: Human serum exposure induces AD-like expression patterns and pathology in cortical organoids, highlighting the pivotal role of blood-brain barrier integrity in AD progression.

Aims: The blood-brain barrier (BBB) plays a crucial role in controlling the balance in the neuronal microenvironment. To enable controlled drug delivery to the central nervous system, it is essential that drugs have the ability to cross this barrier. Many computational methods have been developed with the purpose of studying the transport of compounds across the BBB. However, some of these methods focus on analyzing the effects of the chemical structures of compounds during their interaction with biological receptors. In the present work was analyzed the potential of Octovespin in crossing the Blood-Brain Barrier, employing various computational tools for a detailed study of the process.
Methods: In this study, we opted for a different approach, using molecular dynamics techniques guided by a simplified model of the BBB for a detailed assessment of compound permeability during the transposition process. This methodology is based on creating a non-equilibrium system that includes a force field to guide the compounds through the membrane. In the present work, a peptide bio-inspired from the venom of the wasp *Polybia occidentalis*, called Octovespin, was tested in the BBB simplified model. This compound exhibited an ability in the disaggregation of senile plaques formed by amyloid-beta (Aβ) protein.
Results: Our results indicate that Octovespin has the ability to cross the blood-brain barrier (BBB), which makes it a promising candidate for the treatment of Parkinson's and Alzheimer's diseases.
Conclusions: This method stands out for its rapid implementation and affordable computational cost, which makes it a highly advantageous alternative for the analysis of various compounds. Additionally, it offers the opportunity to perform preliminary tests to evaluate the ability of drugs to successfully penetrate the BBB.

Aims: Communication between the blood and the brain is a dynamic, complex process that occurs at the physical and molecular interphase formed by the blood-brain barrier (BBB). To sustain brain health, the neurovascular unit tightly regulates bidirectional exchanges between these two compartments, but BBB integrity is compromised in people with neurodegenerative disorders such as Parkinson's disease (PD). The objective is to leverage advanced tissue engineering approaches to model the complex cellular and molecular interactions occurring at the BBB in people with PD.
Methods: We established a microfluidic model of the BBB using patient-derived induced pluripotent stem cells (iPSCs) harboring PD-related mutations, including LRRK2 G2019S and SNCA triplication. To identify triggers of BBB dysfunction in PD, we exposed the model to reactive astrocytes harboring PD-related mutations and/or pathological proteins such as alpha-synuclein. We then evaluated changes to barrier integrity, neuroinflammation and neurodegeneration.
Results: We found that several mutations in genes associated with familial PD result in the increased vulnerability of the BBB and the extravasation of plasma proteins from the blood to the brain compartment of the model. In particular, we observed that pro-inflammatory astrocytes induce vessel enlargement and loss of barrier function, as observed in people with PD, but these features can be rescued upon pharmacological treatment.
Conclusions: Our novel PD-BBB model is a versatile tool to study the role of the BBB in disease onset and progression, and it is amenable to pharmacological testing.

BLOOD-BRAIN BARRIER REPAIR IN ALZHEIMER'S DISEASE WITH EPILEPSY

POSTERS: A01.M. DISEASE MECHANISMS, PATHOPHYSIOLOGY: BLOOD-BRAIN BARRIER

Anika Hartz
University of Kentucky, Sanders-brown Center On Aging, Lexington, United States of America

Aims: More than 25% of patients with Alzheimer's disease (AD) develop epilepsy as co-morbidity. In AD with epilepsy (ADxEpi), seizures accelerate cognitive decline and further reduce life expectancy compared to AD alone. One hallmark of both AD and epilepsy is blood-brain barrier dysfunction. We discovered that barrier dysfunction is more severe in ADxEpi patients compared to seizure-free AD patients. Collectively, our data suggest that a combination of Ab and seizure-released glutamate (Aβ/Glu) triggers a dual positive feedback loop which exacerbates barrier dysfunction, seizures, and cognitive decline in ADxEpi. Our goal is to define the mechanism that underlies barrier dysfunction in ADxEpi and to develop a therapeutic intervention.
Methods: We determine signaling steps that lead to Aβ/Glu-mediated barrier dysfunction using isolated mouse brain capillaries and verify these findings *in vivo*. We determine barrier dysfunction in brain tissue from ADxEpi patients and correlate the degree of barrier dysfunction with seizure burden and patient cognition scores. We develop an intervention therapy designed to repair barrier dysfunction using two rodent ADxEpi models.
Results: We found that Aβ/Glu exacerbates barrier leakage compared to Aβ or Glu alone. We also discovered that Aβ/Glu activates NOX/LOX/COX signaling, causing barrier leakage. Using patient samples, we show that ADxEpi patients have increased barrier leakage compared to seizure-free AD patients. Using two ADxEpi rodent models (mouse and rat) we further show that LOX/COX inhibitors combined with a ROS scavenger attenuate barrier dysfunction *in vivo*.
Conclusions: Based on our data we conclude that blocking Aβ/glutamate signaling by inhibiting NOX/LOX/COX repairs barrier dysfunction and has the potential to help reduce seizure burden and slow cognitive decline in AD with epilepsy.

Aims: Blood brain barrier (BBB) dysfunction in Alzheimer's disease (AD) is correlated to an accelerated progression of cognitive decline. It has been shown that pericytes in particular play an important role in neurovascular dysfunction in AD, but how this contributes to disease pathogenesis remains unknown. To elucidate this, we investigated the transcriptome of the cell types in the BBB, including the mural cells, in Amyloid Precursor Protein (*App*) knock-in (App^{NL-G-F}) mice with and without pericyte deficiency.
Methods: Cerebral microvasculature was isolated using CD31 panning, and the cells were analyzed by single cell RNA sequencing (scRNAseq) and subsequently validated using immunohistochemistry. Pericyte deficient $Pdgfb^{ret/ret}$ mice were crossed with App^{NL-G-F} mice and injected with tracer molecules to quantitatively measure BBB leakage. Aβ pathology was investigated by immunohistochemistry.
Results: ScRNAseq data from the cerebral micro vasculature of the App^{NL-G-F} revealed a population of disease-associated microglia characterized by high expression of Cst7. These were found to bridge between Aβ plaque and small and large blood vessels. Data analysis indicates that the point of contact in capillaries could be mural cells suggesting a role of pericytes in neuroinflammation. To further elucidate the role of pericytes on progression of Aβ pathology we studied a new pericyte deficient $App^{NL-G-F}xPdfgb^{ret/ret}$. The tracer studies showed a significant increase of BBB leakage in 3-month-old $App^{NLGFret/ret}$ mice compared to controls. This will be followed by tracer studied in other ages, evaluation of Aβ pathology, and scRNAseq of the BBB.
Conclusions: The BBB in App^{NL-G-F} mice is characterized by vascular associated DAMs. The combination of pericyte deficiency and Aβ amyloidosis increased the leakage of App^{NL-G-F} mice vasculature, which may impact the development of Aβ pathology.

Aims: Blood-brain barrier (BBB) permeability changes may affect early mechanisms of Alzheimer's Disease (AD). We evaluate changes in BBB water permeability between cognitive and amyloid status, measured non-invasively using arterial spin labeling (ASL) MRI.
Methods: Participants older than 50 years were selected from the DDI and from the LCBC cohorts (Table 1). All LCBC participants were cognitively normal (CN), while DDI included both CN and mild cognitive impairment (MCI) participants. We separated the groups as CN_LCBC, CN_DDI, and MCI_DDI. A recently developed multi-delay multi-echo BBB-ASL MRI sequence was used to estimate cerebral blood flow (CBF) and time of exchange (Tex) maps of labeled water across the BBB. Lower Tex is a proxy of higher BBB water permeability. Amyloid status was defined from the available CSF amyloid-beta 42/40 ratio (cut-off ≤ 0.077). Tex and CBF associations with cognition and amyloid status were assessed using general linear models (GLMs) adjusted for age and sex. Statistical analyses were performed in R4.1.2.

Table 1: *Sample characteristics. Units are given as mean ± SD.*

	Total sample (n=116)	
	LCBC (n=77)	**DDI (n=39)**
Age (years)	64.6 ± 8.4	67.7 ± 7.94
Sex (female)	49 (64%)	20 (51%)
Cognitively normal (n)	77	24
MCI (n)	0	15
Total GM CBF (mL/100g/min)	58.3 ± 13.4	75.7 ± 23.2
Females (mL/100g/min)	61.4 ± 14.0	86.9 ± 21.9
Males mean value	52.9 ± 10.3	63.7 ± 18.2
Total GM Tex (s)	0.21 ± 0.04	0.18 ± 0.04
Females mean value	0.22 ± 0.04	0.20 ± 0.04
Males mean value	0.19 ± 0.02	0.17 ± 0.03

CBF: Cerebral blood flow; DDI: Dementia Disease Initiation; GM: Gray matter; LCBC: Center for Lifespan Changes in Brain and Cognition; MCI: Mild cognitive impairment; Tex: time of exchange (proxy of BBB water permeability).

Results: CBF tended to be higher in the A+ group but not statistically significant (t=-1.94, p=0.06, Figure 1). Tex was lower in A+ than A- (t=2.75, p=0.01, Figure 2). GLM analysis showed that both amyloid status and cognitive staging were predictive of BBB water permeability (Tex), with higher permeability in amyloid positive compared to amyloid negative groups when correcting for age, sex, and CBF (β = -35.2, $p < 0.001$) (Table 2). The same pattern was found in MCI subjects compared to healthy controls (Table 3).

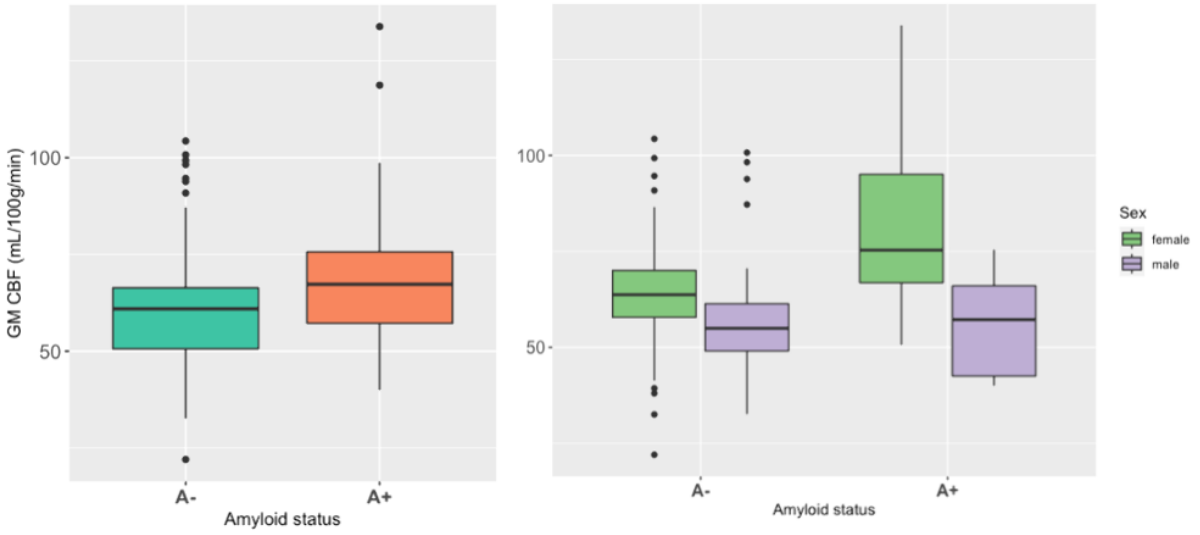

Figure 1 - Gray matter (GM) time of exchange (CBF) stratified by amyloid status and sex

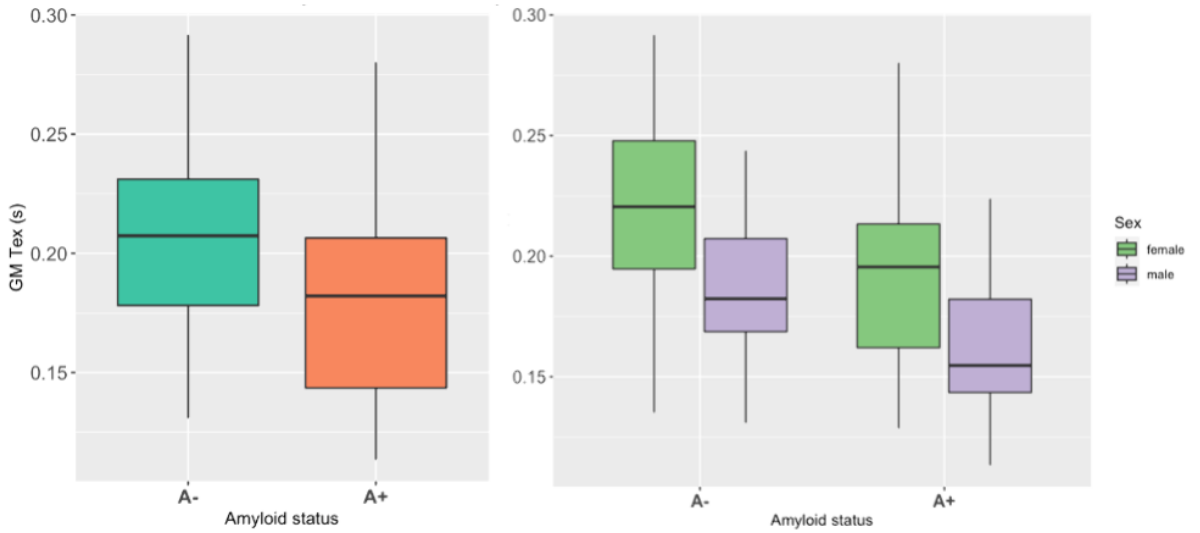

Figure 2 - Gray matter (GM) time of exchange (Tex) stratified by amyloid status and sex.

Table 2: *CBF and Tex GM values associated with amyloid status corrected for age and sex – and CBF in the case of Tex.*

	Amyloid status		Amyloid status + age + sex						Amyloid status + age + sex + CBF							
	β	p	β (A+)	p (A+)	β (age)	p (age)	β (male)	p (male)	β (A+)	p (A+)	β (age)	p (age)	β (male)	p (male)	β (CBF)	p (CBF)
CBF total GM	10.7	*	13.3	**	-0.5	*	-8.4	*	-	-	-	-	-	-	-	-
Tex total GM	-0.028	**	**-0.22**	*	-0.001	**	-0.028	***	**-0.035**	***	-0.001	N.S	-0.02	**	0.001	***

CBF: Cerebral blood flow; GM: Gray matter; NS: non-significant; Tex: time of exchange (proxy of BBB water permeability).
*p<0.05 *, p<0.01**, p<0.001***. Reference groups: A- for amyloid staging and female for sex*

Table 3: *CBF and Tex GM values associated with cognitive staging corrected for age and sex – and CBF in the case of Tex.*

	Cognitive staging				Cognitive staging + age + sex + CBF									
	β (CN)	p (CN)	β (MCI)	p (MCI)	β (CN)	p (CN)	β (MCI)	p (MCI)	β (age)	p (age)	β (male)	p (male)	β (CBF)	p (CBF)
CBF total GM	**19,17**	**	**-0.5**	*	-	-	-	-	-	-	-	-		
Tex total GM	**-0.22**	*	**-0.001**	**	**-0.053**	***	**-0.051**	***	-0.02	N.S.	-0.0002	N.S.	**0.0014**	***

CBF: Cerebral blood flow; CN: here, CN corresponds to cognitively normal subjects from DDI, since the reference group is CN from LCBC; GM: Gray matter; Tex: time of exchange (proxy of BBB water permeability).
*p<0.05 *, p<0.01**, p<0.001***. Reference groups: CN_LCBC for cognitive staging and female for sex*

Conclusions: Our findings suggest that BBB water permeability is increased in amyloid-positive and MCI participants compared to CN, suggesting that BBB water permeability is a potential early imaging biomarker in AD physiology.

POST-TRANSLATIONAL MODIFICATIONS OF BETA-AMYLOID AFFECT ITS TRANSPORT ACROSS THE BLOOD-BRAIN BARRIER

POSTERS: A01.M. DISEASE MECHANISMS, PATHOPHYSIOLOGY: BLOOD-BRAIN BARRIER

Kseniya Varshavskaya, Irina Petrushanko, Vladimir Mitkevich, Alexander Makarov, Evgeny Barykin
Engelhardt Institute of Molecular Biology, Laboratory Of Protein Conformational Polymorphism In Health And Disease, Moscow, Russian Federation

Aims: Beta-amyloid (Aβ) undergoes post-translational modifications that alter its pathogenic properties. Aβ can enter the brain from circulation by binding to RAGE and trigger the pathology of Alzheimer's disease (AD). However, the transport of modified forms of Aβ across the blood–brain barrier (BBB) has not previously been studied. Here, we characterized the transport of phosphorylated (pS8-$Aβ_{42}$) and isomerized (isoD7-$Aβ_{42}$) Aβ across the BBB in comparison with unmodified Aβ.
Methods: Murine brain endothelial cells bEnd.3 seeded on transwell membrane were used as an *in vitro* model of the BBB. The transport of Aβ isoforms was estimated using ELISA. Endocytosis inhibitors and RAGE antagonist were used to characterize the involved mechanisms. Endothelial permeability was evaluated using sodium fluorescein. The parameters of the interaction of Aβ and its isoforms with RAGE were determined using microscale thermophoresis.
Results: IsoD7-$Aβ_{42}$ and pS8-$Aβ_{42}$ cross the BBB better than unmodified $Aβ_{42}$. The transport of all isoforms is caveolin-dependent, but the transport of isoD7-$Aβ_{42}$ is dependent on both caveolin- and clathrin-mediated endocytosis. The RAGE antagonist inhibits the transport of $Aβ_{42}$, but does not affect the transport of pS8-$Aβ_{42}$ and isoD7-$Aβ_{42}$. RAGE binds to isoD7-$Aβ_{42}$ an order of magnitude weaker than to $Aβ_{42}$. Higher levels of $Aβ_{42}$ were detected in cell lysates compared to isoD7-$Aβ_{42}$, suggesting the altered ratio between transport and degradation.
Conclusions: Post-translational modifications of Aβ increase the rate of its transport across the BBB and modify the mechanisms of the transport, which may be important for AD pathology and treatment.

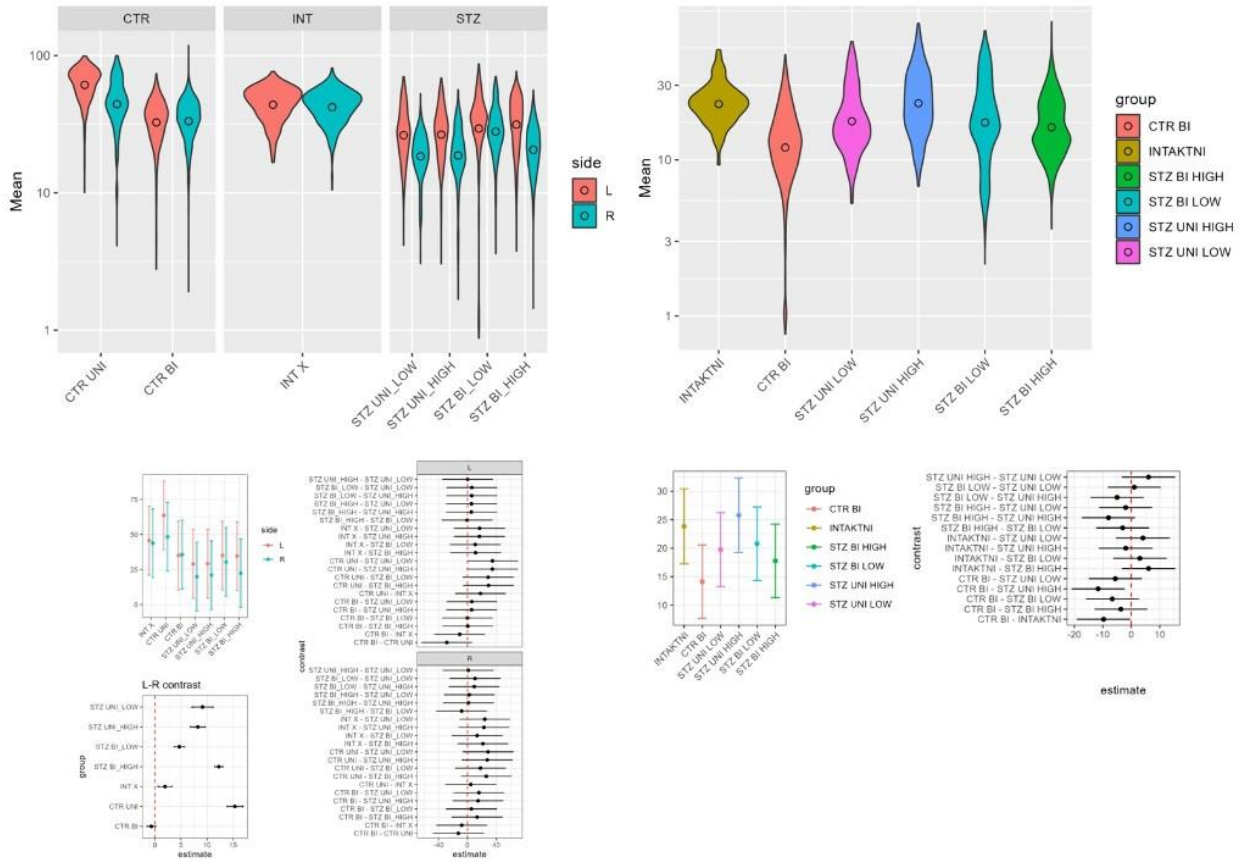
Aims: Transthyretin (TTR), a tetrameric transport protein, commonly associated with aggregation disorders and amyloidosis, has recently been recognized as a potential neuroprotectant in various settings, including Alzeimer's disease (AD). Modeling sporadic AD with intracerebroventricular streptozotocin (STZ-icv) in rodents is widely used and well established in AD research. Here, we aimed to characterize the effects of STZ-icv on TTR in its production site, the choroid plexus (CP) and the hypothalamus (HPT), where it influences metabolism.
Methods: Seven groups with six 3-month-old C57BL/6 mice entered the experiment. Four different STZ-icv dosing regimens were employed; uni- and bi-lateral low (1,5 mg/kg) and high (3 mg/kg) doses with appropriate uni- and bi-lateral controls and intact animals. A month after STZ-icv administration, animals were euthanized and blood and brain samples taken. Plasma glucose and insulin were measured spectrophotometrically and by ELISA. Immunohistochemical staining with polyclonal anti-TTR antibody was performed on 14 µm thick Tissue-tek™-embedded sections.
Results: Plasma glucose and insulin were assessed to exclude systemic diabetes induced by streptozotocin and results were unchanged across all groups. Relative to unilateral controls, model-derived estimates showed both high- and low-dose STZ-icv to lower TTR expression at the injection side in the CP. Interestingly, across all STZ-groups, as well as in the unilateral controls, injection-side CP TTR expression was significantly higher, compared to the contralateral side, irrespective of STZ's impact on cell-count. In the HPT, TTR expression was paradoxically increased by STZ-icv compared to controls receiving vehicle
only.



Conclusions: TTR expression is affected by injection-injury, possibly increasing ipsilaterally as a compensatory measure; and STZ, with different effects depending on brain-site and STZ dose, in different regimens of a mouse model of sporadic AD. Research funded by Pfizer Inc. (73521469) and ZCI-Neuro (GA KK01.1.1.01.0007).

ALTERED AMINO ACID PROFILE IN PATIENTS WITH ALZHEIMER'S DISEASE: INTERACTION BETWEEN MALNUTRITION AND PATHOLOGY

POSTERS: A01.N. DISEASE MECHANISMS, PATHOPHYSIOLOGY: METABOLISM, INSULIN

Matteo Cotta Ramusino[1], Roberto Aquilani[2], Alfredo Costa[3], Manuela Verri[2]
[1]IRCCS Mondino Foundation, Brain And Behavioral Sciences, Pavia, Italy, [2]University of Pavia, Department Of Biology And Biotechnology "lazzaro Spallanzani", Pavia, Italy, [3]University of Pavia, Irccs Mondino Foundation, Pavia, Italy

Aims: Background: Biochemical alterations linked to the neuronal/astroglial dysfunction affect the molecular composition of the interstitial fluid and of the cerebrospinal fluid (CSF). Nutritional status can influence the amino acids (AA) levels in subjects with Alzheimer's disease (AD). This work is aimed to investigate the alterations of AA in CSF and plasma of AD patients and to investigate the possible combined role of malnutrition and pathology on the observed alterations
Methods: In 54 patients with AD (69% males, 74.4 ± 8.2 years) and 17 age-matched control (CTRL) subjects, CSF and venous blood samples were taken for AA measurements. Patients were stratified according to the nutritional status (Mini Nutritional Assessment, MNA, scores).
Results: Compared to CTRL, AD patients showed reduced levels of aspartic acid, and increased levels of taurine and 3-methyl-histidine ($p<0.001$). In addition, amyloid correlated inversely with histidine levels while p-tau correlated positively with serine levels. In the combined group (CG) including malnourished AD (16.7%; MNA < 17) and AD at risk for malnutrition (36.6%, MNA 17−24), all CSF essential amino acids (EAAs) and 30% of non-EAAs were lower compared to the CTRL ($p < 0.018$ to 0.0001), whereas in normo-nourished ADs (46.7%, MNA > 24) the CSF levels of 10% EAAs and 25% non-EAAs were decreased ($p < 0.05$ to 0.00021). Compared to normo-nourished ADs, CG had lower levels of Branched-Chain AA both in plasma and CSF ($p<0.01$).
Conclusions: AD patients had low levels of AA in plasma and CSF, particularly EAA and BCAA. The amino acid profile is an expression partly of the metabolic signature of the disease partly of the nutritional status.

NEURONAL INSULIN RESISTANCE PROMOTES NON-AMYLOIDOGENIC APP PROCESSING

POSTERS: A01.N. DISEASE MECHANISMS, PATHOPHYSIOLOGY: METABOLISM, INSULIN

Steven Alves[1], José João Mendonça Vitória[2], Diogo Trigo[3], Odete Da Cruz E Silva[1]
[1]Institute of biomedicine, University of Aveiro, Department Of Medical Sciences, Aveiro, Portugal, [2]Universidade de Aveiro, Departamento De Ciências Médicas, Aveiro, Portugal, [3]Institute of Biomedicine - iBiMED, Departamento De Ciências Médicas - Dcm, Aveiro, Portugal

Aims: Growing evidence shows that Type 2 diabetes patients are more likely to develop Alzheimer's disease (AD) with ageing. This means that neuronal insulin resistance (IR) must play a role in several key AD mechanisms. Here, we assessed if IR affects normal APP processing.
Methods: For that purpose, an IR model was developed, and APP processing monitored by western blot analysis of SH-SY5Y lysates and respective mediums, BACE1 activity and $A\beta_{1-42}$ secreted into the medium, by ELISA.
Results: IR had no impact in total APP intracellular levels, however it significantly increased by 2-fold the total secreted APP (sAPP) in the medium, implying an increase in APP processing. Furthermore, as seen with total sAPP, sAPPα similarly increased in IR cells. Moreover, no changes in both BACE1 activity and Aβ production were observed with IR, supporting the notion that increased APP processing occurred by promoting non-amyloidogenic cleavage.
Conclusions: Although IR may have a significant role in AD pathogenesis, it does not significantly affect Aβ levels. However, it does alter APP processing, which may affect homeostasis.

Kevin Hascup[1], Samuel Mcfadden[2], Mackenzie Peck[2], Erol Ikiz[2], Yimin Fang[2], Andrzej Bartke[3], Erin Hascup[4]
[1]Southern Illinois University School of Medicine, Dale And Deborah Smith Center For Alzheimer's Research & Treatment; Depts Of Neurology, Pharmacology, And Mmicb, Springfield, United States of America, [2]Southern Illinois University School of Medicine, Dale And Deborah Smith Center For Alzheimer's Research & Treatment; Dept. Of Neurology, Springfield, United States of America, [3]Southern Illinois University School of Medicine, Depts Of Internal Medicine And Mmicb, Springfield, United States of America, [4]Southern Illinois University School of Medicine, Dale And Deborah Smith Center For Alzheimer's Research And Treatment; Depts Of Neurology And Pharmacology, Springfield, United States of America

Aims: A thermoregulatory decline occurs with age due to changes in muscle mass, vasoconstriction, and metabolism that lowers core body temperature (Tc). Although lower Tc is a biomarker of successful aging, we have previously shown this worsens cognitive performance in the APP/PS1 mouse model of Alzheimer's disease (doi.org/10.1093/gerona/glac223). We hypothesized that elevating Tc with thermotherapy would improve metabolism and cognition in APP/PS1 mice.
Methods: From 6-12 months of age, male and female APP/PS1and C57BL/6 mice were chronically housed at 23 or 30°C. At 12 months of age, mice were assayed for insulin sensitivity, glucose tolerance, and spatial cognition. Plasma, hippocampal, and peripheral (adipose, hepatic, and skeletal muscle) samples were procured postmortem and tissue-specific markers of amyloid accumulation, metabolism, and inflammation were assayed.
Results: Chronic 30°C exposure increased Tc in all groups except female APP/PS1 mice (Fig 1A). Thermotherapy improved insulin sensitivity in all groups except male APP/PS1 mice that instead had improved glucose tolerance (Fig 1B-C). Plasma concentrations of insulin-like growth factor 1 (IGF-1) and leptin were decreased in male APP/PS1 mice while IGF-1 was increased in female APP/PS1 mice. **Figure 1**

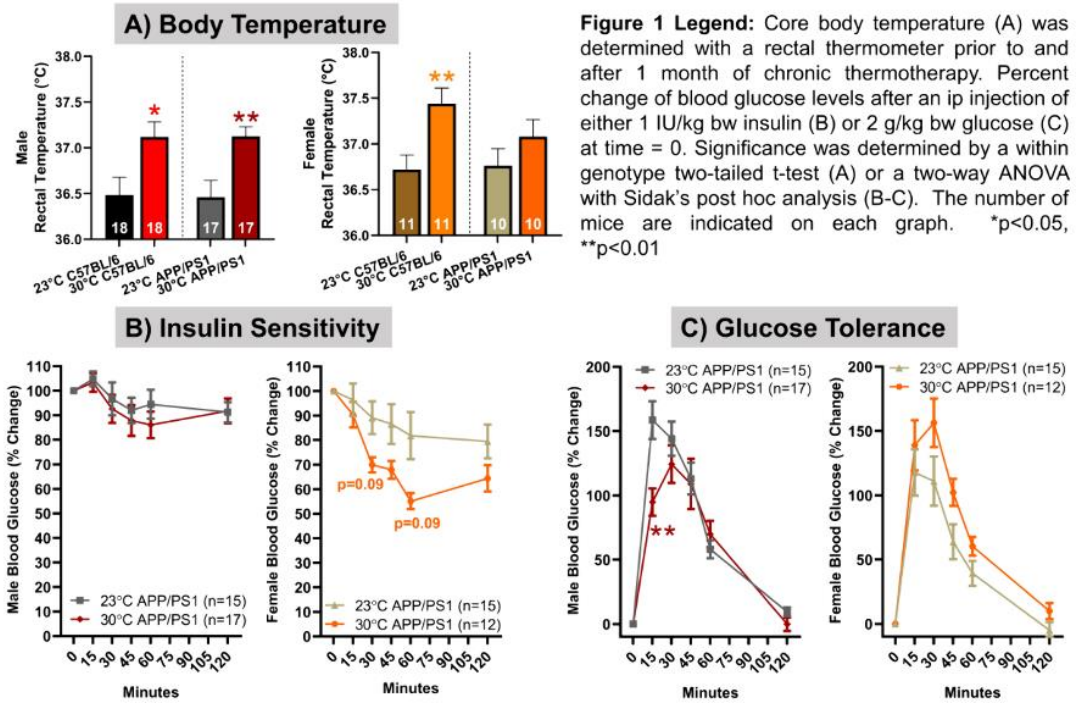

Figure 1 Legend: Core body temperature (A) was determined with a rectal thermometer prior to and after 1 month of chronic thermotherapy. Percent change of blood glucose levels after an ip injection of either 1 IU/kg bw insulin (B) or 2 g/kg bw glucose (C) at time = 0. Significance was determined by a within genotype two-tailed t-test (A) or a two-way ANOVA with Sidak's post hoc analysis (B-C). The number of mice are indicated on each graph. *p<0.05, **p<0.01

Thermotherapy improved spatial navigation in male mice, but this treatment had no effect in female C57BL/6 mice and worsened performance in female APP/PS1 mice (Fig 2). Thermotherapy had no effect on hippocampal amyloid accumulation but did reduce circulating proinflammatory cytokines. Additional mechanistic studies are ongoing to elucidate sex- and tissue-specific metabolic differences to thermotherapy. **Figure 2**

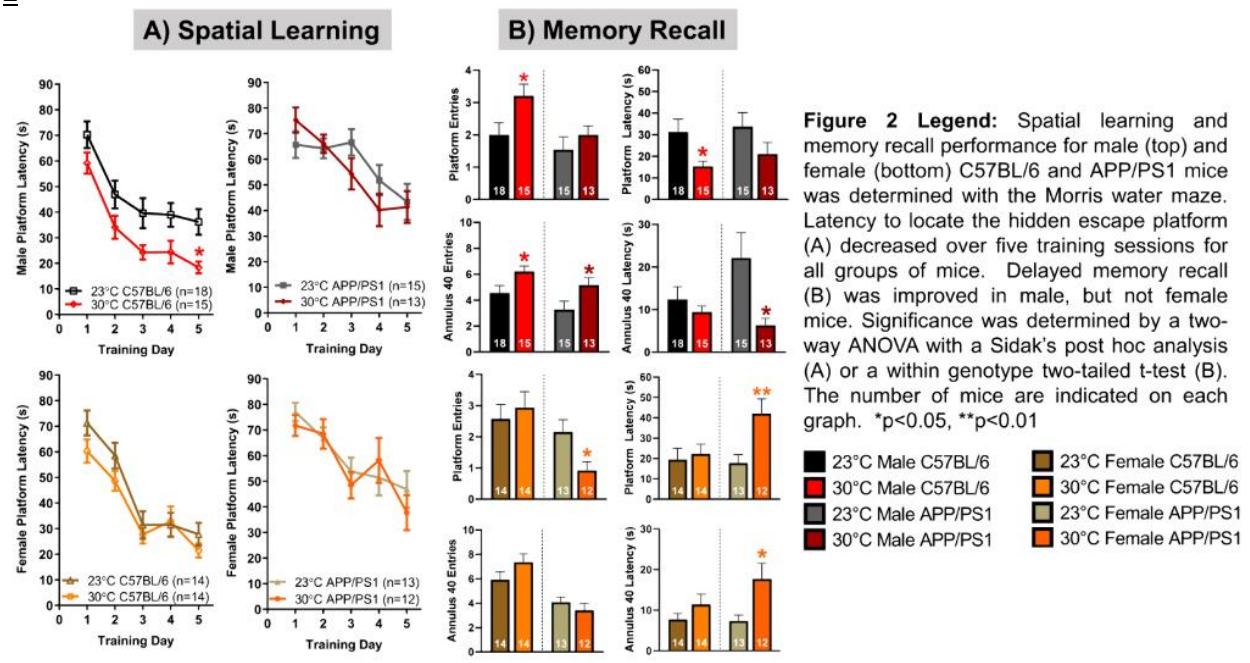

Figure 2 Legend: Spatial learning and memory recall performance for male (top) and female (bottom) C57BL/6 and APP/PS1 mice was determined with the Morris water maze. Latency to locate the hidden escape platform (A) decreased over five training sessions for all groups of mice. Delayed memory recall (B) was improved in male, but not female mice. Significance was determined by a two-way ANOVA with a Sidak's post hoc analysis (A) or a within genotype two-tailed t-test (B). The number of mice are indicated on each graph. *p<0.05, **p<0.01

Conclusions: Although chronic thermotherapy improved either glucose tolerance or insulin sensitivity in all groups, only male mice had better spatial learning and memory recall. Support came from the

NIH (R01 AG057767, AG061937), IDPH (03282005H), Smith Alzheimer's Center, and Kenneth Stark Endowment.

STABILIZED HIF RESPONSE PROTECTS NEURONS IN AN ALZHEIMER'S DISEASE MODEL

POSTERS: A01.N. DISEASE MECHANISMS, PATHOPHYSIOLOGY: METABOLISM, INSULIN

Margareta Kurkela[1], Elitsa Dimova[1], Henna Koivisto[2], Tuulia Ala-Nisula[1], Maiju Uusitalo[1], Petri Kursula[1,3], Johanna Myllyharju[1], Raisa Serpi[1], Heikki Tanila[2], Peppi Koivunen[1]

Virtanen Institute For Molecular Sciences, Kuopio, Finland, [3]University of Bergen, Department Of Biomedicine, Bergen, Norway

Aims: Hypoxia-inducible factor (HIF) regulates transcription of hundreds of genes in pathways such as glycolysis, angiogenesis, and cell proliferation. In normoxic conditions, HIF is targeted for degradation by HIF prolyl 4-hydroxylases (HIF-P4Hs). When oxygen availability decreases, HIF escapes degradation and activates reading of the target genes. HIF-P4H inhibition is already a therapeutical target in anemia but has potential for other diseases since HIF stabilization has been shown to be highly beneficial especially for metabolic health. The aim of our study was to investigate whether genetic HIF stabilization interferes with the disease progression in an Alzheimer's disease model.
Methods: The behavioral phenotype of female *Hif-p4h-2* hypomorphic *APP*swe/*PSEN1*dE9 (*APP/PSEN1*) mice was investigated at 6, 9 and 12 months old using open field and dark light tests in comparison to the *Hif-p4h-2* wild type *APP/PSEN1* mice. Glucose tolerance test (GTT) was carried out at 11 months old, and at 12 months samples were collected for histological, protein and qPCR analyses.
Results: *Hif-p4h-2* hypomorphism in *APP/PSEN1* mice reduced anxiety and maintained activity levels in behavioral tests over the follow-up period in comparison to the *Hif-p4h-2* wild type *APP/PSEN1* mice. The hypomorphic *Hif-p4h-2 APP/PSEN1* mice displayed lowered insulin levels and improved results in GTT. The improved behavioral and metabolic parameters associated with improved neuronal health measured with reduced ATG9A positivity in histological analyses.
Conclusions: Stabilization of the HIF response in *APP/PSEN1* mice resulted in an improved behavioral phenotype, and metabolic health with emphasis on reduced insulin levels. Improved behavioral and metabolic health associated with improved neuronal health. These data suggest that stabilized HIF response improves neural tolerance to detrimental effects of Alzheimer's disease.

INSULIN RECEPTOR KNOCKDOWN IN CHOROID PLEXUS WORSENS PATHOLOGY IN APP/PSEN1 MICE

POSTERS: A01.N. DISEASE MECHANISMS, PATHOPHYSIOLOGY: METABOLISM, INSULIN

Caio Mazucanti, Vernon Kennedy, Jane Tian, Josephine Egan
National Institute on Aging, Laboratory Of Clinical Investigation, Baltimore, United States of America

Aims: This work characterizes insulin signaling in choroid plexus and its possible implications in diseases of the brain by modulating insulin receptor expression in choroid plexus (CP) of APP/PSEN1 mice and assessing plaque burden and behavior.
Methods: Insulin signaling in the choroid plexus of 3-months old APP/PSEN1 mice was disrupted by intracerebroventricular injection of AAV5 carrying insulin receptor shRNA sequence. Tissue specificity of AAV5 infection was confirmed by icv injection of AAV5-Cre in Cre-reporter mice (Ai14), and downregulation of IR expression was confirmed by qPCR both *in vitro* and *in vivo.* Integrity of the tissue was assessed by H&E and immunofluorescence staining. Gross brain morphology was visualized by MRI. Brain sections were stained with Thioflavin-S for amyloid deposits. Nine months after viral injection, locomotor and cognitive behavior were assessed by home cage activity measurements and spontaneous alternation test, respectively.
Results: Intracerebroventricular injection of AAV5 results in exclusive infection of epithelial cells of the choroid plexus. A month after injection, blood-CSF barrier disruption resulted, as shown by ZO-1 and Na+/K+ ATPase immunofluorescence staining. Two months after injection, in vivo MRI imaging shows complete atrophy of CPs and ventricles. H&E staining revealed immune infiltration in CP of insulin receptor knockdown mice. In APP/PSEN1 mice, CP insulin receptor knockdown resulted in increased number of amyloid plaques throughout the brain and worsened behavioral measurements associated with this transgenic mouse model.
Conclusions: These results implicate insulin signaling in the maintenance of one of the most important barriers in the CNS, connecting metabolic conditions such as type 2 diabetes and insulin resistance to neurological disorders.

Aims: Our knowledge regarding the effect of insulin in the brain is still modest. Impaired response to insulin in the brain has been linked to many neurodegenerative disorders like Alzheimer's disease (AD). In line with this finding, an animal model of sporadic AD has been developed by intracerebroventricular (icv) administration of streptozotocin (STZ), which given peripherally causes insulin resistance. To explore the brain insulin effect in the STZ-icv model, we used intranasal insulin (INS) targeting brain.
Methods: Wistar rats were injected icv with STZ (3 mg/kg) or vehicle only (CTR). One month after, INS was given intranasally in both nostrils and animals were sacrificed 3, 7.5, 15, 30, 60 and 120 minutes after administration. C-fos levels, insulin concentration, IRS-1 activation/inhibition were measured in the brain and plasma.
Results: INS increased c-fos levels in temporal cortex (TC) 120 minutes after administration in STZ-icv rats. In CTR, insulin concentration was found increased at earliest time point (3 min) in all observed brain regions and remained increased after 7.5 min only in TC. IRS1 activity increased in TC and hippocampus (HPC) and it was followed by increment of inhibitory phosphorylation of IRS1, and activation diminished through time (up to 30 min). Contrary to this finding, there was no change in IRS activation/inhibition in hypothalamus (HPT).
Conclusions: Most prominent effect of intranasal insulin was found in TC. IRS inhibition follows its activation promptly after INS application in HPC and TC. It seems that in HPT insulin has no effect on pathway including IRS-1. *Supported by HRZZ-IP-2018-01-8938 and co-financed by the Scientific Centre of Excellence for Basic, Clinical and Translational Neuroscience (project"Experimental and clinical research of hypoxic-ischemic damage in perinatal and adult brain",GA KK01.1.1.01.0007 funded by the European Union)*

Aims: Adiponectin secreted by adipose tissue plays a role in the regulation of energy homeostasis, carbohydrate and lipid metabolism, as well as in the modulation of inflammation. The observation of a relationship between Alzheimer's disease (AD) and body mass index (BMI) has highlighted the role of metabolic disorders in its pathophysiology. However, the available body of evidence has reported conflicting results. The exact role and mechanisms of adiponectin in the pathophysiology of AD remain unclear. The aim of this study was to compare plasma adiponectin levels in patients with AD, confirmed by biomarkers, with those of neurological control subjects.
Methods: In a single-center, cross-sectional, observational study we performed chemiluminescent enzyme immunoassay of plasma adiponectin levels in patients diagnosed with AD or as neurological controls. We described the evolution of adiponectin concentration among the age categories in males and females. We also analyzed the relationship between adiponectin and AD using linear regression models including age, gender and BMI.
Results: Two hundred and six patients (142 patients with AD and 64 neurological controls) were included. The mean age of the patients was 69 years, and 56% were women. Plasma adiponectin levels were significantly higher in patients with AD compared with control patients ($p<0.001$). This association was modulated by age, gender and BMI, which were significantly and independently associated with plasma adiponectin levels, while adiponectin was no longer associated with AD in multivariate models. Higher adiponectin concentrations were observed in females and associated with aging.
Conclusions: Adiponectin was associated with the biological diagnosis of AD and may play a key pathophysiological role in AD. Nevertheless, adiponectin levels were strongly related to age, gender and BMI. Further studies are needed to better characterize the "hormonal signature" of AD.

LOW CONCENTRATIONS OF AMYLOID-BETA PEPTIDES TRIGGER PREMATURE FUNCTIONAL AND GENE EXPRESSION ALTERATIONS IN HUMAN-INDUCED NEURONS

POSTERS: A01.O. DISEASE MECHANISMS, PATHOPHYSIOLOGY: NEURAL NETWORKS, PLASTICITY

Marcos Costa
Institut Pasteur de Lille, Inserm U1167, Lille, France

Aims: Alzheimer's disease (AD) is the most prevalent cause of dementia in the elderly, characterized by the presence of amyloid beta (Aβ) plaques, neurofibrillary tangles, neuroinflammation, synapse loss and neurodegeneration in the brain. The amyloid cascade hypothesis postulates that deposition of Aβ peptides is the causative agent of AD pathology, but we still lack comprehensive understanding about the molecular mechanisms connecting Aβ peptides to neuronal dysfunctions in AD. In this work, we investigated the early effects of Aβ peptides accumulation on the functional properties and gene expression profiles of human-induced neurons (hiNs).
Methods: We exposed 6-weeks-old hiNs to low concentrations of cell-secreted Aβ oligomers or synthetic Aβ and performed time-lapse time microscopy to detect fast calcium transients as an indirect readout of neuronal electrical function. Next, we used single-nucleus RNA sequencing (snRNA-seq) to probe early Aβ-mediated gene expression alterations in hiNs and human-induced astrocytes (hiAs). Lastly, we leveraged snRNA-seq data to identify patterns of intercellular communication modulated by Aβ oligomers.
Results: We show that hiNs acutely exposed to low concentrations of both cell-secreted Aβ peptides or synthetic $A\beta_{1-42}$ exhibit alterations in the frequency of calcium transients suggestive of increased neuronal excitability. We also show that cell-secreted Aβ up-regulates the expression of several synaptic-related genes and down-regulates the expression of genes associated with metabolic stress mainly in glutamatergic neurons and to a lesser degree in GABAergic neurons and astrocytes. These neuronal alterations correlate with activation of SEMA5, EPHA and NECTIN signaling pathways, which are important regulators of synaptic plasticity.
Conclusions: Our findings indicate that slight elevations in Aβ concentrations are sufficient to elicit transcriptional changes in human neurons with long lasting consequences to neural network activity.

CORTICAL REGION CONFERS NEURON-TYPE-SPECIFIC VULNERABILITY TO HUMAN APP EXPRESSION

POSTERS: A01.O. DISEASE MECHANISMS, PATHOPHYSIOLOGY: NEURAL NETWORKS, PLASTICITY

Annie Goettemoeller, Matthew Rowan
Emory University School of Medicine, Cell Biology, Atlanta, United States of America

Aims: Preventative treatment for Alzheimer's Disease is of dire importance, and yet, cellular mechanisms underlying early regional vulnerability in Alzheimer's Disease remain unknown. In human patients with Alzheimer's Disease, one of the earliest observed pathophysiological correlates to cognitive decline is hyperexcitability. In mouse models, early hyperexcitability has been shown in the entorhinal cortex, the first cortical region impacted by Alzheimer's Disease. The origin of hyperexcitability in early-stage disease and why it preferentially emerges in specific regions is unclear.
Methods: Using cortical-region and cell-type- specific proteomics and patch-clamp electrophysiology, we uncovered differential susceptibility to human-specific amyloid precursor protein (hAPP) in a model of sporadic Alzheimer's.
Results: Unexpectedly, our findings reveal that early entorhinal hyperexcitability may result from intrinsic vulnerability of parvalbumin interneurons, rather than the suspected layer II excitatory neurons. This vulnerability of entorhinal PV interneurons is specific to hAPP, as it could not be recapitulated with increased murine APP expression. Furthermore, the Somatosensory Cortex showed no such vulnerability to adult-onset hAPP expression, likely resulting from PV-interneuron variability between the two regions based on physiological and proteomic evaluations. Interestingly, entorhinal hAPP-induced hyperexcitability was quelled by co-expression of human Tau, at the expense of increased pathological tau species.
Conclusions: This study suggests early disease interventions targeting non-excitatory cell types may protect regions with early vulnerability to pathological symptoms of Alzheimer's Disease and downstream cognitive decline.

DIVERSITY OF CA1 PYRAMIDAL PLASTICITY MODULATED BY FAST-SPIKING PV INTERNEURONS IN AN AD MOUSE MODEL

POSTERS: A01.O. DISEASE MECHANISMS, PATHOPHYSIOLOGY: NEURAL NETWORKS, PLASTICITY

Yan Zheng[1], Lijuan Li[1], Hanning Hu[1], Zizheng Chen[1], Jianliang Zhang[2]

Aims: Alzheimer's disease (AD) is a refractory disease with complex pathogenesis. The synaptic degeneration and decline in plasticity in the hippocampal circuit play a central role in AD. Previous studies have elucidated the role of hippocampal long-projecting circuits in the AD brain. Nevertheless, how the hippocampal microcircuits are involved in the AD process is unclear. The known pieces of evidence revealed that the fast-spiking parvalbumin (PV) positive basket interneurons (PVBCs) connect the adjacent deep CA1 pyramidal neurons (deep CA1PNs) and superficial CA1 pyramidal neurons (superficial CA1PNs) to form a recurrent inhibitory microcircuit relevant to learning and memory. This study examined how PVBCs regulate CA1 plasticity in an AD mouse model, considering neuronal heterogeneity in the CA1 microcircuit.
Methods: We conducted whole-cell recording on acute hippocampal slices to study individual long-term potentiation (LTP) in CA1 of 5xFAD mice. To evaluate and manipulate hippocampal functions in the AD mouse model, we employed Contextual Fear Conditioning, pharmacology, and optogenetics.
Results: We found that the LTP of superficial CA1PNs was selectively impaired, while deep CA1PNs remained normal in 5xFAD mice at six months, compared to their wild-type littermates. The CA1 PVBCs functioning as filters at higher frequencies were damaged in the 5xFAD mouse brain. In addition, the amplitude of NMDAR-EPSCs in PVBCs was enhanced in the mouse model brain. Intriguingly, the administration of memantine in acute hippocampal slices rescued the diminished LTP in superficial CA1PNs of 5xFAD mice compared to wild-type mice.
Conclusions: We suggest that PVBCs in CA1 are vulnerable to AD-like environments, leading to distinct changes in pyramidal LTP. This may lead to a promising approach of combining NMDAR inhibition and non-invasive electrophysiological modulation for AD.

CHANGES IN PLASMA SMALL RNA TRANSCRIPTOME CAN BE DETECTED UP TO 12 YEARS PRIOR TO AD SYMPTOM ONSET

POSTERS: A01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TRANSCRIPTIONAL & TRANSLATIONAL REGULATION, MICRO RNAS

Aleksandra Beric[1], Charissa Martin[1], Santiago Sanchez[1], Patricia Baldrich[2], Laura Ibanez[1]
[1]Washington University School of Medicine, Psychiatry, Saint Louis, United States of America, [2]The Donald Danforth Plant Science Center, Na, Saint Louis, United States of America

Aims: MicroRNAs (miRNAs) are known to be involved in Alzheimer's disease (AD), but little is known about the other classes of small RNAs (sRNAs) or their potential as early biomarkers. We performed the first comprehensive study of sRNAs in plasma of pre-symptomatic AD participants.
Methods: Sampling included 88 plasma samples from the Knight-ADRC cohort, 51% of which were pre-symptomatic AD participants, 58% female, and with a mean age of 78. After RNA extraction with a Maxwell RSC instrument, we generated sRNA libraries using the RealSeq®-AC sRNA kit version 2. Libraries were aligned to the reference genome and known small RNAs using Bowtie2. After stringent quality control we performed differential expression analyses using DESeq2. We integrated the sRNA data with RNA-seq data from the same samples to test whether any of the dysregulated sRNAs significantly correlate with known AD-genes.
Results: We identified six miRNAs (eg. miR-15b-5p and miR-505-5p) and 244 Piwi-interacting RNAs (piRNAs) that were significantly dysregulated in plasma of pre-symptomatic AD participants. Further, we identified dysregulated sRNAs that significantly correlate with AD associated loci identified by Bellenguez *et al*. HLA-DQA1 correlated positively to miR-15b-5p, miR-505-5p and miR-619, but associated with piR-409995 in the opposite direction. Additionally, we identified significant relationships between eight more piRNAs, and five other AD-related genes.
Conclusions: Our findings emphasize the importance of non-coding RNAs in AD. We showed that sRNAs beyond miRNAs are dysregulated in early stages of AD. Large-scale studies of sRNAs in plasma might be crucial to develop new, more easily accessible, screening tools for AD. Here, we described that several plasma sRNAs correlate with known AD genes up to 12 years prior to disease onset, and thus potentially capture the pathological processes happening in the brain.

TRANSCRIPTOMIC ANALYSIS OF THE PRESENILIN-1 G206A VARIANT IN ALZHEIMER DISEASE INDIVIDUALS FROM PUERTO RICO

POSTERS: A01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TRANSCRIPTIONAL & TRANSLATIONAL REGULATION, MICRO RNAS

Katrina Celis[1], Farid Rajabli[1], Anthony Griswold[2], Larry Adams[1], Kara Hamilton-Nelson[1], Kyle Scott[1], Patrice Whitehead[1], Pedro Mena[1], Jose Sanchez[1], Heriberto Acosta[1], Gary Beecham[1], Briseida Feliciano-Astacio[1], Michael Cuccaro[1], Jeffery Vance[1], Derek Dykxhoorn[1], Juan Young[1], Margaret Pericak-Vance[1]
[1]University of Miami Miller School of Medicine, John P. Hussman Institute For Human Genomics, Miami, United States of America, [2]University of Miami, John P. Hussman Institute For Human Genomics, Miami, United States of America

Aims: The variant G206A in the Presenilin-1 (*PSEN1*) gene has been identified almost exclusively in Alzheimer Disease (AD) Puerto Rican families. The G206A variant is associated with extreme variability in age of onset (AOO), ranging from 30 to 90 years, while other variations at the same amino acid of *PSEN1* have a tighter range of AOO (30-35 years). We aim to identify the molecular mechanisms involved in the age of onset (AOO) variability between *PSEN1* G206A mutation carriers through transcriptomic analysis from whole blood, brains and induced pluripotent stem cells (iPSCs).
Methods: We identified G206A carrying brains from the National Alzheimer Coordinating Center and AD Rapid Decline study. These brains will undergo Single Nucleus RNA sequencing (snRNA-seq) using 10X Chromium platform and will be analyzed using Seurat. iPSC of G206A carriers with different AOO were reprogrammed using non-integrating Sendai virus. RNA was extracted from whole blood and iPSC from G206A carriers and sequenced at 40 million reads/sample using the Illumina Novaseq 6000.
Results: We identified 43 carriers (39 AD and 4 cognitively unimpaired) as part of PRADI. A single African haplotype was identified in all carriers.To perform snRNAseq, we selected six autopsy brains from G206A carriers. Six iPSC line were reprogrammed successfully, all lines were screened using G-band Karyotype, factor loss analyses, genetic finger printing, immunocytochemistry and pluripotency markers. For bulk RNA sequencing, we included six iPSC lines (three with early and three with late AOO) and 28 samples from whole. Transcriptomic results are in progress.
Conclusions: The G206A variant, a founder effect in the Puerto Rican population, exhibits variable AOO. We propose to utilize these unique resources to identify the transcriptomic profile associated with AOO variability. Identification of transcriptome modifiers in G206A carriers could allow us to discover therapeutic targets.

TARGETING CIRCADIAN DYSFUNCTION TO AMELIORATE PATHOLOGY AND COGNITION IN MOUSE MODELS OF ALZHEIMER'S DISEASE.

POSTERS: A01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TRANSCRIPTIONAL & TRANSLATIONAL REGULATION, MICRO RNAS

Daniel Whittaker[1], Daniel Carlin[1], Haylie Romero[1], Laila Akhmetova[1], David Welsh[2], Christopher Colwell[1], Paula Desplats[3]
[1]University of California Los Angeles, Neurosciences, Los Angeles, United States of America, [2]University of California San Diego, Psychiatry, La Jolla, United States of America, [3]University of California San Diego, Neurosciences, La Jolla, United States of America

Aims: Circadian disruptions impact nearly all patients with Alzheimer's disease (AD), who suffer reversal of sleep/wake cycles and evening agitation. Emerging evidence indicates that these alterations occur early in disease and aggravate pathology, thus supporting a causal role for circadian dysfunction in AD, and emphasizing a critical need to investigate the therapeutic potential of circadian-modulating interventions.
Methods: We applied multi-omic profiling to evaluate epigenomic and transcriptomic changes associated with circadian regulation in the brain of APP23 Tg and non-transgenic mice. We tested a circadian and metabolic intervention consistent on time-restricted access to food (TRF) with a 6 h feeding/18 h fasting regimen, without caloric restriction, and with feeding aligned to the active period. We evaluated cage activity, sleep, transcription, pathology and cognition in comparison to mice with *ad libitum* access to food.
Results: We identified progressive circadian disruptions in the APP23 TG mice, including excessive wakefulness, altered behavioral circadian rhythms, and severe deregulation of rhythmic expression of many genes associated with AD pathology and neuroinflammation. TRF improved diurnal locomotor activity patterns and behavioral circadian rhythms and increased total sleep. TRF also normalized the transcription of genes associated with AD, neuroinflammation, lipid processing, and autophagy in the hippocampus of APP23 TG mice. Critically, TRF had a major impact on neuropathology, reducing plaque burden, amyloid deposition, and improving memory in treated mice.
Conclusions: We demonstrated the efficacy of a circadian intervention based on time-restricting feeding in rescuing pathology and behavior in two mouse models of AD. Our study unveils for the first time the pleiotropic nature of timed feeding on AD. Since TRF can substantially modify disease trajectory, this intervention has immediate translational potential for AD patients, as an accessible approach to halt disease progression.

Aims: Alzheimer's disease (AD) is the most prevalent form of dementia. A decline in the expression of the redox-dependent transcription factor Nrf2 is observed in AD brains. Although Nrf2 activation is a promising therapeutic strategy, the current Nrf2 activators suffer from side effects and tolerability issues in patients. BTB and CNC homology 1 (Bach1) is a known transcriptional repressor of the Nrf2 pathway and is elevated in human AD brains and APP/PS1 mouse model of AD. It suggests that Bach1 inhibition might be neuroprotective in AD. The present study aims to validate if genetic deletion of Bach1 and pharmacological inhibition by a newly identified non-electrophilic molecule (HPPE) attenuates AD-like neuropathology in the APP/PS1 mouse model.
Methods: APP/PS1 mice were crossed with Bach1$^{-/-}$ mice to generate Bach1 ablated APP/PS1 mice. Cohorts of post-symptomatic APP/PS1 mice were administered with HPPE for 45 days (20 mg/kg twice a day, 12 h apart). Cognitive performance of mice was evaluated by Barnes maze and novel object recognition tests. Amyloid pathology and microglial activation were monitored by immunohistochemical analyses. The Bach1-regulated pathways were identified by sn-RNA-seq analysis.
Results: Deletion of Bach1 in APP/PS1 mice attenuated cognitive impairment, Abeta plaque formation and microglial activation in the hippocampus. Accordingly, HPPE treatment significantly inhibited amyloid pathology and cognitive dysfunction in the APP/PS1 mice. Single nuclei- functional genomics analysis demonstrated that the neuroprotective effects of Bach1 inhibition in APP/PS1 mice was due to upregulation of genes involved in oxidative phosphorylation in neurons and downregulation of pro-inflammatory genes in oligodendrocytes, astrocytes and microglia.
Conclusions: Present findings suggest that genetic deletion and pharmacologic inhibition of Bach1 attenuates progression of AD-like pathology and that Bach1 inhibition is a promising therapeutic approach.

Aims: Integrative network and machine learning analysis of microRNA (miRNA) can provide insights into Alzheimer's dementia (AD) pathology and prognostic/diagnostic biomarkers.
Methods: We performed co-expression network analysis to identify network modules associated with AD, neuropathology markers, and cognition using brain tissue miRNA profiles from the Religious Orders Study and Rush Memory and Aging Project (ROS/MAP) (N=702) as a discovery dataset. We performed association analysis of hub miRNAs with AD, neuropathology markers, and cognition. For replication, we performed a consensus miRNA co-expression network analysis using the ROS/MAP dataset and an independent dataset (N=16) from the Gene Expression Omnibus (GEO). Furthermore, we performed a machine learning approach to assess the performance of hub miRNAs for AD classification.
Results: Network analysis identified a glucose metabolism pathway-enriched module (M3) as significantly associated with AD and cognition. Five hub miRNAs (miR-129-5p, miR-433, miR-1260, miR-200a, and miR-221) of M3 had significant associations with AD clinical and/or pathologic traits, with miR129-5p by far the strongest across all phenotypes. Consensus network analysis identified two AD-associated consensus network modules, and two hub miRNAs (miR-129-5p and miR-221). Machine learning analysis showed that the AD classification performance (area under the curve (AUC)=0.807) of age, sex, and *apoE* ε4 carrier status was significantly improved by 6.3% with inclusion of five AD-associated hub miRNAs.
Conclusions: Integrative network and machine learning analysis identified miRNA signatures, especially miR-129-5p, as associated with AD, neuropathology markers, and cognition, enhancing our understanding of Alzheimer's disease pathogenesis and leading to better performance of AD classification as potential diagnostic/prognostic biomarkers.

MIRNA EXPRESSION DYSREGULATION IN SYNAPSES OF ALZHEIMER'S DISEASE BRAIN TISSUE

POSTERS: A01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TRANSCRIPTIONAL & TRANSLATIONAL REGULATION, MICRO RNAS

Laia Lidón[1], Raúl Núñez[2], Danna Perlaza[1], Alba Cervantes[1], Natalia Valle[1], Sara Serrano[1], Érika Sánchez-Aced[1], Sònia Sirisi[1], Maria Florencia Iulita[1], Oriol Dols[1], Alberto Lleó[1], Rocío Pérez[3], Olivia Belbin[1]

Aims: Knowing that synapse loss is the major neuropathologic correlate of cognitive impairment in Alzheimer's disease (AD) and that microRNA (miRNA) play an important role in the regulation of synaptic plasticity, our objective was to study the expression of synapse-specific miRNA in AD post-mortem brain tissue.
Methods: We obtained synaptosomes (SYN) and homogenates (H) from temporal cortex from 10 AD (mean age=77.4±4.2) and 10 healthy controls (CN; mean age=72.3±5.9). We extracted and quantified miRNA using the mirVana™ and TaqMan® Advanced miRNA Assay. We performed linear regression to identify differentially expressed miRNA across groups, considering fold changes <0.8 or >1.2 (adj.p<0.05) in AD vs CN. We searched two predictive databases (TargetScan and miRDB) for gene targets of the DE miRNA and performed pathway analysis using the Panther database (PantherDB.org).
Results: We detected 411 miRNA in H and 432 in SYN of the total 751 included on the Openarray. To study the synapse-enriched miRNA, we took forward the 47 miRNA with >1.2-foldchange (adj.p<0.2) in SYN compared to H in either AD or CN. We found that miR-132-3p and miR-132-5p were under-expressed (0.17-fold, p=0.001 and 0.35-fold, p=0.006, respectively) and miR-181a-3p was over-expressed (2.13-fold, p=0.04) in AD vs CN. The gene targets of miR-181a-3p (594), miR-132-3p (474) and miR-132-5p (1230) were overrepresented in pathways regulating synaptic and mitochondrial function. Targets of miR-132 also were overrepresented in pathways related to tau pathology, Aβ production, interleukin production, apoptosis and oxidative stress.
Conclusions: We identified 3 synapse-specific miRNA that are differentially expressed at synapses of AD temporal cortex. Their target genes are involved in pathways related to AD pathogenesis. Future studies will focus on the validation of these miRNA in other brain areas and the potential of these miRNA as therapeutic targets.

EFFECTS OF DNMT3A OVEREXPRESSION/KNOCKDOWN ON SYNAPTIC TRANSMISSION IN THE 5XFAD MODEL OF ALZHEIMER'S DISEASE

POSTERS: A01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TRANSCRIPTIONAL & TRANSLATIONAL REGULATION, MICRO RNAS

Yanzhi Liu[1], Chi Him Poon[1], Charlotte So[1], Benjamin Chun-Kit Tong[2], King-Ho Cheung[2], Harry Steinbusch[3], Lee Wei Lim[1]
[1]The University of Hong Kong, School Of Biomedical Sciences, Pok Fu Lam, Hong Kong PRC, [2]Hong Kong Baptist University, School Of Chinese Medicine, Kowloon City, Hong Kong PRC, [3]Maastricht University, Department Of Neuroscience, Maastricht, Netherlands

Aims: Growing evidence suggests that dysregulations in DNA methylation contribute to the pathogenesis of AD. In this study, we aim to investigate the effects of overexpressing/knockdown DNA methyltransferase 3A (DNMT3A) in the hippocampus of both wildtype mice and the 5xFAD mouse model of AD. The effects of DNMT3A manipulation on the memory performances, CA3-CA1 synaptic transmission and serotonergic neurotransmission are investigated.
Methods: rAAV containing either an overexpression vector or shRNA were used to overexpress/knockdown DNMT3A. Mice (male, 4-6 mo) received bilateral infusion of the virus into the dorsal hippocampus. Behavioral tests (Y-Maze, Morris Water Maze, Open Field and Light Dark Box) were conducted starting from 43 days post-surgery. On day 52, mice were sacrificed, and their brains were harvested for either field electrophysiology or molecular analysis. For field electrophysiology, long-term potentiation and paired pulse facilitation/inhibition were tested on the CA3-CA1 synapse. 5HT fibre density in the hippocampus were assessed by immunohistochemistry. Transcript levels of DNA methylation regulators and 5HT receptors were assessed by RT-qPCR.
Results: 5xFAD mice showed memory impairments in Morris Water Maze test (MWM) compared to WT mice. DNMT3A overexpression and knockdown both led to memory impairments in wildtype (WT) and 5xFAD mice in MWM. 5xFAD mice displayed synaptic hyperexcitability as assessed by field electrophysiology, which was normalized by DNMT3A overexpression. DNMT3A overexpression and knockdown led to differential changes in the expression of DNA methylation regulators, 5HT fiber density and 5HT receptor expression in the hippocampus.
Conclusions: Normal physiological level of DNMT3A is crucial for memory functions in WT and 5xFAD mice. Perturbances in DNMT3A expression led to memory impairments and changes in synaptic excitability, 5HT fiber density and widespread changes in the DNA methylation regulators expression in the hippocampus.

INTEROGATING DNA METHYLATION IN LEWY BODY DEMENTIA IN A CROSS BRAIN-REGION AND MULTI-COHORT STUDY

POSTERS: A01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TRANSCRIPTIONAL & TRANSLATIONAL REGULATION, MICRO RNAS

Katie Lunnon[1], Joshua Harvey[1], Jennifer Imm[1], Byron Creese[1], Leonidas Chouliaras[2], Emma Dempster[1], Clive Ballard[1], John O'Brien[2], Dag Aarsland[3], Jonathan Mill[1], Lasse Pihlstrøm[4], Ehsan Pishva[1,5]

Aims: The Lewy body dementias are a class of neurodegenerative diseases classified by the accumulation of alpha-synuclein in neurons, forming Lewy bodies (LB). We hypothesize that the development of LB pathology is associated with epigenetic changes, as measured by DNA methylation within the brains of patients with Parkinson's disease and Dementia with Lewy bodies.
Methods: In our discovery cohort we profiled 921 DNA samples from the anterior cingulate gyrus and prefrontal cortex of 474 unique donors on the Illumina EPIC array, generating a quantitative measure of DNA methylation for over 850,000 CpG sites. A mixed model was used to identify loci significantly associated with neuropathology as measured by Braak LB staging, controlling for confounding demographic, processing and neuropathological variables. We then meta-analyzed the findings from this cohort with an independent published cohort of 322 frontal cortex samples.
Results: In a cross cortical mixed model analysis in our discovery cohort we found one Bonferroni-corrected significant differentially methylated position (cg13847853, $p = 3.41 \times 10^{-8}$) and a further nine that passed our suggestive association threshold, the second most significant residing within the *PTPRN2* gene (cg10257673, $p = 8.88 \times 10^{-7}$). Our meta-analysis combining a second independent cohort identified nine significant loci after correcting for multiple testing.
Conclusions: We have interrogated the epigenetic basis of neuropathological progression in Lewy body dementia and found a number of associated loci in both our cross-cortex discovery analysis, and meta-analysis. One of the most associated loci resided in the *PTPRN2* gene. *PTPRN2,* which has been has been previously implicated in a number of independent DNA methylation studies of PD, including in blood (Chuang, et al., 2019), brain tissue (Young, et al., 2019) and cortical neurons (Kochmanski, et al., 2021).

SPATIALLY-RESOLVED TRANSCRIPTIONAL CHANGES IN THE HIPPOCAMPUS OF AN AMYLOID MOUSE MODEL OF ALZHEIMER'S DISEASE

POSTERS: A01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TRANSCRIPTIONAL & TRANSLATIONAL REGULATION, MICRO RNAS

Katie Lunnon[1], Millie Sander[1], Ella Margetts-Smith[1], Adam Smith[1], Valentin Laroche[2], Ehsan Pishva[1,2], Jon Brown[1]
[1]University of Exeter, Department Of Biomedical And Clinical Sciences, Exeter, United Kingdom, [2]University of Maastricht, Department Of Psychiatry & Neurophysiology, Maastricht, Netherlands

Aims: A key pathological trait of Alzheimer's disease (AD) is the accumulation of amyloid plaques in the brain. J20 mice harbour mutations in the amyloid precursor protein gene known to be associated with familial AD. These mice exhibit AD-associated pathology and transcriptional changes in the hippocampus. Spatial transcriptomic technology presents a unique and novel opportunity to investigate spatially-resolved transcriptomic changes in tissue of interest. Here, we aimed to identify changes in gene expression, and associated functional pathways, throughout sub-regions of the J20 mouse hippocampus.
Methods: 10µm slices of fresh-frozen tissue were collected from the brains of both J20 and WT mice. All sample preparation, imaging and sequencing protocols were conducted following the 10x Genomics Visium guidelines. Spatial clusters were created based on gene expression profiles, and hippocampal clusters were subset for analysis. Cell deconvolution was conducted in order to assess cell-type composition of said clusters. Differential expression analysis and network analysis were conducted using Seurat and hdWGCNA respectfully. Pathway enrichment analysis was conducted in order to associate said changes with functional outcomes.
Results: Six clusters were found to correspond with known sub-regions of the hippocampus, and were conserved between samples. Cluster-specific differentially expressed genes (DEGs) were identified between J20 and WT mice. Five hdWGCNA models were identified, which exhibited spatially-defined co-expression signatures. Three of these modules were significantly differentially expressed between J20 and WT mice. Both DEGs and significant hdWGCNA modules were found to correspond with distinct biological pathways.
Conclusions: The hippocampus of J20 mice exhibit region-specific transcriptomic changes. Biological pathways associated with these changes provide insight as to the functional and pathological changes occuring throughout the hippocampus during AD.

Hussman Institute For Human Genomics, Miami, United States of America

Aims: This study aimed to establish ancestry-dependent differences in the genomic regulatory architecture (GRA) of oligodendrocytes in the context of Alzheimer's disease (AD) using induced pluripotent stem cell (iPSC)-derived neural spheroids with African, Amerindian, and European ancestral backgrounds. The objective was to provide ancestry-specific insights into the chromatin structure and gene regulation of oligodendrocytes and expand functional resources for gene identification studies in African American and Hispanic/Latino populations.
Methods: iPSCs were derived from individuals with AD or without cognitive impairment, with >85% global ancestry of each ancestral background. The iPSCs were differentiated into oligodendrocyte (OL) enriched neural spheroids using a protocol promoting oligodendroglia development. Multiomic profiling was performed on day 76 of differentiation, involving analysis of chromatin accessibility and transcriptome through Single Cell ATAC and Single Cell RNA-seq techniques. Chromatin interactions were investigated using Hi-C analyses.
Results: Various stages of OL lineage cells were identified, ranging from cycling progenitors and OL precursor cells to fully mature myelinating OLs. Comparisons across ancestries, considering AD cases and controls as well as APOE genotypes, revealed ancestry-dependent differential gene expression in several oligodendroglia clusters, including AD GWAS hits such as *SORL1*, *PLCG2*, and *JAZF1*. Ongoing analyses of other oligodendroglia clusters, astrocytes, and neurons are underway.
Conclusions: This study provides ancestry-specific insights into the chromatin structure and gene regulation of oligodendrocytes in the context of AD. The findings contribute to our understanding of this previously overlooked cell lineage and expand the available functional resources for gene identification studies in African American and Hispanic/Latino populations. The comprehensive characterization of GRA in oligodendrocytes enhances our ability to interpret the variability associated with AD risk genes across populations and supports the development of personalized approaches for AD diagnosis and treatment.

MIR-425-5P AS POTENTIAL GENE REGULATOR FOR IMMUNOLOGICAL PROCESSES IN BRAIN WHITE MATTER LESIONS

POSTERS: A01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TRANSCRIPTIONAL & TRANSLATIONAL REGULATION, MICRO RNAS

Sandra Van Der Auwera, Sabine Ameling, Katharina Wittfeld, Stefan Frenzel, Robin Bülow, Matthias Nauck, Henry Völzke, Uwe Völker, Hans Grabe
University Medicine Greifswald, Department Of Psychiatry And Psychotherapy, Greifswald, Germany

Aims: White matter lesions (WML) emerge as a consequence of vascular injuries in the brain reflecting ischemic damage. While they are commonly observed in the aging brain, associations have been established with both neurodegenerative and neurological disorders such as dementia or stroke. Despite substantial efforts, biomarkers indicating WMLs are still lacking.
Methods: Leveraging data from the general population Study of Health in Pomerania (SHIP), our objective was to identify circulating micro-RNAs (miRNAs) associated with WMLs, thus providing a foundation for a comprehensive biological model. Different regression models as well as extensive biobank search and the usage of bioinformatic tools were used to disentangle the role of miRNAs on WML and elucidate the possible biological pathways.
Results: In 647 individuals we identified *hsa*-miR-425-5p as a key miRNA regulating various genes associated with WML, Alzheimer's Disease, and stroke, with particular emphasis on the *SH3PXD2A* gene. Furthermore, miR-425-5p was found to exert effects on immunological processes based on both human and mouse data. Through interaction analyses, additional noteworthy miRNAs associated with WMLs were identified, primarily moderated by factors such as sex or smoking status. All identified miRNAs exhibited a strong over-representation in neurodegenerative and neurological diseases, as well as pathways related to brain signaling and longevity.
Conclusions: In conclusion, we introduced *hsa*-miR-425-5p as a promising key regulator, implicating its involvement in immunological pathways. Mir-425-5p holds the potential to serve as an early indicator of WMLs shedding light on potential mechanisms and pathways to vascular dementia.

DEFICIENCY OF MIR-223-3P RESULTS IN SEX-BIASED ELEVATION OF CLASS II MAJOR HISTOCOMPATIBILITY COMPLEX AND INFLAMMATORY GENES IN MICROGLIA

POSTERS: A01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TRANSCRIPTIONAL & TRANSLATIONAL REGULATION, MICRO RNAS

Wang-Xia Wang[1,2], Paresh Prajapati[2], Urim Geleta[2]
[1]University of Kentucky, Spinal Cord And Brain Injury Research Center, Lexington, United States of America, [2]University of Kentucky, Sanders-brown Center On Aging, Lexington, United States of America

Aims: Class II major histocompatibility complex (MHC II) molecules are constitutively expressed on antigen presenting cells, including microglia. Aberrant class MHC II expression has been linked to various diseases and pathological conditions such as Alzheimer's Disease (AD) and Parkinson's disease (PD). MicroRNAs (miRNAs) play a key role in regulation of many biological and pathological events including immunity and inflammation. MiR-223-3p is an X-chromosome resided miRNA and its expression enriched in macrophages/microglia. However, the role of miR-223-3p in immunity and neuroinflammation in the context of neurodegenerative diseases is unknown. The objectives of the current study are to understand the regulatory role of miR-223-3p in immune and inflammatory response in microglia.
Methods: MiR-223-3p knockout (KO) and genetic background matched wildtype (WT), female and male mice were used in the studies. Microglia were isolated from the brain tissues of 3-week-old pups using a procedure that included density gradient centrifugation and further selection using the EasySep™ Mouse CD11b Positive Selection Kit. The isolated microglia were then cultured in Microglia culture media for 2 weeks before subject to treatments with interferon gamma and lipopolysaccharide. Following 12 hours incubation, microglia were then harvested, and RNAs were isolated for RT-qPCR quantification of MHC II genes and inflammatory markers.
Results: Our data demonstrated that deficiency of miR-223-3p resulted in elevation of MHC II master transactivator *CII2A*, MHC II (*H2-Aa, H2-Eb1*), and inflammatory (*NLRP3, CTSE, CD86, TNFα*, and *CCL17)* genes in both female and male miR-223-3p KO microglia. Moreover, the elevation of these genes was significantly more pronounced in female relative to male KO microglia.
Conclusions: The current study indicated that miR-223-3p regulates sex-biased expression of MHC II and inflammatory genes, which may contribute to the sexual dimorphic phenomenon observed in neurodegenerative diseases.

EFFECTS OF A NOVEL NOTCH-SPARING PRESENILIN 1 MUTATION ON NEURONAL CELL DEATH

POSTERS: A01.Q. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AUTOPHAGY, APOPTOSIS, CELL DEATH

Isabel Bestard-Lorigados[1], Qinxin Zhu[2], Keenan Sterling[1], Fang Cai[2], Weihong Song[1,2]
[1]University of British Columbia, Psychiatry, Vancouver, Canada, [2]Wenzhou Medical University, Institute Of Aging, Wenzhou, China

Aims: Presenilin 1 (PS1) mutations are the primary cause of familial Alzheimer's disease (AD). These pathogenic mutations increase beta-amyloid levels while inhibiting Notch cleavage and signalling. Recently, our lab identified a unique mutation, called $PS1_{\Delta S169}$, that unlike other PS1 mutations, does not affect Notch signalling, making it an ideal therapeutic target. This study aims to investigate the mechanisms underlying $PS1_{\Delta S169}$'s effect on AD pathogenesis, particularly on neuronal cell death, using *in vitro* and *in vivo* models.
Methods: To examine these effects on neuronal cell death, PS1 plasmids corresponding to the PS1 wild-type (control) and five AD-related PS1 mutations, including the Notch-sparing $PS1_{\Delta S169}$, were transfected into a PS1-knockout neuro2A cell line called N2A-KO cells; thus, corresponding to six experimental groups. The *in vivo* study included three experimental groups corresponding to two knockin mouse models with two different PS1 mutations, including $PS1_{\Delta S169}$, compared to the wild-type control. Various molecular techniques were performed to determine how each PS1 mutation affects cell viability and neurotoxicity, including Western Blots for protein expression, and cell death assays.
Results: Overall, our findings indicate that these pathogenic PS1 mutations significantly decreased cell viability in N2A-KO cells, except in the MTS assay for $PS1_{\Delta S169}$. Furthermore, using N2A-KO cells, we found that the pathogenic PS1 mutations differentially affected cell death markers related to pyroptosis, apoptosis and autophagy. Similarly, synaptic markers were affected in our PS1 knockin models.
Conclusions: Our findings provide novel insights into the pathological effects of the PS1 mutations on different cell death pathways, and these results offer a foundation to further define how the Notch-sparing PS1 mutation affects neurotoxicity and neuronal death as part of the AD pathogenesis process.

LIPID PEROXIDATION ELICITS DIVERGENT INFLAMMATORY RESPONSE PATHWAYS BETWEEN HUMAN NEURONS AND ASTROCYTES

POSTERS: A01.Q. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AUTOPHAGY, APOPTOSIS, CELL DEATH

Elizabeth Calzada[1], Kaitlyn Demeulenaere[1], Pamela Tapia[2], Brenton Laing[2], Eulim Kang[1], Yeka Aponte[2], Christopher Ramsden[1]
[1]National Institute on Aging, Lipid Peroxidation Unit, Laboratory Of Clinical Investigation, Baltimore, United States of America, [2]National Institute on Drug Abuse, Intramural Research Program, Baltimore, United States of America

Aims: Cellular exposure to lipid peroxidation products and reactive aldehydes such as acrolein and crotonaldehyde modifies lipids, proteins, and nucleic acids through chain reactions of free radical propagation and/or biomolecular modification of susceptible chemical groups. Lipid peroxidation, reactive lipid aldehydes, and protein carbonylation have been implicated in Alzheimer's disease pathogenesis; however, whether these by-products drive or are a result of neurodegeneration is unclear. Here, we compared biochemical signaling pathways to aldehyde exposure between human astrocytes and iPSC-derived neurons to evaluate response pathways between cell populations associated with disease pathology.
Methods: Human induced pluripotent stem cells were differentiated to cortical neurons. After neural maturation, cells were exposed to aldehydic products of lipid peroxidation, acrolein and crotonaldehyde, and chemicals known to stimulate lipid peroxidation, cumene hydroperoxide and RSL3, to evaluate cytotoxicity and the molecular effects of these toxins in culture. Parallel experiments were conducted in human post-mortem astrocytes as a comparison. Western blot analysis was used to quantitate expression of proteins involved in cell survival, death, and inflammatory response pathways.
Results: Notably, pre-differentiated neural stem cells were highly sensitive to aldehyde-induced cell death with an approximate median lethal dose of 12.5μM in acrolein and 100μM in crotonaldehyde while differentiated neurons were more resistant to crotonaldehyde and acrolein toxicity (median lethal dose ~200μM and 100μM, respectively). In comparison, astrocyte cultures displayed a median lethal dose of 50μM in acrolein and 200μM in crotonaldehyde. Exposure of astrocytes to chemical agents that perpetuate lipid peroxidation damage consistently elicited an acute heme-oxygenase 1 protein overexpression that was not pronounced in neurons.
Conclusions: This sensitized antioxidant response in astrocytes highlights their reactivity to ameliorate lipid peroxidation damage in the brain and suggests that sustained exposures may prolong activation of anti-inflammatory signaling pathways.

Aims: The primary aim was to investigate the role of TRIM22 in autophagy regulation. We sought to understand how TRIM22 contributes to the autophagic process and whether it has implications for neurodegenerative diseases.
Methods: We examined the effect of TRIM22 on autophagosome-lysosome fusion and the clearance of protein aggregates. These experiments involved molecular and cellular techniques to uncover the underlying mechanisms.
Results: The research revealed a novel function of TRIM22 in autophagy regulation. We found that TRIM22 plays a pivotal role in promoting autophagosome-lysosome fusion by facilitating the association between GABARAP family proteins and PLEKHM1. This, in turn, enhances the autophagic clearance of protein aggregates. Importantly, this function is independent of TRIM22's E3 ubiquitin ligase activity.
Conclusions: The findings demonstrate that TRIM22 acts as a crucial regulator of autophagy, orchestrating the fusion of autophagosomes and lysosomes by serving as a scaffold for autophagy-related proteins. This discovery has significant implications for our understanding of autophagy and its relevance to TRIM22-associated early-onset familial Alzheimer's disease.

ELUCIDATING INTERACTIONS OF SLEEP LOSS AND PROTEOSTASIS FAILURE AS PREDICTORS OF COGNITIVE DECLINE IN ALZHEIMER'S DISEASE

POSTERS: A01.Q. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AUTOPHAGY, APOPTOSIS, CELL DEATH

Christopher Morrone[1], Darcy Wear[1,2], Arielle Tsang[1], Maria Akkawi[1,2], Wai Haung Yu[1,2,3]
[1]Centre for Addiction and Mental Health, Brain Health Imaging Centre, Toronto, Canada, [2]University of Toronto, Department Of Pharmacology And Toxicology, Toronto, Canada, [3]Centre for Addiction and Mental Health, Geriatric Mental Health Research Services,, Toronto, Canada

Aims: Proteostasis, including autophagy, and sleep are implicated in Alzheimer's disease (AD), especially in early disease stages. In light of recent evidence describing their linkage, our central aims are to interrogate the potential positive-feedback-loop between sleep loss and proteostasis impairment in AD, elucidating contributions to cognitive impairment, and to discern neuronal populations vulnerable to failed autophagy and rampant proteinopathy.
Methods: App^{NL-G-F}xMAPT double knock-in (dKI) mice were tested at 3 ages (4-, 8-, 12-month) and compared to MAPT (no major pathology) single knock-ins. Mice were surgically implanted with EEG/EMG headcaps and tested for sleep and neuronal function, before and after sleep disruption. Spatial learning, memory and executive function were assessed in the Barnes maze. Brain tissue was collected for immunohistochemistry.
Results: Immunohistochemistry for β-amyloid (6F3D) and tau (PHF1) demonstrated progressive accumulations, with cortical plaque and neuritic tau from 4-months, moderate hippocampal pathology at 8-months and robust accumulation at 12-months. Neuronal integrity (NeuN) in hippocampus and entorhinal cortex is preserved until the 12-month stage at which dKI mice exhibit loss compared to MAPTs. Sleep impairment including circadian arrhythmicity and loss of rapid eye movement sleep begins at 4-months in dKI mice (compared to MAPTs), and progressively declines over age, more prominently in female mice. Memory and executive function impairments follow sleep loss, starting at 12-months and more prominently in males. Intervening to disrupt sleep increases proteinopathy and disrupts proteostasis (p62) in mouse hippocampus. Conversely, activating autophagy therapeutically with trehalose improves sleep and memory.
Conclusions: Understanding the linkage between sleep and proteostasis, and neuronal populations vulnerable to autophagy impairments, is valuable to predict cognitive decline especially considering sex differences in the behavioural phenotype. Future work can evaluate modulating these processes for AD treatment.

CEREBROSPINAL FLUID ENDOTHELIN LEVELS ARE ASSOCIATED WITH PROAPOPTOTIC IMBALANCE IN ALZHEIMER'S DISEASE.

POSTERS: A01.Q. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AUTOPHAGY, APOPTOSIS, CELL DEATH

Caterina Motta, Chiara Giuseppina Bonomi, Francesca Bernocchi, Alessandro Martorana
University of Rome Tor Vergata, Memory Clinic, Rome, Italy

Aims: Endothelin-1 (ET-1) is a potent vasoconstrictive peptide, primarily secreted by endothelial cells, and is involved in mechanism of neuronal cell death. Our objective was to explore the association between cerebrospinal fluid (CSF) levels of ET-1, core Alzheimer's disease (AD) biomarkers and molecules linked to proapoptotic and antiapoptotic pathways.
Methods: CSF samples of 68 patients belonging to the AD continuum (ADc) and 16 healthy subjects (A-T-) were analyzed: amyloid-β 42 (Aβ42), amyloid-β 40 (Aβ40), Aβ42/Aβ40 ratio (amyR), phosphorylated-tau (p-tau), total tau (t-tau), ET-1, BCL-2, BCL-X, p53. Statistical analyses were calculated for non-parametric comparisons, Pearson's correlations, and mediation analyses.
Results: CSF levels of ET-1 were slightly higher in ADc, although not significantly different respect to A-T-, and no difference was found in CSF levels of BCL-2, BCL-X and p53. Age-adjusted Pearson's analyses in ADc patients showed a significant and positive correlation between ET-1 and p53 (rho=0.40, $p<0.001$), a negative correlation between ET-1 and BCL-X (rho=-0.46, $p<0.001$) and no correlation between ET-1 and BCL-2. The correlation analyses also showed a slight positive correlation between ET-1 and amyR (rho=0.25, p=0.040), as well as between amyR and p53 (rho=0.024, p=0.035). The mediation analysis confirmed a significant total effect of amyR on p53 (p=0.009) not mediated by ET-1 (ACME p=0.131), and a significant total effect of ET-1 on p53 (p=0.004) not mediated by amyR (ACME p=0.215).
Conclusions: We showed for the first time in AD patients that ET-1 CSF levels are associated to the activation of proapoptotic pathways and to the inactivation of antiapoptotic pathways. On the other hand ET-1 and p53 levels appear to be independently correlated with amyR, suggesting a possible compensatory role for amyloid peptides in restoring the apoptotic balance.

EVALUATING NEUROPROTECTIVE POTENTIAL OF BERGENIA LIGULATA AND NELUMBO NUCIFERA AGAINST ALUMINUM CHLORIDE-INDUCED NEUROTOXICITY IN RATS

POSTERS: A01.Q. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AUTOPHAGY, APOPTOSIS, CELL DEATH

Dr. Nilay Solanki, Yamini Patel
Ramanbhai Patel College of Pharmacy, Pharmacology, Changa, India

Aims: Neurodegenerative disorders are characterized by the accumulation of proteins with altered physicochemical characteristics in the brain and surrounding tissues, as well as the gradual loss of neurons. Neurotoxicity occurs when exposure to dangerous chemicals alters the nervous system's normal activities. This may eventually cause disruption or even the death of neurons, which are essential for sending and processing signals in the brain and other regions of the nervous system. Alzheimer's disease (AD) is a brain illness that gradually decreases one's capacity for remembering things, thinking, and doing even the most fundamental tasks. Our present research focused on the possible synergistic neuroprotective effects of Bergenia ligulata and Nelumbo nucifera in rats with neurotoxicity brought on by aluminum chloride.
Methods: The fourty six rats were separated into a number of groups. All groups got AlCl3, which caused neurotoxicity, with one exception. Then Nelumbo nucifera and Bergenia ligulata are supplied as a combined therapy. Numerous factors are assessed, including behavioral testing, AChE estimates, oxidative stress markers, and apoptotic markers.
Results: AChE was elevated by AlCl3 and then decreased throughout therapy. Additionally, it lowers the levels of GSH, SOD, and catalase while raising MDA levels. The opposite result of the therapy was a decrease in oxidative stress. AlCl3 also affects apoptosis by raising caspase-3 levels while decreasing Bcl-2 levels. By reducing caspase-3 levels and improving Bcl-2 levels, the therapy decreased apoptosis pathways.
Conclusions: This leads to the conclusion that Bergenia ligulata and Nelumbo nucifera combined therapy proved neuroprotective in AlCl3-induced neurotoxicity in rats by reducing AChE level, caspase-3 levels and improving Bcl-2 levels.

THE ASSOCIATION BETWEEN FRAILTY INDEX AND ALZHEIMER'S DISEASE BIOMARKERS.

POSTERS: A01.R. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AGING

Simona Buscarnera[1], Federica Ribaldi[2], Valentina Garibotto[2], Giovanni Frisoni[3]
[1]Università la Sapienza di Roma, Dipartimento Di Neuroscienze Umane, Roma, Italy, [2]Geneva Memory Center, Department Of Rehabilitation And Geriatrics, Geneve, Switzerland, [3]University Hospitals of Geneva, Memory Centre, Division Of Geriatrics And Rehabilitation, Geneva, Switzerland

Aims: Frailty has been associated with an increased risk of dementia. Frailty represents the overall organism's aging characteristics and it can be measured using Frailty index (FI). Alzheimer's disease (AD) is the primary cause of dementia. Its pathology could be assessed through in vivo biomarkers as β-amyloid (A) and phosphorylated tau (T). The aim of this study was to investigate the association between frailty and AD biomarkers in a Memory clinic population.
Methods: Data of 269 patients were collected from the Memory Center of the Geneva University Hospital, including individuals cognitively unimpaired, with mild cognitive impairment and dementia. A 36-items FI was developed. A and T positivity, assessed through PET amyloid and tau when available, or CSF ab42 and ptau if missing, was dichotomized and used as A+/A- or T+/T-. Pearson correlations was used to investigate the association between demographics and clinical features and FI. Mann-Whitney test was used to explore the difference of FI in A and T profiles.
Results: Participants had a mean age of 70 (SD 8.6) years, mean education of 14(SD 4) years, and 52% were women. We found a significant positive correlation between age ($r=0.25$, $p<0.001$), depression and anxiety ($r=0.17$, $p=0.008$) and FI, and a trend toward negative correlation between education and FI($r=-11$, $p=0.081$). FI was higher in subjects A- and T- compared to A+ and T+ separately ($p<0.01$).
Conclusions: The results show that FI increases with age in different populations. Cognitive resilience, assessed using education as a proxy, seems to decrease with high FI. FI is higher in people with low levels of brain AD pathology. Next steps include to assess the prognostic value of FI in persons with or without AD biomarkers positivity.

LATE SPLENIC B-CELL DYSREGULATION IN APP/PS1 MICE

POSTERS: A01.R. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AGING

Amit Fruitman, Karin Vardy, Sophie Shirenova, Ravit Madar, Eitan Okun
Bar-Ilan University, Life Sciences, Ramat-Gan, Israel

Aims: The role of adaptive immunity in Alzheimer's disease (AD) remains poorly understood. To date, most attention has addressed T cells, as the CSF and brain parenchyma of AD patients contain potentially harmful and clonally expanded CD8 T cells, especially around amyloid-b (Ab) related plaques. B cells, however, have thus far been thought of as beneficial in AD due to their involvement in humoral responses against Ab. The presence of B cells was recently shown to exacerbate the inflammatory state of disease-associated microglia (DAM). In addition, the presence of B cells or their immunoglobulins in the brain parenchyma is inversely associated with microglial TGF-b1 expression, which is detrimental, as microglial TGF-b1 signaling is critical for tissue homeostasis. Because of their importance in phagocytosis and inflammation suppression, and contrary to current understanding, we hypothesize that parenchymal B cells exacerbate the over-activated state of DAM, thereby promoting AD progression.
Methods: We have characterized age-associated alterations in B cell sub-sets in APP/PS1 mice, which model early onset AD by immuno-profiling sub-sets of B cells using spectral flow cytometry in the blood, spleen, and deep cervical lymph nodes (dcLNs), brain and meninges.
Results: While no significant differences were observed in 12m old APP/PS1 mice compared with WT mice, significant age-associated changes were observed in splenic B cells of 18m old APP/PS1 mice.
Conclusions: Since significant Ab-related pathology appears relatively early in these mice (4 months), these changes could appear relatively late in splenic B cell subsets as secondary to changes in CNS draining lymph nodes such as the dcLNs.

DNA DAMAGE AND NEURONAL SENESCENCE: DIFFERENTIAL VULNERABILITIES OF NEURONS IN DIFFERENT CORTICAL LAYERS

POSTERS: A01.R. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AGING

Gnanesh Gutta, Jiaan Xie, Eliana Brenner, Rody Kingston, Fulin Ma, Karl Herrup
University of Pittsburgh School of Medicine, Neurobiology, Pittsburgh, United States of America

Aims: The risk of Alzheimer's disease (AD) goes up with age as does the accumulation of unrepaired DNA damage. Increased genomic damage increases pressure to re-enter a cell cycle, which leads to expression of senescence markers. Our objective is to uncover how these events link to the pathogenesis of AD.
Methods: Immunohistochemistry for amyloid (6E10), DNA damage (53BP1,
Results: In unaffected human control samples, neurons with DNA damage increased in density with increasing distance from the pial surface. In AD, this pattern was overlaid with a substantial increase in DNA damage in the more superficial cortical layers. The distribution will be correlated with the location of amyloid plaques which varies from region to region. Senescence markers were common in both control and AD neurons, but their subcellular localization changed. For example, the p16 marker was nuclear in controls; in AD the staining shifted cytoplasmic but remained perinuclear. While the expression of senescence markers occurred in the absence of DNA damage, DNA damage was virtually always accompanied by expression of senescent markers.
Conclusions: There is a natural gradient of DNA damage in the aging cerebral cortex. The distribution of senescent markers was broader than expected and was most prominent in neurons with DNA damage. This correlation suggests that the two processes are related but in vitro studies will be required to rigorously determine if this reflects a causal pathway.

AMYLOID-BETA: LINKING ALZHEIMER'S PATHOGENESIS TO PERIPHERAL METABOLIC DYSFUNCTION

POSTERS: A01.R. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AGING

Ju-Hee Kang, Keren Mantik, Sujin Kim, Sohee Moon, Bonsang Gu
College of Medicine, Inha University, Pharmacology, Michuhol-gu, Korea, Republic of

Aims: Amyloid precursor protein is expressed both in the central nervous system and peripheral organs, including skeletal muscle and adipose tissues. While midlife obesity is associated with development of dementia, weight loss is linked to dementia severity and progression of Alzheimer's disease (AD). Moreover, AD is often accompanied by sarcopenia and/or cachexia. Nevertheless, the potential involvement of pathogenic amyloid-beta$_{1\text{-}42}$ (Aβ) in the dysfunction of metabolic organs remains unclear. In this study, we examined the effect of Aβ on myocyte and adipocyte dysfunction.
Methods: We treated C2C12 and 3T3-L1 cells with Aβ-oligomer (Aβo) to assess its impact on the metabolic function of peripheral tissues. Our evaluation encompassed effects of Aβo on cell differentiation, signaling pathways contributing to myogenesis/adipogenesis, muscle atrophy and lipolysis/lipogenesis, myokine/adipokine expression, and mitochondrial function. Additionally, in animal models, we measured Aβ concentration in skeletal muscle and white adipose tissue.
Results: Aβo inhibited the differentiation of C2C12 and downregulated the levels of myogenic transcriptional factors in C2C12 myotubes. Aβo-treated myoblasts induced cellular senescence, as measured by SA-β-gal staining. Specifically, Aβo-treated muscle cells displayed significant pathogenic changes, including mitochondrial dysfunction, apoptosis, and cellular senescence, which are common mechanisms observed in AD and sarcopenia. In differentiated 3T3-L1 adipocytes, Aβo reduced lipid accumulation, which was accompanied by upregulation of lipolysis signaling pathways. In addition, Aβo induced ER stress signaling, inflammatory adipokine expression, and disrupted autophagy progression.
Conclusions: Our results suggest that an increase in Aβ42 levels in peripheral organs as the AD progresses may accelerate sarcopenia/cachexia. Dysregulation of peripheral metabolic organs in advanced AD patient may lead to a "vicious cycle", wherein AD progresses more rapidly in sarcopenic/cachexic individuals.

IDENTIFICATION OF THE ENZYMATIC CLEAVAGE RELATIONSHIP BETWEEN ANTI-AGING PROTEIN A-KLOTHO AND ALZHEIMER'S DISEASE BIOMARKER BACE1

POSTERS: A01.R. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AGING

Xiang Gao, Zuoli Sun, Yuhong Li, Rena Li
Capital Medical University, Beijing Anding Hospital, Beijing, China

Aims: The anti-aging protein α-Klotho is known to be involved in longevity and various age-related diseases, including cognitive impairment. BACE1, an important enzyme associated with the pathological process of Alzheimer's disease (AD), serves as a biomarker for predicting changes in cognitive function. Although both proteins are closely linked to age-related cognitive function, the mechanism of their interaction remains unclear.
Methods: This study included elderly (n = 30, 65-80 years) and young (n = 45, 30-40 years) healthy adults. The cleavage product was identified using Coomassie blue staining, Western blot, and MALDI-TOF mass spectrometry. Plasma levels of α-Klotho and BACE1 were measured using ELISA.
Results: After the digestion reaction between BACE1 and α-Klotho, a new protein product was identified. BACE1 cleaved the α-Klotho peptide 951-981 at the F-T residues. When the FT residues in the peptide were replaced with KK, BACE1 was unable to cleave the mutant peptide. The plasma levels of soluble α-Klotho protein were significantly lower in elderly participants than in young participants ($P < 0.0001$). However, there was no significant difference in plasma BACE1 protein levels between elderly and young participants ($P = 0.164$). In elderly healthy adults, there was a significant positive correlation between plasma BACE1 protein level and α-Klotho protein level ($P = 0.009$, $r = 0.469$), while this correlation was not observed in young healthy adults ($P = 0.170$, $r = -0.208$).
Conclusions: Anti-aging proteinα-Klotho is the substrate of BACE1 with special cleavage site FT, BACE1/α-Klotho pathway may serve as a common axis for age-related cognitive decline.

PRESENILIN1ΔE9 MUTATION IN THE MOUSE: A MODEL OF EARLY COGNITIVE AGING?

POSTERS: A01.R. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AGING

Nathalie Macrez, Azza Sellami, Fanny Tixier, Aline Marighetto
Université de Bordeaux, Neurocentre Magendie - Inserm U1215, Bordeaux, France

Aims: While Presenilin1 (PSEN1) ΔE9 mutation produces early familial forms of Alzheimer's disease (AD), it does not produce AD phenotype in mice. However, co-expression of PSEN1ΔE9 mutation accelerates the appearance of AD-like (cognitive and amyloid) phenotype in the APPswe mouse model. In addition, the PSEN1 mutation was found to decrease cerebral vascular reactivity in middle-aged mice (Toussay et al 2017) resembling those appearing during Cerebral Small Vessel Disease and age-related dementia (Staszewski et al 2021, Li et al 2020). Hence, we hypothesized that PSEN1 mutation may accelerate brain aging.
Methods: To test this hypothesis, we compared neurocognitive changes induced by combined mutations of APP and PSEN1 and by mutation PSEN1 alone to those associated with normal aging in mice. To evaluate cognitive alterations, the animals were trained in a radial-maze task of working memory which interweaves memory and active forgetting to mimic and study peculiarities and complexity of memory function in everyday life (Al Abed et al, 2016; Stevens et al, 2023).
Results:). In this task, middle-aged (10-11 months) PSEN1 mutants display an aging-like cognitive impairment compared to their littermate controls, performing the task at a level close to old (19-20 months) controls, while APP/PS1 mice at young age (5-6 month) display a more severe, AD-like cognitive impairment. Preliminary results of immunohistochemical analyses of Fos protein expression (as a marker of neuronal activation) and vascular network performed post-training in the hippocampus of the same animals also indicate that PSEN1 mutation induces some functional alterations similar to those observed during normal aging.
Conclusions: Altogether our findings suggest that PSEN1 mice could mimic accelerated aging and provide a model of early cognitive aging that turns into AD-like dementia when PSEN1 is co-expressed with human APP.

AMYLOID BETA OLIGOMERS INDUCE SENESCENCE IN HUMAN FIBROBLASTS – INFLUENCE OF HISTONE DEACETYLASE INHIBITORS

POSTERS: A01.R. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AGING

Daniela Marinho[1], Ildete L. Ferreira[1], George Kelly[2], Penny Lovat[3], Viktor Korolchuk[2], A. Cristina Rego[1]
[1]University of Coimbra, Cnc-center For Neuroscience And Cell Biology, Coimbra, Portugal, [2]Newcastle University, Biosciences Institute, Newcastle upon Tyne, United Kingdom, [3]Newcastle University, Institute Of Cellular Medicine, Newcastle upon Tyne, United Kingdom

Aims: Aging is known to be the most important risk factor for sporadic form of Alzheimer's disease (AD). Evidence of post-mitotic neuronal and glial senescence has been recently described in AD. Senescence, a cell phenotype of aging, is characterized by irreversible cell-cycle arrest, pro-inflammatory phenotype, senescence-associated-secretory-phenotype (SASP), mitochondrial dysfunction, among others. Interestingly, mitochondrial dysfunction drives and maintains cell senescence, while cell senescence inducers can promote senescence-associated mitochondrial dysfunction. Moreover, transcription regulation of pro-inflammatory cytokines drives SASP. Therefore, we aimed to evaluate the potential efficacy of transcriptional modifications exerted by histone deacetylase inhibitors (HDACis) in rescuing cell senescence in AD cell models.
Methods: Cell senescence was induced by exposing human fibroblasts to amyloid beta1-42 peptide oligomers (AbetaO) for five consecutive days and the effect of HDACis (sodium butyrate [SB] and tacedinaline [Tac]) was analysed for 24h after AbetaO exposure. HDACis were also tested prior to AbetaO exposure for 24h in human fibroblasts and mouse hippocampal-derived HT22 cells. AD-like senescence phenotype was evaluated by following several cellular markers of senescence by immunocytochemistry. We also assessed mitophagy using mito-Keima, and the transcription activity of key senescence modulators and mRNA levels of selected target genes.
Results: Our results evidence a decrease in Ki67 labelling, along with increased p21 and nuclei area, which was counteracted by SB, and at a lower extent by Tac. Both HDACis prevented the decrease in mitophagy induced by 24h exposure to AbetaO. Under similar conditions, Tac was also shown to reduce NFAT transcriptional activity, which regulates p21. Moreover, Tac was shown to control the mRNA levels of proteins relevant for mitochondrial calcium uptake.
Conclusions: Our data support that HDACis may act as serotherapeutic compounds in AD cell models.

GENOMIC INSIGHTS INTO AGE-RELATED CHANGES IN FRONTAL CORTEX: IMPLICATIONS FOR NEURODEGENERATIVE DISEASES AND STRESS RESILIENCE

POSTERS: A01.R. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AGING

Ashlesh Patil[1], Satyendra Tripathi[2], Vishwajit Deshmukh[3], Jaya Tripathy[4]
[1]AIIMS Nagpur India, Physiology, Nagpur, India, [2]AIIMS Nagpur, Biochemistry, Nagpur, India, [3]AIIMS Nagpur, Anatomy, Nagpur, India, [4]AIIMS Nagpur, Community Medicine, Nagpur, India

Aims: Brain aging is a gradual process characterized by cognitive decline and an increased susceptibility to neurodegenerative diseases. This study aims to investigate the genetic and pathway changes associated with aging in the frontal cortex.
Methods: Two independent datasets were analysed from the Gene Expression Omnibus (GEO) database, GSE53890 for discovery and GSE11882 for validation. Gene expression profiles of adult human brain samples from frontal cortical region were compared between young (<60 years) and old (>60 years) using unpaired t test with Benjamini & Hochberg false discovery rate for multiple testing corrections.
Results: 38 genes were significantly up/downregulated with age in the discovery dataset. 8 genes *(AQP1, CD44, FKBP5, GFAP, HBA2, HBB, SLC14A1, TXNIP)* out of 18 genes in discovery dataset were also found to be significantly upregulated with age in the validation group. 20 genes *(ARPP21, C11orf87, CAMKK2, CBLN4, CRH, FREM3, GPR26, HS6ST3, KCNV1, LINC00507, MAL2, MFSD4A, NECTIN3, NGEF, PAK1, PPP4R4, PRKCB, RGS4, SSTR1, VIP)* were significantly downregulated with age in both datasets.
Conclusions: Genes implicated in neurodegenerative/neuropsychiatric diseases like Alzheimer Disease (*CD44, TXNIP*), Huntington disease (*SLC14A1*), Parkinson's disease (*ARPP21*), Schizophrenia (*CAMKK2*) are altered with age >60 years. Increased *FKBP5* in frontal cortex with age suggests better ability in handling of stress and reducing PTSD like events.

STEREOLOGICAL QUANTIFICATION OF THE IMPACT OF AGING ON DOPAMINERGIC AND CHOLINERGIC NEURONS

POSTERS: A01.R. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AGING

Hannah Phelps[1], Merritt Reece[1], Matthew Burns[2]
[1]University of Florida, Neuroscience, Gainesville, United States of America, [2]University of Florida, Neurology, Gainesville, United States of America

Aims: Parkinson's disease (PD), Dementia with Lewy Body (DLB) and Multiple System Atrophy (MSA) are common and rapidly growing neurodegenerative disorders, with age being the major risk factor. As a result, aged animal models have become increasingly valuable as representative models of disease. Loss of dopaminergic and cholinergic neurons in the substantia nigra and basal forebrain, respectively, are pathological hallmarks of PD, DLB, and MSA, but have also been associated with normal aging, making the use of aged animals for quantification of cell loss associated with disease potentially problematic. Comparing dopaminergic and cholinergic neurons in the young and aged rat brain using unbiased stereological quantification has not been well studied. We aimed to quantify the dopaminergic and cholinergic neurons in the substantia nigra and basal forebrain, respectively, in young and aged rats.
Methods: Using 5 month and 23-month-old Fischer 344 x Brown Norway F1 hybrid rats of both sexes, immunofluorescence and stereology was completed. Immunofluorescence was used to stain for tyrosine hydroxylase (TH) and choline acetyltransferase (ChAT), dopaminergic and cholinergic cell bodies were quantified using the Optical Fractionator probe within Microbrightfield's Stereoinvestigator software.
Results: Preliminary data suggest that the number of dopaminergic cells in the substantia nigra and ventral tegmental area decrease with age, indicating the aging process in rats is similar to that in humans. In addition, female rats possessed more dopaminergic cells than male rats.
Conclusions: These results inform future stereological studies in age-related disease models, particularly PD, DLB, and MSA studies. Although cell loss has been used in animal models as a marker of neurodegenerative disease, these data suggest that there may be age and sex-dependent cell loss to consider in animal models of disease.

THE ROLE OF EXTREMELY LONG-LIVED PROTEINS IN AGING AND ALZHEIMER'S DISEASE

POSTERS: A01.R. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AGING

Jeffrey Savas, Nalini Rao, Ewa Bomba-Warczak, Anika Wilen
Feinberg School of Medicine, Northwestern University, Neurology, Chicago, United States of America

Aims: Loss of proteostasis is a hallmark of aging, and aging is the greatest risk factor for Alzheimer's disease (AD). Deterioration in function and accumulation of damage to the proteome are to a large extent repaired by protein turnover. These turnover mechanisms are particularly important in long-lived postmitotic neurons, which cannot dilute toxic proteins through cell division. We aimed to identify extremely long-lived proteins (ELLPS) that persist for several months or longer across the aging continuum in wild-type mice and in AD mouse models. We hypothesize that these ELLPs represent key points of vulnerability to the decline of the aging proteome and critical substrates of amyloid pathology.
Methods: To identify ELLPs, we used whole-animal metabolic stable isotope labeling of wild-type and App KI mice combined with bottom-up proteomic analysis using liquid chromatograph-tandem mass spectrometry. The results were verified and followed up using biochemical, molecular, and electrophysiological methods.
Results: In wild-type mice we discovered that the brain proteome uniquely undergoes dynamic global turnover fluctuations during aging compared to heart and liver tissue. Parallel analyses of the insoluble fraction revealed that several protein sub-complexes experience impaired turnover, in part due to misfolding. Finally, we discovered that age-associated fluctuations in the activity of the ubiquitin proteasome system are linked to the turnover of the catalytic core subunits. In App KI mice, the turnover of presynaptic proteins is selectively impaired in the early stages of Abeta accumulation. Synaptic vesicle (SV)-associated proteins, have elevated levels, misfold in plaque-independent manner, and interact with APP and Abeta. We also found an enlargement of the SV pool and an increase in presynaptic potentiation.
Conclusions: The identification of ELLPs provides an opportunity to uncover Achillies heals of aging and initial substrates of amyloid pathology.

SEX AND AGE SPECIFIC CSF PROTEOMIC SIGNATURES IDENTIFY DISTINCT CLUSTERS LINKED TO NEURODEGERATION

POSTERS: A01.R. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AGING

Da Hun Seo[1], Cheolmin Lee[2], Gyujin Heo[3], Jigyasha Timsina[3], Lihua Wang[3], Ruiz Agustin[4], Taesung Park[1], Carlos Cruchaga[3], Yun Ju Sung[3]
[1]Seoul National University, Department Of Statistics, Seoul, Korea, Republic of, [2]Northwestern University, Health Sciences Integrated Program, Chicago, United States of America, [3]Washington University School of Medicine, Department Of Psychiatry, St. Louis, United States of America, [4]Universitat Internacional de Catalunya, Ace Alzheimer Center Barcelona, Barcelo, Spain

Aims: Sex and age are major risk factors for neurodegeneration. Studies on age-related molecular changes in plasma provided insights into age-related disease biology. Cerebrospinal fluid (CSF) proteomics can reveal additional insights into brain aging and neurodegeneration.
Methods: Using over 7,000 proteins in CSF obtained from 998 cognitively normal individuals (43-91 years old) across three cohorts (Knight-ADRC, ADNI, FACE), we performed regression to identify sex and age associated proteins (at FDR < 0.05). Similarly, plasma proteome from 1,382 individuals in Knight-ADRC was examined. Weighted gene co-expression network analysis was performed to group proteins with similar sex and aging trajectories. Enrichment for cell-type, disease ontology, and gene ontology was also performed.
Results: We identified 4,682 CSF proteins associated with age and 1,587 proteins with sex difference (1,172 affected by both). Aging effects and sex differences in CSF proteome were weakly correlated with those in plasma proteome. Network analysis identified 16 modules. Module 2 had 723 proteins (including APOE, APP; higher in females and decreasing with ages), enriched in microglia and macrophage. Along with negative regulation of apoptotic process, they were related to cerebral amyloid angiopathy, subarachnoid hemorrhage, and multi-infarct dementia (FDR = 0.029). Module 6 had 234 proteins (including LRRK2, SERPINA3, TREML2) with the strongest sex difference (high in males) and increasing with ages, enriched in endothelial cells. Along with complement activation and phagocytosis, they were related to many diseases including complement deficiency (FDR=2.14E-09), ischemic stroke (FDR=2.0E-7) and mild cognitive disorder (FDR=8.4E-03).
Conclusions: We identified two clusters of CSF proteins with sex and aging signatures related to neurodegeneration, which also show enrichment for other aging diseases. They explain comorbidity across multiple aging diseases, which may help promoting healthy aging and longevity.

DEVELOPMENT OF DEMENTIA AND OPIOID EXPOSURE FOR NON-CANCER PAIN CONTROL: A POPULATION-BASED COHORT STUDY

POSTERS: A01.R. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AGING

Tak Youn[1], Hyong Sook Jun[2], Youngmin Cho[1]
[1]Dongguk University International Hospital, Psychiatry, Goyang, Korea, Republic of, [2]Baewha University, Dept. Of Office Administration, Seoul, Korea, Republic of

Aims: Opioids are linked to cognitive impairment and induce neurotoxicity by modulating various cognitive processes through the mu- and kappa-opioid receptor-ligand systems, as well as multiple cellular and molecular mechanisms. Therefore, opioid exposure can influence the development of dementia. In a previous cohort study(Moradi-Lakeh et al. 2015), individuals with the highest level of exposure to opioids had a slightly elevated risk of developing dementia compared to the general population. We aim to investigate the association between opioid exposure for non-cancer pain control and the development of dementia in patients with chronic non-cancer pain in South Korea.
Methods: This study is a population-based cohort study using big data from National Health Insurance Service database in South Korea. From 2017 to 2021, patients diagnosed with musculoskeletal diseases and chronic non-cancer pain but without psychiatric diseases were included. Patients who had been regularly and continuously prescribed opioids for ≥90 days were classified as opioid users.
Results: A total of 1,176,057 patients with chronic non-cancer pain without psychiatric diseases were included in the final analysis, and among them, 19,375(1.64%) were opioid users. A total of 32,073(2.72%) patients with chronic non-cancer pain were newly diagnosed with dementia from January 2017 to December 2021. Opioid users showed a 15% increased likelihood of developing dementia in comparison to opioid-naïve patients. In addition, compared to opioid-naïve patients, opioid users showed a 16% higher risk of developing Alzheimer's disease and a 15% higher risk of unspecified dementia. However, no significant differences were observed for vascular dementia.
Conclusions: Chronic non-cancer pain patients without psychiatric illness who were opioid users had a higher risk of developing alzheimer dementia compared to opioid-naïve patients.

PLASMATIC CLUSTERIN AS A PERIPHERAL BIOMARKER OF LATE ONSET ALZHEIMER'S DISEASE

POSTERS: A01.R. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AGING

Dina Zekry[1], Benjamin Tournier[2], Kelly Ceyzériat[2,3,4], Antoine Marteyn[1], Quentin Amossé[5], Aurélien Badina[5], Stergios Tsartsalis[2], Francois Herrmann[1], Philippe Millet[2]
[1]Division of Internal Medecine for the aged/Geneva University Hospitals, Rehabilitation And Geriatrics, Thonex, Switzerland, [2]University Hospitals of Geneva, Psychiatry, Geneva, Switzerland, [3]University of Geneva, Cibm Center For Biomedical Imaging, Geneva, Switzerland, [4]University of Geneva, Laboratory Of Child Growth And Development, Geneva, Switzerland, [5]University of Geneva, Psychiatry, Geneva, Switzerland

Aims: Background: Early diagnosis of late onset Alzheimer's disease (LOAD) by peripheral biomarkers remains a challenge; many have been proposed, but not have been evaluated in a prospective manner. Clusterin (CLU), a chaperone protein expressed in the brain and found in relatively high concentrations in plasma is a promising candidate. CLU contributes to the elimination of beta amyloid, is associated to neurofibrillary tangles, is involved in apoptosis and neuroinflammation and is associated to the genetic risk for LOAD. **Objectives:** To assess the risk of developing LOAD based on the dynamics of plasma CLU.
Methods: Methods: A longitudinal measurement of CLU was performed in 4 cohorts of 10 old individuals (interval between measurements 28.3±14.9 months) including healthy controls, MCI and AD. Comparison was performed between groups of subjects that presented a cognitive decline vs those that remained stable.
Results: Results: Repeated two-way ANOVA showed an effect of group, time and the group x time interaction. At baseline, controls have the same CLU rates, whether they subsequently convert to AD or not. Control and MCI patients did not differ in CLU concentrations. In contrast, conversion from control or MCI status to AD was both associated with a significant increase in CLU concentration ($p<0.0001$). Individuals that remained in the same diagnostic category showed no significant CLU changes. To validate that the elevation in CLU is associated with conversion to AD, a replication study showed, in a second group MCI patients converting to AD in the follow-up (20.3±9 months) that CLU levels increased in 16/19 individuals (fold change: 3.5± 2.74; $p<0.01$).
Conclusions: Plasma CLU seems to be a promising marker of cognitive decline, and its association with AD may be a useful complementary diagnostic tool.

CHARACTERIZATION OF THE HUMAN MICROBIOME ISOLATES ON HOST PROTEOSTASIS REVEALS PROTEOTOXIC AND PROTEOPROTECTIVE BACTERIA THAT NON-SPECIFICALLY AFFECT PROTEINS ASSOCIATED WITH NEURODEGENERATIVE DISEASES

POSTERS: A01.S. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROBIOME

Alyssa Walker, Rohan Bhargava, Michael Bucher, Amanda Brust, Daniel Czyz
University of Florida, Microbiology & Cell Science, Gainesville, United States of America

Aims: Neurodegenerative protein conformational diseases (PCDs), such as Alzheimer's, Parkinson's, and Huntington's, are a leading cause of death and disability worldwide and have no known cures or effective treatments. Emerging evidence suggests a role for the gut microbiota in the pathogenesis of neurodegenerative PCDs; however, the influence of specific bacteria on the culprit proteins associated with each of these diseases remains elusive, primarily due to the complexity of the microbiota. We employed the *Caenorhabditis elegans* model to characterize the effect of all culturable bacterial isolates from the Human Microbiome Project. The aim of this study is to decipher the role of the identified proteotoxic and proteoprotective bacteria on disease pathogenesis.
Methods: In the present study, we employed a single-strain screening approach to identify human bacterial isolates that enhance or suppress the aggregation of culprit proteins and the associated toxicity in *C. elegans* expressing Ab_{1-42}, a-synuclein, and polyglutamine tracts.
Results: We reveal the first comprehensive analysis of the human microbiome for its effect on proteins associated with neurodegenerative diseases.
Conclusions: Our results suggest that bacteria affect the aggregation of metastable proteins by modulating host proteostasis rather than selectively targeting specific disease-associated proteins. These results reveal bacteria that potentially influence the pathogenesis of PCDs and open new promising prevention and treatment opportunities by altering the abundance of beneficial and detrimental microbes.

GUT MICROBIAL PERTURBATIONS AFTER THE ONSET OF AMYLOID PLAQUE FORMATION EXACERBATES PATHOLOGIES IN A MOUSE MODEL OF AB AMYLOIDOSIS.

POSTERS: A01.S. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROBIOME

Wade Self, Emily Franke, David Weiner, David Holtzman
Washington University School of Medicine, Neurology, Saint Louis, United States of America

Aims: Multiple studies have corroborated the phenomenon that the presence of gut bacteria early in life regulates amyloid plaque formation and associated neuroinflammation in transgenic mouse models of Aβ amyloidosis. In this study, we aimed to understand how gut microbiota influence the progression of amyloid-associated pathologies at an age where amyloid plaques are present in the mouse brain.
Methods: We treated 5 month old APPPS1-21 mice daily by oral gavage with water or a broad-spectrum antibiotics cocktail containing kanamycin, gentamicin, colistin, vancomycin, and metronidazole for three consecutive days. On the fourth day, we administered either normal drinking water to water-gavaged mice or water containing the antibiotics cocktail at 1/50th the concentration administered via oral gavage to antibiotics-gavaged mice. At 7 months of age, animals were sacrificed and analyzed for changes in amyloid plaque-associated pathologies.
Results: Across independent experiments by two separate investigators, APPPS1-21 mice treated with antibiotics showed increases in amyloid plaque burden and dense-core plaques, neuritic dystrophy, microgliosis and astrocytosis compared to water-treated mice. We observed these results in both male and female mice. Additional analyses will aim to understand changes in gut microbial composition and function and biological pathways after antibiotics treatment that influences the increase in amyloid load.
Conclusions: These findings suggest that the alteration of the gut microbiome induced by antibiotics in adult mice with established amyloid pathology differentially impacts amyloid plaque formation and neuroinflammation compared to manipulations earlier in the animal lifespan. Studying the effects of the altered microbiome in this experimental paradigm may suggest new pathways as to how microbial dysbiosis contributes to AD pathogenesis.

HSV1 INFECTION TRIGGERS THE PRODUCTION OF AMYLOID-BETA (AB) PROTEIN IN BOTH MOUSE AND HUMAN NEURONAL CELLS

POSTERS: A01.S. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROBIOME

Ya Gao[1], Ahmad Mahmoudikouhi[1], Ignacio Agúndez[2], Kathlyn Laval[1]
[1]Ghent university, Department Of Translational Physiology, Infectiology And Public Health, Merelbeke, Belgium, [2]Universidad Politécnica De Madrid, Ingeniería Agronómica, Alimentaria Y De Biosistemas, Madrid, Spain

Aims: Alzheimer's Disease (AD) is a degenerative brain disease and the most common cause of dementia affecting 55 million people worldwide. So far, there is no cure and current treatments are not effective in delaying the progression of the disease. The cause of AD is unknown, but there is growing evidence suggesting that viruses, in particular, Herpes simplex virus type 1 (HSV1), are involved in the pathogenesis of AD. HSV1 is a ubiquitous human pathogen that commonly causes cold sores. This DNA virus initiates a lifelong latent infection in the peripheral sensory neurons of its host. The infection can be reactivated periodically by various factors, including sun exposure or stress. Here, we hypothesize that HSV1 directly contributes to the initiation of AD by specifically triggering the production of amyloid-beta (Aβ) in neurons.
Methods: To test this hypothesis, we compared the kinetics of HSV1 replication with the kinetics of Aβ protein production in both mouse (N2A) and human (SY-SY5Y) neuronal cells. This work was performed by viral titration and immunofluorescence staining techniques.
Results: We found that HSV1 induces the production of Aβ protein in both cell types starting from 9 hpi. Interestingly, no Aβ protein was expressed in mock-infected cells. The Aβ protein accumulated in neurons at later stage of infection (24 hpi) and was found to colocalize with HSV1 immediate-early (ICP0) viral protein in the cell cytoplasm. Finally, we demonstrated that the Aβ protein production efficiency in neuronal cells was viral strain-dependent.
Conclusions: Overall, our findings demonstrate that HSV1 infection initiates the production of Aβ protein in both mouse and human neuronal cells. These results provide increase support for the direct role of HSV1 in the pathogenesis of AD.

ASSOCIATION BETWEEN COGNITIVE AND ORAL STATUS AND MARKER GERMS OF PERIODONTITIS IN PERSONS WITH MILD COGNITIVE IMPAIRMENT AND ALZHEIMER'S DISEASE

POSTERS: A01.S. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROBIOME

Katharina Häberle[1], Christiane Von Ohle[2], Christoph Laske[3]
[1]University Clinic for Dentistry, Oral an Maxillofacial Surgery, Dental Conservation, Tübingen, Germany, [2]University Clinic for Dentistry, Oral and Maxillofacial Surgery, Dental Conservation, Tübingen, Germany, [3]Eberhard Karls University, Department Of Psychiatry And Psychotherapy, Tübingen, Germany

Aims: To investigate the association of marker germs causing periodontitis and the severity of cognitive impairment.
Methods: In the present study we examined 97 individuals with mild cognitive impairment (MCI), Alzheimer's disease (AD) and controls for their oral state and presence and severity of periodontitis. A sample of microbial tooth plaque was taken from all test subjects, in case of periodontitis additionally a subgingival sample from the pathologically deepened areas below the gum line. The quantity of seven marker germs were compared to the severity of cognitive impairment examined by the Mini-Mental-Status-Examination (MMSE) and AD biomarkers in cerebrospinal fluid (CSF).
Results: Periodontitis was significantly more present in AD patients (p = 0,003) compared to controls. Additionally, the severity of periodontitis (increased gingival sulcus depth) was inversely correlated with MMSE score (r = -0,304; p = 0,003) in all participants. Marker germs showed no significant association with AD biomarkers in CSF. In MCI patients we found significantly increased subgingival levels of *Prevotella intermedia* (p = 0,014) compared to controls, and *Porphyromonas gingivalis* (p = 0,042), *Treponema denticola* (p = 0,038), *Prevotella intermedia* (p = 0,012) and *Tanerella forsythia* (p < 0,001) compared to AD patients. Using receiver operating characteristics (ROC) curve analysis we found an area under the curve (AUC) of 0.82 for *Prevotella intermedia* and 0.71 for *Porphyromonas gingivalis* discriminating between MCI patients from controls, and 0.61 for *Prevotella intermedia* discriminating between AD patients and controls.

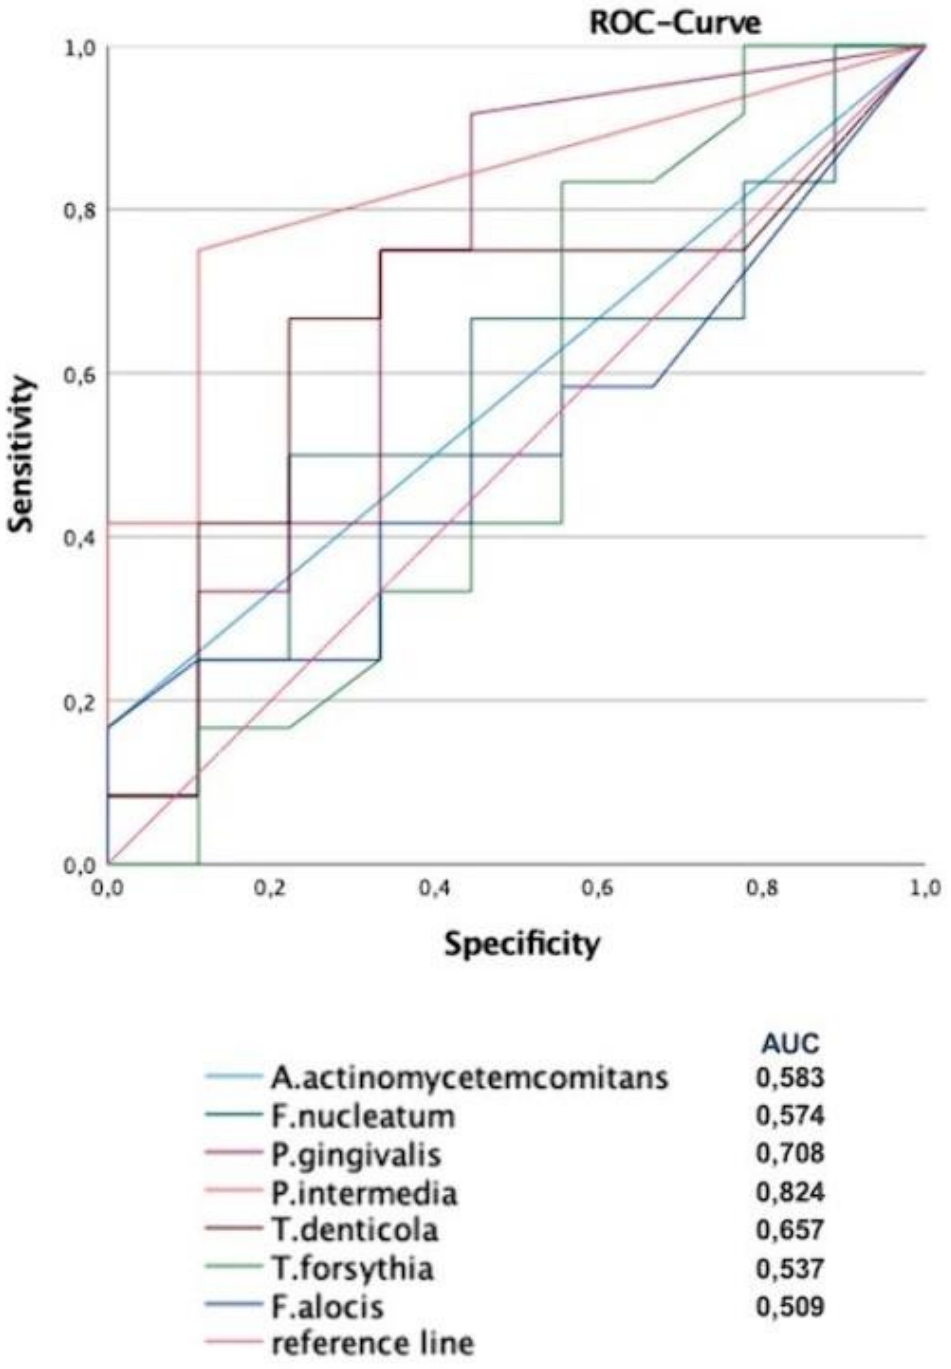

Image 1: ROC-Curve controls to MCI compared to marker germs

Conclusions: Periodontitis marker germs may represent an innovative diagnostic supplement for identification of patients with MCI and AD.

PERIODONTAL MICROBE EFFECT ON THE ENDOTHELIAL TRANSCRIPTOME RESEMBLES CHANGES OBSERVED IN PATIENTS WITH ALZHEIMER'S DISEASE

POSTERS: A01.S. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROBIOME

Kamelija Horvatović[1], Andrea Gelemanović[2]
[1]Faculty of Science, University of Zagreb, Molecular Biology, Zagreb, Croatia, [2]Mediterranean Institute for Life Sciences, Bioinformatics, Split, Croatia

Aims: Among various familiar etiopathologies of Alzheimer's disease (AD), periodontitis is one of the most recent factors suspected to be affecting the onset of this disorder. This in silico study aims to test whether the transcriptomic changes in endothelial cells (EC) induced by common periodontal pathogens such as Fusobacterium nucleatum (FN) or Porphyromonas gingivalis (PG) match changes detected in the EC of AD patients.
Methods: RNA-seq datasets GSE222136 and GSE125050 were acquired from the NCBI GEO database. Differentially expressed genes (DEGs) between different pathologies (FN, PG or AD) and untreated or healthy controls were identified following the DESeq2 pipeline, while the weighted gene co-expression network analysis (WGCNA) pipeline was used to identify highly correlated gene modules. Functional enrichment analysis was performed on DEGs and modules of interest.
Results: In total 15 gene modules were identified of which six modules with 89 key genes were significantly correlated with PG treatment, and four modules with 352 key genes with FN treatment, with most notable change being interferon signaling. 553 and 834 DEGs were identified in PG- and FN-treated ECs, respectively, while 1384 were significantly altered in ECs of AD patients. After comparing all the results, MIRHG1, SLC24A40, and ABHD13 were detected as shared significantly upregulated DEGs in all three pathologies indicating altered RNA interference mechanisms, affected ion channels, and cell adhesion.
Conclusions: This integrated study identified several potential gene candidates of underlying microbe-driven pathological changes in EC physiology that might be key players in AD onset and/or progression.

PROGNOSTIC VALUE OF GUT MICROBIOME FOR CONVERSION FROM MILD COGNITIVE IMPAIRMENT TO ALZHEIMER'S DISEASE DEMENTIA WITHIN 4 YEARS: RESULTS FROM THE ALZBIOM STUDY

POSTERS: A01.S. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROBIOME

Christoph Laske[1], Silke Peter[2], Ulrich Schoppmeier[2]
[1]Eberhard Karls University, Department Of Psychiatry And Psychotherapy, Tübingen, Germany, [2]Eberhard Karls University, Department Of Microbiology, Tuebingen, Germany

Aims: A growing body of evidence suggests that dysbiosis of the gut microbiome is associated with the pathogenesis of Alzheimer`s disease (AD) and can be used as a diagnostic measure. However, longitudinal changes of gut microbiome and its prognostic significance for the development of AD are still unknown. In the present study we investigated the ability of taxonomic and functional gut microbiome data and their combination with clinical data to predict the progression from mild cognitive impairment (MCI) to AD dementia on the basis of clinical classification at 4 years follow-up (4yFU).
Methods: In the present study we investigated intestinal microbiome in 49 MCI patients participating at the AlzBiom study over a mean (SD) follow-up of 3.7 (0.6) years. At the end of the 4yFU, 27 MCI patients converted to AD dementia and 22 MCI patients remained stable. Gut microbiome was measured using shotgun metagenomics. Statistical models were built with features from baseline data that best discriminated between AD dementia converters and stable MCI patients using an ANOVA like test.
Results: The best taxonomic model at baseline for discrimination of AD dementia converters from stable MCI patients included 24 genera, yielding an area under the receiver operating characteristic curve (AUROC) of 0.87. The best functional model at baseline included 33 KO (Kyoto Encyclopedia of Genes and Genomes [KEGG] ortholog) features with an AUROC of 0.79. The combined use of these two models including a clinical model with the 4 parameters age, gender, BMI and ApoE yielded an AUROC of 0.93.
Conclusions: We identified a novel gut microbiome algorithm able to accurately predict progression to AD dementia in individuals with MCI over a 4 years follow-up. Gut microbiome represents an innovative prognostic supplement in AD.

GUT MICROBIOTA GENUS NETWORK REFLECTS ALZHEIMER'S DISEASE CLINICAL STAGES

POSTERS: A01.S. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROBIOME

Amanda Muliterno Domingues Lourenço De Lima[1], Marco Antônio De Bastiani[1], Morghana Machado Da Rosa[2], Luiza Santos Machado[3], Eduardo R Zimmer[1]
[1]Department of Pharmacology, Graduate Program in Biological Sciences: Biochemistry (PPGBioq) and Phamarcology and Therapeutics (PPGFT), Universidade Federal Do Rio Grande Do Sul, Porto Alegre, Brazil, [2]Federal University of Health Sciences of Porto Alegre, Medicine, Porto Alegre, Brazil, [3]Universidade Federal do Rio Grande do Sul, Biochemistry, Porto Alegre, Brazil

Aims: We hypothesized that dysfunctional associations between the bacterial groups of the gut microbiota could be associated with AD clinical stages. Thus, we aimed to compare the gut-microbiota networks in cognitively unimpaired (CU), mild cognitive impaired (MCI), and AD dementia individuals.
Methods: We selected 16S rRNA gene sequencing data from fecal samples of CU, MCI and AD (n = 30, per group) available at NCBI repository (PRJNA489760). Individuals of both sexes aged between 57 and 73 years were included in the study. Adaptors were removed from the FASTQ files using the Trimmomatic tool for each sample and submitted to the DADA2 pipeline. Briefly, after filter and trimming, amplicon sequence variants (ASVs) were inferred using the *dada* function, taxonomic assignment was implemented using the SILVA resource and normalized by rarefaction without replacement. Afterward, normalized centered-log ratio transformed abundance data were used to construct correlation networks between genus for CU, MCI, and AD.
Results: We observed different correlation patterns between bacterial genera in CU, MCI, and AD. More especially, we found a progressive increase in network density toward AD clinical progression. Genus reportedly associated with cerebral amyloidosis and tau show few connections in the CU individuals, which are increased in MCI and highly connected in AD. Interestingly, we also noted that the opportunistic pathogen *Escherichia_Shigella*, strongly associated with AD pathology, was exclusively present in the AD network and showed a negative correlation with *Faecalibacterium*, a reportedly indicator of health.
Conclusions: Microbial association networks at the genus level reflect different pathological stages of AD and could provide insights into preventive therapeutic strategies aiming to delay disease progression through the modulation of the gut microbiota.

University of Luxembourg, Luxembourg Centre For Systems Biomedicine, Esch-sur-Alzette, Luxembourg

Aims: The study aims to utilize multiomics strategies to explore the gut microbiome's role in neuroinflammation, aiming to clarify its impact on both PD and iRBD.
Methods: Using our previously developed methodological framework, we performed a systematic multiomics analysis of DNA, RNA, proteins, and metabolite fractions isolated from a total of 122 flash-frozen fecal samples obtained from PD (46), iRBD (27) patients and healthy controls (49).
Results: Beyond taxonomic differences, we detected significant molecules like β-glutamate, ceramides, arsenite, and flagella-related proteins in PD and iRBD. Glutamate pathways were disturbed, with increased β-glutamate levels in disease cases. Ceramide pathways were down-regulated. Genes linked to arsenate reduction were also altered. Notably, flagellar biosynthesis-related genes displayed significant depletion at the gene level.
Conclusions: The findings from this research will not only enhance our understanding of the microbiome's role in PD but also increase the potential therapeutic targets for addressing the disease.

Aims: Acetylcholine depletion due to amyloid β (Aβ)-induced cholinergic degeneration is a main etiology of Alzheimer's disease (AD). Acetylcholinesterase (AChE) inhibitors do not delay or reverse the disease progress. Antibodies specific for Aβ induce microbleeding and brain edema. We obtained an exosome-rich conditioned medium (ERCM) containing large amounts of functional molecules such as Aβ-degrading neprilysin (NEP) as well as neuroprotective and neuroregenerative growth factors (GFs) and neurotrophic factors (NFs), and assessed its therapeutic effects in AF64A-induced AD model animals.
Methods: The enzymatic activity of NEP in ERCM was assayed for Aβ degradation, and cytoprotective activity was assessed for the production of choline acetyltransferase (ChAT) in F3 neural stem cells. To induce cognitive deficit, mice were injected ICV with a cholinotoxin AF64A, and treated IV once or 4 times with ERCM. Cognitive function was assessed via passive avoidance and Morris water-maze performances, and neuroprotective effects were evaluated by analyzing brain acetylcholine and Aβ concentration, GFs and NFs, and microscopic findings.
Results: ERCM exhibited NEP activity and up-regulated ChAT (acetylcholine-synthesizing enzyme) production in F3 cells. ERCM treatment recovered cognitive function of AD mice, in which repeated treatment was more effective than single injection. The hippocampal pyramidal cell loss and Aβ accumulation induced by AF64A challenge was prevented by treatment with ERCM, in parallel with the recovery of functional molecules such as acetylcholine, GFs and NFs, NEP, and ChAT. In addition, ERCM exerted neuroregenerative activity, as confirmed by increased host nestin-positive neural stem cells and ChAT-positive cholinergic neurons, and decreased GFAP-positive astrocytes.
Conclusions: ERCM ameliorated AF64A-induced dementia. The results indicate that ERCM rich in NEP and GFs/NFs recovers learning and memory functions via amyloid β elimination as well as neuroprotection and neuroregeneration.

THERAPEUTIC EFFECT OF BIOINSPIRED WASP VENOM PEPTIDE FRATERNINE-10 IN A MOUSE MODEL OF ALZHEIMER'S DISEASE

POSTERS: A02.A. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ABETA, TRUNCATED & PGLU-ABETA

Luana Cristina Camargo, Letícia Gomes, Gabriel Campos, Adolfo Carlos De Souza, Márcia Renata Mortari
University of Brasilia, Institute of Biological Sciences, Department Of Physiological Sciences, Laboratory Of Neuropharmacology, Asa Norte, Brasília, Brazil

Aims: Alzheimer Disease (AD) is characterized by the accumulation of Amyloid-β (Aβ) and TAU peptides, which aggregate and become toxic to neurons. Current AD treatments are still limited; therefore, the development of new drugs for AD treatment is necessary. Animal venom compounds are known to be very specific for unique targets, especially for central nervous system receptors, due to evolutionary pressures. Fraternine-10 was bioinspired from Fraternine, a peptide isolated from *Parachartergus fraternus* wasp venom.In this context, we evaluated the potential of Fraternine-10 as a treatment in an AD Aβ-induced mouse model.
Methods: Aβ was infused (400 pmol/animal) into brain lateral ventricle by a neurosurgery. Aβ- infused mice were then treated with three doses of Fraternine-10 (4, 8, and 12 mg/kg; intraperitonial) (n= 7, 9 and 8, respectively) or saline (n=12) one hour after Aβ infusion and for six consecutive days. Then, all groups underwent the Novel Object Recognition Test (ORT), the Open Field test, and the Morris Water Maze (MWM), which consisted of four trials with six sections followed by the test without the platform. Thioflavin T staining was performed to evaluate Aβ aggregation.
Results: The Fraternine-10 (12 mg/kg) exacerbated memory impairment due to Aβ toxicity in the ORT ,while, no improvement was observed in the MWM. No differences amoung groups were observed in the Open Field test. Moreover, Fraternine-10 did not reduce Aβ aggregation in the cortex and hippocampus. Hence, it is likely that Fraternine-10 was degraded over time and lost its potential therapeutic effect.
Conclusions: Further studies are necessary to understand the pharmacokinetic properties of Fraternine-10 and explore possible improvements. Finally, Fraternine-10 could serve as a starting point for developing a promising drug for AD treatment after further modifications.

APP EXON17 SKIPPING AS AN ALTERNATIVE STRATEGY TO DOWNREGULATE APP IN AD

POSTERS: A02.A. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ABETA, TRUNCATED & PGLU-ABETA

Allen Chen, Dominic Walsh, Thierry Bussiere
Biogen, Neurodegenerative Disease Research Unit, Cambridge, United States of America

Aims: The proteolytic processing of the Amyloid Precursor Protein (APP) by β- and γ-secretase generates the Amyloid β-peptide (Aβ) that is deposited in the brains of Alzheimer's disease (AD) patients. Removal of aggregated Aβ by immunotherapy has shown clinical efficacy, making APP a promising target in AD. However, knockdown of APP may lead to safety issues, as knockout mice exhibit certain adverse phenotypes, including reductions in brain and body weight, reduced grip strength, and impairments in spatial learning and long-term potentiation. These phenotypes can be rescued with the soluble fragment of APP generated by α-secretase shedding (sAPPα). Here we examine a novel approach to target APP via skipping of exon17. Exon17 encodes for the transmembrane domain of APP which includes the C-terminus of Aβ. Removal of this exon is predicted to produce a secreted form of APP (APP ΔE17) incapable of generating Aβ. APP ΔE17 is highly similar to sAPPα and may retain its function while attenuating any phenotypes associated with loss of APP. Thus this strategy could prevent generation of Aβ while retaining sAPPα function.
Methods: Cell lines expressing APP ΔE17 were examined for APP secretion as a C-terminal intact protein. Processing by α-/β-secretase was determined by measuring the levels of APP C-terminal fragments and impact of inhibitors on full-length protein. sAPP function on basal neurotransmission was assayed by fEPSP on acute hippocampal slices.
Results: Deletion of exon17 resulted in the secretion of APP with no detectable cleavage by the secretases. However, APP ΔE17 did not retain sAPPα function and, furthermore, led to the accumulation of APP in the conditioned media.
Conclusions: Exon17 skipping does not appear to be a suitable strategy for the downregulation of Aβ production.

BRAIN METABOLIC CONNECTOMICS OF ADUCANUMAB PHARMACODYNAMICS IN 5XFAD MICE

POSTERS: A02.A. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ABETA, TRUNCATED & PGLU-ABETA

Paul Territo[1], Charles Burton[2], Scott Persohn[2], Ethan Miner[2], Kierra Eldridge[2], Sara Quinney[1], Andi Masters[1], Katherine Haynes[3], Kristen Onos[4], Mike Sasner[5], Gareth Howell[5], Gregory Carter[5], Adrian Oblak[2], Bruce Lamb[6], Stacey Sukoff Rizzo[3]

Aims: Objective: The MODEL-AD Preclinical Testing Core established a rigorous drug testing strategy for unbiased assessments. To validate this pipeline, chimeric aducanumab (chAdu) in aged 5XFAD mice was tested. To elucidate the pharmacodynamics (PD), metabolic connectomic modeling was performed.
Methods: Methods: chAdu was synthesized by transfection and qualified by standard methods. To determine the dosing strategy, PK studied were conducted in 9 mos 5XFAD mice of both sexes dosed with chAdu from 0.1 to 30 mg/kg, and blood sampled every 3 days between 0 and 27 days. PK/PD modeling predicted dose levels of 0.1 to 30 mg/kg at Q1W. Brain PD was determined at baseline and conclusion of chronic treatment via 18-FDG PET/CT. Images were registered to the Paxinos-Franklin atlas, extracted, and network connectivity determined by z-score transformation, pairwise covariance analysis. Networks were modularized via multi-resolution-consensus clustering (MRCC), where region set enrichment was conducted. Whole brain and module level statistics were conducted between sexes and across doses.
Results: Results: chAdu showed high purity and stability with freeze/thaw. PK/PD modeling revealed $T_{1/2}$ of ~2.5 days and informed the PD dose regimen (0.1-30 mg/kg Q1W, IP). 12-week treatment with chAdu resulted in dose- and sex-dependent dependent reversal of glycolytic loss in key brain regions. Whole brain covariance analysis of regional 18F-FDG PET uptake thresholded at the $p<0.05$ level, revealed a dose and sex dependent changes in network degree, density, positive and negative connection strength, and clustering coefficient. Network MRCC modules composition and distribution showed dose and sex dependency.
Conclusions: Conclusions: These data indicate that chAdu was selective and stable, and resulted in sex and dose dependent relevant metabolic network changes consistent with neuromodulation, and demonstrate the value of metabolic connectomic modeling for evaluating drug efficacy.

PLASMA EXCHANGE REDUCES ABETA LEVELS IN PLASMA AND AMYLOID PLAQUES IN THE BRAIN OF A MOUSE MODEL OF ALZHEIMER'S DISEASE

POSTERS: A02.A. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ABETA, TRUNCATED & PGLU-ABETA

Aims: In the present study, we investigated the effectiveness of repeated plasma exchange (PE) in removing Aβ peptides from the plasma and decreasing Aβ accumulation in the brain.
Methods: 300 µL of blood was obtained once a month from APP/PS1 mice from the jugular vein. Subsequently, blood was centrifuged to remove plasma, and the same volume was replaced with 5% mouse albumin and reinfused into the jugular. PE started at 3 months of age and animals were euthanized at 7 months. For biochemical and histological analysis, brains were dissected. The right hemisphere was fixed for histological examinations, and the left was snap-frozen in liquid nitrogen. For histology, 10 µm sections were stained with thioflavin S (ThS), or incubated with anti-Aβ 4G8, anti-GFAP, and anti-Iba1 antibodies. Images were analyzed using Image J software. Plasma concentrations of Aβ were measured by ELISA.
Results: show that PE avoids the increase of Aβ levels in mice plasma at 7 months. Also, these animals have less ThS burden in the cortex and hippocampus, as well as a significantly lower number of plaques. This reduction in amyloid pathology measured by histological staining was supported by results showing that PE reduced the accumulation of insoluble Aβ in the brain. Finally, the burden area positive for the microglia and astrocyte was significantly lower in PE-treated animals compared to controls.
Conclusions: The precise mechanism through which PE reduces amyloid pathology in this model remains unclear. The decrease in cerebral amyloid deposition occurred in parallel with a reduction in the concentration of Aβ in plasma, indicating that the mobilization of Aβ from the brain to the bloodstream may play a role in reducing the amyloid burden induced by PE.

Aims: Leqembi (Lecanemab), a humanized monoclonal antibody targeting amyloid β, has secured FDA approval as a treatment for early Alzheimer's disease (AD). There is growing interest in using it for AD in Down syndrome (DS), given over 90% of DS eventually develop AD. However, Leqembi comes with a critical consideration—Cerebral-Amyloid-Angiopathy (CAA)-related hemorrhage. CAA involves amyloid buildup within the brain vasculature. People with DS have a notably higher CAA prevalence compared to the general population, heightening this risk of adverse side effects during Leqembi treatment. To address this pressing clinical concern, our study aimed to determine if Leqembi can detect CAA structures in post-mortem brain tissues from people with DS.
Methods: Since Lecanemab is a human antibody, conducting immuno-histochemical staining on human tissue without significant background staining presented a technical challenge. We have developed a novel method using fragment antigen-binding regions (Fab) to block the endogenous level of human IgG in the brain tissue for reducing the general background caused by human-on-human immunohistochemical staining. We compared 12 brains from people with DS (Ages 49 to 68) to 5 brains from late onset AD (ages 83 to 96).
Results: First, Lecanemab labels a diverse phenotype of amyloid plaques in DS brains, with different plaque morphologies, including coarse-grained, cotton wool, and classic cored structures. Second, Lecanmab labels extensive vascular amyloid deposition in all 12 DS cases. Lecanemab labels particularly widespread leptomeningeal and cortical amyloid angiopathy, including blood vessel and capillary amyloid angiopathy in the cortex. There are also diffuse parenchymal Aβ deposits around the blood vessels.
Conclusions: This discovery raises heightened concerns regarding the safety and suitability of Leqembi's use in people with DS over the age of 50 years, underscoring the need for careful evaluation in clinical applications.

Aims: This studyaims to evaluate the neuroprotectiveaction of a new peptideanalogous to Octovespina, a waspvenompeptide with neuroprotectiveeffects in Alzheimer's Disease (DA)
Methods: In a30-days experimental design, different animalgroupsunderwentstereotaxicsurgery on the first day, with administration of Aß or vehicle, and weretreatedintranasally for evaluationof the peptide in a chronicmodel, with the free or nanoencapsulatedpeptide, in a dose of 2µg/2µL. On the lastfivedays of protocol, the animalsweresubmitted to the Morris WaterMaze test (MWM), consisting of fourdays of training and one day of test. On the fourdays of training, each animal wasput on the watermaze for one minute, in six different sections to find anunderwaterplatform. On the test day, the platformwasremoved and the time spentwithin the platformquadrantwasevaluated.

Results: Whencompared to the control groups, the peptidewasablebringcognitiveimprovement to the animalsevaluated in the Morris WaterMaze at a dose of 2ug/2ul, nanoencapsulated and free. The resultsshowed similar efficacybetween the nanoencapsulated and non-nanoencapsulated doses in terms of improving the cognitivecapacity of the animals in this model, whencompared to the negative control group.
Conclusions: Thesefindingssuggest that the peptideis promising in the treatment of DA, in addition, furtherstudies are underway to betterevaluate the effects of the peptide in otherbehavioraltests andother doses (0,2µg/µL and 20µg/2µL), and at last, deeperevaluate the nanotechnology. This studywasfunded by FAPDF, CNPQ and CAPES.

SIGNATURES OF MODIFIED ABETA VARIANTS IN ALZHEIMER'S DISEASE, DEMENTIA WITH LEWY BODIES AND VASCULAR DEMENTIA

POSTERS: A02.A. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ABETA, TRUNCATED & PGLU-ABETA

Sarah Schrempel[1], Anna Kottwitz[2], Maike Hartlage-Rübsamen[1], Anke Piechotta[2], Jochen Walter[3], Stephan Schilling[2], Steffen Roßner[1]
[1]University of Leipzig, Paul Flechsig Institute For Brain Research, Leipzig, Germany, [2]Fraunhofer Institute for Cell Therapy and Immunology, Department Of Drug Design And Target Validation, Halle (Saale), Germany, [3]University of Bonn Medical Center, Department Of Neurology, Bonn, Germany

Aims: The aggregation of amyloid beta (Abeta) and post-translationally modified Abeta in particular is a neuropathological feature in brains of Alzheimer's disease (AD) patients. In other types of dementia, such as dementia with Lewy bodies (DLB) and vascular dementia (VAD), a role of Abeta in the pathology is hypothesized. We propose distinct pathogenic profiles of Abeta post-translational modifications (PTMs) in AD and other types of dementia.
Methods: We employed novel and established monoclonal antibodies for comparative analyses of different Abeta PTMs in *post mortem* human brain tissue of pre-symptomatic and symptomatic AD cases, of subjects who suffered from DLB and VAD, respectively, and of control subjects. Using machine learning protocols, we quantified immunohistochemical stainings of Abeta PTMs and compared the results with the quantification of Abeta variants employing ELISAs. For the latter technique, tissue fractions were prepared based on differential solubility of Abeta variants in detergents and formic acid. Furthermore, histopathological findings were correlated with clinical data.
Results: In human brain tissue, labeling with antibodies raised against Abeta PTMs isoaspartate 7 (isoD7), pyroglutamate 3 (pE3) or phosphoserine 8 (pSer8) showed a lower percentage of stained plaque area compared to labeling of total Abeta. The isoD7-Abeta variant was the most abundant among the Abeta PTMs investigated. Both the total plaque load and abundance of Abeta variants were highest in AD cases, followed by DLB and pre-symptomatic AD, and lowest in VAD cases.
Conclusions: Abeta plaque pathology in general and the percentage of Abeta variants compared to total Abeta can be quantified using single labeling immunohistochemistry and machine learning protocols. Abeta PTMs, and in particular the abundant isoD7-Abeta variant, might be considered for diagnostic and therapeutic approaches in different types of dementia.

Aims: Immunotherapy against amyloid-beta has been shown as a promising treatment option for Alzheimer's disease (AD). In a phase 3 clinical trial in early AD subjects, lecanemab demonstrated disease-modifying effects on clinical endpoints and clearance of amyloid-beta plaques in the brain. Lecanemab is a humanized IgG1 monoclonal antibody, selectively targeting amyloid-beta protofibrils. Soluble amyloid-beta protofibrils are believed to be the most toxic species of amyloid-beta. Immunotherapy with antibodies targeting amyloid-beta is associated with amyloid-related imaging abnormalities with edema (ARIA-E). The incidence of ARIA-E might correlate with antibody binding to amyloid-beta in cerebral amyloid angiopathy (CAA) in vessels. Here we have studied binding of lecanemab and other amyloid-beta-binding antibodies to different amyloid-beta species isolated from AD brain.
Methods: Amyloid-beta species were measured in human postmortem brain isolated from parenchymal and meningeal tissue. MSD/ELISA and mass spectrometry were used for measurement and characterization. Binding studies with amyloid-beta antibodies were carried out using immunoprecipitation.
Results: Soluble amyloid-beta protofibrils were mainly composed of amyloid-beta-42 and levels were significantly elevated in AD brains compared to non-demented controls. Amyloid-beta 40 was identified as the major amyloid-beta species in CAA. Pyroglutamate-3 modified amyloid-beta was significantly elevated in insoluble brain fraction at later Braak stages as compared to lower Braak stages. Lecanemab showed strong binding to all sizes of amyloid-beta protofibrils isolated from AD brains, and showed low binding to amyloid-beta fibrils prepared from CAA.
Conclusions: Lecanemab has a unique binding profile with a high selectivity for soluble amyloid-beta protofibrils. This was shown when different amyloid-beta antibodies were compared regarding their binding properties to amyloid-beta species isolated from human postmortem brain tissue. These differences could have an impact on clinical efficacy and safety when treating AD patients.

Aims: Amyloid-β (Aβ) peptides of various lengths are produced by sequential proteolysis of the transmembrane amyloid precursor protein (APP) by the β- and the γ-secretases that both operate in the cholesterol-rich membrane bilayer. We previously showed that increase of membrane cholesterol triggers APP endocytosis and the production of toxic Aβ peptides. Furthermore, we found that K to A mutation in the cholesterol-binding site of APP at position 28 in the Aβ sequence leads to the generation of short and non-toxic Aβ peptides (mainly Aβ33) in HEK293T cells, likely by increasing the carboxypeptidase activity of the γ-secretase. Here we wish to investigate the effect of the K28A mutation on APP processing in neuroblastoma cells and in human iPSC-derived neurons, and test whether this mutation can counteract the deleterious effects of the London mutation producing toxic Aβ42 in familial AD.
Methods: Using CRISPR/Cas9 technology and pEBV vector expression, human neuroblastoma cell lines (SH-SY5Y, BE(2)-C and SK-N-AS) and human iPSC clones were engineered
Results: We successfully developed several new human neuroblastoma cell lines by first silencing endogenous APP and concomitantly expressing stably inducible or constitutive APP with or without the K28A mutation. In addition, we generated new hiPSC lines with the K28A mutation starting from iPSC from a patient carrying the London mutation (V717I) and its isogenic control obtained by reversing the V717I mutation using CRISPR/Cas9. We will present data on APP processing in these new cell lines
Conclusions: Collectively these data support the premise of new gene-editing therapy to mitigate the overproduction of toxic Aβ species in the context of AD, similarly to g-secretase modulators but may be more efficiently by reducing the size to Aβ33

ANTI-ABETA LIPOSOMAL VACCINE, ACI-24.060, RETAINS MEMORY IN AN AGGRESSIVE MOUSE MODEL OF ALZHEIMER'S DISEASE

POSTERS: A02.B. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: IMMUNOTHERAPY

Emma Fiorini, Chiara Babolin, Catherine Morici, Aurélie Guillaume-Gentil, Fabiana Tione, Harishini Balachandiran, Maxime Ayer, Marie-Gabrielle Beuzelin, Rakel Carpintero, Stefania Rigotti, Andrea Pfeifer, Marie Kosco-Vilbois, Marija Vukicevic
AC Immune SA, Research, Lausanne, Switzerland

Aims: ACI-24.060 is a Phase 2 clinical stage anti-Abeta active immunotherapy that induces sustained antibody responses targeting pathological Abeta species. We have assessed the ability of ACI-24.060 to maintain neuronal health, and thus memory, in the aggressive 5xFAD mouse model of Alzheimer's disease (AD).
Methods: 5xFAD mice were immunized with ACI-24.060 or vehicle, from 1.5 months of age until 10.5 months. Anti-Abeta antibody titers induced by the immunotherapy were assessed by ELISA. To evaluate cognitive performance, learning and memory, ACI-24.060-treated and vehicle-treated 5xFAD mice, and C57BL/6 mice (non-diseased controls), were assessed in the Morris Water Maze (MWM) after a 4-day training period followed by a test trial. The effect of ACI-24.060 on spatial learning was assessed by quantifying escape latency, swim distance, quadrant preference and cognitive score.
Results: In the 5xFAD mouse model, at 10.5 months of age, vehicle-treated mice exhibited substantially impaired learning in the MWM compared to non-diseased animals. ACI-24.060 immunization led to the significant maintenance of learning and memory, reaching similar levels to non-diseased controls. This included learning during the training period (as measured by escape latency and swim distance on the last training day) and the cognitive score over the course of the testing. These significant cognitive improvements were associated with a robust and sustained anti-Abeta IgG response.
Conclusions: The widely used 5xFAD mice that reportedly recapitulates many AD-related phenotypes including amyloid plaques, neuron loss and pronounced amyloidosis, displayed severe cognitive decline before 11 months of age. Treatment with the Abeta targeting vaccine, ACI-24.060, maintained both learning and memory capabilities to the levels of non-diseased animals. These neurological functional results are consistent with the accumulating immunohistochemical data on the activity of ACI-24.060 and strongly support its continued clinical development.

Aims: Alzheimer's disease (AD) is a major cause of dementia and one of the intractable neurodegenerative diseases. Neuroinflammation is one of the causes of AD, and microglia play an important role in neuroinflammation in the central nervous system. Galectin-3 (Gal-3) is a protein that has the function related to proinflammatory processes and its expression is observed in activated microglia. Recently, cerebrospinal fluid (CSF) Gal-3 levels were reported to be elevated in AD patients. In this study, we assessed CSF Gal-3 levels in AD patients, including those with mild cognitive impairment (MCI) due to AD, and investigated the effect of a vaccine targeting Gal-3 in mice.
Methods: First, we measured CSF Gal-3 of non-AD and AD patients including those with MCI due to AD. Then, we designed a Gal-3 vaccine using virus-like particle (VLP) and administered it intramuscularly to 5xFAD mice at a dose of 10 micrograms three times over a four-week period. Serum samples were collected two weeks and approximately three months after the final injection to measure anti-Gal-3 antibody titers. To investigate the effect of the vaccine on the brain, we conducted western blot analysis of Gal-3.
Results: In our study, we found that CSF Gal-3 in AD patients increased even in the MCI stage compared to non-AD patients. We also observed that the anti-Gal-3 antibody titer of all immunized mice increased both 2 weeks and 3 months after immunization. Furthermore, western blot analysis demonstrated the vaccine reduced Gal-3 levels in the cortex of 5xFAD mice.
Conclusions: Our data suggest that neuroinflammation related to Gal-3 occurs in the early stage of AD and the vaccine we developed could be a potential therapeutic drug for AD.

Aims: Anti-amyloid active immunotherapies are a promising maintenance strategy to preserve and potentially improve clinical benefits driven by initial treatment with amyloid-targeting monoclonal antibodies (mAbs). Lecanemab treatment reduces both amyloid burden and plasma pTau181 levels and increases the plasma ratio of Abeta42/40. However, the antibody levels needed to stabilize biomarkers at post-mAb treatment levels, i.e., in a maintenance clinical setting, may be quite different to those achieved during initial treatment. In this study, mathematical models were developed to predict biomarker responses to anti-amyloid active immunotherapies administered as maintenance therapies with the objective of defining target antibody levels required to maintain key biomarkers at levels achieved following initial mAb treatment.
Methods: A previously published Lecanemab exposure-response model was implemented and a minimal QSP model developed. These models provided a quantitative framework for exploring ongoing biomarker responses to a range of mAbs as well as to active immunotherapy following initial mAb therapy.
Results: Both models predict that the maintenance plasma antibody levels needed to stabilize biomarkers at levels achieved following initial mAb treatment are lower than those achieved with initial mAb therapy. However, as compared to the antibody levels predicted to prevent re-accumulation of amyloid plaque, higher antibody levels are required to prevent a return to baseline of the plasma pTau181 concentration and plasma Aβ42/40 ratio as compared to those predicted to prevent re-accumulation of amyloid plaque.
Conclusions: By leveraging QSP models for mAbs, we have improved understanding of the target antibody levels to be achieved by anti-amyloid active immunotherapies in the maintenance context. In addition, such an approach can be extended beyond exploration of maintenance immunotherapy to investigate responses to anti-amyloid active immunotherapy for other clinical contexts such as primary prevention.

MULTI-MODAL AMYL THERAPEUTICS INHIBIT AGGREGATION AND PROMOTE CLEARANCE OF AMYLOID AGGREGATES FROM NEURODEGENERATIVE DISEASES

POSTERS: A02.B. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: IMMUNOTHERAPY

Aditya Iyer, Julie Goemaere, Karine Goraj
Amyl Therapeutics, Research And Development, Seraing, Belgium

Aims: Preliminary results from *in vitro and ex vivo* studies with pan-amyloid therapeutics demonstrate the ability to inhibit aggregation, bind and destabilize amyloid fibrils, and promote clearance by phagocytosis of $A\beta_{1-42}$, Tau, and α-synuclein aggregates.
Methods: We have used fluorescence spectroscopy to assess the inhibitory effect of our therapeutics on the aggregation of $A\beta_{1-42}$, Tau, and α-synuclein. We have applied a combinatorial strategy where surface plasmon resonance (SPR), ELISA, and immunogold labeling have been used to confirm *in vitro* binding. Therapeutic-dependent phagocytosis of amyloid aggregates was evaluated in a THP-1 cell assay, and *ex vivo* target engagement was assessed in human tissues.
Results: Our therapeutics have been generated by fusing a human IgG Fc to a M13 bacteriophage protein, and first-generation therapeutics have been shown to specifically bind and destabilize amyloid fibrils from antibody light chain, $A\beta_{1-42}$, Tau, and α-synuclein (Asp et al.2019). Our first-generation therapeutics also reduced amyloid burden ($A\beta_{1-42}$ and Tau) in mouse models with no toxic side effects (Levenson et al., 2016). We present preliminary data with improved therapeutics showing markedly reduced immunogenicity, enhanced aggregation inhibition, nanomolar binding affinities to amyloid aggregates, and effective clearance of amyloid aggregates by phagocytosis. Additionally, we share data confirming binding to amyloid deposits in tissues from Alzheimer's disease (AD) and Parkinson's disease (PD) patients.
Conclusions: Our therapeutics act to inhibit aggregation, destabilize existing aggregates, and promote the clearance of amyloid aggregates. Together with previous data generated with LC fibrils, these results strengthen our platform technology as a potential therapeutic solution in neurodegenerative diseases like AD and PD.

NASAL PROTOLLIN MODULATES PERIPHERAL MONOCYTES THAT PROMOTE INCREASED CLEARANCE OF BRAIN AMYLOID BETA IN APPPS1 MICE

POSTERS: A02.B. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: IMMUNOTHERAPY

Panagiota Kolypetri, Patrick Da Silva, Christian Gauthier, Rachael Cecere, Estefania Solana, Lei Liu, Howard Weiner
Brigham and Women's Hospital, Neurology, Boston, United States of America

Aims: Nasal administration of Protollin, a proteosome-based adjuvant, leads to reduction of brain amyloid beta (Abeta) in mice developing Alzheimer's disease (AD). In this study, we investigated the effects of nasal Protollin on peripheral monocytes and their contribution on clearance of Abeta in the brain.
Methods: Ly6C^{high} monocytes from peripheral lymphoid organs and brain of APP/PS1 mice were profiled by RNA sequencing; single-cell (sc) RNA-seq of brain cells was conducted using the 10x Genomics Chromium technology; multi-color flow cytometry and ELISA were used to quantify monocytes and brain Abeta respectively; cognitive deficits were assessed using the Y-maze and Morris water maze tests.
Results: We profiled the transcriptome of Ly6C^{high} monocytes from peripheral lymphoid organs and we detected tissue-specific changes after nasal Protollin. In the brain, we found increased recruitment of Ly6C^{high} monocytes that acquired a Protollin-induced transcriptional signature. We directly addressed the role of Protollin-treated monocytes on AD by adoptive transfer of monocytes from nasally treated mice to APP/PS1 animals. Recipient mice showed improved performance in behavioral tests as well as lower brain Abeta compared to controls. To identify unique monocyte-resident brain cell interactions, we performed scRNA-seq and we discovered novel brain cell subsets expressing genes that promote neuronal growth and function. Currently, we investigate the crosstalk between infiltrating monocytes and the newly identified brain cell subsets as well as their impact on Abeta clearance in Protollin-treated mice.
Conclusions: Our data demonstrate that nasal Protollin 1) induces transcriptional changes in peripheral monocytes that migrate to the brain promoting Abeta clearance and improving cognitive deficits and 2) generates unique brain cell subsets promoting neuronal growth and function. Protollin is a novel immunologic approach and it is currently being tested in human trials.

LECANEMAB SUPPORTS PHENOTYPIC CHANGE OF GLIAL CELLS : EVIDENCES IN A VITRO MODEL OF ALZHEIMER'S DISEASE

POSTERS: A02.B. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: IMMUNOTHERAPY

Laura Rouviere, Sarah Lieger, Alexandre Henriques, Esther Steidl, Philippe Poindron, Noëlle Callizot
Neuro-sys SAS, Neuropharmacology Dpt, Gardanne, France

Aims: Alzheimer's disease (AD) is characterized by the extracellular accumulation of senile plaques composed of beta-amyloid (Aβ) and the intracellular deposition of neurofibrillary tangles composed of hyperphosphorylated tau (Tp). Aβ induces a chronic neuroinflammation that contributes to the neurite network disorganization and finally neuronal death. Lecanemab, a humanized monoclonal antibody (Ab) that recognizes protofibrils/oligomers and prevents Aβ deposition, is the first US approved Ab for AD. Its mode of action especially on inflammatory cells is still vague. In this study, we investigated Lecanemab's effect on microglial cells and astrocytes phenotype after Aβ stress.
Methods: Here primary rat cortical neurons, co-cultured with microglia and astroglial cells were used. After 11 days of culture, cells were injured with Aβ for 24 to 72h. Lecanemab was applied one hour before Aβ injury. After fixation, immunocytochemistry was performed in order to analyze different microglial and astroglial markers. For both cell types, pro and anti-inflammatory markers were assessed.
Results: Application of Aβ induced a proliferation of astrocytes and microglial cells. In addition, a significant increase in M1 microglia was observed associated with increase of TREM2/OX-41, 72h after Aβ application and microglial phagocytosis phenotype. A strong reduction of CD206 (M2 markers) was also detected. For astrocytes, a moderate astrogliosis was observed. Interestingly, Lecanemab treatment was able to increase number of S100A (+) cells (A2 population), associated with a moderate increase of GFAP area. This highlights that Lecanemab can induce a change in the astrocyte phenotype.
Conclusions: Altogether, these results showed that microglia and astrocytes phenotypes and functions were modified in disease context, and Lecanemab was able to modulate the Aβ neuroinflammatory response. These results tried to decipher the complex and unclear mode of action of Lecanemab.

SUBSTRATE ECTODOMAIN DEFINES GAMMA-SECRETASE SEQUENTIAL PROTEOLYSIS, AND THEREBY ABETA PRODUCT PROFILES, BY MODULATING PRODUCT RELEASE

POSTERS: A02.C. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: SECRETASES, PROTEASES

Matthias Koch[1], Thomas Enzlein[2], Shu Chen[3], Martin Zacharias[3], Carsten Hopf[2], Lucía Chávez-Gutiérrez[1]

Aims: Sequential proteolysis of the amyloid precursor protein (APP) by γ-secretases (GSECs) defines the proportion of short-to-long amyloid-ß (Aß) peptides that are released into the extracellular/luminal space. This proportion is tightly linked to Alzheimer's disease (AD) pathogenesis. Here, we studied the mechanism(s) controlling the sequential GSEC proteolysis (processivity) and its modulation by small compounds, including GSEC modulators (GSMs) and GSEC inhibitors (GSIs).
Methods: *In vitro* GSEC activity assays were performed to investigate the molecular foundations of enzyme processivity. Thermoactivity assays assessed enzyme-substrate (E-S) stability. GSEC activity and processivity were estimated by western blotting, ELISA and/or mass spectrometry. Analysis of WT/mutant APP_{C99} processing was performed in the presence or absence of pharmacological inhibition or modulation.
Results: We found that polar interactions established by the ectodomain (ECD) of the substrate restrain both the extent and degree of GSEC processivity of APP and Notch. Most importantly, our study shows that the substrate ECD drives product release by destabilizing enzyme-substrate (E-S) interactions; and that increasing hydrophobicity at the APP_{C99} ECD, due to mutation or GSM binding, attenuates this substrate-driven product release mechanism and rescues the effects that AD pathogenic variants exert on Aß profiles. Finally, our study reveals that the paradoxical production of longer Aßs caused by some GSIs (e.g. DAPT and semagacestat) arises from a competitive mechanism, wherein GSI binding to the substrate-binding site either blocks substrate entry or results in the release of partially digested Aß peptides. The APP_{C99} ECD facilitates this process.
Conclusions: These findings assign a pivotal role to the substrate ECD in the sequential proteolysis by GSEC, and suggest it as a sweet spot for the potential design of APP targeting compounds, selectively promoting its processing by GSECs.

DIPHENYLPYRAZOLE COMPOUNDS INHIBIT ABETA PEPTIDE PRODUCTION IN INDUCIBLE SY5Y-C99 CELLS.

POSTERS: A02.C. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: SECRETASES, PROTEASES

Adriana Figueroa Garcia[1], Raphaëlle Pardossi-Piquard[2], Luc Buee[1], Patricia Melnyk[1], Frédéric Checler[2], Nicolas Sergeant[1]

Aims: Amyloid precursor protein (APP) cleavage by the β-secretase produces the β-CTF or C99 that is then endoproteolysed by the γ-secretase to produce the Aβ peptides. Cell expressing the C99 precludes the β-secretase cleavage to study its turnover along with the Aβ peptides. We described a diphenylpyrazole family of compounds that reduces the Aβ production and the soluble β-APP fragment counterpart, suggesting an indirect β-secretase inhibitory mode of action in APP-expressing cells. To better understand the diphenylpyrazole compounds' mode of action, inducible SY5Y-C99 expressing cells were used, and C99 expression and Aβ 1-40/42 and x-40/42 were quantified. We aimed to use structure-activity relationship to decipher the mode of action of the diphenylpyrazole compounds on APP metabolism downstream of the β-secretase cleavage of APP.
Methods: Inducible neuroblastoma SH-SY5Y cells expressing the C99 APP fragment were treated with the diphenylpyrazole compounds in comparison to lead compounds from our previously families of compounds (piperazine and polyaminobiaryl-derived compounds) along with proteasome, lysosomotropic, and γ-secretase inhibitors. C99 expression and metabolism were analyzed by immunoblotting. ELISA measured Aβ 1-40/42 and x-40/42 cell-medium concentration.
Results: Although Aβ 1-40/42 and x-40/42 were diminished by 50 and 75% for all diphenylpyrazoles, respectively, three types of carboxy-terminal fragments profiles distinguish 3 types of activity either comparable to a lysosomotropic class of drugs or proteasome inhibitors.
Conclusions: Structure-activity relationship of the diphenylpyrazole compounds suggests Aβ peptide inhibitors whose mode of action includes activity towards a lysosomotropic or proteasome inhibitory process. Further complementary data will be presented to decipher between these proteostasis mechanisms.

HUMAN GAMMA-SECRETASE FAMILY: DIFFERENTIAL STABILITIES OF ENZYME-SUBSTRATE COMPLEXES EXPLAIN DIFFERENCES IN PROCESSIVITY AND REGULATE RESPONSE TO MODULATORS

POSTERS: A02.C. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: SECRETASES, PROTEASES

Katarzyna Zoltowska, Maria Szaruga, Sara Gutiérrez-Fernandez, Sam Lismont, Lucía Chávez-Gutiérrez
VIB, Vib-ku Leuven Center For Brain & Disease Research, Leuven, Belgium

Aims: Gamma-secretases are multifaceted intramembrane proteolytic systems, the dysfunction of which leads to early-onset Alzheimer's disease (AD). They are composed of four subunits: presenilin (PSEN1 or PSEN2, catalytic subunit), nicastrin (NCSTN), presenilin enhancer 2 (PEN2) and anterior pharynx defective 1 (APH1A or APH1B). In humans, PSEN and APH1 heterogeneity gives rise to four complexes with distinctive proteolytic profiles. Here, we investigated the mechanistic basis for differences in kinetic and pharmacological properties of the human gamma-secretase family, with a focus on amyloid beta production.
Methods: Gamma-secretases and their substrates were expressed using baculoviral expression system and purified via affinity chromatography. *In vitro* gamma-secretase activity assays were performed in the presence or absence of pharmacological modulation. Thermoactivity assays informed about enzyme-substrate (E-S) complex stability.
Results: We found that significant differences in E-S complex stabilities, which define enzyme processivity and amyloid beta length, arise from the composition of gamma-secretases, with PSEN having the greatest impact. Notably, PSEN2-type complexes presented lower E-S stabilities, similar to those observed for early-onset AD-linked PSEN1 variants. The differential E-S complex stabilities modulated the processing of substrates, including the amyloid precursor protein. Finally, thermoactivity assays performed in the presence of gamma-secretase modulators (GSMs) demonstrated that the differential E-S stability translates not only into a distinct degree of enzyme processivity but also has an impact on the response to GSMs.
Conclusions: Our analyses demonstrated a marked impact of gamma-secretase complex composition on enzyme processivity and pharmacological modulation by GSMs. These findings are relevant for the design and analysis of drugs selectively targeting particular subtypes of gamma-secretase complexes in therapy.

Aims: Beta-site APP cleaving enzyme-1 (BACE1) is the rate-limiting enzyme for amyloid-beta (Aβ) production and has been extensively investigated as a therapeutic target for Alzheimer's disease (AD). However, small molecule BACE1 inhibitors have consistently failed in clinical trials. An alternative is the use of low-dose BACE1 inhibition with a highly specific peptidomimetic compound, such as BACE1 inhibitor C3. However, this compound does not cross the blood-brain barrier (BBB). To overcome this, we used rapid short-pulse focused ultrasound (FUS) to transiently disrupt the BBB, allowing for targeted delivery of C3 to the brain. We hypothesise that C3 delivered by FUS is safe and will reduce amyloid pathology in the 5XFAD mouse model of AD.
Methods: Three-month old male 5XFAD mice were randomly assigned to four groups: untreated control, FUS+vehicle, C3 only and FUS+C3. Mice were treated with 0.6mg/kg C3 delivered by 1MHz FUS in a rapid-short pulse sequence targeted to the left hippocampus once a week for 3 weeks. The effects of the treatment were compared among groups and between ipsilateral and contralateral hemispheres. BACE1 activity, plaque load, glial activation and neuronal density were assessed by western blot, ELISA and immunohistochemistry.
Results: Chronic treatment with FUS+C3 reduced amyloid plaque load in the ipsilateral hippocampus compared to the contralateral hippocampus, but did not affect aggregated amyloid. Chronic treatment with FUS+C3 also significantly decreased β-CTF and Aβ expression when compared to the untreated control in frontal cortex homogenates. There were no differences in microglial activation, astrocyte coverage or neuronal density within groups.
Conclusions: C3 can be safely delivered across the BBB by FUS using a rapid short-pulse sequence. Chronic treatment with FUS+C3 reduced BACE1 activity in the cortex and amyloid plaque load in the targeted hippocampus.

RETINOID SIGNALLING REGULATION OF ADAM SECRETASES AND MITOCHONDRIA AS A POSSIBLE AD MOLECULAR THERAPY

POSTERS: A02.C. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: SECRETASES, PROTEASES

José João Mendonça Vitória, Diogo Trigo, Odete Da Cruz E Silva
Institute of Biomedicine - iBiMED, Departamento De Ciências Médicas - Dcm, Aveiro, Portugal

Aims: Introduction: Alzheimer's Disease (AD) is characterized by extracellular deposits of Aβ peptide, resulting from amyloid cleavage of APP. This processing is controlled by α-, β- and γ-secretase. Resulting fragment toxicity is a direct outcome of the first cleavage: β-secretase (BACE1) causes amyloid cleavage, while the competing α-secretases (ADAM10 and ADAM17) produce a protective cleavage. AD is also linked to several cellular alterations at the mitochondrial level. These anomalies can contribute to disease progression but may also trigger cellular rescue mechanisms. Objectives: This study assessed the potential of retinoid signalling as a therapeutic strategy for AD, by modulating cellular and molecular characteristics.
Methods: Methods: Differentiated SH-SY5Y cells were treated with diverse Retinoic Acid Receptor (RAR) agonists and antagonists, the oxidative agent Paraquat, and Aβ peptide. Protein alterations were assessed by western blotting. Mitochondrial changes and homeostasis were analysed by live imaging confocal microscopy.
Results: Results: Results showed a decrease in APP β-cleavage with RARα activation, potentially impacting protein levels via phosphorylation mediated modifications. Retinoid signalling appears to rescue oxidative stress induced mitochondrial damage.
Conclusions: Conclusion: These results lay the foundation to a promising therapeutic strategy, impacting several cellular processes towards neuronal health. MOLECULAR DYNAMICS ACTIVATION OF GAMMA-SECRETASE FOR PROCESSIVE CLEAVAGE OF AMYLOID PRECURSOR PROTEIN AND NOTCH SUBSTRATES

POSTERS: A02.C. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: SECRETASES, PROTEASES

Hung Do[1], Sujan Devkota[2], Shweta Malvankar[2], Michael Wolfe[2], Yinglong Miao[3]
[1]University of Kansas, Department Of Molecular Biosciences, Lawrence, United States of America, [2]University of Kansas, Department Of Medicinal Chemistry, Lawrence, United States of America, [3]University of North Carolina - Chapel Hill, Computational Medicine Program And Department Of Pharmacology, Chapel Hill, United States of America

Aims: γ-Secretase, the "proteasome of the membrane", cleaves within the membrane of 150+ peptide substrates including amyloid precursor protein (APP) and Notch. γ-Secretase carries out endoproteolytic (ε) cleavage and then tripeptide trimming of the substrates. Presenilin-1 (PS1) is the catalytic subunit of γ-secretase and its mutations cause early-onset familial Alzheimer's disease (FAD). Here, we aim to determine molecular mechanisms of γ-secretase activation for processive cleavage of APP and Notch, as well as the effects of FAD mutations.
Methods: We combine all-atom simulations using a novel Gaussian accelerated Molecular Dynamics (GaMD) method and biochemical experiments (including mass spectrometry and western blotting) to investigate processive proteolysis of APP and Notch by γ-secretase, in the presence and absence of FAD mutations.
Results: We have previously reported that aromatic residues such as Phe are not tolerated in the P2' position for γ-secretase cleavage of APP substrate. We now show that this sequence specificity rule applies to Notch1 substrate as well and is therefore likely a general rule for all substrates. GaMD simulations have captured the slow dynamic conformational transitions of γ-secretase and proper cleavages of both the wildtype and mutant Notch1 substrate. In addition, our highly complementary simulations and experiments have revealed that FAD mutations reduced fluctuations the enzyme-substrate complex during the ε cleavage and tripeptide trimming of APP.
Conclusions: We have built the first dynamic models for cleavage of Notch1 and uncovered the effects of FAD mutations in processive proteolysis of APP by γ-secretase through novel GaMD simulations, which were highly consistent with complementary experimental findings. They have provided important mechanistic insights into the effects of mutations in substrate processing of APP and Notch by γ-secretase.

INVESTIGATING THE ROLE OF RARE GENETIC VARIANTS IN ANGIOTENSIN-1-CONVERTING ENZYME IN ALZHEIMER'S DISEASE PATHOGENESIS

POSTERS: A02.C. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: SECRETASES, PROTEASES

Miranda Salvo[1], Leah Cuddy[1], Dmitry Prokopenko[2], Rudolph Tanzi[2], Robert Vassar[1]
[1]Northwestern University, Neurology, Chicago, United States of America, [2]Mass General Institute for Neurodegenerative Disease, Massachusetts General Hospital, Genetics And Aging Research Unit, Department Of Neurology, Charlestown, United States of America

Aims: Recent genome-wide association studies discovered angiotensin-converting enzyme (*ACE*) as a risk locus for developing late-onset Alzheimer's disease (LOAD). The protein ACE1 is known for its role as a blood pressure regulating enzyme in the renin-angiotensin system; however, it is also present in the brain and has other substrates, including amyloid-β. Hypertension is associated with increased risk for developing AD, and people taking some ACE1-targeting therapeutics have reduced incidence of AD. Recent whole genome sequencing (WGS) of LOAD families revealed rare *ACE* coding variants. Previous work from our lab demonstrated that one such variant, rs4980, caused hippocampal neurodegeneration, which was exacerbated by amyloid pathology in a knock-in mouse model. Additional rare AD-risk and AD-protective variants were discovered by WGS in LOAD family cohorts. This project seeks to characterize these rare variants in a cellular model system in order to understand the mechanisms by which they could alter ACE1 processing, expression, function, and affect cell viability.
Methods: SH-SY5Y neuroblastoma cell lines stably expressing each *ACE* variant were used in the following experiments. Cell lines were differentiated for 5 days in retinoic acid, then subjected to experimental procedures to determine ACE1 expression and function as well as markers of apoptosis.
Results: AD-risk variants increased ACE1 catalytic activity while AD-protective variants altered ACE1 membrane expression and ectodomain shedding. No mutations caused overt cell death, indicating the potential involvement of other cell types in AD pathogenic mechanisms.
Conclusions: Increased ACE1 protein activity correlates with AD Braak staging, verifying our activity results. Furthermore, ACE1 ectodomain shedding from the cell membrane may be a protective characteristic in this culture model. Future directions include investigating pathogenic ACE1 substrates such as $A\beta_{42}$, C3, and angiotensin I.

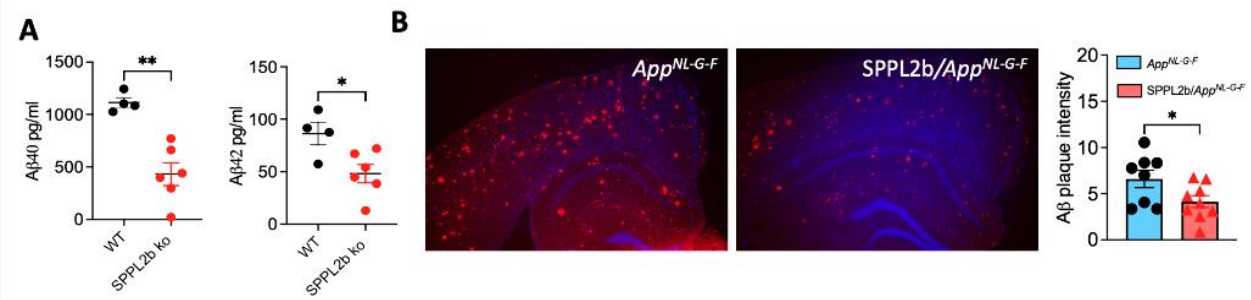
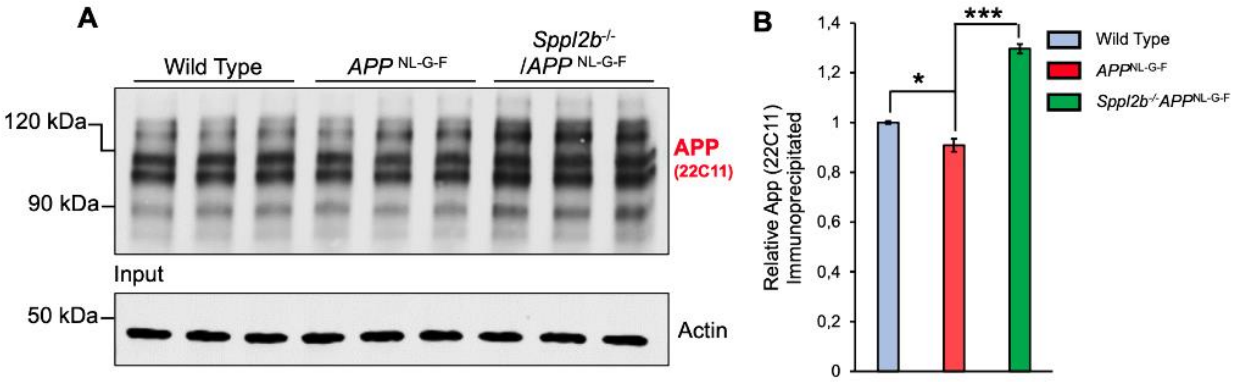
Aims: Signal Peptide Peptidase-Like 2b (SPPL2b) is a promising brain-specific intramembrane protein involved in the cleavage of Alzheimer's disease (AD)-related proteins, such as BRI2, inflammatory-related proteins like CD74, TNFalpha, and Clec7a, and synaptic function proteins Neuregulin-1 and VAMP 1-4. SPPL2b is expressed specifically in the hippocampus and cortex. The cleavage of TNFalpha by SPPL2b promotes the inflammatory pathway. Conversely, the SPPL2b substrate BRI2 regulates amyloid precursor protein cleavage and Aß production. This work explores the pathophysiological role of SPPL2b in AD pathogenesis and investigates the potential of inhibiting SPPL2b as a novel therapeutic strategy.
Methods: To characterize the role of SPPL2b in the APP cleavage process, we used primary cell cultures from WT and SPPL2b-deficient mice. Furthermore, we assessed the therapeutic potential of inhibiting SPPL2b by employing a new AD mouse model generated through crossbreeding state-of-the-art AppNL-G-F knock-in mice with SPPL2b-deficient mice. Secreted Aβ peptides were quantified using ELISA. Cells and mouse brain samples were analyzed through western blotting, immunoprecipitation, and immunofluorescence.
Results: The results showed a significant increase in BRI2 staining, followed by a substantial reduction in soluble APP, Aβ40, and Aβ42 in the media of SPPL2b KO neurons (Fig.1A). Most importantly, a notable decrease in brain on Aβ42 levels and Aβ plaque deposition was observed at 4 months of age in SPPL2b-deficient/AppNL-G-F mice (Fig.1B). Furthermore, immunoprecipitation of BRI2 from the cortex of those mice revealed an increased interaction between BRI2 and APP
(Fig.2).





Conclusions: The results outlined in this study support a relevant connection between SPPL2b and AD. In a global scenario characterized by the need to identify novel strategies to prevent and counteract AD progression, this study highlights and strengthens the importance of SPPL2b as a novel therapeutic approach for AD.

Hoffmann-La Roche AG, Pharma Research & Early Development, Neuroscience And Rare Diseases Translational Area, Neuroscience Early Development, Basel, Switzerland

Aims: Cerebral amyloid accumulation is an important causal factor of AD pathobiology. Long Aβ fragments such as Aβ42 are the major drivers of amyloid accumulation in the brain. Gamma Secretase Modulators (GSMs) reduce the production of amyloidogenic Aβ42 and Aβ40 while proportionally increasing the non-amyloidogenic shorter fragments Aβ38 and Aβ37. Here we investigated how the activity of GSMs is influenced by ADAD mutations and the type of GSMs studied.
Methods: The ADAD mutations PSEN1 E280A ('Columbian mutation'), PSEN1 L166P, and PSEN2 N141I ('Volga German') were studied for their sensitivity to GSMs in vitro.
Results: The PSEN1 E280A mutation showed equivalent sensitivity to GSMs compared to the WT allele, judged by the GSM's capacity to lower Aβ42 levels, compared to the PSEN2 N141I and PSEN1 L166P mutations. The latter two mutations were less sensitive to an early generation NSAID-type GSM compared to latest generation non-NSAID GSMs.
Conclusions: Responses to GSMs have been described for wild type Gamma Secretase (sporadic AD; healthy volunteers) but can differ in ADAD with mutated Gamma Secretase. We show that the presence of ADAD PSEN1/2 mutations profoundly impact the sensitivity of gamma secretase to GSMs. Both non-NSAID and NSAID GSM can ameliorate the effect of specific ADAD mutations, as judged by their Aβ42 lowering potential. However, the efficacy of NSAID and next generation non-NSAID GSMs is variable depending on the nature of specific PSEN1/2 ADAD mutations. Our studies emphasize the importance of carefully characterizing the pharmacology of GSMs in the presence of specific PSEN1/2 ADAD mutations for assessing the potential therapeutic effects of various GSMs in subjects with ADAD mutations.

CHEMICAL, BIOCHEMICAL, CELLULAR, AND PHYSIOLOGICAL CHARACTERIZATION OF LEUCETTINIB-21, A DOWN SYNDROME AND ALZHEIMER'S DISEASE DRUG CANDIDATE

POSTERS: A02.D. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: KINASES, OTHER ENZYMES

Laurent Meijer, Emmanuel Deau, Gaëlle Hogrel, Mattias Lindberg
Perha Pharmaceuticals, Neurosciences, Roscoff, France

Aims: Memory and learning disorders in **Down syndrome** (**DS**) and **Alzheimer's disease** (**AD**) are associated with an increased activity of **DYRK1A** (dual specificity, tyrosine phosphorylation regulated kinase). In DS, DYRK1A is overexpressed by a 1.5-fold factor (*Dyrk1a* gene on chromosome 21) while, in AD, DYRK1A is cleaved by calpains to a low-molecular weight form with enhanced activity and stability. Genetic and pharmacological inhibition of DYRK1A corrects these cognitive disorders in DS/AD animal models, encouraging the development of a **clinical DYRK1A inhibitor** to treat memory/learning difficulties in patients with AD or DS.
Methods: Inspired by **Leucettamine B**, a marine sponge natural product, we synthesized, optimized and extensively characterized >500 analogues, **Leucettines**, followed by a second-generation family, **Leucettinibs** (>670 analogues) and selected an orally available drug candidate, **Leucettinib-21** with favorable pharmacological properties.
Results: Leucettinib-21 was chosen as a drug candidate following extensive structure/activity studies and multiparametric evaluations. We will present its **physico-chemical properties** (X-ray powder diffraction, differential scanning calorimetry, stability, solubility, crystal structure) and **drug-like profile**. Leucettinib-21's **kinase inhibitory selectivity** (analyzed by radiometric, fluorescence, interaction, thermal shift, residence time assays) reveals DYRK1A as the first target, but also some 'off-targets' which may contribute to the drug's biological effects. Leucettinib-21 was **co-crystallized with CLK1** and **modelled in the DYRK1A structure**. Leucettinib-21 inhibits native, endogenous DYRK1A in cells (demonstrated by direct catalytic activity, and phosphorylation levels of Thr286-cyclin D1 or Thr212-Tau). Leucettinib-21 **corrects memory disorders** in the Down syndrome mouse model Ts65Dn.
Conclusions: Leucettinib-21 is entering safety/tolerance phase 1 clinical trials in Q4-2023.

UNVEILING PHYTOCONSTITUENTS WITH INHIBITORY POTENTIAL AGAINST TYROSINE-PROTEIN KINASE FYN: A COMPREHENSIVE VIRTUAL SCREENING APPROACH TARGETING ALZHEIMER'S DISEASE

POSTERS: A02.D. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: KINASES, OTHER ENZYMES

Anas Shamsi[1], Akhtar Atiya[2], Saleha Anwar[3]
[1]Ajman University, Centre Of Medical And Bio-allied Health Sciences Research (cmbhsr), Ajman, United Arab Emirates, [2]King khalid university, Pharmacognosy, Abha, Saudi Arabia, [3]jamia millia islamia, Cirbsc, New Delhi, India

Aims: Tyrosine-protein kinase Fyn (Fyn) is a critical signaling molecule involved in various cellular processes, including neuronal development, synaptic plasticity, and disease pathogenesis. Dysregulation of Fyn kinase has been implicated in various complex diseases, including neurodegenerative disorders such as Alzheimer's and Parkinson's diseases, as well as different cancer types. Therefore, identifying small molecule inhibitors that can inhibit Fyn activity holds substantial significance in drug discovery. The aim of this study was to identify potential small-molecule inhibitors among bioactive phytoconstituents against tyrosine-protein kinase Fyn.
Methods: Through a comprehensive approach involving molecular docking, drug likeliness filters, and molecular dynamics (MD) simulations, we performed a virtual screening of a natural compound library. This methodology aimed to pinpoint compounds potentially interacting with Fyn kinase and inhibiting its activity.
Results: Our study finds two potential natural compounds: Dehydromillettone and Tanshinone B. These compounds demonstrated substantial affinity and specific interactions towards the Fyn binding pocket. Their conformations exhibited compatibility and stability, indicating the formation of robust protein-ligand complexes. A significant array of non-covalent interactions supported the structural integrity of these complexes.
Conclusions: Dehydromillettone and Tanshinone B emerge as promising candidates, poised for further optimization as Fyn kinase inhibitors with therapeutic applications. In a broader context, this study demonstrates the potential of computational drug discovery, underscoring its utility in identifying compounds with clinical significance. The identified inhibitors hold promise in addressing a spectrum of cancer and neurodegenerative disorders. However, their efficacy and safety necessitate validation through subsequent experimental studies.

EVIDENCE FOR DISEASE MODIFYING PROPERTIES OF MEMANTINE WHEN ADMINISTERED PROPHYLACTICALLY TO TRANSGENIC AD AND PURE TAUOPATHY MODEL MICE

POSTERS: A02.E. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: NEUROTRANSMITTERS & RECEPTOR-BASED

Antonia Silva[1], Anna Wasserman[1], Dora Wang[1], Taylor Kim[1], Maurits Jansen[2], Jeremy Gatesman[3], Ileana Mauldin[4], Stuart Berr[2], George Bloom[1]
[1]University of Virginia, Dept. Of Biology, Charlottesville, United States of America, [2]University of Virginia, Radiology And Medical Imaging, Charlottesville, United States of America, [3]University of Virginia, Center For Comparative Medicine, Charlottesville, United States of America, [4]University of Virginia, Dept. Of Pathology, Charlottesville, United States of America

Aims: Our laboratory previously reported that memantine potently blocks neuronal cell cycle re-entry, which precedes most neuron death in AD, when provided to Aβ oligomer-treated cultured mouse neurons and Tg2576 AD model mice (https://doi.org/10.1016/j.jalz.2018.05.017). Those results raised the possibility that memantine, which is FDA-approved for treating moderate to severe AD, has previously unrecognized disease-modifying properties that can be harnessed prophylactically for AD and related diseases (ADRDs). To test that possibility, the current study compared effects of treating AD and pure tauopathy mice with memantine, beginning either before cognitive deficits occur (early) versus when they first appear (late).
Methods: J20 (AD), hTau (pure tauopathy) and congenic wild type (WT) mice had *ad libitum* access to memantine in drinking water. Early treatments began at 5 weeks, and late treatments began at 4 and 6 months, respectively, for J20 and hTau mice. All animals were periodically evaluated by Morris water maze (MWM), novel object recognition (NOR), live animal amyloid PET (J20s only) and MRI, and immunohistochemistry. The experiments ended when mice reached 18 months.
Results: Baseline MWM and NOR performances at the beginning were indistinguishable by strain. At 18 months, however, all mice treated early with memantine had improved MWM performances compared to untreated or late treated mice of the same strain. NOR performance at 18 months was similarly improved for early treated J20s. Early, but not late treatment of J20s caused a striking reduction in plaques at 18 months.
Conclusions: When administered prophylactically to AD and pure tauopathy mice, but not when treatment begins at symptom onset, memantine has disease modifying properties, and reduces learning and memory loss associated with normal aging. These results justify testing memantine prophylactically for human ADRDs.

ONESTX-1, A STEROID SULFATASE INHIBITOR, AS A NOVEL PHARMACOLOGICAL APPROACH TO TREAT ALZHEIMER'S DISEASE

POSTERS: A02.E. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: NEUROTRANSMITTERS & RECEPTOR-BASED

Manuel J. Muñoz[1,2], Mercedes M. Pérez-Jiménez[1,2], Juan Antonio Fernández Cabrera[3], Almudena Ramos Pozo[1], Ines Sánchez Romero[3], Carlos Gómez Marín[1], José María Hernández Curiel[3], Viñas Andrés Simón[2], Sandra Gavaldá[2], Ángel Cebolla[2], Ángel Carrión Rodríguez[2,3]
[1]Centro Andaluz de Biología del Desarrollo (CABD), J.A., UPO, Molecular Biology And Biochemical Engineering, Sevilla, Spain, [2]OLAVIDE NEURON STX, Company, Sevilla, Spain, [3]University Pablo de Olavide, Physiology, Anatomy And Cellular Biology, Sevilla, Spain

Aims: ONESTX-1/STX64/irosustat is a small molecule that inhibits steroid sulfatase (STS) and showed to be active against Alzheimer and Parkinson in animal models. Oral administration of ONESTX-1 induces increment in the ratio of sulfated vs free steroids in animals and humans. In addition, ONESTX-1 showed a good safety and tolerability profile studied in several clinical trials for previous oncology indications. ONESTX-1 increased the lifespan of *C. elegans*, produced beta-amyloid decrease and memory recovery in Alzheimer mice models (Pérez-Jiménez, 2021). In this work, we studied if memory recovery in old mice could be associated to the activation of the cholinergic activity and other pathways associates to starvation.
Methods: Old mice showing cognitive impairment were used in chronic treatment for 6 months (2 mg/L ONESTX-1 in water from a concentrated stock of 5 mg/mL in DMSO). The passive avoidance test was used to assess memory recovery. Nematodes were treated with 1mM of aldicarb to assay cholinergic activity in wild type or in mutants of putative target genes.
Results: Old mice showed memory recovery in the passive avoidance test with ONESTX-1 or epitestosterone sulfate. Others hallmarks of aging, that appear exacerbated in AD, like acetylcholine deficiency, adult neurogenesis decrease and neuroinflammation seems to be rescued by ONESTX-1 treatment. Using mutant strains in *C. elegans*, we started to elucidate the molecular mechanism triggering this effect.
Conclusions: ONESTX-1 may act at different levels against the progression of Alzheimer's disease according to the preclinical data. The antiaging effect of ONESTX-1 at different levels has been shown to be a novel strategy to fight Alzheimer and Parkinson diseases. One of the downstream actions of ONESTX-1 administration was to induce cholinergic activity, which is impaired in Alzheimer's disease.

LEVETIRACETAM PREVENTS AB42 PRODUCTION BY MODULATING APP PROCESSING AND DECELERATES SYNAPSE LOSS IN MOUSE MODELS OF AMYLOID PATHOLOGY.

POSTERS: A02.E. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: NEUROTRANSMITTERS & RECEPTOR-BASED

Nalini Rao, Jeffrey Savas
Feinberg School of Medicine, Northwestern University, Neurology, Chicago, United States of America

Aims: Impaired proteostasis in a hallmark of Alzheimer's disease (AD) and the inability to degrade $A\beta_{42}$ drives downstream pathologies such as synapse deterioration, plaque formation, and neurofibrillary tangles. While downstream repercussions of hampered proteostasis are documented, we lack an understanding of early AD-pathologies that may serve as therapeutic targets. We previously discovered impaired degradation of synaptic vesicle (SV) proteins in *App*-KI mouse models that importantly occurred before $A\beta_{42}$ accumulation. In this work, we investigated how targeting SVs pharmacologically with FDA-approved anticonvulsant Levetiracetam (Lev) could rescue amyloid pathology.
Methods: To achieve this, we utilized *App*-KI models combined with proteostasis reporter lines, mass spectrometry-based analysis, biochemistry, and *in vitro* parallels to address this question.
Results: First, we found a functional proteostasis impairment at presynaptic sites in *App*-KI mice. Next, isolation of SVs from *App*-KI and human Down Syndrome brains with proteolysis determined the orientation of App in SVs. From this finding, we hypothesized the inability to degrade SVs may result in increased amyloidogenic processing. To target SVs, we utilized Lev as this drug binds SV2a and has been shown to slow cognitive decline in AD patients, however the mechanism of action remains unknown. Utilizing *in vivo* stable-isotope mass spectrometry-based quantification, we discovered that Lev notably prevents production of $A\beta_{42}$ via altering the App processing pathway. Next, using an *in vitro* parallel of *App*-KI mice, we found that this function of Lev is SV2a-dependent and modulates amyloidogenic processing by maintaining App plasma membrane localization. Lastly, we demonstrate that Lev treatment decelerates synapse loss in J20 mice.
Conclusions: Taken together, this work determines the mechanism of action for Lev's therapeutic effect in AD, which represents a robust drug-repurposing candidate as it prevents the early stage of $A\beta_{42}$ production.

DESIGN, SYNTHESIS, IN SILICO AND BIOLOGICAL EVALUATION OF MULTI-TARGETABLE CHALCONE DERIVATIVES BEARING N-ARYL PIPERAZINE FOR THE TREATMENT OF ALZHEIMER'S DISEASE

POSTERS: A02.E. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: NEUROTRANSMITTERS & RECEPTOR-BASED

Sushil Kumar Singh, Ashok Kumar, Nilesh Bajad
Indian Institute of Technology (BHU), Department Of Pharmaceutical Engineering & Technology, Varanasi, India

Aims: To develop a drug molecule targeting by two or more mechanisms i.e., a multi-target-directed ligand (MTDL). It is one of the worthwhile approaches in drug discovery against multifactorial diseases like Alzheimer's disease (AD).
Methods: The novel potential MTDLs were designed by scaffold hopping guided strategy and subjected to *in silico* studies and molecular properties analysis. Accordingly, a series of 17 novel multi-targetable chalcone derivatives were synthesized and evaluated for the inhibition of ChEs (eeAChE and eqBuChE), hBACE-1 and blood-brain barrier permeability assay. Furthermore, *in-vivo* behavioural studies were performed on scopolamine-induced amnesia model.
Results: The synthesized lead molecule showed optimal inhibitory activities in micro-molar range against AChE with IC_{50} value of **14.84 ± 1.562** µM and significant BuChE inhibition. It also showed promising blood-brain barrier (BBB) permeability, potential BACE-1 inhibitory activity, and Aβ1-42 aggregation inhibition. The binding mode analysis and protein-ligand stability of the optimal compound with AChE and BACE-1 were revealed with the molecular docking and dynamics simulation studies. The compound showed significant mprovement in memory function in the scopolamine-induced mice model.
Conclusions: Amongst all the tested derivatives, lead-bearing unsubstituted benzylpiperazine fragment and para-bromo substation at chalcone scaffold exhibited potent AChE inhibitory property with significant inhibition of *h*BACE-1. In particular, the findings revealed that the carbon linker between the piperazine and aryl ring-bearing electronegative substituent was essential for the potential activity. Overall results indicated that the multi-targetable chalcone derivatives bearing n-aryl piperazine may be potential novel therapeutic agent for the management of AD.

SYNERGISTIC EFFECTS OF GALANTAMINE AND COTININE IN A TRANSGENIC RAT MODEL OF AD

POSTERS: A02.E. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: NEUROTRANSMITTERS & RECEPTOR-BASED

Carla Wahlich, Johanna Habermeyer, Stephan Von Hörsten
University Hospital Erlangen, Department Of Experimental Therapy And Preclinical Experimental Animal Center, Erlangen, Germany

Aims: Since current treatment strategies for AD show limited efficacy and substantial side effects, new and innovative approaches are needed to provide successful therapy within a worldwide aging population. The aim of this study is to pin down synergistic effects of chronic co-treatment using cotinine, a positive allosteric modulator of alpha7-nicotinic acetylcholine receptors plus galantamine, an acetylcholine-esterase inhibitor. Single and combined preclinical therapeutic efficacy of both components is evaluated in hAPP-transgenic rats with endpoints in information processing, emotionality, memory, attention and cognition.
Methods: 6-month-old pre-symptomatic McGill-R-Thy1-APP and wildtype rats receive either galantamine (3 mg/kg/24h) or cotinine (2 mg/kg/24h) individually or combined via drinking water for 13 weeks. General phenotyping evaluating metabolism (activity and calorimetry) and sensorimotor function (startle response) is conducted before and during the treatment phase. Effects of treatment on emotionality, memory (object recognition), cognitive flexibility and attention (operant conditioning) are assessed starting at the eighth week of the treatment phase.
Results: Evaluation of sensorimotor function confirmed genotype differences such as reduced pre-pulse inhibition in transgenic animals in accordance with previous studies in rodents and patients. Co-treatment remarkably increased pre-pulse inhibition suggesting potentiated benefits compared to single compound administration.
Conclusions: Our project aims to tackle AD symptoms by boosting the cholinergic neurotransmission in a dual manner using galantamine and cotinine, both with promising clinical properties. Effects of their co-treatment on pre-pulse inhibition confirm the successful administration and appropriate dosage of the drugs and support the hypothesis of a positive outcome of synergistic cholinergic modulation on AD pathology. Lack of genotype and treatment effects on advanced memory tasks may be due to the relatively young age of the animals and the comparatively long treatment phase (7 weeks) before behavioral testing.

Aims: Adeno-associated (AAV) vectors are the therapeutic platform of choice for delivery of genetic cargoes; nevertheless, their small packaging capacity is not suitable for the delivery of large constructs, including most CRISPR/dCas9-effector systems. To circumvent this limitation, here we aimed to develop a compact dCas9-based repressor system packaged within a single, optimized AAV vector. We aimed to evaluate the developed system on its ability to silence *APOE*, the primary genetic risk factor for late onset Alzheimer's disease (LOAD).
Methods: To circumvent small packaging capacity of AAVs, here we applied a robust reporter-based single- virus resolution screening method to devise and select for a compact dCas9-based repressor system packaged within a single, optimized vector. The developed system uses a smaller dCas9 variant derived from *Staphylococcus aureus* (*Sa*). A novel repressor was engineered by fusing the small transcription repression domain (TRD) from MeCP2 with the KRAB repression domain. The final d*Sa*Cas9-KRAB-MeCP2(TRD) construct can be efficiently packaged, along with its associated gRNA, into AAV particles.
Results: The AAV-based system, outlined in this study, supported efficient and long-term and sustainably repressing of the expression of multiple genes-of-interest, both *in vitro* and *in vivo*. Most relevantly, we successfully silenced *APOE*, the primary genetic risk factor for late onset Alzheimer's disease (LOAD).
Conclusions: Here we develop a compact dCas9-based repressor system packaged within a single, optimized AAV vector. This new platform will broaden the CRISPR/dCas9 toolset available for transcriptional manipulation of gene expression in research and therapeutic settings.

FUNCTIONAL AND MORPHOLOGICAL EFFECTS OF 12 KDA C-TERMINAL APOE FRAGMENTS IN RAT CORTEX CULTURES

POSTERS: A02.F. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: APOE & LIPOPROTEIN-BASED

Christina Nodin[1], Charlotte Mattsson[2], Charlotte Sahlin[2], Christer Möller[2], Johanna Fälting[2], Johan Pihl[1], Paul Karila[1], Susanne Fabre[2]
[1]Cellectricon AB, Cellectricon Ab, Mölndal, Sweden, [2]BioArctic AB, Research & Development, Stockholm, Sweden

Aims: In a previous study, 12 kDa C-terminal ApoE fragments were identified to be increased in Alzheimer's disease (AD) brain as compared to non-demented controls (NDC). To evaluate potential effects of these fragments in AD pathogenesis we used optical electrophysiology and high content imaging (HCA)-based assays to study effects on function and morphology of neurons and astrocytes in neuronal rat cortical cultures.
Methods: Embryonic rat cortical (rCtx) 384-well format cultures were either transduced with Adeno-associated viruses (AAVs) carrying vectors encoding C-terminal ApoE fragments, or fragments were added directly to cells. Neuronal and astrocyte morphology was quantified using HCA. Further, an optical electrophysiology platform was used to investigate effects on neuronal network activity.
Results: Extracellular addition of 12 kDa C-terminal ApoE fragments to rCtx cultures did not result in any effects on either morphological or functional parameters. This was probably caused by an inadequate uptake of the fragments by the cells. However, using AAV-based expression of 12 kDa C-terminal ApoE fragments, successful expression was demonstrated intracellularly in both neurons and astrocytes. As a result of fragment expression, the number of astrocytes and the density of the astrocytic network was decreased, whereas no effects were observed on the neuronal morphology. The astrocytes thus appeared to be more vulnerable to transduction with AAV-ApoE fragments compared to the neurons. Interestingly, spontaneous neuronal activity was affected by expression of ApoE fragments.
Conclusions: An AAV-based approach to achieve intracellular expression of ApoE fragments was established. Expression of ApoE fragments caused a decrease in astrocytic number and cellular network density. Further, neuronal activity was altered in presence of the 12 kDa C-terminal ApoE fragments. Future studies should include appropriate AAV-controls to ensure the specific effects observed.

Aims: The epsilon4 (E4) allele of apolipoprotein E (APOE) is a major genetic risk factor for late-onset Alzheimer's disease (AD), yet the pathological mechanism is not fully understood. Compared to ApoE2 and ApoE3, ApoE4 is more vulnerable to undergo proteolytic cleavage generating fragments, some of which have been found to be neurotoxic. We analyzed ApoE fragments in brain extracts from AD and non-demented controls (NDE) and identified fragments that were increased in AD brain. Antibodies selective for the identified fragments were developed.
Methods: ApoE fragments in brain extracts from AD and NDE were analyzed using immunoprecipitation (IP) and Western blot (WB), and ApoE bands were excised from SDS/PAGE gel. Protein sequences were identified using nanoLC-MS/MS. Antibodies towards the N-terminus of the different fragment neo-epitopes were generated using hybridoma technique and fragment selectivity was tested using ELISA. Monoclonal antibodies were assessed for target binding by IP of human AD brain extracts and by immunohistochemistry (IHC) on AD brain sections.
Results: WB analysis of human brain extracts revealed a 12 kDa ApoE band that showed increased intensity in AD brain as compared to NDE. NanoLC-MS/MS analysis of the isolated ApoE band demonstrated fragments cleaved at position L198, A199 and G200, all with an intact C-terminus. Monoclonal antibodies selective for the three ApoE fragments were generated and shown to have >1000-fold selectivity for the fragments versus full length ApoE. IP using the fragment selective antibodies demonstrated specific binding in AD brain extracts. Moreover, IHC showed association of the ApoE fragments to amyloid plaques and cerebral amyloid angiopathy on AD brain sections.
Conclusions: C-terminal ApoE fragments were identified as increased in AD brain. Monoclonal antibodies selective for the three fragment variants were generated and used for further characterization.

TARGETING TNF RECEPTORS IN THE TREATMENT OF ALZHEIMER`S DISEASE

POSTERS: A02.G. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-INFLAMMATORY

Irem Bayraktaroglu[1], Natalia Ortí-Casañ[1], Roman Fischer[2], Melanie Eschborn[2], Peter De Deyn[3], Ulrich Eisel[1]
[1]University of Groningen, Department Of Molecular Neurobiology, GRONINGEN, Netherlands, [2]Resano GmbH, Resano Gmbh, Mainz, Germany, [3]University of Groningen, Department Of Neurology And Alzheimer Center, Groningen, Netherlands

Aims: Tumor necrosis factor alpha (TNF-α), a pro-inflammatory cytokine, has been implicated in the pathogenesis of AD. However, anti-TNF therapies failed so far in treating Alzheimer's disease due to the opposing functions of TNF receptors, with TNFR1 associated with neurodegeneration and TNFR2 associated with neuroprotection. Thus, specific targeting TNFR could represent a promising strategy for AD treatment. In this study, we investigate the efficacy of a TNFR1 antagonist and novel TNFR2 agonist in the J20 mouse model of AD.
Methods: Mice will be treated with the TNFR1 antagonist or the novel TNFR2 agonist via intraperitoneal (ip) injections for 6 weeks, twice a week, while the control group will receive phosphate-buffered saline (PBS) injections. At the end of the treatment, behavioral tests will be conducted to assess spatial memory, working memory, and anxiety levels. After the perfusions, FACS analysis will be performed to determine the peripheral effects of the treatment. The brain sections will be immunohistochemically stained for different markers, not only but including Aβ plaques, microglial activation, phagocytic microglia, and inflammasome formation.
Results: Our group has recently shown that a TNFR2 agonist ameliorated neuropathology and improved cognition in an AD mouse model. Moreover, we demonstrated that a TNFR1 antagonist reduces memory deficits in an acute mouse model of neurodegeneration. Thus, in this study, we expect improved cognition, reduced AB plaques, increased microglial activation, and increased phagocytic microglia around the plaques. We also expect to see changes in T-cell response and pro-inflammatory response.
Conclusions: Our study aims to evaluate the efficacy of the TNFR1 antagonist and a novel TNFR2 agonist in mitigating AD neuropathology and improving cognition as well as finding peripheral changes to support the hypothesis that AD is more than a brain disease.

ENHANCED IN VIVO BLOOD BRAIN BARRIER TRANSCYTOSIS OF A P2X7 RECEPTOR BLOCKING MACROMOLECULAR CARGO USING AN ENGINEERED PH-SENSITIVE MOUSE TRANSFERRIN RECEPTOR BINDING NANOBODY

POSTERS: A02.G. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-INFLAMMATORY

David Brody
Uniformed Services University of the Health Sciences, Neurology, Bethesda, United States of America

Aims: The blood brain barrier (BBB) limits entry of macromolecular diagnostic and therapeutic cargos. BBB transcytosis via receptor mediated transport systems, such as the transferrin receptor, can be used to carry macromolecular cargos with variable efficiency. We hypothesized that pH-dependent unbinding of transport shuttles can be used to improve BBB transport efficiency.
Methods: A mouse transferrin receptor binding nanobody, NIH-mTfR-M1, was engineered to confer greater unbinding at pH 5.5 vs 7.4 by introducing multiple histidine mutations. Multi-nanobody constructs including the mutant $M1_{R56H,\ P96H,\ Y102H}$ and two copies of the P2X7 receptor-blocking 13A7 nanobody were produced to test proof-of-concept macromolecular cargo transport *in vivo* using quantitatively verified capillary depleted brain lysates and *in situ* histology. All animal studies were approved by the NINDS IACUC.
Results: Levels of the heterotrimeric construct $M1_{R56H,\ P96H,\ Y102H}$ -13A7-13A7 in capillary depleted brain lysates peaked at 1 hour and were 60% retained at 8 hours. A control construct with no brain targets was only 15% retained at 8 hours. At 30-60 minutes, the biotinylated nanobody construct was visualized in capillaries using *in situ* histochemistry, whereas at 2-16 hours it was detected in diffuse hippocampal and cortical cellular structures. Levels of the construct reached more than 3.5% injected dose/gram of brain tissue after 30 nmol/kg intravenous injection. However, higher injected concentrations did not result in higher brain levels, compatible with saturation and an apparent substrate inhibitory effect.
Conclusions: The pH-sensitive mouse transferrin receptor binding nanobody may be useful for rapid and efficient modular transport of macromolecular cargos across the BBB in mouse models. Additional development will be required to determine whether this nanobody-based shuttle system will be useful for brain imaging and fast-acting therapeutics to reduce aberrant neuroinflammatory P2X7 signaling.

NETWORK PROXIMITY IS PROMISING IN ANTI-INFLAMMATORY DRUGS TO ALZHEIMER'S DISEASE TARGETS

POSTERS: A02.G. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-INFLAMMATORY

Jingchun Chen, Joan Cue, Davis Dammann, Jeffrey Cummings
University of Nevada, Las Vegas, Nevada Institute Of Personalzied Medicine, Las Vegas, United States of America

Aims: Disease-modifying therapies (DMTs) for Alzheimer's disease (AD) have a near 100% failure rate in clinical trials. One common cause is the lack of engagement with protein targets relevant to the disease. A promising approach to address this concern is to calculate the network proximity of drug targets to AD-associated targets within the graph network of the human protein-protein interactome (PPI).
Methods: In this preliminary study, we assessed the network proximity of drugs with anti-inflammatory mechanisms of action that are currently in the AD clinical trial pipeline (n=21) to AD risk targets. All candidate drugs and their targets were obtained from the DrugBank database, and AD-associated targets were from a recent GWAS. We calculated the closest proximity of targets for each drug to the AD target module within the human PPI network. We then generated relative distances (z-scores) along with their *p*-values. Finally, we established the drug-disease relationships based on randomly sampled modules with the same number of connections as the original drug-disease modules. Drugs with a negative z-score and $p < 0.05$ are considered to be closer to the target disease than expected by chance, whereas drugs with a positive z-score are farther away.
Results: Our results indicate that Masitinib, as well as a combination of Dasatinib and Quercetin, exhibited significant relative proximity to the AD module ($p < 0.05$).
Conclusions: Of note, the proximity of Masitinib is particularly promising, given that a recent phase 3 trial of the drug demonstrated significant improvement in cognition and daily living compared to the placebo. Further validation including more drugs in proximity calculations with cell-type-specific AD target modules, along with patient electronic health records data and comparator drugs is warranted.

INHIBITION OF P38ALPHA MAPK RESCUES SYNAPTIC FUNCTION AND BEHAVIORAL PERFORMANCE IN A MOUSE MODEL OF MIXED VASCULAR AND AMYLOID PATHOLOGIES

POSTERS: A02.G. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-INFLAMMATORY

Hilaree Frazier, David Braun, Verda Davis, Meggie Coleman, Colin Rogers, Linda Van Eldik
University of Kentucky, Sanders-brown Center On Aging, Lexington, United States of America

Aims: Cerebrovascular dysfunction is frequently comorbid with Alzheimer's disease (AD), yet the mechanistic consequences of this mixed pathology remain unclear. Recent work suggests that p38alpha MAPK, a regulator of neuroinflammation, may represent an effective target for AD therapies. For example, MW150, a small molecule p38alpha inhibitor, was shown to improve cognition and decrease cytokines in amyloidogenic mice. However, p38alpha inhibition in the context of mixed vascular and AD pathologies has yet to be thoroughly characterized. We therefore tested if MW150 could reduce neuroinflammation, synaptic dysfunction, and cognitive impairment in a model of mixed amyloid and cerebral small vessel disease (hyperhomocysteinemia [HHcy]).
Methods: To induce HHcy, 5xFAD mice were transferred to a B-vitamin-deficient diet for 8-weeks. WT animals were maintained on control diet. During diet exposure, animals also received intraperitoneal injections of saline vehicle or MW150. Endpoints included behavioral assessments, quantification of cytokines, immunohistochemistry, neuroimaging, and extracellular field recordings.
Results: Mixed dementia (MD) mice had altered cerebrovascular function, increased proinflammatory cytokines and glial cell activation, impaired synaptic transmission, reduced synaptic proteins, and worsened behavioral performance. No effect of MW150 was detected on cytokines, amyloid or vascular pathology, or glial cell activation. Surprisingly, however, the compound did rescue several measures associated with synaptic dysfunction, including population spike thresholds, LTP maintenance, synaptic protein expression, and hippocampal synapse numbers. Behavioral performance on the Morris water maze test was also significantly improved in MD MW150 mice.
Conclusions: These findings support further investigations of p38alpha inhibitors in the clinic, and suggest p38alpha may mediate pathways associated with hippocampal synaptic plasticity. Future work will use a similar technique in other mixed models in order to characterize the translatability of this approach across pathologies (i.e. HHcy and tau).

Aims: Our ANIMATE-FCT project aims at disentangling the clinical value of inflamma-miRNAs and exosomes in Alzheimer's disease (AD). Our previous studies revealed that miR-124-3p modulation reduces APP695 toxicity and tau phosphorylation. Here, we aimed to validate miR-124 as a therapeutic strategy in the neuronal-microglia crosstalk, using 'organ-on-a-chip' (OoC) microfluidic devices and miRNA-engineered neuronal exosomes as a delivery vehicle.
Methods: Exosomes isolated from neuroblastoma SH-SY5Y cells, were enriched with miR-124 (EF124) using ExoFect™. Cellular models included mouse primary microglia, human cell lines, such as SH-SY5Y APP(Swe) cells, CHME-3 microglia, and immortalized human astrocytes, which were cultured in 5:3:2 ratio at OoCs. Exosomes were isolated by differential ultracentrifugation and characterized by NTA and Western Blot. H_2O_2 (10 µM) was used to favor AD oxidative/aging conditions. miRNA/gene expression profiles were determined by RT-qPCR, and proteins by western blot and immunofluorescence.
Results: Both mouse primary microglia and human neuron-astrocyte-microglia microfluidic chips revealed higher EF124 cellular uptake and miR-124 increase, compared with other delivery approaches. In primary microglia, EF124 inhibited Iba1 immunofluorescence, iNOS transcription, and induced arginase-1/TREM2 gene expression. In the AD OoCs, EF124 restored neurite health, improved glial cell morphology, reduced S100B levels, and regulated microglial P2RY12. Transcriptional analysis upon EF124 treatment suggests benefits in neurons (nNOS reduction, PSD95/synaptophysin elevation), microglia (MHC-II reduction, TREM2 elevation), and astrocytes (S100B reduction). miRNA profiling revealed increased miR-124-3p across all the cell types, and of miR-146a-5p in neurons and astrocytes. Upregulated miR-125b-5p and downregulated miR-21-5p/miR-155-5p were exclusive of astrocytes from EF124-treated OoCs tricultures.
Conclusions: In summary, EF124 demonstrates promise to foster neuroregenerative effects through its immunomodulatory capacity under an AD milieu. Scaling up EF124 production using bioreactors will facilitate clinical translation and therapeutic benefits will be confirmed in the 5xFAD mouse model.

OPTIMIZATION AND EVALUATION OF PYRIDINYL VINYL SULFONES AS NRF2 ACTIVATOR FOR THE ANTIOXIDANT AND ANTI-INFLAMMATORY EFFECTS

POSTERS: A02.G. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-INFLAMMATORY

Byungeun Kim[1,2], Ki Duk Park[1,2]
[1]Korea Institute of Science and Technology, Center For Brain Disorders, Seoul, Korea, Republic of, [2]University of Science and Technology, Daejeon,, Division Of Bio-medical Science & Technology, Daejeon, Korea, Republic of

Aims: Many studies have reported that chalcone-based compounds exhibit biological activities such as anticancer, antioxidant, anti-inflammatory and neuroprotective effects. Among the published chalcone derivatives, (E)-1-(3-methoxypyridin-2-yl)-3-(2-(trifluoromethyl)phenyl)prop-2-en-1-one (VEDA-1209), which is currently undergoing preclinical study, was selected as a starting compound for the development of new nuclear factor erythroid 2-related factor 2 (Nrf2) activators. Based on our previous knowledge, we attempted to redesign and synthesize VEDA-1209 derivatives by introducing the pyridine ring and sulfone moiety to ameliorate its Nrf2 efficacy and drug-like properties.
Methods: Based on the VEDA-1209 scaffold, we synthesized the optimized analogs by attempting to modify sulfoxide, sulfone, and various functional groups. The synthetic method is divided mainly into producing vinyl sulfoxides and vinyl sulfones. A route for the preparation of final compounds is specified in **Scheme.**
Results: Among the synthesized compounds, (E)-3-chloro-2-(2-((3-methoxypyridin-2-yl)sulfonyl)vinyl) pyridine (10e) was found to have approximately 16-folds higher Nrf2 activating effects than VEDA-1209 (10e: EC50 = 37.9 nM vs VEDA-1209: EC50 = 625 nM) in functional cell-based assay. In addition, 10e effectively improved drug-like properties such as CYP inhibition probability and metabolic stability. Finally, 10e demonstrated excellent antioxidant and anti-inflammatory effects in BV-2 microglial cells and significantly restored spatial memory deficits in lipopolysaccharide (LPS)-induced neuroinflammatory mouse models.
Conclusions: Most of the synthesized compounds showed excellent Nrf2 activation and improved drug-like properties by introducing sulfone core, pyridine rings, and functional groups of VEDA-1209. The compound 10e was selected for further evaluation as it exhibited potent Nrf2 activation and favorable drug-like properties. Furthermore, the 10e remarkably upregulated Nrf2-dependent antioxidant response genes, and suppressed NO production and proinflammatory cytokines in the BV-2 microglial cells. Finally, the 10e ameliorated memory deficit and suppressed the inflammatory response in the LPS-induced mouse model.

SYSTEMIC ADMINISTRATION OF A TNF RECEPTOR 2 AGONIST IMPROVES NEUROPATHOLOGY AND COGNITIVE FUNCTIONS IN A HUMANIZED ALZHEIMER'S DISEASE MODEL

POSTERS: A02.G. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-INFLAMMATORY

Natalia Ortí-Casañ[1], Harald Wajant[2], H. Bea Kuiperij[3], Marcel Verbeek[3], Peter De Deyn[4], Petrus Naude[4], Ulrich Eisel[1]
[1]University of Groningen, Molecular Neurobiology, Gelifes, Groningen, Netherlands, [2]University Hospital Wurzburg, Molecular Internal Medicine, Wurzburg, Germany, [3]Radboud University, Neurology, Nijmegen, Netherlands, [4]University of Groningen, Neurology And Alzheimer Center, Groningen, Netherlands

Aims: Alzheimer's disease (AD) is a progressive neurodegenerative disorder and the most common cause of dementia. Accumulating experimental evidence shows the important role of tumor necrosis factor-α (TNF-α) signaling in AD, but the exact role of TNF-α in AD is still not completely understood. Although TNF-inhibitors are successfully used for treatment of several autoimmune diseases, like rheumatoid arthritis, total inhibition of TNF-α can cause adverse side effects in neurological diseases. This is attributed to the opposing roles of the two receptors of TNF-α. TNF receptor 1 (TNFR1) predominantly mediates inflammatory and pro-apoptotic signaling pathways, whereas TNF receptor 2 (TNFR2) is related to neuroprotection and promotes tissue regeneration. Thus, the specific activation of TNFR2 signaling seems a promising strategy for AD therapy.
Our approach consists on treating an APP overexpressing AD mouse model that contains a chimeric human TNFR2 with a human-specific TNFR2 agonist to investigate its effectiveness in AD-related pathology.
Methods: Treated and control animals were evaluated in behavioral tests and neuropathological changes were investigated.
Results: Our results showed that administration of the TNFR2 agonist resulted in a drastic reduction of Aβ plaques and beta-secretase 1 (BACE-1). Moreover, we observed an increase in microglial activation and phagocytosis, which could be related to a higher clearance rate of Aβ. Finally, at the behavioral level, our treatment showed an improvement in cognitive functions.
Conclusions: These results suggest that activation of TNFR2 might be useful as a potential treatment for AD.

INVESTIGATION OF PRO-INFLAMMATORY CYTOKINE RELEASE IN A HUMAN MONOCYTE-DERIVED MICROGLIAL MODEL IN RESPONSE TO PURINERGIC AGONISTS AND ANTAGONISTS

POSTERS: A02.G. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-INFLAMMATORY

Omar Qureshi[1], Jamie Cowley[2], Ashley Pegg[2], Arshpreet Kaur[2], Leila Sallie[2], Ines Morano[2], Hujo Chan[2], Zhi Li[2], Neale Harrison[2], Mark Bryant[2], Catherine Brady[2], John Gordon[2], Nicholas Barnes[2]
[1]Celentyx, In Vitro Pharmacology, Birmingham, United Kingdom, [2]Celentyx Ltd, In Vitro Pharmacology, Birmingham, United Kingdom

Aims: Neuroinflammation is generally accepted as a major driver of neurodegeneration with genetic evidence linking 'myeloid' associated genes (e.g. TREM2, CD33, ABCA7 and CR1) with AD risk and supporting a role for microglia (and infiltrating monocytes) in mediating pathology. Microglia express several purinergic receptors including P2X7, P2X4, A2A, A3, P2Y4, P2Y6 and P2Y12 receptors which regulate their function.
Methods: We exposed human monocytes to a cocktail of CNS-associated cytokines over 5-10 days to generate a cell type with features of human microglia (iMDM). We then used these iMDM to investigate cytokine release in response to purinergic stimulation.
Results: IL-1b release from LPS-primed iMDM was evoked by the P2X7 agonist BzATP, which was prevented in a concentration-dependent manner by P2X7 antagonists and NLRP3 inhibitors. However, BzATP also had a suppressive effect on TNFa release that was not P2X7-independent. While this suppressive effect on TNFa release could be mimicked by adenosine receptor agonists, use of receptor specific antagonists suggested the BzATP-mediated inhibition was occurring via a distinct pathways. The anti-inflammatory impact of adenosine however was mixed, as when present during iMDM differentiation, adenosine increased release of IL-6. While suramin to an extent was able to reverse the impact of BzATP on TNFa release, individual P2Y antagonists did not have the same impact suggesting a more complex pharmacology that may involve different or heteromeric receptors. Finally while TNFa release in response to LPS was not sensitive to NLRP3 inhibition, in the presence of BzATP, responses exhibited a degree of sensitivity to NLRP3 inhibitors.
Conclusions: These findings suggest purinergic signalling has the potential to regulate neuroinflammation and is likely determined by integrated crosstalk from different purinergic receptors.

BIPOLAR DISORDER AS DELAYED AND INITIAL MANIFESTATION OF LYME DISEASE: IMPROVEMENT AFTER ANTIBIOTIC TREATMENT

POSTERS: A02.G. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-INFLAMMATORY

Iva Sarac[1], Helena Sarac[2], Neven Henigsberg[3], Fran Borovečki[4], Zdravko Krešić[5]
[1]University of Zagreb, School Of Medicine, Zagreb, Croatia, [2]KBC Zagreb, Neurology, Zagreb, Croatia, [3]University of Zagreb, Schoool of Medicine, Psychiatry, Zagreb, Croatia, [4]University of Zagreb, School of Medicine, Neurology, Zagreb, Croatia, [5]General Health Center East, General Practice, Zagreb, Croatia

Aims: Patients with Borrelia burgdorfer (bB) infection are at increased risk of later suffering from psychiatric disorders. So, far, very few cases of patients with history of Bb infection have been described, presenting with psychosis, mood disorders, schizophrenia and schizoaffective disorder bipolar type. This case describes schizoaffective disorder, bipolar type as presenting manifestation of Lyme disease in a patient with a long history of Bb infection.
Methods: A 42-year-old male was initially presented to the Department of Neurology in 2022 due to long-lasting behavioural changes despite psychiatric treatment. His medical history revealed that he had numerous tick bites throughout his life, in 2013 with erythema migrans that was not treated with antibiotics. He has had his first mood symptoms since 2017, since then they have been in constant progression. He was treated with haloperidol, flufenazinchloride, olanzapine. Since 2020 he feels weakness, fatigue and paresthesias. A lyme-disease-serologic tests were positive. He had been treated with a three week course of doxycycline and there were no signs of active Bb infection. However, his bipolar symptoms persisted. Control serologic tests were positive and ceftriaxone was given for 3 weeks.
Results: Several days after ceftriaxone treatment, psychotic symptoms partially improved. His somatic delusions began to improve. On the combination of olanzapine 5 mg in the morning and clonazepam 0.5 mg at bedtime, psychotic symptoms and mood symptoms improved even more. At the time of discharge the patient denied somatic delusions.
Conclusions: This case demonstrated that psychiatric disturbances in Lyme disease may be improved after adequate antibiotic therapy, which is contrary to earlier cases in which psychiatric symptoms persisted or worsened which could be a secondary consequence of inflammation-induced neurodegeneration.

DISCOVERY AND OPTIMIZATION OF NOVEL POTENT BRAIN PENETRANT NLRP3 INHIBITORS

POSTERS: A02.G. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-INFLAMMATORY

Tamara Seredenina[1], Jerome Molette[1], Chantal Alliod[1], Roger Moser[1], Alessio Mylonas[1], Véronique Dehlinger[1], Kasia Piorkowska[1], Thomas Jaquier[1], Alexandra Casel-Teav[1], Gloria Pittet[1], Lea Champion[1], Davide Basco[1], Sonia Poli[1], Andrea Pfeifer[2], Marie Kosco-Vilbois[2]
[1]AC Immune, Research, Lausanne, Switzerland, [2]AC Immune SA, Research, Lausanne, Switzerland

Aims: NLRP3 inflammasome activation in microglia is involved in multiple pathological mechanisms of neurodegenerative disorders including Alzheimer's disease (AD). Misfolded proteins, dying neurons, mitochondrial and lysosomal dysfunction all activate NLRP3, promoting a proinflammatory microenvironment and decreasing the efficiency of microglial phagocytosis resulting in further aggregation of misfolded proteins. Genetic NLRP3 deficiency and first-generation NLRP3 inhibitors demonstrated therapeutic benefit in multiple models of neurodegeneration. However, NLRP3 inhibitors with improved brain penetration need to be developed and validated.
Methods: The efficacy of NLRP3 inhibition was evaluated in cell-based assays and in a mouse model of LPS-ATP induced acute peritonitis. Target engagement was confirmed using a MCC950-competition BRET assay. Selectivity over other inflammasomes, ADME properties and safety were evaluated, and pharmacokinetic profile explored in rodents.
Results: Using rational drug design and iterative medicinal chemistry optimization, several distinct chemical scaffolds of small molecule NLRP3 inhibitors were generated. Following NLRP3 activation, IL-1β production by primary human and mouse macrophages, microglia and whole blood, was potently inhibited by selected compounds with efficacy in the low nanomolar range. *In vivo*, this translated into a potent inhibition of NLRP3 in the acute peritonitis model showing IC_{50} = 10 nM. Selected compounds displayed excellent physico-chemical properties, good safety margin in hERG inhibition, no genotoxicity and no off-target binding. Brain penetration was optimized to reach unbound brain-to-plasma partition coefficient (Kp,uu,brain) > 0.3 and ensure efficient NLRP3 inhibition in the brain for 24h at 50 mg/kg.
Conclusions: These novel, potent, selective and brain penetrant NLRP3 inhibitors will enable the preclinical and clinical validation of the therapeutic potential of safely restoring microglial homeostasis in neuroinflammatory and neurodegenerative diseases including AD, alone or in combination with successful Abeta-lowering therapies.

NOVEL PYROPTOSIS INHIBITORS AND THEIR THERAPEUTIC POTENTIAL

POSTERS: A02.G. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-INFLAMMATORY

Shijun Zhang
Virginia Commonwealth University, Medicinal Chemistry, Richmond, United States of America

Aims: Pyroptosis is a type of inflammasome-dependent cell death, and has been indicated critical roles in neurodegenerative disorders including Alzheimer's disease (AD). However, small molecule pyroptosis inhibitors that target the downstream of inflammasome activation are scarce and only a limited number of compounds that have been used for other indications or purposes were reported to show inhibitory activities on pyroptosis. Therefore, rationally designed pyroptosis inhibitors would be valuable as chemical probes and lead compounds for development of therapeutics. Recently, we have identified a small molecule lead compound as pyroptosis inhibitor and preliminary characterization demonstrated promising protective activities of this lead compound. In this presentation, we will descibe and report 1) Rational design of new analogs to improve potency; 2) mechanistic studies using biophysical and chemical biology methods; 3) systemic characterization of the selected compounds.
Methods: The following methods have been employed: 1. Rational design and chemical synthesis. 2. Binding affinity measurement using MST and fluorescence spectrometer. 3. Chemical biology studies using photoaffinity labeling and protein thermal shift assay. 4. Cellular testing using iBMDMs to examine membrane pore formation, LDH amd IL-1beta release, and cleavage of GSDMD.
Results: A lead compound with novel chemial scaffold was identified. This compound exhibits protection of LPS/nigericin induced pyroptosis with a nanomolar potency. Mechanistic studies suggetsed gasdermin D as a potential target for this lead compound.
Conclusions: Structure-activity relationship studies of a hit compound led to the identification of a new lead compound as pyroptosis inhibitor with nanomolar potency. The observed protective activity of this lead compound is, at least partially, through its binding interactions with gasdermin D and inhibiting its pore formation. The results strongly encourage further development of this scaffold to provide novel pyroptosis inhibitors.

Aims: Alzheimer's disease (AD) is the leading cause of dementia and loss of autonomy in the elderly, with increasing incidence and no cure, indicating the need for novel approaches to AD therapy. Here, we aimed to evaluate the neuroprotective function of two novel alkaloids of the pyrrocidin family, CL0179 and its structural analogue CL0670, against amyloid-β (Aβ) toxicity in mice, both *in vitro* and *in vivo*.
Methods: We used an $A\beta_{25-35}$ oligomers (10 μM) toxicity model in primary neurons to assess neuroprotective and antioxidant activity. Moreover, we used an $A\beta_{25-35}$ (9 nmol) intracerebroventricular (icv) injection model in mice to evaluate neuroinflammation, neurodegeneration and cognitive performance.
Results: In primary neurons, we found that CL0179 and CL0670 compounds prevents Aβ-induced oxidative stress and apoptotic death. In Aβ-injected mice, both CL0179 and CL0670 compounds protected against Aβ-induced gliosis and neurodegeneration. Furthermore, animals treated with these pyrrocidine alkaloids preserved their memory after Aβ icv injection. Finally, using RNA-seq analysis in neurons led to the identification of several molecular hits likely regulated by these alkaloids that may be responsible for their antioxidant and neuroprotective activity.
Conclusions: The pyrrocidine alkaloids CL0179 and CL0670 show marked neuroprotective modulatory brain response against Aβ damage in living mice, strongly suggesting that these novel compounds are promising therapeutic candidates in AD. Funded by The Instituto de Salud Carlos III (PI21/00727 and PMP22/00084, cofunded by the European Union -); Agencia Estatal de Investigacion (PID2019-105699RB-I00; PID2022-138813OB-I00); FEDER; Junta de Castilla y León (CS/151P20; 04/18/LE/0017).

DEVELOPMENT OF NOVEL POLYMER-DRUG CONJUGATES: TOWARDS A MULTI-TARGET TREATMENT FOR ALZHEIMER'S DISEASE

POSTERS: A02.H. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-OXIDANTS

Nuruddin Mahadik, Gemma Barron, Paul Kong Thoo Lin, Colin Thompson
Robert Gordon University, School Of Pharmacy And Life Sciences, Aberdeen, United Kingdom

Aims: To design novel antioxidant and anticholinesterase polymer-drug conjugates (PDCs) to treat Alzheimer's Disease (AD).
Methods: An antioxidant drug was conjugated to a cationic polymer (NM15) and an anticholinesterase drug was conjugated to an anionic polymer (N10) and each was characterized by FT-IR and ^{1}H NMR. The antioxidant activity of NM15 was analysed *in vitro* using the ORAC and ABTS assay. The AChE and BuChE activity of N10 was analysed *in vitro* using Ellman's assay. Cell viability and cellular protection from oxidative damage and inflammation were determined in SH-SY5Y and BV-2 cells treated with NM15 *in vitro* using the MTT assay.
Results: Successful conjugation of NM15 and N10 was shown with FT-IR and ^{1}H NMR. NM15 showed significantly enhanced *in vitro* antioxidant activity in ORAC (11333±463 µmolTE/1g) and ABTS (IC_{50}= 19.07±1.1 µg/mL) assay compared to parent antioxidant drug (ORAC 6553±491 µmolTE/1g, ABTS activity IC_{50}= >10 mg/mL) and polymer (ORAC activity could not be determined, ABTS IC_{50}= 44.08±1.56 µg/mL) ($p \leq 0.0001$). Using Ellman's assay, N10 significantly increased AChE (IC_{50}= 0.340±0.01 µg/mL) and BuChE activity (IC_{50}= 1.26±0.1 µg/mL) compared to the parent anticholinesterase drug (AChE IC_{50}=1.67±0.1 µg/mL, BuChE IC_{50}=4.16±0.5 µg/mL) ($p \leq 0.0001$). NM15 was toxic to both cell lines (below 80% cell viability), so a polyelectrolyte complex (PEC) was developed. PEC NM15 significantly protected SH-SY5Y and BV-2 cells from oxidative damage. Results showed 30% and 40% protection against H_2O_2 in SH-SY5Y and BV-2 cells ($P \leq 0.0001$), respectively, as well as 35% protection against Rotenone/Antimycin A in SH-SY5Y ($P \leq 0.0001$) and 25% protection in BV2 cells ($P \leq 0.01$) against Lipopolysaccharide-(LPS) induced inflammation.
Conclusions: This work has demonstrated the possible use of PDCs for the future development of a multi-target treatment option for AD.

Aims: Cognitive reserve plays a crucial role in how individuals cope with age-related or Alzheimer's disease (AD) cognitive decline. Investigating neurobiological pathways involved in cognitive resilience can uncover mechanisms and potential therapeutic targets.
Methods: We investigated early cognitive stimulation's effects (training and regular Delayed Non-matched to Sample task performance from 3 to 18 months) on memory (novel object recognition), functional and structural MRI-based connectomics (Rs-fMRI and DWI), synaptic plasticity markers, and microglia morphology. Our study followed a longitudinal design, including male and female wildtype (WT) rats and the TgF344-AD (TG) AD rat model.
Results: A three-way ANOVA on the recognition index at 19 months showed a cognitive stimulation effect ($p<0.05$). Trained TG males exhibited improved recognition memory compared to untrained rats, with no treatment effect in females. Structural connectomics showed a significant treatment-genotype interaction ($p<0.05$), assessed using a linear mixed model, preserving integration and segregation over time in male trained WT and TG rats vs their untrained counterparts. Intriguingly, functional connectomics analysis indicated a significant treatment effect ($p<0.01$) only in female rats. Western blot analysis revealed enhanced expression of synaptic plasticity markers (PSD95, pGluR1 and pS6), in trained TG animals, primarily in males. Concerning microglia, various morphological features assessed through IF techniques demonstrated a transient neuroinflammatory protection in TG animals at 11 months of age, which was primarily observed only in trained TG males at 19 months of age.
Conclusions: Our study suggests that cognitive stimulation enhances specific synaptic plasticity-related biological pathways and promotes a healthier neuroinflammatory cell population. This leads to sustained neuroplasticity, improved ability to reconfigure large-scale connectivity, and increased resilience against AD-induced memory deficits. This cognitive stimulation may have a greater impact in male than in female.

BIOANALYSIS OF PYRROLOQUINOLINE QUINONE, A POTENTIAL COGNITIVE ENHANCER IN MICE BRAINS.

POSTERS: A02.H. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-OXIDANTS

Mai Mostafa[1], Reham Abdelkader[2], Rasha Hanafi[1]
[1]German university in Cairo, Pharmaceutical Chemistry, Cairo, Egypt, [2]German university in Cairo, Pharmacology And Toxicology, Cairo, Egypt

Aims: Pyrroloquinoline quinone (PQQ) has recently shown enhancing cognitive functions in animal studies and healthy adults. In attempt to understand the mechanism of action, whether it acts centrally or peripherally, bioanalysis of PQQ in mice brains is performed. Our research question is can PQQ pass the blood-brain barrier (BBB)? the aim of research is qualitative bioanalysis using gas chromatography-tandem mass spectrometry to assess PQQ BBB permeability and its metabolites in mice brains.
Methods: A neuroinflammatory mouse model was treated intraperitoneally (i.p.) with PQQ. PQQ was extracted from mice brains using acetonitrile. PQQ derivatization by silylation where N,O-Bis(trimethylsilyl)trifluoroacetamide was the reagent of choice. GCMSMS method of 15min run time was developed.
Results: BBB shows permeation to PQQ after i.p. administration of PQQ with lipopolysaccharide that mimics Alzheimer's disease induced neuroinflammation. Moreover, the BBB is permeable to PQQ in healthy mice showing intact BBB. Dietary PQQ was identified in mice brains whose standard diet contained soybeans which is rich in PQQ. Based on the preliminary validation, PQQ concentration in mice brains from dietary source as chow diet is 1.59±0.27µg in 250µg brain homogenate while PQQ concentration in treated mice brain with saline and PQQ is 3.89±0.30µg in 250µg brain homogenate (P=0.0006). Pharmacokinetic profile of PQQ in mice brains was performed (Tmax=2hrs).
Conclusions: A novel fast simple GCMS/MS bioanalysis method of BBB permeability of PQQ and its metabolites in mice brains is successfully developed. This is the first study to derivatize PQQ by silylation, extract PQQ from biological samples not only in a single step but also using one solvent following green chemistry guidelines, report PQQ qualifier and quantifier ions and identify PQQ metabolite in mice brains. These findings form novel approach as co-treatment in targeting CNS.

YOUTH-ASSOCIATED BLOOD-BORNE PROTEIN TIMP2 REGULATES AD PATHOLOGY IN MULTIPLE MOUSE MODELS OF BETA-AMYLOIDOSIS

POSTERS: A02.I. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: NEUROTROPHIC, SYNAPTIC PLASTICITY, REPAIR, REGENERATIVE MEDICINE

Alejandro Grau-Perales, Ana Catarina Ferreira, Brittany Hemmer, Jacob Rosenstadt, Ralphyn Pallikunnath, Suhani Yerapathi, Joseph Castellano
Icahn School of Medicine at Mount Sinai, Neuroscience, New York, United States of America

Aims: Accumulating evidence supports the concept that processes dysregulated in both the aging and AD brain are responsive to signals in the periphery across lifespan. Though we previously showed that the youth-associated blood-borne protein, tissue inhibitor of metalloproteinases-2 (TIMP2), revitalizes hippocampal function in aged mice, the mechanisms have remained unclear. We hypothesize that TIMP2 and other blood-borne factors regulate synaptic plasticity processes and amyloid-beta metabolism in the hippocampus.
Methods: Using behavioral assessments, RNA-sequencing, and super-resolution confocal microscopy in TIMP2 deletion models, including a novel conditional deletion model, we explored how TIMP2 removal regulates adult neurogenesis, dendritic complexity via iontophoretic dye-filling, and hippocampus-dependent behavioral testing. We deleted TIMP2 in several mouse models of AD pathology and examined perturbations in amyloid-beta metabolism and markers of the neurovascular unit, and we addressed rescue using viral-mediated overexpression strategies to examine behavioral improvements.
Results: We found that TIMP2 deletion causes dysfunction in adult neurogenesis and a loss in dendritic complexity with concomitant accumulation of extracellular matrix components. Removing this accumulation via intrahippocampal targeting of ECM components results in rescue, arguing that TIMP2 acts through the extracellular matrix to facilitate synaptic plasticity. Loss of TIMP2 exacerbates gliosis, and pathways related to activation and senescence are significantly altered. Deleting TIMP2 in APP-knockin and 5XFAD mice significantly exacerbates amyloid-beta plaque deposition and corresponding gliosis in several brain regions.
Conclusions: TIMP2 regulates a diverse set of phenotypes across normal hippocampal physiology and in the context of AD pathology, including in processes that depending on flexibility for removal of pathological debris. Together our results argue that age-relevant factors in the systemic environment have long-range roles in shaping hippocampal function, including processes that depend on the dynamics of extracellular matrix homeostasis.

NEUROPROTECTIVE MECHANISMS OF FOSGONIMETON AGAINST EXCITOTOXICITY IN PRIMARY NEURON CULTURE

POSTERS: A02.I. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: NEUROTROPHIC, SYNAPTIC PLASTICITY, REPAIR, REGENERATIVE MEDICINE

Sherif Reda[1], Wei Wu[1], Andree-Anne Berthiaume[1], Sharay Setti[2], Robert Taylor[1], Jewel Johnston[1], Kevin Church[2]
[1]Athira Pharma, Inc., Research, Bothell, United States of America, [2]Athira Pharma, Research, Bothell, United States of America

Aims: We have previously shown that fosgonimeton, a small-molecule positive modulator of the neurotrophic hepatocyte growth factor (HGF) system, promotes neuroprotective effects in preclinical models of Alzheimer's disease (AD). We hypothesized that such effects may be driven by activation of HGF-mediated pro-survival signaling mediators, such as AKT. Herein, we characterize signaling effectors downstream of AKT including Bcl-2 (promotes mitochondrial health), GSK3β (mediates tau phosphorylation), and the ribosomal S6 kinase (regulator of cell growth and survival) to provide mechanistic insight into the neuroprotective effects of fosgonimeton against glutamate toxicity.
Methods: Rat primary cortical neurons were challenged with glutamate with or without the active metabolite of fosgonimeton (fosgo-AM), and immunostained for microtubule-associated protein-2, mitochondrial ROS (MitoSox), and phospho-tau (AT100) to determine neuronal survival, neurite network integrity (total neurite length), ROS production, and phospho-tau levels. Western blotting quantified activity status of intracellular signaling effectors such as PI3K, AKT, Bcl-2, and GSK3β. Additionally, we interrogated the requirement of S6 kinase in fosgonimeton neuroprotection assays using pharmacological inhibition.
Results: Fosgo-AM treatment significantly improved neuronal survival, preserved neurite networks, inhibited mitochondrial ROS production, and reduced phospho-tau levels after glutamate injury. Protein analyses indicated that fosgo-AM increased PI3K/AKT activity and upregulated Bcl-2 expression. Fosgo-AM treatment also led to a significant increase in GSK3β phosphorylation, an effect expected to inhibit its ability to phosphorylate tau. Interestingly, the neuroprotective effects of fosgonimeton were abolished under the inhibition of S6 kinase.
Conclusions: Our in vitro data suggest that the neuroprotective effects of fosgonimeton against glutamate toxicity are driven, in part, by signal transduction pathways that promote cell survival and growth and counteract neurodegenerative hallmarks such as mitochondrial dysfunction and tau pathology. Fosgonimeton is currently in clinical trials for mild-to-moderate AD (NCT04488419; NCT04886063).

ENGINEERING LIMK1 TO BOOST DENDRITIC SPINE PLASTICITY AND MEMORY IN EXPERIMENTAL MODELS OF ALZHEIMER'S DISEASE

POSTERS: A02.I. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: NEUROTROPHIC, SYNAPTIC PLASTICITY, REPAIR, REGENERATIVE MEDICINE

Cristian Ripoli[1,2], Raimondo Sollazzo[2], Pietro Renna[2], Francesco Pastore[2], Martina Battistoni[2], Sara Martini[2], Fabiola Paciello[2], Marco Rinaudo[2], Claudio Grassi[1,2]
[1]Fondazione Policlinico Universitario A. Gemelli IRCCS, Preclinical Neuroscience, Rome, Italy, [2]Università Cattolica del Sacro Cuore, Department Of Neuroscience,, Rome, Italy

Aims: LIMK1 regulates dendritic spine plasticity by phosphorylating and inhibiting ADF/cofilin proteins, promoting actin polymerization. This, in turn, promotes the enlargement and stabilization of dendritic spines, enhancing the glutamatergic synaptic strength. Dysregulation of LIMK1 has been linked to several neurological disorders, including Alzheimer's disease (AD), in which dendritic spine density is reduced. Developing an extrinsically disordered form of LIMK1 that can be rapidly and specifically activated with a well-tolerated, clinically approved, blood-brain barrier permeant drug, such as rapamycin. Precise LIMK1 modulation could offer a hopeful therapeutic strategy for enhancing glutamatergic synaptic function in AD, addressing diminished dendritic spine density and neuronal connectivity.
Methods: Biochemistry, 2-photon imaging, electrophysiology and behavioral tests in AAV-infected mice were used to investigate the therapeutic potential of the engineered LIMK1 in 3×Tg-AD mice and human iPSC-derived neurons from AD patients.
Results: Chemogenetic LIMK1 activation promoted a direct and inducible control of cofilin phosphorylation, long-term enlargement of dendritic spines and enhancement of glutamatergic synaptic transmission in wild-type animals. Given the reduced expression and phosphorylation of LIMK1 and cofilin, we observed in human AD neurons and in the hippocampi of 3xTg-AD mice, we tested the ability of the engineered LIMK1 to restore the function of these proteins in our experimental models of AD. Activation of engineered LIMK1 effectively promoted cofilin phosphorylation, thus significantly increasing dendritic spine density in hippocampal CA1 pyramidal neurons of 3xTg-AD mice and morphological neurites restoration in human AD neurons. Notably, the activation of engineered LIMK1 *in vivo* improved memory encoding and slowed cognitive decline in 3xTg-AD mice.
Conclusions: Our results indicate that the proposed chemogenetic LIMK1 has the potential to be translated into a therapeutic strategy for reversing cognitive decline in AD.

INVESTIGATING PROTECTIVE EFFECTS OF NRF2 IN 5XFAD MODEL OF ALZHEIMER'S DISEASE

POSTERS: A02.I. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: NEUROTROPHIC, SYNAPTIC PLASTICITY, REPAIR, REGENERATIVE MEDICINE

Katherine Sadleir[1], Karen Gomez[1], Armana Patel[1], Makenna Ley[1], Sidhanth Chandra[1], Yunlu Xue[2], Constance Cepko[2], Robert Vassar[1]
[1]Northwestern University, Neurology, Chicago, United States of America, [2]Harvard Medical School, Genetics, Boston, United States of America

Aims: The aim is to test the effects of neuronal overexpression of nuclear factor erythroid 2-related factor 2 (Nrf2) transcription factor on pathology in 5XFAD mouse model of Alzheimer's β-amyloid deposition. Nrf2 upregulates expression of antioxidant and detoxification genes and is neuroprotective in retina. In Alzheimer's patients neuronal loss contributes to cognitive impairment. Nrf2 mRNA is decreased in Alzheimer's brains and deletion of the Nrf2 gene increased BACE1 (β-secretase) and Aβ, and worsened cognitive deficits in amyloid mouse models. We hypothesized that neuronal Nrf2 overexpression would reduce BACE1 and amyloid and protect against neuronal loss.
Methods: To overexpress Nrf2 in 5XFAD mouse brains, AAV8 hSyn-Nrf2 and hSyn-GFP or AAV8 hSyn-GFP alone were injected into the ventricles of day-old mouse pups. At 9.5 months of age, the mice were perfused, and half the brain fixed for sectioning and immunofluorescence, the other half dissected into cortex and hippocampus and frozen for mRNA and protein analysis. Immunofluorescence was used to assess plaque load, neuronal loss, neuroinflammation, dystrophic neurites and tau phosphorylation.
Results: Overexpression of Nrf2 reduced BACE1 protein, especially in dystrophic neurites around plaques, but did not decrease neuron loss, neuroinflammation or amyloid deposition. Phospho-tau 181, which accumulates in dystrophic neurites, was also reduced. Bulk mRNA sequencing revealed elevation of Nrf2 targets Hmox1 and Txnrd1 in Nrf2 overexpression mice confirming activation of antioxidant pathways, but in general pathways altered in 5XFAD compared to non-transgenic mice were not corrected by Nrf2 overexpression.
Conclusions: Neuronal overexpression of Nrf2 may provide a method to specifically decrease dystrophic neurites, which could decrease tau pathology seeding and spreading. Future work will elucidate the mechanism by which dystrophic neurites are decreased, and explore Nrf2 overexpression in other cell types such as astrocytes.

ACD856 IS A BIASED POSITIVE ALLOSTERIC MODULATOR OF TRK-RECEPTORS - ENHANCES NEURITE OUTGROWTH BUT DO NOT AFFECT PAIN SIGNALING

POSTERS: A02.I. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: NEUROTROPHIC, SYNAPTIC PLASTICITY, REPAIR, REGENERATIVE MEDICINE

Pontus Forsell, Veronica Lidell, Azita Rasti, Gunnar Nordvall, Johan Sandin
AlzeCure Pharma, R&d, Huddinge, Sweden

Aims: The neurotrophins BDNF and NGF have been studied extensively and have important roles in neuronal survival, differentiation, neurogenesis, and synaptic plasticity, making these mechanisms of high interest for therapeutic development within Alzheimer's disease. However, they are also involved in other functions such as pain signaling. This broad range of effects is a result of a complex downstream signaling pathway diversifying their physiological effects. The aim of these studies was to explore if ACD856, a novel positive allosteric modulator of Trk-receptors currently in clinical development for the treatment of Alzheimer's disease, showed any selectivity for different TrkA-signaling pathways.
Methods: Primary mouse cortical neurons were treated with ACD856 and neurite outgrowth, as measured by neurite total length, was studied. Potential effects of ACD856 on pain signaling was assessed using the Hargreaves plantar test assessing thermal allodynia in male Sprague-Dawley rats. The animals had received an intra-plantar injection of NGF in the left hind paw and paw withdrawal latencies were assessed on both ipsilateral and contralateral paws.
Results: In vitro data show that ACD856 can enhance neurite outgrowth in mouse primary cortical neurons. Interestingly, results from the in vivo plantar test in rats showed that ACD856 does not induce heat allodynia, nor does it potentiate NGF-induced heat allodynia.
Conclusions: The results indicate that while ACD856 can enhance neurite outgrowth, it does not induce or aggravate NGF-induced heat allodynia. These findings indicate that the compound acts as a biased Trk-PAM with the advantages of neurotrophic support and cognitive enhancing effects of neurotrophins, but without pain inducing effects. This differential activation pattern of downstream signalling pathways would provide for a significantly improved therapeutic and tolerability profile for this novel class of compounds.

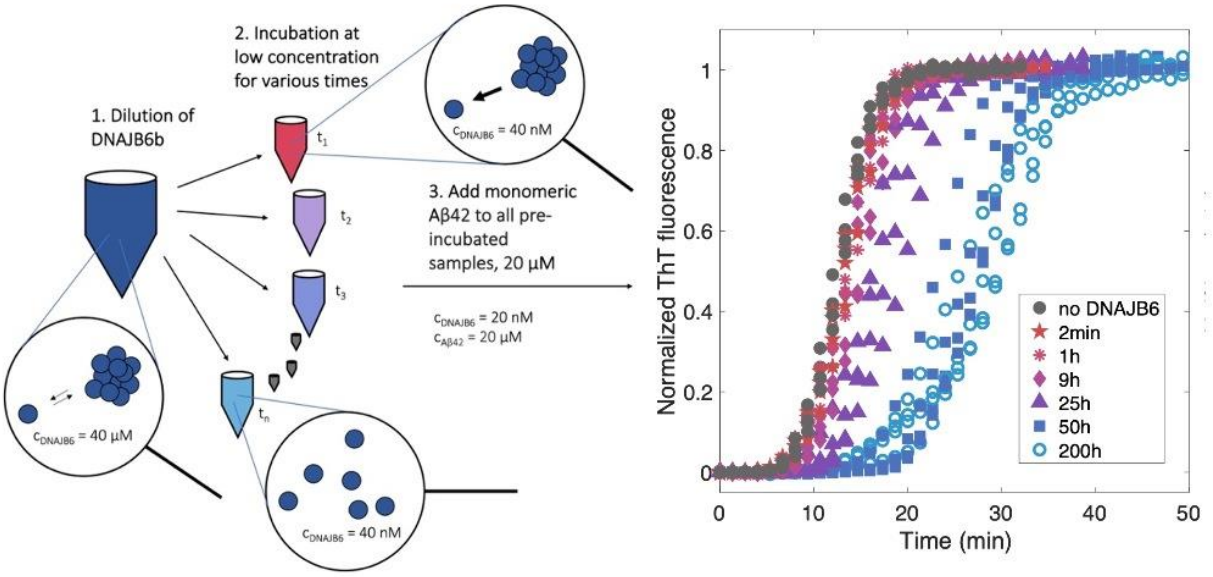
THE ABILITY OF THE CHAPERONE PROTEIN DNAJB6 TO PREVENT AMYLOID BETA 42 FIBRILLATION DEPENDS ON ITS AGGREGATION STATE

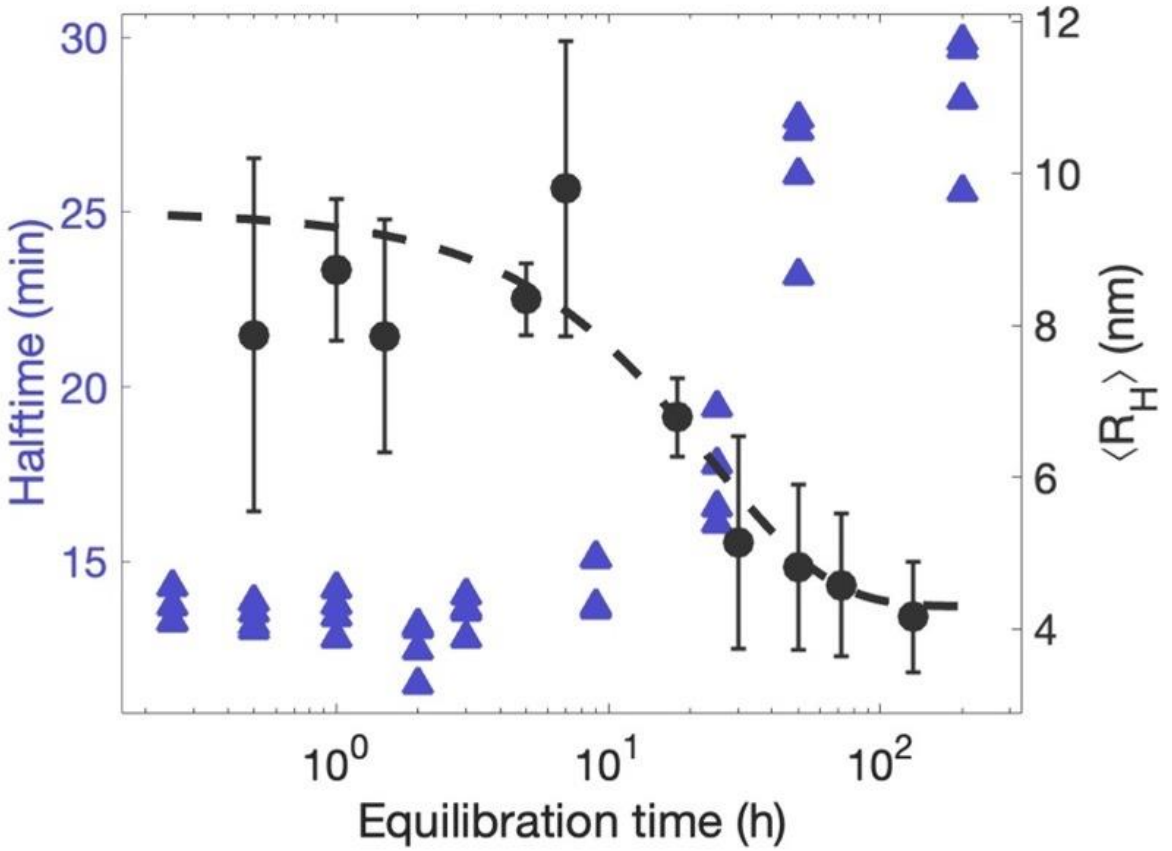
POSTERS: A02.J. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: PROTEIN AGGREGATION, MISFOLDING, CHAPERONES

Andreas Carlsson[1], Ulf Olsson[2], Emil Axell[1], Sara Linse[1]
[1]Lund University, Biochemistry And Structural Biology, Lund, Sweden, [2]Lund University, Physical Chemistry, Lund, Sweden

Aims: The human chaperone DNAJB6 increases the solubility of proteins involved in protein aggregation diseases and suppresses the formation of amyloid structures. Thus, DNAJB6 has received increasing attention over the past decade. Understanding the DNAJB6 chaperone mechanism may aid the design of amyloid inhibitors. DNAJB6 is known to self-associate in a concentration dependent manner. Here, we examine how the oligomeric state is related to its amyloid prevention.
Methods: The ability to delay Aβ42 amyloid formation was examined using ThT fluorescence for various equilibration times of DNAJB6 after a step dilution from 40 μM to 40 nM, in quadruplicates. After various times after dilution (room temperature incubation), ranging from 2 min to 8 days, equal volume of monomeric Aβ42 was added to a final concentration of 20 μM, resulting in a DNAJB6 concentration of 20 nM. A plate reader was used to follow the change in ThT signal upon Aβ42 aggregation. The average hydrodynamic radius of DNAJB6 was followed over time (using MDS) after dilution of 6 μM to 100 nM, allowing for comparison between oligomeric size and amyloid prevention.
Results: It was found that DNAJB6 was more efficient in delaying Aβ42 fibrillation if the aggregates were diluted more than 10 h before the addition of Aβ42 monomers, compared to if the addition was made just after the dilution. This time correlates with the dissociation rate of DNAJB6 oligomers into its subunits.



Experimental setup and the resulting fibrillation kinetics of Aβ42, where the colours represent to how long time DNAJB6 was at the diluted concentration before addition of Aβ42 monomers.



*In blue triangles, halftimes of Aβ42 aggregation as function of the equilibration time of DNAJB6 at 40 nM. In black, the change in average hydrodynamic radius after dilution from 6 µM to 100 nM, with plotted standard deviations as error bars. Fitted line f(t) = 4.3nm*e$^{-t/24h}$.*

Conclusions: The data suggest that the high order DNAJB6 oligomers are less prone to delay Aβ42 amyloid formation compared to their subunits.

CHAPERONE MULTIMERS SUPPRESS THE GENERATION OF AB42 NEUROTOXIC OLIGOMERS IMPLICATED IN ALZHEIMER´S DISEASE

POSTERS: A02.J. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: PROTEIN AGGREGATION, MISFOLDING, CHAPERONES

António Figueira[1], Joana Saavedra[2], Isabel Cardoso[2], Cláudio Gomes[1]
[1]Faculdade de Ciencias da Universidade de Lisboa, Bioisi – Biosystems & Integrative Sciences Institute, Lisboa, Portugal, [2]Universidade do Porto, I3s–instituto De Investigação E Inovação Em Saúde, Porto, Portugal

Aims: Alzheimer's disease (AD) involves extracellular aggregation of Aβ42 into toxic oligomers and fibrils, whose emergence is regulated by molecular chaperones. These include S100B alarmin, a homodimeric EF-hand protein with intra and extracellular functions which acts as a Ca^{2+}-switched Aβ42 anti-aggregation chaperone. However, S100B occurs also as a homotetramer, with uncharacterized neuroprotective roles. Here, we compared the chaperone activities of both S100B multimers and explored their impact on the formation of Aβ42 oligomers (AβO).
Methods: S100B anti-aggregation activity was evaluated by thioflavin-T (ThT) Aβ42 aggregation assays. Aβ42 conformers targeted by S100B were accessed by computational and structural-biophysical spectroscopies. Aβ42 oligomer distributions were determined through mechanistic analysis of fibril formation and via early detection of Aβ42 species using the X-34 fluorophore.
Results: Aβ42 aggregation kinetics revealed that, unlike the dimer, tetrameric S100B delays Aβ42 aggregation and reduces the amounts of fibrils formed at sub/equimolar ratios, an effect that persists even in the absence of Ca^{2+} binding. Structural analysis revealed that this enhanced catalytic efficiency results from a secondary Ca^{2+}-independent binding site formed upon tetramerization of S100B, with which monomeric and fibrillar Aβ42 interact (Figueira et al JMB 2022). Kinetic and mechanistic analysis revealed that dimeric and tetrameric S100Bpreferentially inhibit Aβ42 fibril surface-catalyzed nucleation, decreasing the reactive influx towards oligomers down to <10%. Such results comply with an independent screening of AβO using a combination of the thioflavin-T and X-34 fluorophores (Figueira et al Front. Neurosci. 2023).
Conclusions: Our study sheds new insights on the functional landscape of S100B chaperone multimers, suggesting its critical role in the regulation of proteopathic Aβ42 aggregation and oligomerization in AD.

Aims: Pharmacological activation of TREM2 represents a novel therapeutic approach to slow Alzheimer´s disease progression, strongly supported by human genetics linking TREM2 to early- and late-onset AD. Lack of TREM2 locks microglia in a homeostatic state in animal models, preventing a switch to a disease-associated state required for phagocytotic clearance of misfolded proteins and cellular debris. Here, we study the impact of TREM2 agonism on the receptor signaling complex and downstream signaling cascades leading to microglia activation.
Methods: TREM2 agonist induced receptor complex dynamics were assessed in vitro in HEK, THP-a and hIPSC derived microglia cells by nanoBiT, western blot and alphaLISA assays. To study TREM2 agonism on human microglia in vivo, xenografted mice were treated systemically with increasing doses of selective, potent and brain penetrant TREM2 agonists in the presence of amyloid pathology. Subsequently, human microglia were isolated and analyzed by qPCR and single-cell RNA sequencing.
Results: Small molecule mediated TREM2 activation leads to TREM2/DAP12 receptor complex formation required for downstream signaling. In vivo, human TREM2 is expressed by pathology associated microglia and induced by amyloid plaques. Systemic treatment with TREM2 agonists leads to differential gene expression patterns in xenografted human microglia only in the presence of amyloid pathology. Effects were observed at compound exposure levels in the brain consistent with in vitro agonist potency.
Conclusions: TREM2 activation by small molecule agonists leads to the rapid formation of a receptor complex required for downstream signaling. In vivo, TREM2 agonism modulates gene networks in human microglia selectively in the presence of amyloid pathology. Human microglia xenografted into rodent pathology models is therefore a valuable approach to study the effects of pharmacological TREM2 activation in the context of AD.

Aims: Women are at greater risk than men for developing Alzheimers disease during lifetime.The aim of our study is to determination the realarionship between FSH and TREM 2 in the serum of patienssuffering from premature ovarian failure
Methods: In the serum of affected patiens, FSH and TREM 2 were determinated using the Elisa techique.
Results: The resalts of our study conducted on 78 patiens suffering from POF and 75 controls showed that there is a positive corelation the values of FSH and TREM2 inthe serum.
Conclusions: From this, we can concluded that FSH and TREM 2 can be a target for future therapeutic research.

FLUORINATED NANOCARRIERS TO TARGET THE BRAIN AND TREAT NEUROLOGICAL DISEASES

POSTERS: A02.J. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: PROTEIN AGGREGATION, MISFOLDING, CHAPERONES

Joana Loureiro[1], Meghna Dabur[1], Stephanie Andrade[1], Maria João Ramalho[1], Maria Carmo Pereira[2]

Aims: Blood-brain barrier (BBB) crossing commonly hinders currently available treatments for brain diseases; almost all attempts to produce new drugs have failed in clinical trials. Strategies based on nanotechnology have been deployed as drug carriers and have successfully surmounted the challenges inherent in BBB crossing. On the other hand, fluorinated compounds have been found to have therapeutic characteristics and exhibit hydrophobicity, lipophilicity, and high metabolic stability. A new strategy combining nanotechnology and fluorinated molecules is addressed to acquire the physiochemical properties for overcoming the BBB passage.
Methods: Different types of nanoparticles (lipid- and polymer-based) were produced, having fluorine molecules and brain-targeting molecules on their surface. The fluorination of poly (lactic-co-glycolic acid) (PLGA), a long chain fatty acid (Palmitic acid) and 1,2-distearoyl-sn-glycero-3-phosphoethanolamine-N-[carboxy(polyethylene glycol)-2000] (sodium salt) (DSPE-PEG2000-COOH) was achieved using a fluorinating source (trifluoro-ethylamine). The fluorination of the compounds was confirmed by nuclear magnetic resonance spectroscopy for both proton and fluorine. The conjugation of transferrin (a targeting molecule with affinity with transferrin receptors overexpressed in the BBB) to the surface of the formed nanoparticles was quantified using Bradford dye assay.
Results: Fluorinated liposomes and PLGA nanoformulations appeared to have low polydispersity and sizes below 200 nm, which is the size required to cross the BBB. No significant variations in physicochemical properties were identified in the nanocarriers containing fluorine nor in the formulations modified with transferrin.
Conclusions: The developed fluorinated nanocarriers have shown potential to be used in the treatment of brain diseases, such as Alzheimer`s disease. Rather than the ability to transport therapeutic molecules, the produced nanoparticles present anti-amyloidogenic properties.

SINGLE-CELL STUDY OF MICROGLIA TRANSCRIPTIONAL STATE HETEROGENEITY ACROSS HUMAN AND IPSC-DERIVED MODELS

POSTERS: A02.K. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: TREM2

Anjali Garg[1], Brenna Novotny[1], Ricardo Albanus[1], Logan Brase[2], Celeste Karch[1], John Morris[3], Richard Perrin[4], Greg Sutherland[5], Bruno Benitez[6], Oscar Harari[1]
[1]Washington University Saint Louis, Psychiatry, St. Louis, United States of America, [2]Washington University in St. Louis, Psychiatry, St. Louis, United States of America, [3]Washington University in St. Louis, Hope Center For Neurological Disorders, St. Louis, United States of America, [4]Washington University at Saint Louis, The Charles F. And Joanne Knight Alzheimer Disease Research Center, St. Louis, United States of America, [5]University of Sydney, Medicine And Health, New South Wales, Australia, [6]Beth Israel Deaconess, Harvard Medical School, Center For Life Sciences,, MA, United States of America

Aims: Single-cell study of microglia transcriptional state heterogeneity across human and iPSC-derived models
Methods: We leveraged single-nuclei transcriptomic profiles (snRNA-seq) of human microglia (parietal cortex from 67 donors from the Knight ADRC and DIAN brain banks; N=15,726; Dataset1), iPSC-MLC CRISPRi/a-based genetic screens in human iPSC-derived microglia (N= 15,350; Dataset2), and WT and R47H TREM2 xenografted microglia (xMGs), isolated from chimeric AD mice (N= 25,407; Dataset3) to build a comprehensive atlas of microglia heterogeneity, that captures transcriptional states fairly well represented in each dataset. We employed Seurat v4 to integrate the data, and scArches to build classifiers. We leveraged this new reference to classify and annotate novel microglia in additional cohorts, species and experiments.
Results: We identified homeostatic, activated, interferon (IFN), and IL1B clusters across datasets present in all data we had integrated. In addition, we identified MHCII. We observed that some of the clusters of original states were combined into single clusters. For example, CXCL10-IFN and INF. Furthermore, we build a multiclassifier to label novel microglia generated from hundreds of samples, and data from various experimental models. The cross-validation analyses indicate that the overall accuracy of the classifier (scArches) is 0.85, although it changes for the distinct datasets. For human microglia in Dataset1 the accuracy was 0.79, while for iPSC-MLC was 0.73 and 0.96 for Dataset 3. Our results indicate that this multi-model reference can capture subtle differences better that study-centric analyses.
Conclusions: We are repurposing microglia transcriptomic single-cell data to build a cross-species and experimental iPSC-MLC to bridge across cohorts, species, and experiments. Our results, indicate that this new resource allows to simultaneously interrogate gene expression across different experiments and transcriptional states, and providing the foundation to integrate additional single-cell molecular data.

SPLICEOGENIC VARIANTS IN TREM2 AND THEIR INTERPLAY WITH NEURODEGENERATION-RELEVANT SPLICING FACTORS

POSTERS: A02.K. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: TREM2

Olena Korvatska[1], Maria Lukes[2], Kostantin Kiianitsa[1], Wendy Raskind[2]
[1]University of Washington, Department Of Psychiatry And Behavioral Sciences, Seattle, United States of America, [2]University of Washington, Department Of Medicine, Division Of Medical Genetics, Seattle, United States of America

Aims: RNA splicing defects caused by mis-localized RNA binding proteins and splicing factors (SF/RBP), exemplified by TAR DNA-binding protein 43 (TARDBP/TDP-43) and fused in sarcoma protein (FUS), are important contributors to the neurodegenerative process in amyotrophic lateral sclerosis (ALS) and frontotemporal lobar degeneration (FTLD). Currently known mis-spliced targets are predominantly neuronally expressed genes, and little is known about the pathogenicity of splicing defects in other brain cell types. TREM2 is a microglia-expressed immune receptor that modulates risk of Alzheimer's disease (AD) and causes early-onset dementia, such as Nasu-Hakola disorder and behavior variant of frontotemporal dementia (FTD), through several mechanisms including aberrant splicing. We recently discovered that several pathogenic missense TREM2 variants thought to affect protein code only also affected its splicing. To extend this observation, we comprehensively screened additional disease-relevant *TREM2* variants for splicing defects. We also tested whether SF/RBP involved in ALS and FTLD regulate *TREM2* splicing and whether they potentiate the effect of spliceogenic *TREM2* variants.
Methods: We selected SF/RBPs known to be causative/associated with neurodegenerative diseases and to be expressed in human microglia. Predicted splicing defects of TREM2 variants were scored by SpliceAI. We experimentally confirmed these effects in human microglia cell line HMC3 using a full-length TREM2 reporter co-transfected with either an overexpressing construct or siRNA to a correspondent SF/RBP
Results: We confirmed an effect on TREM2 isoform balance for multiple predicted spliceogenic variants in intron 1 and exon 2. We also found that several RBP/SF potentiate the effect of spliceogenic genetic variants on exon skipping.
Conclusions: TREM2 is a subject of complex regulation via an interplay of multiple trans-acting splicing factors with cis-regulatory genetic variants. Certain SF/RBPs perturbed in ALS and FTLD may affect microglia function via TREM2 mis-splicing.

PRECLINICAL NEURONAL MODELS TO SCREEN THE EFFECTIVENESS OF DRUGS DIRECTED TO SLOW DOWN ALZHEIMER'S AND PARKINSON'S DISEASE PROGRESSION

POSTERS: A02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: MICROGLIA

Jolien Beeken, Anaïs Luykx, Teun Van Nunen, Yanick Fanton
InnoSer, Neurology Research Group, Diepenbeek, Belgium

Aims: Alzheimer's (AD) and Parkinson's (PD) disease drug development is held back due to the lack of in vitro reproducible models that represent human complexity and can be used to screen disease-modifying therapeutics relatively inexpensively, efficiently, and fast. Most therapies for neurodegenerative diseases (NDD) currently focus on relieving symptoms rather than preventing disease progression. New and more powerful therapeutic approaches targeting disease pathology are needed to address the acceleration and severity of NDD. The goal of InnoSer is to validate in vitro disease-induced cell models of mono SH-SY5Y and HMC3 cell cultures and co-culture models to screen disease-modifying drugs for NDDs prior to screening in vivo.
Methods: Microglial (HMC3) and differentiated neuronal-like cells (SH-SY5Y) were treated with pre-formed Amyloid beta (Aβ) or alpha-Synuclein (αSyn) fibrils to mimic AD and PD pathophysiology. The HMC3 cells' phagocytic capacity was investigated by treatment with pHrodo labelled pre-formed fibrils and detected by an IncuCyte S3 Live-Cell Analysis System, while cell viability was assessed using the MTT kit.
Results: Following Aβ or αSyn fibril treatment, HMC3 cells' phagocytic capacity was significantly increased indicating the internalization of the fibrils. Simultaneous treatment with Aβ and Aducanumab significantly increased HMC3 cells' phagocytic capacity compared to fibril treatment alone. Glutamate, the most common neurotransmitter that generates glutamate-induced excitotoxicity in AD and PD, appears neurotoxic for SH-SY5Y and HMC3 cells in high concentrations as cell viability was significantly decreased after glutamate treatment. After 24 hours of incubation with Aβ, the HMC3 and SH-SY5Y cells' viability was significantly decreased.
Conclusions: This NDD model of pre-formed fibril treatment on HMC3 and SH-SY5Y cells will serve as a cheaper, easier, and faster alternative model to screen AD and PD disease-modifying drugs before screening in vivo.

Aims: ALSP is a rare, autosomal dominant primary microgliopathy caused by heterozygous mutations in colony stimulating factor1 receptor (CSF1R). CSF1R signaling is necessary for microglial differentiation and survival. As a result, patient brains have fewer microglia that exhibit a chronically activated proinflammatory phenotype. ALSP patient brains also exhibit an array of neuropathologies including axonal spheroids, reactive astrocytosis, lipid accumulation, white matter atrophy, and myelin disruption. Recent analysis of two homozygous mutant CSF1R cases revealed a complete absence of microglia and more extensive calcification, accompanied by extreme intellectual disability and prenatal mortality.
Methods: To explore the therapeutic potential of human microglial transplantation, we generated a xenotolerant mouse model that harbors a deletion of the *fms*-intronic regulatory element (FIRE) of CSF1R leading to an absence of microglia. At 2months of age the resulting 'hFIRE' mice were transplanted with PBS or human iPSC-derived microglia progenitors. 6.5 months later, mice were sacrificed, and brains harvested for RNA-sequencing, immunohistochemistry and biochemical analysis. To increase translational relevance, ALSP patient-derived L786S-Het iPSCs were CRISPR-corrected, and iPSC-microglia transplanted into 4-month-old hFIRE mice.
Results: By 8.5months of age, hFIRE mice exhibit large numbers of axonal spheroids, robust astrogliosis, brain calcification, lipid accumulation, and white matter abnormalities. Remarkably, transplantation of iMG restores microglial transcript levels and prevents ALSP-related neuropathologies, including the onset of disease-associated oligodendrocytes(DOLs). In addition, CRISPRcorrection rescues proliferative deficiency and increases homeostatic marker expression in xenotransplanted L786L-corrected iMG. Surprisingly, transplantation of CRISPR-corrected iMG, but not uncorrected L786S-Het iMG, into 4-month-old mice significantly reduces pre-existing spheroid, astrogliosis, and calcification within just 6 weeks.
Conclusions: Taken together, these results indicate hFIRE mice model the diverse neuropathologies of ALSP patients and provide initial evidence iPSC-microglia could be further developed as a promising new therapeutic strategy.

Aims: Alzheimer´s disease pathology is characterized by the formation of amyloid beta positive plaques and phospho-tau containing neurofibrillary tangles leading to neurodegeneration and cognitive decline. Around 30% of amyloid plaque positive elderly, however, remain cognitively healthy. We hypothesize that cellular mechanisms downstream of amyloid stress underlie cellular resilience to amyloid pathology, preventing tau phosphorylation, neurodegeneration and dementia.
Methods: Human postmortem brain samples (n=50, dorsolateral prefrontal cortex) were collected from individuals characterized by amyloid pathology with (AD+Dem) or without (AD-Dem) cognitive deficits. Samples were analyzed by Visium spatial transcriptomics, histology for amyloid beta and pTau, and single nuclei transcriptomics. Findings were validated using Xenium to reveal the cellular resolution of transcripts of interest and their spatial relationship to pathology *in situ*.
Results: We identified 54 cellular subpopulations and several gene co-expression networks that were differentially responsive to amyloid beta and pTau pathology in the presence or absence of dementia. In AD+Dem samples, pTau positive neuritic plaques were surrounded by cells including microglia with prominent inflammatory gene networks, while in AD-Dem samples these cells were localized around amyloid plaques with no or minimal tau pathology. Differential gene expression networks in cells near amyloid plaques in the presence and absence of tau pathology included those involved in protein folding, mitochondria health, cell death and microtubule-based transport. These mechanisms may play important roles in cellular resilience to amyloid-induced tau pathology.
Conclusions: Spatial transcriptomics from human brain tissue is a powerful approach to identify cellular mechanisms of resilience towards neuropathology. These mechanisms represent a rich source for the identification of novel therapeutic targets for the treatment of AD.

Aims: Myeloid cells are innate immune effectors involved in the surveillance and maintenance of tissue homeostasis. Although displaying phenotypic and functional heterogeneity, myeloid cells share a common ontogeny in the yolk sac during early stages of development. Previous studies have profiled human myelopoiesis *in vivo*. However, wide access to human embryonic tissue is limited. Hence, development of in vitro protocols mimicking this biological process is key to model myeloid cells physiology and disease. Here, we aimed at generating yolk sac-like myeloid progenitor cells *in vitro* and validating their multipotency to generate different tissue-resident macrophages, such as microglia.
Methods: We used single-cell transcriptomics and proteomics approaches to explore the heterogeneity of human pluripotent stem cell-derived myelopoiesis. Then we used immunophenotyping and cell sorting to characterize and isolate different cell populations, and xenotransplantation of human stem-cell-derived myeloid progenitors to test differentiation capacity *in vivo*.
Results: We confirmed the generation of inducible yolk sac myeloid progenitors (iYSMPs) *in vitro*, whose transcriptional profile overlapped with myeloid progenitor cells described in published human embryonic datasets. Using pseudotime, we inferred that iYSMPs were able to differentiate into macrophages, neutrophils and erythrocytes lineages, mimicking human ontogeny. We found that the production of iYSMPs was restricted to a specific time window of the differentiation process, after which they transitioned towards myeloid lineages. Finally, we were able to functionally validate iYSMPs multipotency *in vivo* by xenografting different mouse tissues, where thanks to environment-specific cues they generated microglia and brain macrophages in the brain, and Kupffer cells in the liver.
Conclusions: Overall, we provide evidence of the generation of human iYSMPs, which coupled to genetic manipulations and multi-omics approaches could address a variety of questions concerning physiology, development and pathology of human myeloid cells.

NICOTINIC ACID RECEPTOR HCAR2 AFFECTS MICROGLIA RESPONSE AND AMYLOID PATHOLOGY AT EARLY- AND LATE-STAGE DISEASE

POSTERS: A02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: MICROGLIA

Miguel Moutinho[1], Israel Coronel[1], Samantha Geis[2], Martin Benito[2], Paul Fallen[1], Abigail Wallace[1], Shweta Puntambekar[2], Adrian Oblak[3], Gary Landreth[1]
[1]Stark Neurosciences Research Institute, Indiana University, School of Medicine, Anatomy, Cell Biology And Physiology, Indianapolis, United States of America, [2]Indiana University School of Medicine, Stark Neuroscience, Indianapolis, United States of America, [3]Stark Neurosciences Research Institute, Indiana University, School of Medicine, Department Of Radiology & Imaging Sciences, Indianapolis, United States of America

Aims: Alzheimer's disease (AD) is a progressive neurodegenerative disease and a leading cause of dementia worldwide. Although we have recently showed that the niacin receptor HCAR2 stimulates a protective microglia phenotype in an amyloid mouse model at a stage of rapid amyloid accumulation and neuronal dysfunction, it is unclear whether HCAR2 plays a role at different stages of disease. Our aim is to study the function of HCAR2 at early and late stages of amyloid pathology
Methods: We analyzed amyloid pathology and microglia response in 2-month- and 8-month -old 5xFAD mice lacking the HCAR2 receptor, corresponding to early and late stage of disease respectively. To examine if activation of HCAR2 exerted beneficial effects, 2-month-old 5xFAD mice were provided with high doses of nicotinic acid through food pellets for 4 months and 8-month-old mice were treated with an FDA-approved formulation of nicotinic acid (Niaspan®) by daily oral *gavage* for 30 days. Brain tissue of treated mice was processed for biochemical and imaging analysis.
Results: Our preliminary results show that the lack of HCAR2 exacerbates amyloid pathology in 2 and 8-month-old 5xFAD accompanied by deficits in microglia mobilization to plaque-rich areas. Interestingly, the number of microglia is reduced in 2-month animals which is accompanied by a reduction in proliferation. Both the provision of a nicotinic acid-enriched diet to 2-month-old 5xFAD animals and the treatment of 8-month-old 5xFAD mice with Niaspan® attenuated amyloid burden.
Conclusions: These preliminary data demonstrate that HCAR2 impacts amyloid pathology and microglia response throughout the course of amyloid pathology, highlighting an important role of this receptor in disease and its potential as a therapeutic target. Our findings with nicotinic acid-treated mice further support the therapeutic potential of HCAR2 in Alzheimer's disease.

[1]Mental Health and Neuroscience, QIMR Berghofer Medical Research Institute, Cellular And Molecular Neurodegeneration, Brisbane, Australia, [2]Mental Health and Neuroscience, QIMR Berghofer Medical Research, Genetic Epidemiology, Brisbane, Australia, [3]Ingham Institute for Applied Medical Research and School of Medicine, School Of Medicine, Sydney, Australia, [4]The University of Melbourne, Florey Institute Of Neuroscience And Mental Health, Parkville, Australia, [5]ALS Clinical Research Centre and Laboratory of Neurochemistry, University of Palermo, Department Of Neurology And Psychiatry, Palermo, Italy

Aims: Neurodegenerative disorders, including Alzheimer's disease (AD) and amyotrophic lateral sclerosis (ALS), pose a significant challenge due to the absence of effective treatments. Recent findings highlight the pivotal role of neuroinflammation, primarily orchestrated by microglia, the resident immune cells of the brain, in the pathogenesis of these diseases. Consequently, targeting microglia has emerged as a promising therapeutic avenue. Nonetheless, existing microglial models inadequately capture the intricate and multifaceted contributions of microglia within the complex milieu of brain tissue, thereby impeding drug development success.
Methods: To address this limitation, we adapted an established protocol to generate human-induced microglia cells (MDMi) derived from peripheral blood mononuclear cells as an alternative approach to using microglia derived directly from human brain tissues. Our prior work with MDMi has elucidated dynamic and functional differences between microglia derived from ALS and age-match healthy individuals. Importantly, we show that the MDMi platform mirrors the natural biological and clinical heterogeneity in patients, allowing a personalised therapeutic regime instead of a one-size-fits-all strategy, which has yielded limited success.
Results: Our study now extends to AD MDMi where RNAseq has identified Paired immunoglobin-like Type 2 receptor (PILRB) and chitotriosidase-1 (CHIT-1) as crucial genes upregulated in AD but not in aged-matched MDMi. Interestingly, the upregulation of PILRB expression in AD was coupled with altered subcellular localisation to the plasma membrane from the mitochondria compared to age-matched individuals. PILRB translocation in AD was further exacerbated when treated with amyloid-beta (1-42) peptide compared to age-matched MDMi. Unpublished data also showed impaired microglial morphology and phagocytosis in AD MDMi, which confirmed a significant role of microglia implicated in AD.
Conclusions: Overall, utilising MDMi can identify biomarkers for developing microglial-targeted therapies to improve AD treatment outcomes.

TARGETING IMMUNE CHECKPOINT TIM3 REGULATES MICROGLIAL FUNCTION AND AMELIORATES ALZHEIMER'S DISEASE PATHOLOGY

POSTERS: A02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: MICROGLIA

Zhuoran Yin[1], Kimitoshi Kimura[1], Ayshwarya Subramanian[1], Yufan Wu[1], Danyang He[1], Karen Dixon[1], Udbhav Chitta[1], Xiaoming Zhang[1], Ahad Khalilnezhad[1], Thomas Pertel[1], Ruihan Tang[1], Samuel Myers[2], Aastha Aastha[1], Masashi Nomura[3], Vasundhara Singh[2], Lei Liu[1], Conner Lambden[1], Kilian Kleemann[1], Neha Gupta[1], Yiran Cheng[1], Sebastian Silveira[1], Huiyuan Zhang[1], Aamir Suhail[1], Toni Delorey[2], Orit Rosenblatt-Rosen[2], Dennis Selkoe[1], Aviv Regev[2], Mario Suvà[2], Oleg Butovsky[1], Vijay Kuchroo[1]

Aims: Microglia, the resident brain immune cells, play a critical role in brain homeostasis and disease progression. Our previous studies show that microglia acquire the neurodegenerative phenotype (MGnD) in Alzheimer's disease (AD), which is beneficial for limiting disease progression. *Havcr2*, encoding immune checkpoint molecule Tim3, has recently been identified as a risk gene for late-onset AD. However, its role in microglia, which is important given its role in inducing T cell exhaustion, remains unknown. Our study aims to understand the function of microglia-specific Tim3 in AD.
Methods: We specifically targeted microglia-specific Tim3 in transgenic AD mice. We used RNAseq and immunohistochemistry (n = 6-8) to investigate the gene expression profile and AD pathology. Additionally, we utilized single-cell RNAseq to identify microglial clusters. We performed forced alternation tests to evaluate cognition (n = 15-22). Moreover, we conducted IP-MS (immunoprecipitatioin-mass spectrometry) screening and confirmatory IP-WB (IP-western blot) analysis to identify the intracellular binding patterns for Tim3.
Results: We demonstrate that the deletion of Tim3 in microglia induces an MGnD activation state in developing brains with enhanced phagocytosis ability. Genetically targeting microglial Tim3 in 5xFAD mice reduces Aβ plaque load, decreases dystrophic neurites, attenuates plaque-associated synaptic degradation, and improves cognition. Furthermore, we show that Tim3 binds to Smad2, a key molecule in TGFβ signaling. Motif enrichment analysis identifies Smad2 as a core transcription factor regulating the transcriptome of Tim3-deficient microglia. Detailed analysis shows that the C terminus of Tim3 is necessary for their binding and enhanced phosphorylation of Smad2.
Conclusions: Our study demonstrates a novel Tim3-mediated regulatory mechanism of MGnD and underscores the beneficial role of targeting Tim3 in restricting neurodegenerative pathology in AD mouse models. This highlights Tim3 as a promising target for AD.

COMPARISON OF HUMAN PRIMARY MICROGLIA AND HUMAN IPSC DERIVED MICROGLIA CELLS AS IN VITRO MODELS FOR MICROGLIA ACTIVATION

POSTERS: A02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: MICROGLIA

Matteo Zanella[1], Malika Bsibsi[1], Kimberly Lo[1], Berke Gurkan[1], Cheng-Chih Hsiao[2], Lieke Geerts[1], Malathi Raman Srivastava[3], Camilla Fairbairn[3], Stefan Kostense[1], Jeroen Degroot[1], David Fisher[4], Marijn Vlaming[1]

Aims: Microglia are resident immune cells in the central nervous system (CNS) and play an essential role in neuroinflammation and neurodegenerative disease. Microglia can be isolated from both control and diseased post-mortem human brain tissue. However, the limitation on brain collection and yield of isolated cells restricts the ability to perform screening studies. Induced pluripotent stem cells (iPSCs)-derived microglia, may provide a suitable alternative for large-scale compound validation. Yet, to effectively use iPSC-derived microglia, one must characterize the extent to which these cells faithfully represent biological processes in brain tissue.
Methods: Here, we compared morphological and functional properties of primary human microglia cells and iPSC-derived microglia.
Results: Exposure of primary and iPSC-derived microglia to LPS resulted in increased cytokine secretion in a concentration and time dependent manner. Cytokine secretion was strongly inhibited by dexamethasone. Priming of primary and iPSC-derived microglia with LPS and treatment with nigericin, a potent inflammasome activator, resulted in robust secretion of IL-1β and IL-18. Furthermore, nigericin induced IL-1β and IL-18 release was inhibited by the inflammasome inhibitor MCC950 in both cell types. Similarly to in house isolated microglia, iPSC-derived microglia showed a strong expression of specific microglia markers and cytokine release upon LPS- and nigericin-treatment. Finally, the *in vitro* phagocytosis by uptake of pHrodo™ BioParticles, labeled human myelin, α-synuclein and β-amyloid fibrils was monitored over time by high-content imaging. Time-dependent uptake was observed and was sensitive to disruption of the actin-cytoskeleton with cytochalasin D.
Conclusions: Taken together, we successfully demonstrated that primary and iPSC-derived microglia respond similarly to different stimuli. Therefore, these cell types could serve as a reliable tool for evaluating the efficacy of prospective drugs for neurological diseases associated with microglia activation, such as Alzheimer's and Parkinson's Disease.

EVALUATING THE TREATMENT OUTCOMES OF REPETITIVE TRANSCRANIAL MAGNETIC STIMULATION IN PATIENTS WITH MODERATE-TO-SEVERE ALZHEIMER'S DISEASE

POSTERS: A02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: MICROGLIA

Shouzi Zhang
Beijing Geriatric Hospital, Department Of Psychiatry,, Beijing, China

Aims: The repetitive transcranial magnetic stimulation (rTMS) shows great potential in the treatment of Alzheimer's disease (AD). However, its treatment efficacy for AD patients in moderate to severe stage is relatively evaluated. In this study, we further evaluate the treatment efficacy of rTMS in moderate-to-severe phase of AD.
Methods: we proposed a randomized, sham-controlled, clinical trial of rTMS among 35 moderate-to-severe AD patients. A high frequency (10 Hz) stimulation of the left dorsal lateral prefrontal cortex (DLPFC), 60-session long treatment lasting for 3 months procedure was adopted in the trial. Each participant completed a battery of neuropsychological tests at baseline and post-treatment for evaluation of the rTMS therapeutic effect. Twelve of them completed baseline resting-state functional magnetic resonance imaging (fMRI) for exploration of the underlying neural contribution to individual difference in treatment outcomes.
Results: The result showed that the rTMS treatment significantly improved cognitive performance on the severe impairment battery (SIB), reduced psychiatric symptoms on the neuropsychiatric inventory (NPI), and improved the clinician's global impression of change (CIBIC-Plus). Furthermore, the result preliminarily proposed resting-state multivariate functional connectivity in the (para) hippocampal region as well as two clusters in the frontal and occipital cortices as a pre-treatment neuroimaging marker for predicting individual differences in treatment outcomes.
Conclusions: The finding could brought some enlightenment and reference for the rTMS treatment of moderate and severe AD patients.

NETSSEQ REVEALS DEEP MOLECULAR INSIGHTS INTO ASTROCYTE BIOLOGY AND IDENTIFIES NOVEL THERAPEUTIC TARGETS FOR ALZHEIMER'S DISEASE

POSTERS: A02.N. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ASTROGLIA

Xiao Xu, Clare Bender, Jenna Harvey, Bernadino Ossola, Daniel Barker, Justin Powell, David Cadwalladr, Toni Cheung, Jason Lawrence, Steven Sheardown, Gabriela Crane, Keith Page, Mark Carlton, Nicola Brice, Lee Dawson
Cerevance, Neuroscience, Cambridge, United Kingdom

Aims: An integrated understanding of specific cell types in neurodegenerative disease is essential for developing novel therapeutics. Using Cerevance's proprietary Nuclear Enriched Transcript Sort Sequencing (NETSseq) platform on post-mortem human brain tissue, individual cell types in control and disease donors have been profiled, thereby enabling the identification of novel drug targets.
Methods: Using NETSseq on tissue across multiple brain structures from Alzheimer's disease (AD) and control donors, we have generated deep RNA-seq transcriptomic profiles (expression of >12,000 genes per sample) and ATAC-seq epigenetic profiles for multiple glial and neuronal cell types. These data have enabled us to stratify donors across the disease continuum, to identify cell-type specific genes that change across this continuum, and to identify gene signatures associated with different glial activation states.
Results: NETSseq data demonstrate clear glial expression of genes that are known genetic risk factors for AD. In astrocytes, we observe gene signatures and chromatin changes associated with regional differences, disease progression, and multiple disease-associated activation states. Many pathways are altered in disease, including those involved in glutamate homeostasis. We found that the inwardly rectifying K+ channel Kir4.1/KCNJ10 is specifically expressed in astrocytes, changes expression during AD progression and astrocyte activation, and when modulated, affects glutamate uptake, suggesting KCNJ10 is an example of a novel target for preventing neuronal hyperexcitability in AD.
Conclusions: Highly reproducible molecular profiles from specific cell types have been generated using NETSseq. The identification of numerous astrocyte-specific genes that change across the AD disease continuum, suggests that astrocyte dysfunction may contribute to disease progression. These data are being used to pinpoint and prioritize novel targets for drug discovery, potentially offering promising prospects for the development of transformative therapies for AD and other diseases.

CENTRAL NERVOUS SYSTEM-DIRECTED ADENO-ASSOCIATED VIRUS (AAV) INDUCED EXPRESSION OF A PROTECTIVE APOE VARIANT IN CYNOMOLGUS MONKEYS

POSTERS: A02.O. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: GENE THERAPY AND GENE EDITING

Aims: Polymorphism in the apolipoprotein E (*APOE*) gene is a major genetic risk determinant of late-onset Alzheimer's Disease (AD), with the *APOE*ε4* allele conferring an increased risk and the *APOE*ε2* allele conferring decreased risk relative to the common *APOE*ε3* allele. The objective of this study is to evaluate expression of *APOE* in the brain tissue and cerebrospinal fluid (CSF) of cynomolgus monkeys (*Macaca fascicularis*) following a single administration of an adeno-associated virus (AAV) encoding a protective *APOE* transgene through intra-CSF injections.
Methods: We measured AAV vector DNA and *APOE* mRNA levels in the brain tissue of monkeys. Additionally, we measured the expressed human ApoE protein in CSF, brain tissue and plasma of these monkeys.
Results: After a single intra-CSF administration of AAVs, we successfully expressed human *APOE* in cynomolgus monkeys. We detected vector DNA copies and *APOE* mRNA molecules as well as human ApoE protein in different brain areas and CSF.
Conclusions: Our study demonstrates CNS-specific expression of a protective variant of human *APOE* in cynomolgus monkeys implicating potential of a one-time administered gene therapy by overexpressing a protective APOE variant as a treatment for autosomal dominant AD.

THERAPEUTIC EFFECTS OF MIR-937-3P OF NEURAL-INDUCED HUMAN ADIPOSE TISSUE-DERIVED STEM CELLS ON A-BETA ALZHEIMER'S DISEASE MODEL

POSTERS: A02.O. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: GENE THERAPY AND GENE EDITING

Sujeong Jang, Jiyun Choi, Han-Seong Jeong
Chonnam National University Medical School, Physiology, Hwasun-gun, Korea, Republic of

Aims: Alzheimer's disease (AD), which is the most common type of dementia causes 60~70% of dementia cases, has continuous impairment of cognitive and behavioral function. Until now, there is no cure except symptomatic treatment such as cholinesterase inhibitors. In this study, we investigated whether the therapeutic and neuroprotective effects of human adipose tissue-derived MSC (hADSC) miRNAs on the Aβ-induced Alzheimer's disease model in neuroblastoma cells by investigating the apoptosis pathway.
Methods: We isolated and differentiated hADSCs into neuronal cells, and then performed the microarray to analyze the miRNA candidates by comparing the expression between hADSCs and neural-induced hADSCs (NI-hADSCs). Following KEGG and GO analysis, miR-937-3p can action of axonal guidance, nervous system development, and synaptic transmission. Neuroblastoma cells were induced as an Alzheimer's disease with Aβ and then treated with miR-937-3p. To figure out the therapeutic and neuroprotective effects of miR-937-3p, we investigated the signaling pathway using immunocytochemistry (ICC), FACS, western blotting analysis, qPCR, and protein array.
Results: We found that the cells treated with miR-937-3p showed neurite outgrowth and morphological changes into mature neurons with increased neuronal markers via ICC. Aβ-induced apoptosis was decreased with miR937-3p via FACS analysis by Annexin V and PI staining. Treatment of miR-937-3p increased Bcl-2 and Mcl-1 expression and decreased Bax, cleaved-caspase-3, -7, and -9. In addition, the neuronal markers (NFH, NeuN, MAP2, Tuj1) and oligodendrocyte markers (OLIG2, CNPase) were increased with miR937-3p compared to Aβ group. After miR937-3p treatment, Wnt5α was increased, and downstream pathways were activated. Interestingly, both Wnt/Ca^{2+} and Wnt/PCP pathways activated and regulated PKC, Cdc42, RhoA, Rac1/2/3, and p-JNK.
Conclusions: Therefore, miR-937-3p induces the differentiation of cells into mature neurons and reduces the apoptotic death by activating the Wnt/Ca^{2+} and Wnt/PCP pathways and inhibiting apoptosis.

MIR-132 GENE THERAPY FOR ALZHEIMER'S DISEASE IN NON-HUMAN PRIMATES

POSTERS: A02.O. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: GENE THERAPY AND GENE EDITING

Boutheyna Khelaifia[1], Brittney Armitage-Brown[2], Dana Mika[2], Claudia Goupil[1], Douglas Munoz[2], Sébastien Hébert[1]
[1]Université Laval - Centre de Recherche du CHU de Québec, Neurosciences, Québec, Canada, [2]Queen's University, Department Of Medecine, Kingston, Canada

Aims: Accumulating evidence suggests that multi-target drugs will be required to completely restore neuronal dysfunction and cognitive loss in AD. This could be feasible using microRNAs (miRNAs) by simultaneously targeting key disease genes and phenotypes. Neuronal miR-132 is the most strongly downregulated during AD progression and has been shown to rescue disease phenotypes (Amyloid, Tau, cognition) in mice and cells. The study aims to advance the preclinical development of a miR-132 mimic (miR-132m) for AD gene replacement therapy. Specifically, we performed pharmacokinetics and biosafety studies following miR-132m delivered to the central nervous system (CNS) of non-human primates.
Methods: We first used naive cynomolgus monkeys injected with fluorescent miR-132m into the cisterna magna. CSF and blood samples were collected, and the animals were euthanized 72 hours after injection. CNS tissues were dissected. Quantification of miR-132m and miRNAs associated with neuro-inflammation and degeneration was performed by qRT-PCR. Next, a biosafety study was conducted in monkeys treated with an unmodified miR-132m through continuous intrathecal infusion for 30 days. Blood tests were conducted during this treatment.
Results: We observed a significant increase of miR-132m levels in the CSF up to 8h post-injection, in serum up to 1h post-injection, and in various tissues post-mortem, including the entorhinal cortex, midbrain, pons, cerebellum, and spinal cord. In contrast, the other tested miRNAs remained stable. Finally, no signs of toxicity were observed after the continuous infusion of miR-132m into the CSF.
Conclusions: These results suggest that the direct injection of miR-132m into the CSF is effective and well-tolerated by the organism. Further studies are underway to assess the cellular distribution and genes targeted by miR-132m in the CNS. These findings will be used in developing Phase I clinical trials in humans.

NOVEL RIVASTIGMINE DERIVATIVES AS PROMISING MULTI-TARGET COMPOUNDS FOR POTENTIAL TREATMENT OF ALZHEIMER'S DISEASE

POSTERS: A02.Q. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

M. Amélia Santos[1], Inês Dias[1], Leo Bon[1], Marlène Emmanuel[1], Paul Vogt[1], Daniel Chavarria[2], Fernanda Borges[2], Catarina Guerreiro-Oliveira[3], Sandra Morais Cardoso[4], Sílvia Chaves[1]
[1]Instituto Superior Técnico, Universidade de Lisboa, Centro De Quimica Estrutural, Lisboa, Portugal, [2]University of Porto, Department Of Chemistry And Biochemistry, Porto, Portugal, [3]University of Coimbra, Cnc-center For Neuroscience And Cell Biology, Coimbra, Portugal, [4]Instituto Superior Técnico, Cnc-center For Neuroscience And Cell Biology, Coimbra, Portugal

Aims: The main goal is to develop new drugs to combat the multi-faceted Alzheimer's disease (AD), with no cure so far. Pursuing the drug design strategy of extra-functionalization of drugs already approved for AD, a series of polyfunctional hybrids were developed and assayed as multitarget-directed ligands. Thus, Rivastigmine (RIV) templates, (for cholinesterase, ChE, inhibition) were hybridized with other moieties to provide the conjugates with extra pharmacological responses to tackle several important hallmarks of AD.
Methods: The RIV hybrids were firstly designed on the basis of computational simulations and then selected compounds were prepared by usual methods of organic synthesis. Using standard spectroscopic techniques (UV-Vis absorption and fluorescence), the new compounds were evaluated in aqueous solution for their biological activity, namely the inhibition of important enzymes (as AChE, BChE and MAO), inhibition of Aβ aggregation and capacity for radical scavenging. Effects of these compounds in cell viability and neuroprotection were also assessed in neuroblastoma cell lines after $A\beta_{1-42}$ and ROS induced toxicity.
Results: The results obtained, namely for the inhibition of enzymatic activity and Aβ aggregation, the radical scavenging capacity and also cell viability, are rationalized on the basis of structural variations, specifically the type of the extra-functional moieties linked to the rivastigmine template, their substituent groups (mainly *O*- or *N*-electron donors) and also the length of the linker between the two main moieties. Discussion is also made in comparison our previous results with other RIV conjugates previously studied by us [D. Vicente-Zurdo, *et all*, *Biomed.* **2022**, *10*, 1510].
Conclusions: The new hybrids show good activity for the inhibition of ChEs (AChE and BChE), MAO and $A\beta_{1-42}$ self-aggregation, and also neuroprotection, thus appearing as potential pleiotropic drugs against Alzheimer´s disease.

HEARING IMPAIRMENT EXACERBATES COGNITIVE DYSFUNCTION AND ACCELERATES THE PROGRESSION OF ALZHEIMER'S DISEASE BY INCREASING INFLAMMATION IN THE BRAIN

POSTERS: A02.Q. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Hyong Ho Cho[1], Byeong C. Kim[2], Min-Kyung Song[3]
[1]Chonnam National University Medical School, Otolaryngology, Gwangju, Korea, Republic of, [2]Chonnam National University Medical School & Hospital, Neurology, Gwangju, Korea, Republic of, [3]Gwangju City Hospital, Neurology, Gwangju, Korea, Republic of

Aims: Hearing loss as the most significant risk factor for developing Alzheimer's disease. However, the precise mechanisms that connect hearing impairment and Alzheimer's disease are still unclear. The study aimed to investigate the impact of drug-induced hearing loss (DIHL) on cognitive function, memory retention, and protein expression closely related to the progression of Alzheimer's disease in 5XFAD and Tg2576 mice.
Methods: The DIHL animal models were established by injecting kanamycin and furosemide into mice aged 3.5 to 4 weeks. Cognitive function and long-term potentiation (LTP) were measured to investigate the potential correlation between hearing loss and Alzheimer's disease. Immunohistochemistry and immunoblotting were utilized to assess the accumulation and expression of beta-amyloid, p-tau, Iba-1, and GFAP. The protein expression levels of the mammalian target of rapamycin (mTOR) signaling pathway and its downstream pathways, as well as pro-inflammatory cytokines, were analyzed.
Results: DIHL exacerbated cognitive dysfunction and resulted in a significant increase in the accumulation of beta-amyloid and hyperphosphorylated tau in the hippocampus and cortex of mice with Alzheimer's disease, when compared to the control group. The levels of protein expression for neuroinflammatory markers, such as Iba1 and GFAP, as well as pro-inflammatory cytokines, including interleukin-1β (IL-1β), IL-6, and tumor necrosis factor-α (TNF-α), were found to be elevated. Additionally, DIHL increased the protein expression of phosphorylated mTOR and the phosphorylation of p70 ribosomal S6 protein kinase 1 (S6K1) and S6 pathways. Furthermore, restoring hearing loss reversed the impaired LTP in both wild-type and Alzheimer's disease mice.
Conclusions: Hearing loss exacerbates cognitive dysfunction, impairs memory retention, and significantly increases the accumulation of beta-amyloid and hyperphosphorylated tau protein aggregates in the brain. Activation of the mTOR pathway, astrocytes, and microglia can also occur that exacerbate the progression of Alzheimer's disease.

NETWORK-INFORMED UNBIASED GLOBAL PROTEOMICS STRATEGY TO DISCOVER BIOMARKERS FOR E2511, A NOVEL TRKA MODULATOR

POSTERS: A02.Q. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Satya Saxena[1], Yuanqing Ye[2], Luigi Giorgi[2], Viswanath Devanarayan[3], Allan Levey[4], Duc Duong[4], Kiran Pandey[5], Nicholas Seyfried[4], Michael Irizarry[6], Kanta Horie[1], Pallavi Sachdev[1]
[1]Eisai Inc, Translational Medicine, Nutley, United States of America, [2]Eisai Inc., Neurology, Nutley, United States of America, [3]Eisai, Inc, Real World Evidence And Medical Value, Global Medical Affairs At The Neurology Business Group, Nutley, United States of America, [4]Emory University School of Medicine, Center For Neurodegenerative Disease, Atlanta, United States of America, [5]Emtherapro, Inc., R&d, Atlanta, United States of America, [6]Eisai, Inc, Neurology Business Group, Nutley, United States of America

Aims: Here, we describe the utility of an orthogonal network-informed unbiased tandem-mass tag spectrometry (TMT-MS)-based global proteomics strategy to further support the effect of E2511 treatment on CSF proteins that overlap with brain modules linked to axonal and synaptic activity.
Methods: A total of 32 healthy subjects from E2511-A001-005, a Phase 1 randomized, double-blind, placebo-controlled, multiple ascending (MAD) study, were randomly assigned to receive either placebo or once daily doses of 10, 20, 40 and 80 mg E2511 for 14 days. In this study, pre (day -2)- and post (day 13)-treatment CSF samples from placebo and highest dose level cohort (80 mg) were analyzed using TMT-MS. CSF proteome from the placebo and 80 mg cohorts were mapped to 44 brain-derived co-expression modules from the proteomes of over 500 control, asymptomatic AD and AD brains[2].
Results: Compared to previous results, TMT-MS global proteomics achieved cumulative CSF proteome depth of 2,040 proteins. We identified 91 differentially altered proteins (unadjusted $p < 0.05$) when comparing CSF proteomes of placebo and 80 mg E2511-treated subjects. 40/91 proteins altered by E2511 treatment mapped to 20 brain-derived co-expression modules linked to AD. Treatment had a significant effect on CSF proteins that overlap with brain modules linked to axonal and synaptic activity (M1, M4, M19, M22-9 proteins), protein folding (M14-4 proteins), cell-extra cellular matrix interaction (M11, M27- 6 proteins), and matrisome (M42- 2 proteins).
Conclusions: Human brain network-informed proteomic-profiling of CSF provided a powerful and unique tool to identify hubs within protein co-expression modules related to E2511 MoA. This biomarker discovery strategy helped to corroborate the mechanism of action (MoA) and target engagement of E2511 in regulating axonal and synaptic biology. Further studies to confirm E2511 proof-of-mechanism and support dose-selection are planned.

[1]Institut de Chimie (UMR 7177), Université de Strasbourg-CNRS, Laboratory Of Biometals And Biological Chemistry, Strasbourg, France, [2]Institut des Neurosciences Cellulaires et Intégratives (INCI), CNRS, Université de Strasbourg,, Intracellular Membrane Trafficking In The Nervous And Neuroendocrine Systems, Strasbourg, France

Aims: Alzheimer's disease (AD) remains the most common neurodegenerative disease with hallmarks including the apparition, in specific parts of the brain, of intracellular neurofibrillary tangles and extracellular amyloid plaques. The latter results from an abnormal metabolism of Amyloid-beta precursor protein (APP) leading to the accumulation of Aβ in plaques or lack of clearance therein. *Ex vivo* analysis of AD patients' brains show abnormally elevated concentration of Cu, Zn and Fe in these plaques. Further studies demonstrated a reduced Cu level in the entire brain and more specifically in regions heavily affected in AD. This decrease is accompanied by a decline in neuronal Cu levels and by an increase in extracellular labile Cu promoting reactive oxygen species (ROS) generation. To correct this Cu dyshomeostasis in the brain of AD patients, we designed and synthesized novel Cu(II)-selective peptide shuttles, with the goal of equilibrating normal neuronal cell Cu homeostasis in the context of AD
Methods: The physicochemical properties of these Cu(II)-selective peptide shuttles were validated using Uv-vis spectroscopy, Fluorescence spectrometer and Mass spectrometry. Their biological properties were also characterized using the PC12 cell neuronal model and organotypic hippocampal slices (OHSCs) model.
Results: Our novel Cu(II) selective peptide shuttles possess high affinity and stability towards Cu(II) and are capable of selectively retrieving Cu(II) from extracellular Aβ, and importing Cu into cells. We also demonstrated the capacity of these new Cu-shuttles to protect OHSCs from Cu- Aβ-induced insult and their ability to rescue microglial activation and proliferation in these brain slices
Conclusions: These new Cu(II)-selective peptides have proven to be good candidates for Cu shuttles capable of preventing Cu induced toxicity in the context of AD and could be important tools in tracking the mechanistic of Cu trafficking

ANTI-PHOSPHO-TAU SERINE 396/404 SCFV ANTIBODIES ELIMINATE HYPERPHOSPHORYLATED TAU BY INDUCING AUTOPHAGY VIA ENDOPLASMIC-RETICULUM STRESS PATHWAY IN ALZHEIMER'S DISEASE CELL MODEL

POSTERS: A02.Q. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Soi Moi Chye
International Medical University, Division Of Applied Biomedical Science And Biotechnology, Bukit Jalil, Malaysia

Aims: In this study, anti-phospho-Tau serine 396/404 single chain variable fragment (scFv) antibody was generated by using Ph.D-12 phage display library. The effectiveness of scFv antibodies to eliminate hyperphosphorylated tau and mechanism invovlvement was investigate in Alzheimer's disease cell model.
Methods: Anti-phospho-Tau serine 396/404 single chain variable fragment (scFv) antibody was generated by using Ph.D-12 phage display library. SH-SY5Y cells were transfected with Tau-441 2N4R and treated with okadaic acid to serve as Alzheimer's disease cell model. Methyl Thiazolyl Tetrazolium (MTT) assay was used to evaluate the effectivenes of scFv antibodies to protect hyperphorylated tau induced cell death. The molecular mechanism invovement was measured by Western blot.
Results: Three scFv antibodies, FPLNSEENPFEL, FPLNSEENPLEL and FPLNSEENAFEL were identified. Based on MTT results, the cell viabilities of treated okadaic acid alone was 58.06%. However, after treated with FPLNSEENPFEL or FPLNSEENPLEL or FPLNSEENAFE, the cell viability increased to 79.38, 83.28%, 74.69%, respectively. For Western blot analysis, the pSer396 protein expression was increased 1.51-fold for okadaic acid treatment only if compare with control. However, after treated with FPLNSEENPFEL or FPLNSEENPLEL or FPLNSEENAFE, the pSer396 protein expression decreased to 0.79-fold, 1.09-fold and 0.72-fold, respectively. Moreover, PHF-1 protein expression was 2.69-fold for okadaic acid treatment only if compare with control. However, after treated with FPLNSEENPFEL or FPLNSEENPLEL or FPLNSEENAFE, the PHF-1 protein expression decreased to 0.74-fold, 0.76-fold, 0.92-fold, respectively. Moreover, protein expression level of selected proteins (IRE-1-α, Calnexin, PERK, Atg12, Beclin-1 and eIF-2α) which involved in ER-stress pathway were decreased by treating T-SH-SY5Y cells with scFv antibodies if compared with treated with oxalic acid alone.
Conclusions: In conclusion, three scFv antibodies are able to reduce cytotoxicity of hyperphosphorylated Tau proteinvia ER-stress signalling pathway. in Alzheimer's disease cell model.

IMPROVED CLINICAL PERFORMANCE OF PLASMA MICRORNA-BASED DIAGNOSTICS USING THE APO-EASY® IVD KIT FOR EARLY ALZHEIMER DIAGNOSIS.

POSTERS: A02.Q. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Seval Kul[1], Gabriel Sanchez[2], Stéphanie Boutillier[2], Lucas Pham-Van[1], Rodwell Mkhwananzi[2], Bruno Dubois[3], Hüseyin Firat[2]
[1]FIRALIS AMONETA, Amoneta, HUNIGUE, France, [2]Firalis, Amoneta, Huningue, France, [3]Pierre et Marie Curie University, Alzheimer Research Center Im2a, Paris, France

Aims: Improved clinical performance of plasma microRNA-based diagnostics using the APO-Easy® IVD kit for early Alzheimer diagnosis.
Methods: Total RNA from 600µl of Plasma-EDTA samples were extracted for miRNA quantification using qPCR. In parallel, a Real Time PCR test has been developed for the detection of APOE genotypes (variants of rs429358 and rs7412). This new kit, named APO-Easy® underwent rigorous analytical and clinical validation against the current gold standards, both Sanger sequencing and NGS. The Clinical diagnostic performance of both miRNA and APOE genotyping have been assessed in 1000 samples from two cohorts; ADDIA (NCT03030586) collected at 13 European clinical centres
Results: We employed five distinct predictive models, employing a five-fold cross-validation approach with 20 replicates. When employing the three microRNAs, the mean area under the curve (AUC) in the training set, as determined by the lasso model, stood at 0.71 (95% CI=0.68-0.72), with corresponding test set sensitivity and specificity values of 0.57 and 0.87, respectively. Notably, the introduction of APO-Easy® qPCR testing led to a significant enhancement in the AUC of the training set, elevating it to 0.84 (95% CI=0.82-0.86). Consequently, the test set sensitivity and specificity saw substantial improvements, reaching values of 0.71 and 0.87, respectively. Additionally, the APO-Easy® kit have been fully analytically and clinically validated for IVDR and FDA approval using 800 samples from ADDIA, and 200 samples from ADKIT cohorts with 100% accuracy versus both Sanger sequencing and NGS.
Conclusions: Three microRNAs, coupled with the APO-E genotyping using the APO-Easy® kit, represents an effective blood-based diagnostics for early-stage AD diagnosis and its differentiation from other non-AD dementia.

NEOCOPRIDE, A NOVEL DISEASE-MODIFYING DRUG CANDIDATE TO TREAT ALZHEIMER DISEASE

POSTERS: A02.Q. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Patrick Dallemagne[1,2,3], Alexandre Henriques[4], Maria-Letizia Campanari[4], Romain Legrand[1], Noëlle Callizot[4], Christophe Rochais[1,2,3]
[1]Caen Normandie University, Ufr Santé, Caen, France, [2]Centre d'Etudes et de Recherche sur le Médicament de Normandie, Ufr Santé, Caen, France, [3]RonomA, R&d, Saint Etienne du Rouvray, France, [4]Neuro-Sys, -, Gardanne, France

Aims: Alzheimer disease (AD) represents a major medical problem where mono-therapeutic interventions demonstrated only a limited efficacy so far. Neocopride is a novel pleotropic molecule which targets both acetylcholinesterase and 5-HT_4 receptor. The present poster describes for the first time the results of the biological evaluation of Neocopride.
Methods: Neocopride was tested in an in vitro model of AD on rat primary hippocampal neurons injured with Aβ at concentrations between 5 pM to 100 nM. The efficacy of the compounds was compared to the one of donepezil (1 µM), as reference compound. Then, an in vivo AD model was used by Intra-hippocampal injections of a solution containing AβO in aged mice to test daily administration of Neocopride at 3 mg/kg per os. This model induces short- and long-term memory deficits. The cognitive dysfunctions are associated and well correlated with the neuronal loss and the activation of microglial cells. Donepzil at 1mg/kg by intraperitoneal was used as reference substance
Results: In vitro, Neocopride improved neuronal survival at 1 nM and 5 nM. At these doses it also increased the length of neurites per neurons and decreased the hyperphosphorylation of Tau. Interestingly, Neocopride successfully increased the number of synapses (50 pM to 5 nM). In mice, Neocopride was found to significantly restore short and long-term memory impairment induced by Aβ1-42. Neocopride improved also neuronal survival and neuroinflammation by decreasing microglial activation and astrogliosis. Moreover, protein level of PSD95 were assessed and revealed that Neocopride was able to restore synapses to a level similar to control mice.
Conclusions: Altogether, these results show that Neocopride displayed synergistic beneficial effects and could be a promising drug candidate for Alzheimer's disease. Neocopride is currently involved in a regulatory preclinical study.

EVALUATION OF THE NEUROPROTECTIVE EFFECTS OF THE BIOINSPIRED PEPTIDE NEUROVESPINE IN A PARKINSON'S DISEASE MODEL

POSTERS: A02.Q. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Francisca Marques, Gabriel Campos, Márcia Renata Mortari
Institute of Biological Science, Department Of Physiology, Brasília, Brazil

Aims: To assess the anti-parkinsonian efficacy of the bioinspired peptide Neurovespine in a Parkinson's Disease model induced by unilateral intrastriatal injection of the neurotoxin 6-OHDA. This will be achieved by quantifying lesion severity in the experimental animals through direct counting of dopaminergic neurons in the Substantia Nigra using immunofluorescence labeling.
Methods: A 22-day experimental protocol was established, starting from the induction of the 6-OHDA lesion and continuing until the termination of the experiment when the animals were euthanized. Neurovespine (1mg/kg, 4mg/kg, or 7mg/kg) was administered i.p. 30 minutes before the lesion and after the lesion at 24h, 48h, and 72h. For each animal, three sections of the substantia nigra were selected for analysis. Immunohistochemical analysis was performed to evaluate the presence and condition of neurons in the substantia nigra. Anti-tyrosine hydroxylase (TH) immunolabeling was utilized for this purpose.
Results: In the analysis of the remaining TH-positive (THr) neurons in the substantia nigra, a significant difference was observed between the means of the 4 mg/kg Neurovespine treatment group and the Injured control group. This finding suggests a neuroprotective effect of the peptide on dopaminergic neurons at this dosage. Statistical significance was determined using [the Mann-Whitney test followed by the Dunn test] with a p-value threshold of [$p<0.05$].
Conclusions: The data presented in this study demonstrate that the administration of Neurovespine peptide at a dosage of 4 mg/kg effectively preserved dopaminergic neurons in the Substantia Nigra. These findings highlight the potential of Neurovespine as a valuable tool for Parkinson's Disease research and suggest its potential as a model drug for the development of novel neuroactive compounds. Funding: CAPES, CNPq e FAPDF.

CENTRAL AND PERIPHERAL TARGETS OF KETOGENIC DIETARY INTERVENTIONS IN PRECLINICAL MODELS OF ALZHEIMER'S DISEASE

POSTERS: A02.Q. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Paule Mbra[1,2], Laura Hamilton[1], Gaël Moquin-Beaudry[2], Federico Pratesi[2], Myriam Aubin[1], Chenicka-Lyn Mangahas[1], Marian Mayhue[1], Anne Aumont[1], Martine Tétreault[1], Mariano Avino[1], Eric Massé[1], Karl Fernandes[1,2]

Aims: Alzheimer's Disease (AD) remains a major global health concern, requiring innovative therapeutic strategies. Increasing evidence support benefits of ketogenic dietary interventions on cognition. In this study, we investigate the central and peripheral targets of such diets in AD mouse models.
Methods: 3xTg-AD and 5xFAD mice and their control strain/genotype mice were fed a standard carbohydrate-rich diet (Control diet, 70% carbohydrate, 20% fat, 10% protein), an identical diet supplemented with ketogenic medium-chain triglycerides (MCT, a ketogenic substrate), or challenged with an extreme ketogenic diet (CFHF, carbohydrate-free high fat diet). Cognitive assessments were conducted using the Morris water maze, while the underlying cellular mechanisms were investigated through Golgi staining and bulk RNA-sequencing of the hippocampus. Peripheral metabolism was monitored by variety of longitudinal measures (blood sampling, EchoMRI, indirect calorimetry), followed by bulk RNA-sequencing of the liver and 16S rRNA-sequencing of fecal matter.
Results: AD mice on the MCT and CFHF ketogenic interventions showed improved learning performances after 1 month. After 6 months on the MCT and KD ketogenic interventions, the hippocampus of AD mice retained increases in the number of dendritic spines and correction of 41% (with MCT) and 56% (with CFHF) of differentially expressed genes. The analysis of peripheral metabolism revealed a distinct vulnerability of AD mice to hyperleptinemia and body weight gain when submitted to CFHF, whereas MCT showed evidence of improving peripheral energy metabolism. Interestingly, AD mice showed hundreds of deregulated genes in the liver and microbiome alterations, and these were also differentially affected by the MCT and CFHF diets.
Conclusions: This study highlights the cognitive benefits of ketogenic diets in AD models and reveals similarities and differences between MCT and CFHF interventions. It underscores the intricate relationship between diet, genes, metabolism, and microbiome.

MAGNETIC TARGETED DELIVERY OF THE SPIONS-LABELED MESENCHYMAL STEM CELLS DERIVED FROM HUMAN WHARTON'S JELLY IN ALZHEIMER'S RAT MODELS

POSTERS: A02.Q. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Mehdi Mehdizadeh[1], Farshid Qiyami Hour[2], Amir Johari Moghadam[3], Ali Shakeri-Zadeh[4], Mehrdad Bakhtiyari[1], Ronak Shabani[1]
[1]Iran University of Medical Sciences, Department Of Anatomy, Tehran -, Iran, [2]University of Manitoba, Department Of Human Anatomy And Cell Science, Manitoba, Canada, [3]Iran University of Medical Sciences, Department Of Neuroscience, Tehran, Iran, [4]Johns Hopkins University, School Of Medicine, Baltimore, United States of America

Aims: Alzheimer's disease (AD) as a progressive neurodegenerative disorder is one of the leading causes of death globally. Among all treatment approaches, mesenchymal stem cells (MSCs)-based therapy is a promising modality for neurological disorders including the AD. This study aimed to magnetically deliver human Wharton's jelly-derived MSCs (WJ-MSCs) toward the hippocampal area within the AD rat's brain and determine the effects of them in cognitive improvement.
Methods: Rats were randomly divided into five groups as follow: vehicle-treated control, AD model (injection of 8 μg/kg of amyloid β 1–42), IV-NTC (treated with IV-injected Non-Targeted Cells), IV-TC (treated with IV-injected Targeted Cells), and ICV-NTC (treated with Intracerebroventricular-injected Non-Targeted Cells). WJ-MSCs were labeled with dextran-coated superparamagnetic iron oxide nanoparticles (dex-SPIONs, 50 μg/ml), by bio-mimicry method.
Results: SPIONs-labeled MSCs were highly prussian blue positive with an intracellular iron concentration of 2.9 ± 0.08 pg/cell, which were successfully targeted into the hippocampus of AD rats by a halbach magnet array as magnetic targeted cell delivery (MTCD) technique. Presence of SPIONs-labeled cells in hippocampal area was proved by magnetic resonance imaging (MRI) in which signal intensity was reduced by increasing the number of these cells. Behavioral examinations showed that WJ-MSCs caused memory and cognitive improvement. Also, histological assessments showed functional improvement of hippocampal cells by expression of choline acetyltransferase (ChAT) and acetylcholinesterase (AChE).
Conclusions: Overall, this study indicates MTCD approach as an alternative in MSC-based regenerative medicine because it approximately has the same results as invasive directly ICV-injection method has.

COMPUTATIONAL ANALYSIS OF LONGITUDINAL ELECTROENCEPHALOGRAMS OF TREATMENT OUTCOME IN ALZHEIMER 'S DISEASE USING HIERARCHICAL DYNAMIC CAUSAL MODELING.

POSTERS: A02.Q. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Tak Youn[1], Hae-Jeong Park[2]
[1]Dongguk University International Hospital, Psychiatry, Goyang, Korea, Republic of, [2]yonsei University, Nuclear Medicine, Seoul, Korea, Republic of

Aims: Both acetylcholinesterase(AChE) inhibitor and non-competitive antagonist of N-methyl-D-aspartate(NMDA) receptor are approved for the clinical treatment of Alzheimer's disease(AD). To understand the long-term effects of neuropharmacological intervention on neurobiological properties at different hierarchical levels, we explored long-term changes in neurobiological parameters of an NMDA canonical microcircuit model(CMM-NMDA) in the default mode network using dynamic causal modeling of longitudinal EEG in patients with AD.
Methods: Resting-state EEG was recorded from a total of 69 AD patients when starting medication after diagnosis of AD. We divided the patients into two groups, good and poor respondent groups according to clinical evaluation after treatment and dosage changes of AD medication with MMSE score change. We analyzed brain EEG connectivity among the 246 cortical regions defined by the Brainnetome atlas using the fieldtrip toolbox by evaluating spectral coherence for five frequency bands (delta, theta, alpha, beta, and gamma). We then analyzed each EEG connectivity between groups using ANCOVA with age, sex, and the initial MMSE scores as covariates.
Results: Our study found that the difference in brain EEG connectivity, especially intrahemispheric regional connectivity in gamma frequency bands, is increased at multiple regions of right hemisphere and DLFPC and hippocampal areas, DLFPC and caudate nucleus, middle frontal and inferior parietal areas in poor respondent group($p<0.00001$).
Conclusions: This study shows increased gamma bands EEG connectivity between right anterior and posterior areas in poor respondent group. Elevated gamma band power was observed in AD when compared to MCI and control subjects was reported in a previous study. Our results suggest the potential of the gamma EEG connectivity of initial EEG when starting treatment as a biomarker to predict long-term medical treatment for AD medication.

LICOCHALCONE-A IN ALZHEIMER'S DISEASE: NEUROPROTECTION AND BLOOD-BRAIN BARRIER PERMEABILITY

POSTERS: A02.Q. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Dalia Nour[1], Rasha Hanafi[2], Reham Abdelkader[1]
[1]German University in Cairo, Pharmacology And Toxicology, cairo, Egypt, [2]German University in Cairo, Pharmaceutical Chemistry, cairo, Egypt

Aims: There is growing interest in the neuroprotective effects of flavonoids however, their effectiveness hinges on their ability to cross the blood-brain barrier (BBB). This raises questions about whether their protective effects are purely systemic. We were able to show that Licochalcone-A (LCA), a natural flavonoid, acts as a potential neuroprotective agent and cognitive enhancer. Therefore, we aimed to investigate the potential of LCA in Alzheimer's disease (AD) by assessing its ability to cross BBB in an *in vivo* AD mouse model.
Methods: Gas chromatography–tandem mass spectrometry (GC-MS/MS) technique was applied to characterize and detect LCA in brain samples of LPS-neuroinflammatory mouse model. Mice received intraperitoneal (i.p.) injections of 250 µg/kg LPS for seven consecutive days, along with 20 mg/kg LCA starting on the fourth day. Sample extraction was performed using liquid-liquid extraction and acid hydrolysis followed by N,O-bis(trimethylsilyl)trifluoroacetamide derivatization. With Icaritin as an internal standard, method validation and quantification in the biological samples were performed.
Results: A rapid, sensitive, and selective GC–MSMS method was developed (LOD= 0.15 µg/ml, LOQ= 0.5 µg/ml) with a total run time of 15 min. Good linearity (R^2>0.994) was observed within the concentration range of 0.5–20 µg/ml. The quantifier and the qualifier MRM transitions were established for LCA. Using the developed method, LCA was detected in the mice brain samples at its specific retention time with an estimated amount of 1.8 ±0.56 mg/ 300 mg brain.
Conclusions: This is the first study to report that LCA crosses the BBB exhibiting its neuroprotective effects inside the central nervous system (CNS). These findings open new avenues to further investigate its underlying signaling pathways in CNS. The developed procedure can be easily expanded to confirm the permeability of other flavonoids.

BIODEGRADABLE NANOPARTICULATE FORMULATIONS OF LEUPROLIDE ACETATE TO COMBAT ALZHEIMER'S DISEASE THROUGH INTRANASAL DELIVERY

POSTERS: A02.Q. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Tosha Pandya[1], Abhay Dharamsi[2]
[1]INDRASHIL UNIVERSITY, School Of Pharmacy, RAJPUR,Mehsana highway, India, [2]PARUL INSTITUTE OF PHARMACY, Pharmaceutics, VADODARA, India

Aims: This research work aimed to develop a nanoparticulate delivery system that can deliver LA directly to the brain through the intranasal route. Nanoparticles made of PLGA and Chitosan efficiently entrap peptide drugs and can deliver drugs directly to the brain by passing through the olfactory lobe.
Methods: PLGA nanoparticles were developed using nanoprecipitation and Chitosan nanoparticles encapsulating leuprolide acetate were prepared using the ionic gelation method. Optimization was done using response surface methodology.The optimized nanoparticles were evaluated by DSC study, TEM analysis, *in vitro* drug release study, ex vivo diffusion study, histopathology study, and accelerated stability study. They were also evaluated for *in vivo* kinetic and dynamic study to see the anti-Alzheimer potential of nanoparticles.
Results: The optimized PLGA nanoparticles had particle size of 182.6 ± 1.5 nm, PDI (0.3), %EE (77.3 ± 0.6), and Zeta Potential (-5.6 mv ± 0.2), whereas the optimized chitosan nanoparticles of leuprolide acetate exhibited particle size of 254.3 ± 10.74 nm, %EE of 85.59 ± 0.76 %, and zeta potential of +18.00 ± 0.23 mv. The in vitro drug release from optimized nanoparticles indicated sustained release. The Ex vivo diffusion study indicated an apparent permeability coefficient for the drug-containing nanoparticles higher than for plain drug solution. Sheep nasal toxicity and accelerated stability study proved the intranasal safety and stability of the developed formulation. The in vivo drug uptake study indicated a greater brain drug concentration from Chitosan nanoparticles than from PLGA NPs and plain drug solution. The anti-Alzheimer potential was also evident from the Y maze study and histopathology of Alzheimer-induced rat brain treated with drug-loaded nanoparticles.
Conclusions: Thus, the biodegradable nanoparticulate formulations of leuprolide acetate was found to have great potential for Alzheimer's disease management.

AN RNAI THERAPEUTIC TARGETING APP REDUCED BETA-CTF AND CORRECTED ENDOSOMAL ABNORMALITIES IN MULTIPLE HUMAN ALZHEIMER'S DISEASE IPSC LINES

POSTERS: A02.P. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ASO AND RNAI

Lan Dang, Matthew Stricos, Nishitha Kodali, Diana Cha, Olufemi Adeduji, Kevin Fitzgerald, Kirk Brown
Alnylam Pharmaceuticals, Biology, Cambridge, United States of America

Aims: Endosomal-lysosomal abnormalities are hallmark of Alzheimer's disease (AD). Endolysosomal dysfunction contributes to abnormal amyloid precursor protein (APP) clearance; concurrently, peptides resulting from dysregulated APP metabolism can also impair endolysosomal function, creating a cycle of endolysosomal dysfunction and APP metabolism dysregulation. An RNAi therapeutic targeting *APP* mRNA is intended to reduce APP production. To explore the impact of APP lowering on endolysosomal dysfunction, we evaluated the effect of an siRNA targeting *APP* mRNA on downstream APP cleavage products, including beta-secretase-derived APP C-terminal fragment (beta-CTF), and on endosomal defects in multiple human AD induced pluripotent stem cell (iPSC) lines.
Methods: Early-onset AD patient-derived iPSCs carrying pathogenic mutations in PSEN1 and CRISPR/Cas9-edited iPSCs carrying APP homozygous Swedish mutation (swe/swe) lines were differentiated to neurons and astrocyte cocultures, transfected with siRNA targeting *APP* mRNA or control siRNA on Day 7. Beta-CTF, soluble APP-alpha, soluble APP-beta protein analysis by Meso Scale Discovery enzyme-linked immunosorbent assay, and high content imaging for Rab5+ early endosome and Rab7+ late endosome size were performed on Day 30.
Results: An RNAi therapeutic targeting *APP* mRNA significantly reduced *APP* mRNA and levels of downstream APP cleavage products in human AD patient-derived iPSC lines with pathogenic mutations in PSEN1. Reducing APP expression reduced early endosomal enlargement defects. Immunohistochemistry showed high accumulation of intracellular beta-CTF in both APP and PSEN1 mutation lines, which was significantly reduced in cells treated with *APP* siRNA.
Conclusions: By lowering both intracellular and extracellular drivers of AD pathology, an RNAi therapeutic targeting *APP* may potentially alter the cascade of pathological events that result in neurodegeneration. The Phase 1 first-in-human study of ALN-APP, an investigational RNAi therapeutic targeting *APP* mRNA, is ongoing in patients with early-onset AD (NCT05231785).

NEW LOW-DOSE CURCUMIN DERIVATIVES WITH THERAPEUTIC POTENTIAL IN ALZHEIMER'S DISEASE

POSTERS: A02.Q. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Beatriz Rodrigues[1], Eduarda Ventura[1], Patricia Moreira[2], Rosa Resende[2], Armanda Santos[1,2], Cláudia Pereira[2,3], Maria Teresa Rosete[1,2], Maria Paula Robalo[4,5], Ana Silva[2], Sónia Silva[1,6]
[1]University de Coimbra, Faculty Of Pharmacy, Coimbra, Portugal, [2]University of Coimbra, Center For Neuroscience And Cell Biology, Coimbra, Portugal, [3]University of Coimbra, Faculty Of Medicine, Coimbra, Portugal, [4]instituto Politécnico de Lisboa, Instituto Superior De Engenharia De Lisboa, Lisboa, Portugal, [5]Instituto Superior Técnico, Centro De Química Estrutural, Lisboa, Portugal, [6]University of Coimbra, Coimbra Institute For Clinical And Biomedical Research, Coimbra, Portugal

Aims: Objectives: Curcumin has been suggested as a promising treatment for Alzheimer's disease (AD) since it inhibits the formation and extension of Aβ aggregates and destabilizes pre-formed ones. However, curcumin's low bioavailability limits its therapeutic use. Two curcumin derivatives were synthesized to improve low-dose efficacy.
Methods: Methods: The anti-inflammatory, antioxidant, and anti-amyloidogenic effects of curcumin derivatives were evaluated *in vitro* using BV-2 cells exposed to lipopolysaccharide as a neuroinflammation cell model and N2a-APPswe cells as an AD model. *In vivo* evaluation was accomplished using APPswe/PSEN1dE9 mice and their wild-type counterpart. One-year-old animals were orally administered with derivative 27 (50 mg/kg/day) or vehicle for 28 days.
Results: Results: Both molecules significantly reduced nitric oxide (NO) production and the protein levels of inducible NO synthase, Pro-interleukin-1β and, for derivative 27, also cyclooxygenase-2 protein levels in lipopolysaccharide-exposed BV-2 cells. Moreover, Derivative 27 activated Nrf2, and significantly increased Nrf2 and heme-oxygenase-1 mean fluorescence intensity, in N2a-APPswe cells. *In vivo*, Derivative 27 significantly decreased Pro-interleukin-1β and amyloid protein precursor protein levels in the hippocampus and Aβ levels in the hippocampus and plasma.
Conclusions: Conclusion: These data suggest that both curcumin derivatives at low doses seem to be more effective than curcumin, in mitigating some of AD hallmarks.

NONCLINICAL AND CLINICAL DEVELOPMENT OF PPI-1011, AN ORAL PLASMALOGEN PRECURSOR, AS A TREATMENT FOR ALZHEIMER'S DISEASE

POSTERS: A02.Q. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Tara Smith[1], Kaeli Knudsen[1], Shawn Ritchie[2]
[1]Med-Life Discoveries LP, Therapeutics, Saskatoon, Canada, [2]Med-Life Discoveries LP, Therapeutics, SASKATOON, Canada

Aims: Plasmalogen deficiency is strongly correlated with the onset and progression of Alzheimer's disease (AD). This, combined with the role of plasmalogens in many neuronal functions, has led to the hypothesis that plasmalogen deficiency underlies the development of AD. Plasmalogen augmentation has therefore been hypothesized as a novel therapeutic strategy for AD and other conditions of plasmalogen deficiency. PPI-1011 is a novel synthetic plasmalogen precursor that we have advanced into the clinic and is the first plasmalogen-system targeted therapy undergoing formal regulatory approval. This poster summarizes the nonclinical and Phase 1 safety data generated to date.
Methods: Nonclinical safety studies included 28-day GLP-studies in primates and rats, AMES and micronucleus genotoxicity, and a hERG. C14-labeled ADME studies in rats were performed to characterize pharmacokinetics, mass balance, excretion, and distribution. Currently, a Phase 1 study is on-going to evaluate the safety, tolerability, and pharmacokinetics of both single and 14-day repeat dosing of PPI-1011 in healthy adult volunteers.
Results: Orally administrated PPI-1011 was well tolerated up to 400 mg/kg/day in primates and 500 mg/kg/day in rats. Neither genotoxicity nor cardiotoxicity was observed. In rats, the pharmacokinetics were characterized by strong bioavailability, with over 50% of the compound absorbed. Plasma levels peaked between 6-12 hours, with a $t_{1/2}$ of 40 hours. Quantitative whole-body autoradiography demonstrated uptake across all tissues, including the brain. The 14-day repeat dose portion of the Phase 1 study is on-going, but single administrations of PPI-1011 were well-tolerated up to 100 mg/kg.
Conclusions: PPI-1011 is well-tolerated in both animals and humans, representing a novel treatment modality to address the plasmalogen deficiency observed in AD. A Phase 2 clinical protocol is under development to evaluate the effects of PPI-1011 on cognitive decline in AD patients.

IN SILICO INVESTIGATION OF THE ABILITY OF OCTOVESPIN TO ACT AS MULTITARGETS AGAINST ALZHEIMER'S AND PARKINSON'S DISEASE

POSTERS: A02.Q. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Yuri Só[1], Caio Costa[2], Luana Cristina Camargo[3], Ricardo Gargano[1], Márcia Renata Mortari[3]
[1]Universidade de Brasília, Physics, Brasília, Brazil, [2]University of Brasilia, Physics, Brasilia, Brazil, [3]Institute of Biological Science, Department Of Physiology, Brasília, Brazil

Aims: Natural compounds are important sources of substances with medicinal potential to treat neurological disorders, such as Alzheimer's disease (AD) and Parkinson's disease (PD), which are emerging health problems in the 21st century. Existing medications for AD and PD have limited efficacy and side effects, so it is important to investigate new potential compounds and drugs that are less harmful and more effective. This study investigates two compounds: Octovespin, a peptide modified from a peptide isolated from *Polybia occidentalis* wasp venom, and Fraternine-10, a peptide isolated from the venom of the wasp *Parachartergus fraternus*. Those peptides had promising results in AD and PD mice models, although the its action mechanism have not been investigated. To evaluate the molecular effect of Octovespin and fraternine-10, we conducted *in silico* studies, starting with molecular docking against five common targets for AD (ACE, BACE1, GSK-3, TACE, and AChE) and four targets for PD (A2A-AR, ASN, COMT, MAO-B).
Methods: We compared our findings with four standard drugs for AD (Donepezil, Galantamine, Rivastigmine, and Tacrine) and PD (Dopamine, Rasagiline, Safinamide, and Selegiline) using AutoDock 4.1. We also performed molecular dynamics (MD) simulations with the docking complexes to analyze the dynamic behaviors and binding free energy at 100 ns time scale. In addition, we investigated frontier molecular orbitals and density-functional theory (DFT) from computational quantum mechanics.
Results: Overall, the potential binding affinity from molecular docking and MD-simulation suggest that Octovespin and fraternine-10 could be a suitable therapeutic lead for AD and PD treatment, since these compounds present high or equivalent values of binding affinity.
Conclusions: Our results can help us understand the characteristics and capabilities of natural compounds like Octovespin and Fraternine-10 to interact with common targets of AD and PD.

A GLIMMER OF SUSTAINED HOPE: RETROSPECTIVE CLINICAL OBSERVATIONS ON TRANSCRANIAL PULSE STIMULATION IN ALZHEIMER'S CARE

POSTERS: A02.Q. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Catherine Widmann, Barbara Kofler, Sarah Bernsen, Monika Sommer, Luisa Kaluza, Sergio Castro-Gomez, Ullrich Wüllner
University of Bonn Medical Center, Neurodegenerative Diseases And Geriatric Psychiatry, Bonn, Germany

Aims:

or alternative treatments for Alzheimer's Disease (AD), this retrospective analysis focuses on Transcranial Pulse Stimulation (TPS), an eme
nary objective is to assess the preliminary efficacy of TPS in enhancing cognitive outcomes across multiple domains in a cohort of 28 patien
.

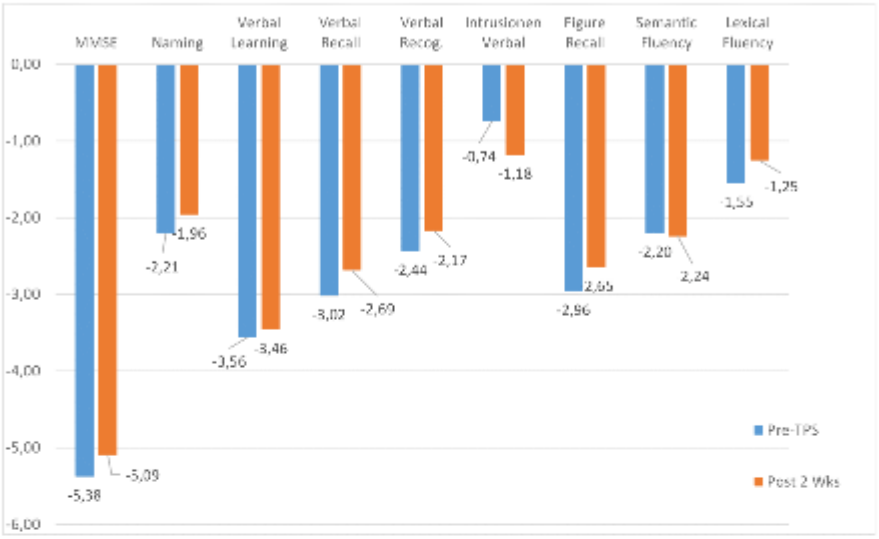
Methods:

ales, 11 males; average age 73.6 ± 8.6 years) underwent a standardized TPS protocol comprising six sessions over two weeks and again a
al cognitive status (MMSE), language, and executive function—were conducted pre- and post-TPS and at two-week and 6-month follow-up
loyed to analyze the data, adjusting for age, sex, and education.

Results: Findings indicated short-term stability in all tested cognitive domains (e.g., verbal memory, language, executive function). In a limited 6-month follow-up (n=5), significant improvements were noted in general cognition, verbal learning, and semantic fluency, albeit limited by the small sample size. Over 80% of patients, either remained stable or showed cognitive improvement two weeks post-TPS, a trend sustained at 6-month follow-

Figure 1.

CERAD z-Scores 2 weeks post TPS versus pre-TPS



Note. Data from 28 AD patients: 17 female (60.7%); mean age 73.6 ± 8.6 years.

ups.

Table 1.

Tests Paired means 2 Wks Post TPS and 6 Mo FU

Parameter Comparisons	Mean Diff.	SE	95% CI		T	Sig.	Hedges Corr. Point Estimate	Effect Size
			LL	UL				
MMSE	1.56	0.52	0.12	3.00	3.01	**0.04**	**1.22**	**large effect size**
Naming	0.34	0.35	-0.63	1.31	0.98	0.38	0.39	
Verbal Learning	1.78	0.59	-0.12	3.67	2.98	**0.06**	**1.30**	**large effect size**
Verbal Recall	0.93	0.43	-0.46	2.31	2.13	0.12	0.92	
Intrusions	1.20	0.99	-1.94	4.34	1.22	0.31	0.53	
Verbal Recog.	-0.33	0.19	-0.93	0.28	-1.72	0.18	-0.75	
Figure Recall	0.24	0.24	-0.43	0.91	1.00	0.37	0.40	
Semantic Fluency	0.76	0.22	0.15	1.37	3.45	**0.03**	**1.39**	**large effect size**
Lexical Fluency	0.24	0.21	-0.35	0.83	1.14	0.32	0.46	

Note. Preliminary 6-month data (n = 5) compared to 2 weeks Post TPS. Hedges' correction is generally considered a more accurate point estimate for effect sizes than Cohen's d since it applies a correction factor to account for bias in small samples. Hedges' corrected point estimates in a paired t-test, commonly used benchmarks for effect sizes are as follows: Small effect: g=0.2, Medium effect: g=0.5, Large effect: g=0.8.

Conclusions: This retrospective analysis supports TPS as a tolerable, potentially efficacious non-pharmacological intervention for AD. Stable cognitive performance was noted in a two-week follow-up. Preliminary data suggest TPS may have clinical

utility in AD management and warrant further longitudinal studies. Earlier work, such as Beisteiner et al. (2020), queried TPS's ability to alter cognitive trajectory in AD. The TPS mechanism may involve central nervous system stimulation or unexplored lymphatic effects. Given challenges in anti-amyloid antibody trials, our findings at two-week and 6-month follow-ups highlight the need for expanded TPS studies.

THE MITOCHONDRIAL ENZYME ABAD AS A POTENTIAL THERAPEUTIC TARGET – INHIBITION OF AMYLOID-BETA-ABAD INTERACTION USING BRAIN-TARGETED NANOPARTICLES

POSTERS: A02.Q. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Yomna Youssef[1], Salma Tammam[2], Sanjay Mathur[3], Shaista Ilyas[3], Basma Elshenawy[2], Alaa Gad[2], Reham Abdelkader[4]
[1]German International University, Clinical Neurophysiology, Cairo, Egypt, [2]German University in Cairo, Pharmaceutical Technology, Cairo, Egypt, [3]Faculty of Mathematics and Natural Sciences, University of Cologne, Inorganic And Materials Chemistry, Cologne, Germany, [4]German university in Cairo, Pharmacology And Toxicology, Cairo, Egypt

Aims: The interaction between amyloid-beta and the mitochondrial enzyme amyloid-beta-binding alcohol dehydrogenase (ABAD) elicits many detrimental events, including the excessive generation of reactive oxygen species leading to mitochondrial dysfunction and apoptosis of neuronal cells. In this work, hindrance of the amyloid-beta-ABAD interaction is attempted by developing brain-targeted chitosan nanoparticles (CS-NPs) and loading them with a decoy peptide (DP) that can inhibit ABAD and eliminate amyloid-beta-induced toxicity, modulating the pathogenesis of Alzheimer's disease.
Methods: CS-NPs of two sizes; small (S-CS-NPs) with a hydrodynamic diameter (HD) of 59 ± 6 nm and large (L-CS-NPs) with a HD of 89 ± 6 nm were formulated to study the effect of NP size on the efficiency of delivering the DP across the blood-brain barrier (BBB). The DP was loaded into NPs, and the ability of NPs to bypass the BBB and allocate to the brain in neuroinflammatory mouse models was evaluated by conducting biodistribution studies. Cognitive functions were tested by performing the Y-maze test, and amyloid-beta, estradiol, adenosine triphosphate (ATP) and activity of the antioxidant enzyme superoxide dismutase (SOD) were quantified in the brains of the mice by ELISA.
Results: *In vivo* studies demonstrated the ability of S-CS-NPs, but not L-CS-NPs, to accumulate in the brains of mice in which neuroinflammation was induced, but not healthy ones. Upon intravenous administration of free DP and DP-loaded S-CS-NPs, only animals receiving DP-loaded S-CS-NPs displayed an improvement in cognition. A decrease in their amyloid-beta concentrations was observed and their levels of estradiol, ATP and activity of SOD were normalized indicating preservation of the ABAD normal function.
Conclusions: DP-loaded S-CS-NPs can deliver DP to the brain in animals with neuroinflammation enhancing their cognitive functions due to the possible impediment of amyloid-beta-ABAD interaction.

DEVELOPMENT OF ANTI-HMGB1 ANTIBODY FOR DEMENTIAS

POSTERS: A03.A. DRUG DEVELOPMENT, CLINICAL TRIALS: IMMUNOTHERAPY

Hitoshi Okazawa
Change Cure, Ceo, Yokohama, Japan

Aims: Initiated from our previous comprehensive phosphoproteome analyses of cerebral cortex tissues from four mouse AD models and postmortem human AD patients (Tagawa et al, Hum Mol Genet 2015), we found that HMGB1, a DAMP molecule released from necrosis, triggers secondary neurite degeneration (Fujita et al, Sci Rep 2016) and neuronal necrosis of surrounding neurons. In addition, we confirmed that TRIAD necrosis (Hoshino et al, JCB 2006), the subtype of necrosis via DNA damage occurring in AD, initiates in cortical neurons of frontotemporal lobar degeneration across multiple gene mutations from the early pathological stage. The TRIAD necrosis phenotype resembles two reports published in Nature Neuroscience (Lee JH et al, Nature Neurosci 2022) and Nature (Yuan P et al, Nature 2022) that followed our observation (Tanaka et al, Nature Commun 2020). TRIAD phenotypes are also confirmed in postmortem brains of human AD and FTLD patients (Tanaka et al, Nature Commun 2020; Homma et al, Life Sci Alliance 2021; Tanaka et al, Commun Biol 2021). Based on these notions, we are currently developing human anti-HMGB1 monoclonal antibody as a new drug against FTLD, AD and other neurodegenerations.
Methods: for phosphoproteoma analysis, biochemical analysis, behavioral tests, pathological analysis, human pathologies and so on were described in our previous publications in details (Tagawa et al, Hum Mol Genet 2015; Tanaka et al, Nature Commun 2020; Homma et al, Life Sci Alliance 2021; Tanaka et al, Commun Biol 2021).
Results: We confirmed therapeutic effects on four types of cognitive function test, morphological changes in immunohistochemistry, and biochemical changes in western blot and so on. We also obtained results of non-clinical GLP tests.
Conclusions: In the presentation at ADPD2024, we will report our proceeding in human clinical trial.

DESIGN OF A RANDOMIZED PHASE 2B, PLACEBO-CONTROLLED TRIAL ASSESSING SAFETY AND EFFICACY OF AD04 IN EARLY ALZHEIMER'S DISEASE ("ADVANCE")

POSTERS: A03.A. DRUG DEVELOPMENT, CLINICAL TRIALS: IMMUNOTHERAPY

Benjamin Haaland[1,2], Sam Dickson[3], Joshua Christensen[3], Agustín Fernández-Fernández[4], Timo Grimmer[5], Oliver Peters[6], Suzanne Hendrix[7], Achim Schneeberger[8]
[1]Pentara Corporation, Statistics, Salt Lake City, United States of America, [2]Pentara Corporation, Statistical Consulting, Millcreek, United States of America, [3]Pentara Corporation, Statistics, Millcreek, United States of America, [4]University of Oviedo, Institute Of Oncology Of Asturias (iuopa), Oviedo, Spain, [5]Technical University Munich, Center For Cognitive Disorders, Munich, Germany, [6]Department of Psychiatry, Charité-universitätsmedizin Berlin, Campus Benjamin Franklin, Berlin, Germany, [7]Pentara Corporation, Ceo, Millcreek, United States of America, [8]Advantage Therapeutics, Cmo, Miami, United States of America

Aims: Therapeutic options for patients with Alzheimer's disease (AD) are limited. The AFF006 randomized controlled trial (RCT) compared two doses of AD04 with three formulations of AD02, and demonstrated benefits of 2mg AD04 in post-hoc analyses. We present the study design of a follow-up RCT - ADVANCE - presenting evidence from AFF006 and estimated success probability for ADVANCE.
Methods: The findings for the 2mg AD04 analysis are post-hoc and may have been a false positive result. A statistical analysis was performed to account for selecting the best study arm compared to the remaining arms (multiplicity issue). Instead of performing a traditional power calculation, ADVANCE was designed using a conservative assurance analysis which factors in the uncertainty introduced by using treatment effect estimates and SDs from the small sample size of AFF006. The probability of success was estimated incorporating an attenuated treatment effect, and the potential impact of more frequent dosing in ADVANCE.
Results: ADVANCE plans to enroll 122 patients with early AD, MMSE 22-30, randomized 1:1 to 2mg AD04 or placebo monthly. Early AD includes patients with either an AD-type CSF signature (abeta and tau), or evidence of hippocampal atrophy based on a Schelten's score, with clinical confirmation based on FCSRT≤40 or Free Recall≤17. The primary endpoint will be time savings estimated based on adapted ADAS-cog, ADCS-ADL and CDR-sb scores. The multiplicity-adjusted p-value for the AFF006 study was p=0.02. Assurance calculations estimate a success probability of 85% for ADVANCE's primary endpoint.
Conclusions: The ADVANCE RCT is evaluating a novel immune-stimulating intervention for patients with early AD, based on evidence from AFF006 (phase 2). The study has a high estimated probability of success.

PHARMACOKINETIC COMPARABILITY STUDY OF ADUCANUMAB (BIIB037) ADMINISTERED SUBCUTANEOUSLY VERSUS INTRAVENOUSLY IN HEALTHY VOLUNTEERS

POSTERS: A03.A. DRUG DEVELOPMENT, CLINICAL TRIALS: IMMUNOTHERAPY

Philip Montenigro, Gioacchino G. Curiale, Jackson Burton, Gab-Jin Park, Jennifer Murphy, Jing Xie, John O'Gorman, Gersham Dent, Kate Dawson
Biogen Inc., Medical Affairs, Cambridge, United States of America

Aims: Aducanumab (BIIB037) has accelerated approval for patients with early Alzheimer's disease (AD) via intravenous (IV) infusion. Study 221HV104 (NCT05216887) evaluated the pharmacokinetic (PK) comparability and safety and tolerability of aducanumab administered by subcutaneous (SC) injection versus IV infusion, potentially offering a more convenient and accessible route of administration.
Methods: An open-label, parallel-arm study compared a single weight-based 10 mg/kg IV dose of aducanumab with two 700 mg SC doses of aducanumab administered 2 weeks apart. 124 healthy volunteers were randomized and dosed with study treatment, with 120 participants included in the PK Analysis Set.
Results: Aducanumab AUC_{inf} in participants treated with aducanumab 10 mg/kg IV and participants treated with two aducanumab 700 mg SC doses were comparable, with a geometric LS mean ratio of 93.9% (0.939, 90% CI [0.863, 1.022]). Aducanumab was well tolerated in healthy volunteers after a single 10 mg/kg IV dose or two 700 mg SC doses. The overall incidence of adverse events (AEs) was 50.8% in the IV arm and 30.2% in the SC arm**.** Headache was the most common AE in both arms. One serious AE (enterocolitis) in the SC arm was assessed as severe, related to treatment, led to treatment discontinuation, and resolved. All other AEs reported during the study were classified as mild or moderate and resolved or were resolving. No deaths occurred during the study. Three participants (4.8%) in the SC arm developed treatment-emergent anti-aducanumab antibodies.
Conclusions: Aducanumab administered as two 700 mg SC doses demonstrates a high degree of PK comparability to aducanumab administered as a single weight-based 10 mg/kg IV dose and is well tolerated in healthy volunteers.

APOLLOE4 PHASE 3 TRIAL OF ORAL ANTI-AMYLOID AGENT ALZ-801/VALILTRAMIPROSATE IN APOE4/4 EARLY ALZHEIMER'S PATIENTS: STUDY DESIGN AND BASELINE CHARACTERISTICS

POSTERS: A03.B. DRUG DEVELOPMENT, CLINICAL TRIALS: AMYLOID CLEARANCE

Earvin Liang[1], Susan Abushakra[1], Rosalind Mclaine[1], David Watson[2], Merce Boada Rovira[3], Karim Bennys[4], Niels Prins[5], Daphne Troost[6], Anton Porsteinsson[7], Marwan Sabbagh[8], Susan Flint[1], Winnie Pak[1], John Hey[1], Martin Tolar[9]
[1]Alzheon, Medical, Framingham, United States of America, [2]Alzheimer's Research and Treatment Center, Alzheimer's Research And Treatment Center, Wellington, United States of America, [3]Ace Alzheimer Center Barcelona, Ace Alzheimer Center Barcelona, Barcelona, Spain, [4]University Hospital Montpellier, Center For Alzheimer's Disease, Montpellier, France, [5]Brain Research Center, Ceo, Amsterdam, Netherlands, [6]Brain Research Center, Brain Research Center, Amsterdam, Netherlands, [7]University of Rochester, Department Of Psychiatry, Rochester, United States of America, [8]St. Joseph's Hospital and Medical Center, Barrow Neurological Institute, Phoenix, United States of America, [9]Alzheon, Ceo, Framingham, United States of America

Aims: ALZ-801/valiltramiprosate, an oral inhibitor of amyloid oligomer formation, showed meaningful efficacy, hippocampal protection, and favorable safety in APOE4 carrier Alzheimer's disease (AD) patients (Abushakra 2016, Kocis 2017, Hey 2018). APOE4/4 homozygotes who have high burden of amyloid pathology showed strongest benefits (Abushakra 2017), with no amyloid related imaging abnormalities (ARIA) that are seen with anti-amyloid antibodies. A 78-week pivotal Phase 3 trial is ongoing to assess cognitive, functional, and volumetric MRI effects of ALZ-801 265mg BID in APOE4/4 homozygotes with Early AD.
Methods: APOLLOE4 (NCT04770220), a Phase 3, double-blind, placebo-controlled multicenter-study enrolled APOE4/4 Early AD subjects ages 50-80 years, MMSE ≥22, CDR-G=0.5/1. Screening/baseline MRIs allowed microhemorrhages (MH) >4 and siderosis; vasogenic edema (ARIA-E) was exclusionary. Stable cholinesterase inhibitors were allowed, anti-coagulants were excluded. Study is powered to detect ~2.5 placebo-adjusted ADAS-cog13 effect at 78 weeks, the primary endpoint; hippocampal volume, and functional outcomes are main secondary outcomes.
Results: This pivotal study enrolled 325 subjects, 51% female, mean age 69 years, 65%/35% MCI/Mild AD, 82% Caucasian, 35% on cholinesterase inhibitors, baseline MMSE=26, ADAS-cog13=24, CDR-SB=3.0, and CDR global=0.6. Of the 313 subjects with baseline 1.5/3T MRIs, 32% and 9% had any MH or >4 MH, 9% had siderosis, 90% had mild or moderate white matter-disease. With enrollment completed, results are expected in 3Q 2024. The study's independent safety monitoring board oversees safety. No increased ARIA-E risk has been detected to date in the blinded Phase 3 and open-label Phase 2 study.
Conclusions: ALZ-801, an oral potentially disease-modifying agent, shows favorable safety and tolerability in ongoing APOE4 carrier studies, including homozygotes at highest risk for ARIA, and may become a safe, convenient alternative to anti-amyloid antibodies in APOE4 carrier AD patients.

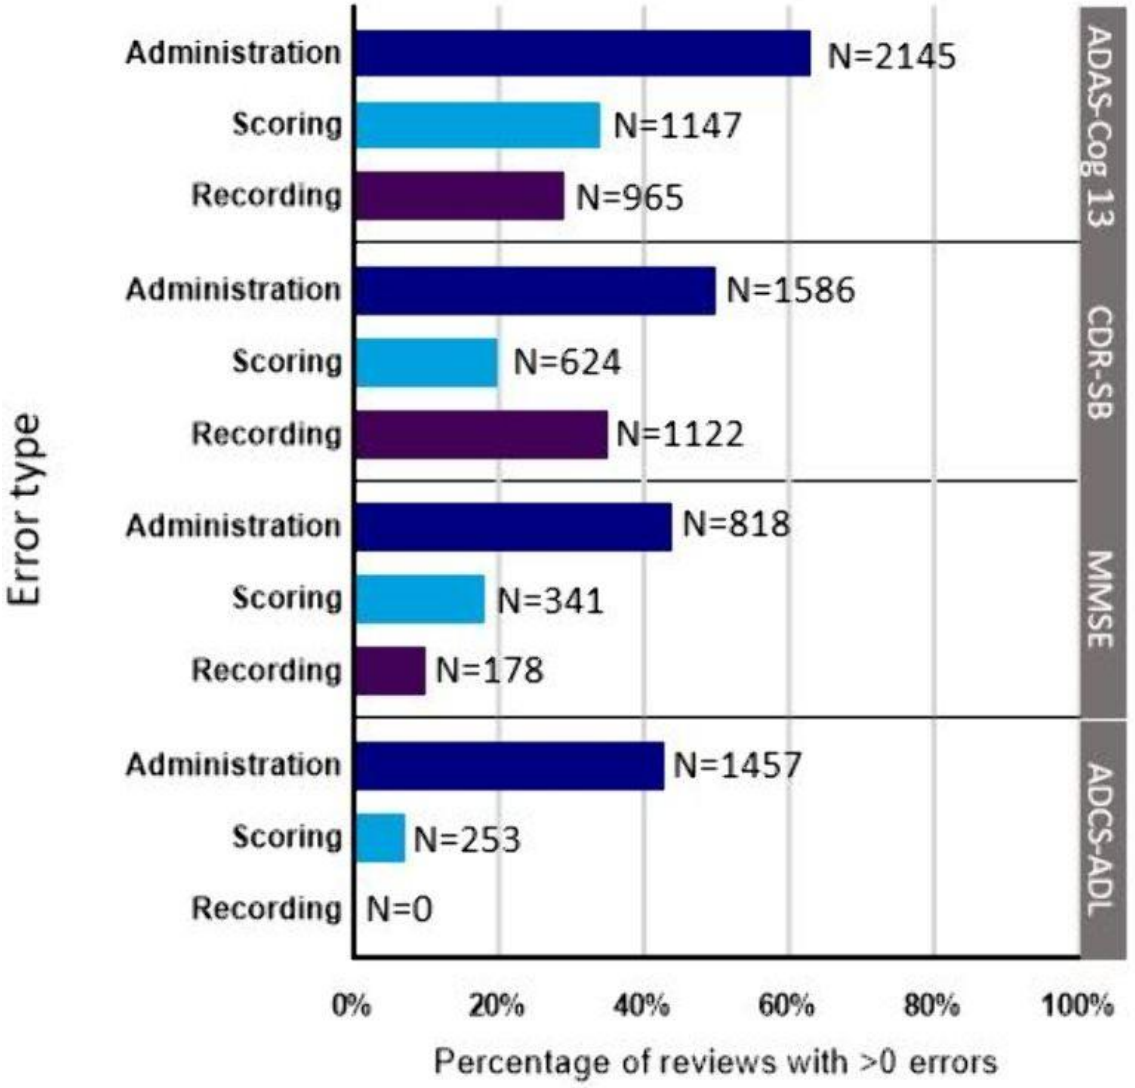
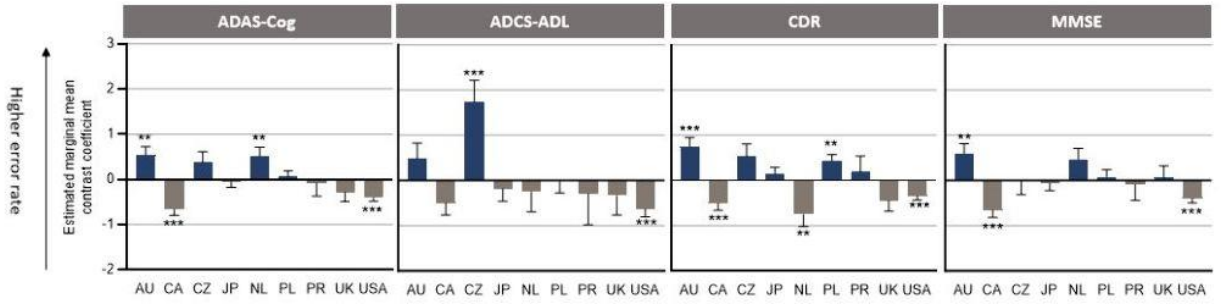
CENTRAL MONITORING OF RATER PERFORMANCE AND CHARACTERISTICS OF EFFICACY ASSESSMENTS IN THE TRAILBLAZER-ALZ 2 STUDY

POSTERS: A03.B. DRUG DEVELOPMENT, CLINICAL TRIALS: AMYLOID CLEARANCE

Giulia Tronchin[1], Lisle Kingery[2], Robyn Leventhal[3], Edward Bartolic[3], Svenja Wacker[3], Jordan Barbone[3], Alette Wessels[1]
[1]Eli Lilly and Company, Neuroscience, Indianapolis, United States of America, [2]Work carried out while an employee of Cogstate, Ltd., New Haven, United States of America, [3]Cogstate, Ltd., New Haven, United States of America

Aims: Raters are qualified and trained in scale administration, but errors can occur in administration, recording, and scoring on outcome scales used in Alzheimer's disease (AD) clinical trials. In TRAILBLAZER-ALZ 2, Rater Performance Central Monitoring (RPCM) was employed to identify and reduce rater errors. RPCM facilitates ongoing feedback on administration and scoring practices to enhance standardization within and across raters, while improving overall quality of study data. The objectives were to describe the RPCM methodology and rater performance on efficacy assessments in TRAILBLAZER-ALZ 2.
Methods: RPCM was performed for AD Assessment Scale- Cognitive subscale 13-item, Clinical Dementia Rating, AD Cooperative Study- Activities of Daily Living Scale, and Mini-Mental State Examination. RPCM was conducted in a standardized manner by neuropsychologists, who reviewed and reported on raters' administration, recording, scoring, and interview skill competencies via a Scale Review Form (SRF). Assessment worksheets and audio recordings were reviewed, feedback was shared with raters and errors were corrected throughout the duration of the trial by email and/or teleconference. Estimated marginal contrasts for country differences were extracted from Poisson mixed models fitted to predict error rate (total number of errors recorded per SRF by country). Models were independently fit for each assessment. Each model included raters as random effect, offset by the log number of reviews completed per rater.
Results: Data available for analyses were from 809 raters across eight countries. Error prevalence was quantified for each efficacy assessment (Figure 1). Error detection rate differences for countries were reported by review type and scale (Figure
2).





Conclusions: RPCM in TRAILBLAZER-ALZ 2 identified and corrected errors in scale administration procedures and improved overall data integrity. Country specific differences observed will help in tailoring monitoring programs towards optimizing rater performance.

TARGET ENGAGEMENT IN INTERCEPT-AD: DEVELOPMENT OF A NOVEL ASSAY MEASURING ACU193-AMYLOID BETA OLIGOMER COMPLEXES IN HUMAN CSF

POSTERS: A03.B. DRUG DEVELOPMENT, CLINICAL TRIALS: AMYLOID CLEARANCE

Erika Cline[1], Elizabeth Johnson[1], Oladayo Oladiran[2], Jennifer Gillies[2], Derrick Johnson[3], Nathan Mcowen[3], Caitlin Hansen[2], Jacob Wohlstadter[2], Eric Siemers[4], Hugo Vanderstichele[5], Robert Dean[6], Jasna Jerecic[1]
[1]Acumen Pharmaceuticals, Inc., Bioanalytical Methods, Charlottesville, United States of America, [2]Meso Scale Diagnostics, LLC, Assay Development, Rockville, United States of America, [3]B2S Life Sciences, Assay Development, Franklin, United States of America, [4]Acumen Pharmaceuticals, Inc., Medical, Charlottesville, United States of America, [5]Biomarkable, Biomarkable, Gent, Belgium, [6]Indiana University School of Medicine, Department Of Pathology And Laboratory Medicine, Indianapolis, United States of America

Aims: We sought to develop an assay to measure target engagement of ACU193, a monoclonal antibody selective for soluble amyloid beta oligomers (AβOs), in the Phase 1 trial INTERCEPT-AD. So far, antibodies targeting Aβ protofibrils or fibrils have relied on plaque reduction as an indication of target engagement. Due to the AβO selectivity of ACU193, we used a different approach of measuring the ACU193-AβO complex in cerebrospinal fluid (CSF).
Methods: The assay was developed on the ultrasensitive MSD S-PLEX platform. Multiple antibody pairs comprising anti-idiotypic antibodies for ACU193 capture and anti-Aβ antibodies for AβO detection were screened for sensitivity, specificity, and selectivity to the ACU193-AβO complex in AD and non-AD CSF. A semi-quantitative reference standard was developed comprising a pre-formed complex, with AβOs titrated and ACU193 at a constant concentration. Assay recovery and reproducibility were evaluated.
Results: Screening antibody pairs in ACU193-spiked CSF enabled selection of the reference standard and detection antibody that optimized quantitation of endogenous AβOs. The ACU193-specificity of the anti-idiotypic capture antibody and the AβO-selectivity of the detection antibody yielded an assay with low background in untreated AD and non-AD CSF, with quantifiable signal dependent on the presence of ACU193 in CSF. Non-competition and competition assays demonstrated specificity and selectivity of the assay for AβOs over monomeric Aβ. The assay recovery and intra- and inter-run reproducibility met assay design specifications.
Conclusions: Development efforts highlight the importance of using AβO reference standards and anti-Aβ detection antibodies optimally suited for quantifying endogenous CSF AβOs. The resulting MSD S-PLEX assay was specific and selective for the ACU193-AβO complex in CSF. Application of the assay to INTERCEPT-AD CSF samples showed dose-dependent target engagement of ACU193 approaching Emax at highest doses administered.

PLASMA PROTEOMIC ANALYSIS FROM ALZHEIMER'S PATIENTS IN SPARC CLINICAL TRIAL TO IDENTIFY PHARMACODYNAMIC BIOMARKERS OF THE S2R MODULATOR CT1812

POSTERS: A03.B. DRUG DEVELOPMENT, CLINICAL TRIALS: AMYLOID CLEARANCE

Britney Lizama[1], Duc Duong[2], Kiran Pandey[3], Valentina Di Caro[1], Adam Mecca[4], Ryan O'Dell[4], Christopher Van Dyck[4], Michael Grundman[5], Anthony Caggiano[1], Nicholas Seyfried[2], Mary Hamby[1]
[1]Cognition Therapeutics, Inc., Research, Pittsburgh, United States of America, [2]Emory University School of Medicine, Department Of Biochemistry, Atlanta, United States of America, [3]Emtherapro, Inc., R&d, Atlanta, United States of America, [4]Yale School of Medicine, Alzheimer's Disease Research Unit, New Haven, United States of America, [5]Global R&D Partner, -, San Diego, United States of America

Aims: An unbiased assessment of plasma proteomes from patients completing the randomized, double-blind, placebo-controlled 6-month trial SPARC (NCT03493282) was performed to identify plasma pharmacodynamic biomarkers of CT1812, and for comparative analyses with a previous analysis identifying CSF pharmacodynamic biomarkers of CT1812.
Methods: Tandem-mass tag mass spectrometry proteomics was performed on baseline, 1-month, and 6-month plasma from 17 treatment-compliant SPARC participants testing two doses (100 mg, 300 mg; oral, once daily) of CT1812 compared to placebo in patients with mild-to-moderate AD. Treatment effects were assessed through differential abundance analyses (pooled drug vs placebo; $p \leq 0.1$) followed by pathway analyses (MetaCore, STRING). Plasma proteomes were compared across timepoints and to CSF proteomes, to identify plasma and CSF biomarkers commonly altered by CT1812. SPARC plasma proteomes were compared to that from the interim SHINE cohort (SHINE-A) to identify congruent plasma biomarkers across trials.
Results: Across plasma samples, 2738 proteins were detected. At 1 mo, 155 ($p \leq 0.1$) proteins were differentially abundant (CT1812 vs placebo). At 6 mo, 68 ($p \leq 0.1$) proteins were differentially abundant. Pathway analysis was performed using significant ($p \leq 0.1$) differentially abundant proteins. Immune response, amyloid-beta, and beta-catenin related pathways were significantly ($p \leq 0.05$) altered by CT1812 vs placebo at 1 mo, with similar pathways observed at 6 mo. Fifteen proteins were commonly altered in 1 and 6 mo plasma (CT1812 vs placebo; $p \leq 0.1$). Nine proteins were significantly ($p \leq 0.1$) changed in CT1812-treated patients across plasma and CSF at 6 mo. Pathways affected by CT1812 in SPARC were similarly enriched in SHINE-A plasma proteomic analyses, further supporting CT1812 mechanism of action.
Conclusions: SPARC plasma biomarker findings shed light on potential biological pathways affected by CT1812. Comparative analyses identify candidate biomarkers that replicate across independent clinical trial cohorts and/or biofluids.

APOE4/4 HOMOZYGOUS ALZHEIMER'S PATIENTS WITH COMORBID CEREBRAL AMYLOID ANGIOPATHY: BASELINE ANALYSES FROM PHASE 3 TRIAL OF ORAL ANTI-AMYLOID AGENT ALZ-801/VALILTRAMIPROSATE

POSTERS: A03.B. DRUG DEVELOPMENT, CLINICAL TRIALS: AMYLOID CLEARANCE

Aidan Power[1], Earvin Liang[1], Rosalind Mclaine[1], Susan Abushakra[1], David Watson[2], Merce Boada Rovira[3], Jon Snaedal[4], Anton Porsteinsson[5], Marwan Sabbagh[6], Susan Flint[1], Winnie Pak[1], John Hey[1], Martin Tolar[7]
[1]Alzheon, Medical, Framingham, United States of America, [2]Alzheimer's Research and Treatment Center, Alzheimer's Research And Treatment Center, Wellington, United States of America, [3]Ace Alzheimer Center Barcelona, Research Center And Memory Clinic, Barcelona, Spain, [4]National University Hospital, Department Of Geriatrics, Reykjavik, Iceland, [5]University of Rochester, Department Of Psychiatry, Rochester, United States of America, [6]St. Joseph's Hospital and Medical Center, Barrow Neurological Institute, Phoenix, United States of America, [7]Alzheon, Ceo, Framingham, United States of America

Aims: APOE4 is a major risk factor for Alzheimer's disease (AD) and cerebral amyloid angiopathy (CAA) with gene-dose effect. APOE4 carriers with CAA have higher risk of amyloid-related imaging abnormalities (ARIA) with anti-amyloid antibodies, including ARIA-E/edema, microhemorrhages (MH), lobar macrohemorrhages, and cortical superficial siderosis. APOE4 carriers have higher risk of hyperlipidemia and cardiovascular disease (CVD). Prevalence of CVD risk factors was analyzed in the Phase 3 trial of ALZ-801/valiltramiprosate, an oral inhibitor of amyloid oligomer formation.
Methods: APOLLOE4 Phase 3 trial (NCT04770220) enrolled 325 APOE4/4 Early AD subjects (MMSE ≥22, 50-80 years); 313 had baseline MRIs, centrally read. Subjects with MH and siderosis were allowed; ARIA-E was exclusionary. Subjects with CAA (>4 MH, any siderosis, any macrohemorrhage) were compared to rest of population.
Results: Study population: 51% female, age 69 years, MMSE 26, 65% MCI, 82% Caucasians. CAA group included 47/313 subjects (15%), mostly male (70% vs 45%), older (71 vs. 68 years, p=0.004), more advanced (MMSE 25 vs 26, p=0.018; ADAS-cog 27 vs. 23, p=0.002) with more severe deep white matter disease (p=0.015). Both groups had similar prevalence of hypertension, diabetes, obesity, hyperlipidemia, and statin use. CAA group had higher prevalence of coronary artery disease (CAD; 17% vs. 8%, p=0.049) and anti-platelets use (38% vs 22%, p= 0.026). Anticoagulants were not allowed.
Conclusions: ALZ-801 showed no ARIA-E in prior studies, providing potential safer alternative to anti-amyloid antibodies. Th pivotal APOLLOE4 trial evaluating ALZ-801 enrolled homozygous APOE4/4 AD subjects with higher CAA burden than anti-amyloid antibody trials. APOE4/4 CAA subjects were older with more advanced AD and higher rates of CAD and antiplatelets use than non-CAA subjects, which may increase brain edema and microhemorrhage risk, requiring heightened vigilance with anti-amyloid antibody infusions.

IDENTIFICATION OF NEW PHARMACODYNAMIC BIOMARKERS OF CT1812 THAT CORRELATE WITH FAVORABLE FUNCTIONAL CONNECTIVITY OF THE BRAIN

POSTERS: A03.B. DRUG DEVELOPMENT, CLINICAL TRIALS: AMYLOID CLEARANCE

Valentina Di Caro[1], Kiran Pandey[2], Eunah Cho[1], Duc Duong[3], Willem De Haan[4], Michael Grundman[5], Nicholas Seyfried[3], Anthony Caggiano[6], Everard Vijverberg[7], Mary Hamby[1]
[1]Cognition Therapeutics, Inc., Research, Pittsburgh, United States of America, [2]Emtherapro, Inc., R&d, Atlanta, United States of America, [3]Emory University School of Medicine, Department Of Biochemistry, Atlanta, United States of America, [4]Alzheimer Center, Department Of Neurology, amsterdam, Netherlands, [5]Global R&D Partner, -, San Diego, United States of America, [6]Cognition Therapeutics, Inc., R&d, Purchase, United States of America, [7]Vrije Universiteit Amsterdam, Amsterdam UMC location VUmc, Alzheimer Center Amsterdam, Neurology, Amsterdam, Netherlands

Aims: Synaptic function and brain functional connectivity is impaired in Alzheimer's disease (AD). Recently, in the SEQUEL phase 2 clinical trial (NCT04735536) in AD patients, we have shown that our drug candidate, CT1812, can favorably impact the functional connectivity as measured by the quantitative EEG measure corrected Amplitude Envelope (AECc p=0.034). To identify synaptic markers of CT1812 associated with this favorable change, we performed Pearson correlation analyses between multiple EEG parameters and the CSF proteome from SEQUEL.
Methods: Participants (n=16) receive four-weeks of either CT1812 (300 mg, PO, qD) or placebo following a two-week washout, then switched treatment for another four-week period. Tandem-mass tag mass spectrometry proteomics was performed on CSF at baseline, after both treatment periods. Pearson correlation analyses were performed across EEG parameters including AECc and each protein (2,612) in the CSF proteome ($p<0.05$) from CT1812 treated patients only. Comparative analyses were performed across EEG parameters followed by pathway analysis using STRING ($p<0.05$).
Results: Sets of proteins were identified to be significantly correlated, using Pearson correlation analyses, with global alpha AECc power ($p\leq 0.05$). Amongst the most correlated biomarkers identified were SLC4A1 (r=0.86), ALDH1A1 (0.79), PIK3IP1 (r=-0.83) and MALRD1 (r=-0.77). Pathway analysis of proteins commonly associated across multiple alpha AECc parameters indicated an impact on proteasomal (PSMA, PSMB), extracellular exosomal (WNT4, ALDL1A1) and vesicular (PRDX2) biologies.
Conclusions: In summary, here we identify potential molecular correlates to parameters of brain activity as assessed via EEG. Whether these molecular correlates could be surrogate biomarkers of brain connectivity warrants further study. These findings are consistent with the mechanism of action of CT1812 in impacting synaptic function, and may support the clinical development of therapeutics that impact functional connectivity or synaptic activity.

VPS35-BASED THERAPEUTIC TARGET EFFICACY IN SUBTYPES OF ALZHEIMER'S DISEASE DEMENTIA BASED ON NEUROPATHOLOGICAL PROFILES

POSTERS: A03.B. DRUG DEVELOPMENT, CLINICAL TRIALS: AMYLOID CLEARANCE

Shadi Ghourchian[1], Oluwaseun Ogunbona[2], Jaclyn Lilek[3], Callen Spencer[4], Kaouther Ajroud[4], Margaret Flanagan[5]
[1]Downstate University at OBH, Department Of Neurology, Brooklyn, United States of America, [2]Bigg's institute, Pathology, Texas, United States of America, [3]Mesulam Center, Northwestern University, Chicago, United States of America, [4]Northwestern University, Mesulam Center, Chicago, United States of America, [5]University of Texas Health San Antonio, Pathology And Bigg's Institute, San Antonio, United States of America

Aims: Previously, we showed the potential protective effect of vacuolar protein sorting ortholog 35 (VPS35) on cognitive function in Alzheimer's Disease (AD), for the first time in the human brain. Recent studies have introduced a VPS35-based therapeutic approach for neurodegenerative diseases. This study aims to identify the most responsive patient group for this new VPS35-targeted therapy based on analyzing proteins via digital spatial profiling (DSP).
Methods: We employed NanoString GeoMx™ Digital Spatial Profiling to analyze protein levels in NeuN "masked" neurons within the hippocampus of individuals with mixed pathologies (Amyloid Beta (Ab) plaques, Tau tangles, TDP43 proteinopathy). We compared neuronal VPS35 levels in hippocampal areas across autopsy brain samples with various combinations of Tau tangles, Ab plaques, and TDP43 proteinopathy. Correlation tests were used to assess how VPS35 might vary regionally and across individuals with different combinations of Ab plaques, Tau tangles and TDP-43 proteinopathy. AD-associated proteins (Ab1-42, pTau231, pTDP43) were also compared across groups.
Results: Findings revealed that the dentate region had the most variation in neuronal VPS35 compared to CA1 and entorhinal cortex. Neuronal VPS35 changes appeared to be most significant, in addition to Ab1-42, and Amyloid precursor protein in the Tau+/TDP43+ cases lacking co-existing Ab plaques in the dentate region, specifically.
Conclusions: Our results highlight the utility of a personalized medicine approach when treating dementia. Individuals may be assessed using Tau and amyloid PET combined with a TDP43 biomarker in CSF to identify which patients will benefit the most from a VPS35-based approach. Individual patient benefit to VPS35 targeted therapies may be attributed to VPS35's overexpression, aiding in the clearance of Ab. Enhancing VPS35 expression levels or improving VPS35 function may offer therapeutic benefits for specific patient groups

SYSTEMIC AND CENTRAL NERVOUS SYSTEM BIOLOGICAL PATHWAY ALTERATIONS ASSOCIATED WITH GINKGO BILOBA TREATMENT IN NON-DEMENTED SUBJECTS

POSTERS: A03.E. DRUG DEVELOPMENT, CLINICAL TRIALS: NEUROPROTECTIVE & MITOCHONDRIAL COMPOUNDS

Julius Popp[1,2], Christopher Clark[1]
[1]University of Zurich, Department For Psychiatry, Psychotherapy And Psychosomatics, Zurich, Switzerland, [2]Lausanne University Hospital, Old Age Psychiatry, Department Of Psychiatry, Lausanne, Switzerland

Aims: Ginkgo biloba extract showed neuroprotective effects in animal studies but little is known about how it affects cognition in humans. Here, we sought to identify the biological pathways affected by Ginkgo treatment in non-demented older subjects.
Methods: Twenty-six non-demented subjects undergoing a treatment by Ginkgo extract for 3 months or longer and 35 subjects without treatment matched for age and BMI were selected from a well-characterised cohort of participants from an Alzheimer's disease biomarker study. Clinical and neuropsychological data, the APOEε4 genotype and albumin ratio were available in both groups. Targeted and untargeted omics approaches were used to quantify analytes covering over 8 biological modalities in paired cerebrospinal fluid (CSF) and peripheral blood samples. Group comparisons and multivariate ROC analysis using MetaboAnalyst 5.0 were used to identify features differing between groups. Pathway enrichment analysis was performed using hypergeometric distribution tests in the Reactome database.
Results: Group comparisons identified 22 molecules in CSF and 29 in peripheral blood with different concentration levels. The identified neuroinflammatory markers, proteins, minerals and lipids were related to changes in insulin signalling and hemostasis in blood and to intracellular signaling in the CSF. Multivariate analysis of untargeted metabolomics data in peripheral blood further identified 463 differentially expressed features between groups, mainly related to amino acid and energy metabolism.
Conclusions: We have identified biological alterations in blood and in CSF at neuroinflammatory, proteomic, lipidomic, and metabolite levels associated with Ginkgo treatment. Some of the identified analytes have previously been shown to be associated with dementia and cognitive decline. In further steps, we will relate these alterations to clinical evolution, considering both cognitive and non-cognitive symptoms.

ANALYSIS OF CSF SAMPLES FROM A PHASE 2 CLINICAL TRIAL IN ALZHEIMER'S PATIENTS SHOW THAT CT1812 CAN MODULATE A-SYNUCLEIN

POSTERS: A03.B. DRUG DEVELOPMENT, CLINICAL TRIALS: AMYLOID CLEARANCE

Valentina Di Caro[1], Kiran Pandey[2], Duc Duong[2,3], Nicholas Seyfried[3], Michael Grundman[4], Everard Vijverberg[5], Anthony Caggiano[1], Charlotte Teunissen[6], Mary Hamby[1]
[1]Cognition Therapeutics, Inc., Research, Pittsburgh, United States of America, [2]Emtherapro, Inc., R&d, Atlanta, United States of America, [3]Emory University School of Medicine, Department Of Biochemistry, Atlanta, United States of America, [4]Global R&D Partner, -, San Diego, United States of America, [5]Vrije Universiteit Amsterdam, Amsterdam UMC location VUmc, Alzheimer Center Amsterdam, Neurology, Amsterdam, Netherlands, [6]Amsterdam UMC, Neurochemistry Lab, Amsterdam, Netherlands

Aims: Objectives: The presynaptic protein α-synuclein (αSyn), mainly associated with synucleinopathies like dementia with Lewy bodies (DLB), is also involved in the pathophysiology of AD. To understand if our clinical leading candidate, CT1812, can modulate αSyn, we assessed the αSyn level in CSF samples from a phase 2, cross-over, clinical trial in patients with mild/moderate AD (NCT04735536) and performed Pearson correlation analysis between αSyn concentrations and the CSF proteome.
Methods: Methods: Participants (n=16) received four-weeks of either CT1812 (300 mg, orally, daily) or placebo following a two-week washout, then switched treatment for another four-week period. αSyn in CSF was measured by ELISA. TMT-mass spectrometry proteomics was performed on CSF at baseline and after both treatment periods. Pearson correlation analysis was performed between αSyn levels and CSF proteomes ($p \leq 0.05$) from CT1812 treated patients only. Pathway analysis was performed using STRING ($p \leq 0.05$).
Results: Results: After period 1, a statistically significant change from baseline was seen for αSyn (mean -82.32 ng/L p=0.02) in CSF samples of CT1812 treated patients. Sets of proteins were identified to be significantly correlated using Pearson correlation analyses with αSyn levels ($p \leq 0.05$). Highly correlated protein included HSPA8 (r=0.99), PLXDC1 (r=0.99), LINGO1(r=0.99) and SERPINA5 (r=-0.99), Pathways analysis of the correlated protein ($p \leq 0.05$; $r = |0.5|$) showed to be associated to the GO terms complement, lysosomes, and dopamine metabolic processes.
Conclusions: Conclusions: A decrease in CSF αSyn levels was observed after 4-weeks of treatment with CT1812. Proteins correlated with the change from baseline of αSyn level were associated with inflammation, dopaminergic, and lysosome pathways. These findings support our mechanism of action hypothesis for CT1812 and we plan to validate findings the upcoming readout of the Phase 2 CT1812 clinical trial in DLB (NCT05225415).

FROM CLINIC TO CELL: COBALAMIN'S MULTI-FACETED APPROACH TO UNDERSTANDING DEFENSE AGAINST AMYLOID BETA OLIGOMER NEUROTOXICITY

POSTERS: A03.E. DRUG DEVELOPMENT, CLINICAL TRIALS: NEUROPROTECTIVE & MITOCHONDRIAL COMPOUNDS

Atsushi Kimura[1], Mayumi Tsuji[2], Hitoshi Shimada[1,3], Hidetomo Murakami[4], Kenjiro Ono[5]
[1]Niigata University, Brain Research Institute, Niigata, Japan, [2]Showa University, Pharmacology Research Center, Tokyo, Japan, [3]National Institutes for Quantum Science and Technology, Department Of Functional Brain Imaging, Chiba-shi, Japan, [4]Showa University, Department Of Internal Medicine, Division Of Neurology, Tokyo, Japan, [5]Kanazawa University, Department Of Neurology, Kanazawa, Japan

Aims: Amyloid beta oligomers (Aβo) play a major role in Alzheimer's disease (AD). Recently, we have observed that cobalamin (vitamin B12) may be effective in alleviating cognitive dysfunction in AD. However, the mechanism is still unclear. We investigated the relationship between cobalamin and cognitive function, regional cerebral blood flow, and structural MRI in AD patients. Furthermore, we evaluated the mechanism of cobalamin's protective effect against Aβo neurotoxicity from both basic and clinical perspectives.
Methods: MMSE, SPECT, high-resolution MRI, and serum cobalamin levels were measured in 151 patients aged 51 to 93 who visited our memory clinic from 2016 to 2020. Cortical structures were analyzed by measuring the gyrification index, which represents cortical complexity, using surface-based morphometry. The protective effect of cobalamin against neuronal cell injury induced by 5 μM Aβo was evaluated using human neuroblastoma cells (SH-SY5Y cells).
Results: We discovered an association between cobalamin levels and hippocampal cerebral blood flow and a correlation between cobalamin levels and the cortical gyrification index in memory-related areas. In cellular experiments, Aβo increased the production of reactive oxygen species (ROS) and decreased cell viability. In mitochondria, it elevated mitochondrial ROS species, reduced MnSOD levels and mitochondrial permeability transitions, and increased ATP production. Cobalamin mitigated these oxidative stresses and significantly inhibited cellular injury caused by Aβo.
Conclusions: Cobalamin suppressed Aβo-induced cell injury through its robust antioxidant effect, suggesting that cobalamin may help protect brain microstructures in AD.

SINGLE ASCENDING DOSE STUDY OF THE NOVEL DONEPEZIL LONG-ACTING INJECTION VERSUS ARICEPT® TABLETS IN HEALTHY ADULT PARTICIPANTS

POSTERS: A03.F. DRUG DEVELOPMENT, CLINICAL TRIALS: NEUROTRANSMITTER-BASED MODULATORS

Heesun Kim[1], Sangno Lee[2], Mase Lee[3], Juhee Kim[4]
[1]Inventagelab, Clinical Development, Seongnamsi, Korea, Republic of, [2]Inventagelab, Ifc Research Center, Seongnamsi, Korea, Republic of, [3]Inventagelab, Ivc Development Division, Seongnamsi, Korea, Republic of, [4]Inventagelab, Ceo, Seongnamsi, Korea, Republic of

Aims: IVL3003 (donepezil-loaded microspheres) is a long-acting injectable(LAI) form for the treatment of dementia of alzheimer's type. The use of a LAI formulation offers potential benefits, including sustained drug levels in the blood, fewer adverse effects, and improved patient compliance. The purpose of this study was to evaluate the safety profiles and characterize the pharmacokinetic(pk) and pharmacodynamic profiles of IVL3003 and Aricept® 10mg tablets in healthy adult participants.
Methods: Approximately 52, healthy adult males between ≥18 and ≤55 years of age were planned to be included in this study across 4 cohorts. Tolerability of the injections were assessed throughout the study. The plasma concentrations of donepezil, 6-O-desmethyl donepezil and AChE levels will be determined using a validated analytical method.
Results: Overall, the safety profiles of single SC IVL3003 dose and multiple doses of Aricept (donepezil) 10mg tablets in healthy adult subjects was generally safe and well tolerated. A major difference in the observed PK over 672hours following SC IVL3001 was the more consistent donepezil plasma concentrations without initial burst and the absence of sharp fluctuations in peak and trough levels which are typical of daily oral dosing. The exposure to IVL3003 (AUC and Cmax) following single SC ascending doses, increased in a dose proportional manner. The PD effects of IVL3003 were consistent with the expected mechanism of action.
Conclusions: The safety and pharmacokinetic/pharmacodynamic properties of IVL3003 confirmed through this trial showed that it achieved a fast effective concentration and maintained a stable effective concentration, unlike the conventional oral drug administered daily. IVL3003 was confirmed to be developed as a therapeutic agent for Alzheimer's disease (AD).

Aims: With age, people with Down syndrome (DS) develop dementia due to Alzheimer's disease (AD). Both pathologies share a high production of ß-amyloid peptides from the APP gene located on human chromosome 21 and several studies suggest that a common pathogenic mechanism exists between AD and DS, involving alterations in neurotransmitter systems (the cholinergic, GABA-ergic, serotonergic, glutamatergic and adrenergic). Therefore, some common therapeutic targets have been identified. Faced with the multifactorial origin of these diseases, a pleiotropic intervention is now widely recommended. This project aims at designing new multi-target directed ligands (MTDL) for intranasal administration, acting as prodrugs, with potential therapeutic interest in DS and AD. The prodrugs are activated by the covalent inhibition of butyrylcholinesterase (BuChE), capable of counteracting cholinergic neurodegeneration in AD. The released drugs will then target the 5-HT_4 serotonin receptors to display a potential disease-modifying effect. Liposomal formulation and intranasal administration will enhance central nervous system distribution of prodrugs for selective activation by brain BuChE, to enhance central effects of released drugs and potentially avoid their peripheral side effects.
Methods: First, the synthetized prodrugs and their associate active metabolites have been tested and selected on their capacity to inhibit or activate their target. Then, the canditate's ability to counteract amyloid toxicity is evaluated *in vitro*, on stressed primary neuronal culture of rat hippocampal neurons, and finally *in vivo* in 5xFAD transgenic mice model.
Results: After caracterization of the pharmacological profile of the synthetized drugs, the screening of the drugs allowed to select candidates that protect neurons from amyloid toxicity *in vitro*, and that will be tested *in vivo* in 5xFAD transgenic mice model.
Conclusions: At the end, this project should provide a multi-fonction drug with therapeutic interest in Alzheimers disease.

PHASE 1 CLINICAL STUDY OF LEUCETTINIB-21, A DYRK1A KINASE INHIBITOR DRUG AIMING AT THE CORRECTION OF COGNITIVE DISORDERS

POSTERS: A03.H. DRUG DEVELOPMENT, CLINICAL TRIALS: MEDICINAL CHEMISTRY APPROACHES, DRUG REPURPOSING

Laurent Meijer, Emilie Chretien, Emmanuel Deau, Gaëlle Hogrel, Mattias Lindberg
Perha Pharmaceuticals, Neurosciences, Roscoff, France

Aims: Cognitive disorders (memory, learning) observed in patients with **Down syndrome** (**DS**) and **Alzheimer's disease** (**AD**) are associated with an excess activity of **DYRK1A** (dual specificity, tyrosine phosphorylation regulated kinase). Genetic and pharmacological inhibition of DYRK1A corrects these cognitive disorders in DS/AD animal models, encouraging the development of a clinical DYRK1A inhibitor to treat memory/learning difficulties in patients with AD or DS.
Methods: Inspired by **Leucettamine B**, a marine sponge natural product, we synthesized, optimized and extensively characterized >500 analogues, **Leucettines**, followed by a second-generation family, **Leucettinibs** (>670 analogues) and selected an orally available drug candidate, **Leucettinib-21**.
Results: Regulatory preclinical toxicity/tolerance studies, carried out with rats (NOAEL: 20 mg/kg) and mini-pigs (NOAEL: 100 mg/kg), showed that Leucettinib-21 is well tolerated in these animals at doses much higher than active doses (correcting memory disorders) on animal models of DS and AD (0.3-0.5 mg/kg). **Immediate-release tablets** of Leucettinib-21 and placebo have been prepared. A double-blind, placebo-controlled clinical phase 1 study ('Leucetta') involving 120 participants, will be launched in Q4-2023, to investigate safety and pharmacokinetics of Leucettinib-21. Blood samples collected from all participants will be used to analyze plasma proteomic and phosphoproteomic profiles as well as AD-specific biomarkers. The Leucetta trial comprises Single Ascending Dose, Food Effect and Multiple Ascending Dose studies in 96 healthy volunteers. Furthermore, 12 adults with DS and 12 AD patients will receive a single Leucettinib-21 dose for pharmacokinetics and biomarkers analysis.
Conclusions: The first results of this phase 1 clinical study will be presented. The study should be completed by Q4-2024, hopefully opening the door to phase 2a studies to evaluate the ability of Leucettinib-21 to correct cognitive disorders in children with DS and patients with early AD.

THE BRAIN PERMEABLE IMMUNOPROTEASOME-SPECIFIC INHIBITOR AR-55 IS A PROMISING DRUG CANDIDATE FOR ALZHEIMER'S DISEASE

POSTERS: A03.H. DRUG DEVELOPMENT, CLINICAL TRIALS: MEDICINAL CHEMISTRY APPROACHES, DRUG REPURPOSING

Ji Eun Park[1], Chhabi Chaudhary[2], Deepak Bhattarai[2], Kyung Bo Kim[1]
[1]Florida International University, Center For Translational Research, Port St. Lucie, United States of America, [2]University of Kentucky, College Of Pharmacy, Lexington, United States of America

Aims: We previously reported that inhibition of the immunoproteasome (iP), which has been shown to be upregulated in reactive glia surrounding amyloid-β (Aβ) plaques in the brain of patients with Alzheimer's disease (AD), improves cognitive function in AD amyloidosis mouse model via suppressing microglia-mediated inflammation in an Aβ independent manner.
Methods: We assessed the pharmaceutical properties of our lead iP inhibitors developed based on macrocyclic peptide epoxyketone backbone, investigating the stability and blood-brain barrier (BBB) permeability using human liver microsomes and Caco-2 monolayers mimicking BBB, respectively. Among the compounds investigated, AR-55 has been identified as the most promising AD drug candidate and thus further evaluated for its pharmacokinetic properties and biodistribution in healthy mice.
Results: The macrocyclic AR-55 displayed significantly improved metabolic stability (29-fold increased half-life), permeability (4-fold lower efflux ratio), and solubility, compared to carfilzomib (Kyprolis®), the FDA-approved linear peptide epoxyketone proteasome inhibitor. Furthermore, AR-55 effectively inhibited the activity of the mouse brain iP with no apparent signs of toxicity up to 100 mg/kg i.v. for 72 hr, indicating its ability to cross the BBB.
Conclusions: The results suggest that AR-55 may hold great potential as an AD drug that needs further investigation in clinical settings.

COMPUTATIONAL SCREENING OF COUMARIN DERIVATIVES AS INHIBITORS OF THE NACHT DOMAIN OF NLRP3 INFLAMMASOME FOR THE TREATMENT OF ALZHEIMER'S DISEASE

POSTERS: A03.H. DRUG DEVELOPMENT, CLINICAL TRIALS: MEDICINAL CHEMISTRY APPROACHES, DRUG REPURPOSING

Sushil Kumar Singh, Powsali Ghosh, Ravi Singh, Chayanika Chatterjee, Ashok Kumar
Indian Institute of Technology (BHU), Department Of Pharmaceutical Engineering & Technology, Varanasi, India

Aims: Our study aimed to find coumarin derivatives that can inhibit NLRP3 inflammasomes to combat neuroinflammation in Alzheimer's Disease (AD).
Methods: A library of coumarin derivatives was constructed from four different databases. OpenBabel was used to remove duplicates based on InChI code, and Knime was used to eliminate compounds violating the 'Lipinski Rule of Five' and 'REOS rule', having TPSA above 70 Å and PAINS fragments. HTVS and molecular docking studies were performed to obtain compounds exhibiting better binding affinity than standard ligand MCC950. *In silico* ADMET studies were performed using SwissADME, eMolTox, and PreADMET webservers to retain only the molecules showing acceptable physicochemical properties. The best three virtual hits were subjected to molecular dynamics (MD) simulations in the MD simulation software Desmond in an environment replicating the human cell conditions to analyze the stability of protein-ligand complexes. The results were analyzed using the 'simulation event analysis' panel and interpreted to find the best virtual lead compound.
Results: The initial dataset comprising 9762 compounds was cleaned and 203 duplicates were removed. Among 9559 unique compounds, 688 were found to have drug-like properties. HTVS study revealed 175 molecules to have better protein binding than the co-crystal ligand. In the three-stage molecular docking studies, 36 compounds displayed better binding affinity than MCC950. Three of these compounds are predicted to be bioavailable, BBB-permeable, and non-toxic. MD simulation results showed that MolPort-050-872-358 formed the most stable protein-ligand complex.
Conclusions: Among a diverse set of compounds containing the coumarin nucleus, which has proven anti-inflammatory properties, MolPort-050-872-358 was found to be a promising NLRP3 inhibitor. Utilizing the coumarin scaffold to develop novel therapeutic treatments for AD can block neuroinflammation by inhibiting the NLRP3 inflammasome.

COMBINATION OF CIPROFLOXACIN/CELECOXIB AS A NOVEL THERAPEUTIC APPROACH FOR ALZHEIMER'S DISEASE

POSTERS: A03.I. DRUG DEVELOPMENT, CLINICAL TRIALS: PERSONALIZED MEDICINES, SEX /RACE, AI, AND COMBINATION THERAPY

Shiran Salomon-Zimri[1], Rachel Ben-Hayun[2], Nitai Kerem[1], Niva Russek-Blum[1], Diana Shtossel[1], Vered Sasson[1], Eidan Lushi[1], Rafi Hadad[2], Natalia Yarovinsky[2], Judith Aharon Peretz[2], Ferenc Tracik[1], David Tanne[2]
[1]NeuroSense Therapeutics, Research And Development, Herzliya, Israel, [2]Rambam Health Care Campus, Stroke And Cognition Institute, Haifa, Israel

Aims: AD's pathophysiology is complex and underlies multiple pathways including neuroinflammation, impaired recycling, and autophagy. Due to its complexity and diverse manifestation, combined multi-targeted therapy is needed. PrimeC is a combination of ciprofloxacin, a miRNA regulator, and celecoxib, a COX-2 inhibitor reducing inflammation, oxidative stress, and amyloid aggregation. PrimeC showed beneficial synergistic effects in ALS, where it altered key pathologies such as neuroinflammation, autophagy, and TDP-43 levels. NeuroSense's AD studies showed alterations in indicative biomarkers related to PrimeC's MoA (TDP-43 $p<0.05$; LC3 $p<0.01$). The combined treatment affected Aβ-induced inflammatory response of microglia, survival, and morphology of neurons. We aim to assess the safety and tolerability of PrimeC in AD patients. Clinical outcomes, AD hallmarks and target engagement markers from plasma and CSF will be examined. Furthermore, a PoC *in-vitro* study will be conducted in an AD cell line to elucidate PrimeC's MoA.
Methods: 20 mild to moderate non-familial AD patients will be recruited at Rambam Health Care Campus, Israel, for a Phase 2 randomized, prospective double-blind, placebo-controlled study. Participants will be administered with PrimeC BID for 12 months. Plasma and CSF will be measured for a cassette of biomarkers, and clinical outcomes (e.g., ADCS-iADL, MMSE, etc.) will be monitored. The *in-vitro* study will observe PrimeC and each of its comprising compounds' effect on neurite outgrowth of an AD transgenic SH-SY5Y cell line.
Results: from the clinical study could illuminate the safety, tolerability, and efficacy of PrimeC on AD patients, complemented by the *in-vitro* results advancing our understanding of PrimeC's MoA.
Conclusions: This work could potentially shed light on a new therapeutic approach to halt AD progression using a combined therapeutic strategy targeting multiple pathways. It may also identify new biomarkers for target engagement.

MEDICATIONS FOR ALZHEIMER'S DISEASE: ANALYSIS OF THE COGNITIVE CHANGES AFTER TWO YEARS OF THERAPY IN ALZHEIMER'S DISEASE PATIENTS FROM THE NATIONAL ALZHEIMER'S COORDINATING CENTER.

POSTERS: A03.I. DRUG DEVELOPMENT, CLINICAL TRIALS: PERSONALIZED MEDICINES, SEX /RACE, AI, AND COMBINATION THERAPY

Krisztina Marosi[1], Liana Apostolova[2,3,4], Sophie Sokolow[1,5]
[1]UCLA, School Of Nursing, Los Angeles, United States of America, [2]Indiana University School of Medicine, Radiology And Imaging Sciences, Indianapolis, United States of America, [3]Indiana University School of Medicine, Department Of Medical And Molecular Genetics, Indianapolis, United States of America, [4]Indiana University School of Medicine, Department Of Neurology, Indianapolis, United States of America, [5]UCLA, Brain Research Institute, Los Angeles, United States of America

Aims: The goal of the study was to analyze the changes in cognitive function after 2-year use of Alzheimer's Disease (AD) medication in AD patients using the National Alzheimer's Coordinating Center (NACC) Uniform Data Set (UDS).
Methods: AcetylCholinesterase Inhibitors [AChEIs] and memantine use, AD diagnosis, MMSE and CDR-scores were retrieved from the NACC UDS. Linear regression models were used to compare the treatment effect on cognitive changes after 2-year pharmacotherapy in AD patients.
Results: AD subjects treated with AChEIs or memantine showed a greater decline in MMSE and a greater rise in CDR-SB scores after 2 years compared to non-treated ones. There was no significant difference in MMSE at baseline between AChEIs and untreated groups. However, a significant difference in MMSE at baseline was observed between memantine-treated patients compared to the untreated ones. A significant difference in CDR-SB scores at baseline was observed between those on AD medication compared to untreated controls.
Conclusions: These findings indicate that AD patients who were prescribed memantine were more severely affected cognitively when their pharmacotherapy was initiated. This is in accordance with the FDA-approval of memantine for moderate to severe AD. Our data also show that AD patients on any AD medications were more severely affected by the disease compared to their untreated counterpart, as the progression of their cognitive decline was faster despite 2-years of pharmacotherapy. This observation extends our previous study in MCI subjects from the AD Neuroimaging Initiative showing that physicians prescribe AChEIs to those who present with more severe clinical impairment. Furthermore, these findings underscore the importance of personalized medicine approaches in the treatment of AD, as individual patient characteristics and disease severity play a significant role in the choice and timing of therapeutic interventions.

SCOP: A COMPUTATIONAL TOOL TO PREDICT INTERCELLULAR CROSSTALK OF ALZHEIMER'S DISEASE USING SINGLE-NUCLEUS RNA SEQUENCING DATA

POSTERS: A03.I. DRUG DEVELOPMENT, CLINICAL TRIALS: PERSONALIZED MEDICINES, SEX /RACE, AI, AND COMBINATION THERAPY

Li Yang, Jianting Sheng, Shaohua Qi, Yuliang Cao, Amna Irfan, Stephen Wong
Houston Methodist research institute, T. T. & W. F. Chao Center For Brain, Houston, United States of America

Aims: The epidemiological studies of Alzheimer's disease (AD) have been benefited from single-nucleus RNA sequencing (snRNA-seq) to delineate cell-type-specific communications. However, deciphering the intricated intracellular crosstalk between the different executive functional cells identified in the brain remains challenging. The main objective of this study is to develop a computational tool to fill the gap.
Methods: Database Curation: The study curates a cell-cell communication database by collecting data on ligand and receptor pairs from the KEGG database, supplemented with subsequent signaling and gene interaction information from KEGG, Reactome, and Ingenuity Pathway Analysis (IPA). Development of SCOP: SCOP (**S**ingle-cell **C**r**O**sstalk **P**redictor) is developed as a computational tool that utilizes the curated database and snRNA-seq data input to predict intercellular crosstalk and intracellular pathways in AD. Machine Learning Models: SCOP employs machine learning to predict the impact of individual genes on downstream pathways.
Results: SCOP takes various inputs, including gene expression data, protein-protein interaction networks, and ligand-receptor interactions, to provide a comprehensive view of intercellular crosstalk in the AD brain and rank potential crosstalk targets for AD treatment as outputs. SCOP is applied to human AD brain snRNA-seq datasets, leading to the identification of the top 18 pairs of crucial ligand-receptor interactions, and 11 pathways involved in AD pathology different cell types, including microglia, astrocytes, and inhibitory/excitatory neuron cells. Eight top-ranking interactions within astrocyte-neuron crosstalk are selected as case studies for validation. *In vitro* and *in vivo* validation experiments confirm the selected gene expression levels and immunocytochemical signals with the systemic analysis conducted by SCOP.
Conclusions: SCOP acts as a valuable tool for comprehensively analyzing and understanding the heterogeneous cell-cell communication in the AD brain, benefiting early marker detection and novel therapeutic strategies development.

DESIGN OF A STATE-OF-THE-ART PHASE 2B TRIAL TO EVALUATE THE EFFICACY OF A SPECIFIC INHIBITOR OF 11B-HSD1, XANAMEM®, IN MILD AND MODERATE ALZHEIMER'S DISEASE

POSTERS: A03.J. DRUG DEVELOPMENT, CLINICAL TRIALS:NEW CLINICAL TRIAL DESIGNS; SIMULATION OF PROGRESS-DIGITAL TWINS

Jack Taylor[1], Dana Hilt[1], Tamara Miller[1], John Harrison[2,3,4], Chistopher Chen[5], Craig Ritchie[2]
[1]Actinogen Medical, Clinical Science, SYDNEY, Australia, [2]Scottish Brain Sciences, Neuropyschology, Edinburgh, United Kingdom, [3]Institute of Psychiatry, Psychology & Neuroscience, King's College London, Department Of Psychological Medicine, London, United Kingdom, [4]Amsterdam UMC, Alzheimer's Center, Amsterdam, Netherlands, [5]Yong Loo Lin School of Medicine, National University of Singapore, Department Of Pharmacology, Singapore, Singapore

Aims: Xanamem®, a brain-penetrant inhibitor of 11β-HSD1, which converts intracellular cortisone to cortisol, has been evaluated in 3 independent placebo-controlled trials. These trials suggest Xanamem may be both a procognitive drug and disease-course modifying agent. The XanaMIA Phase 2b trial aims to evaluate the cognitive and clinical benefits of Xanamem.
Methods: XanaMIA is a phase 2b, double blind, randomized, placebo-controlled, 36-week trial to assess the safety, tolerability, and efficacy of Xanamem 10 mg daily in patients with mild or moderate dementia due to AD. This multi-centre trial will randomise (1:1) 220 participants over 50 years old meeting the diagnostic criteria for AD with a CDR global score of 0.5-1, a MMSE of 18-26, and elevated plasma p-tau181. Participants will also be required to have a 0.5 SD cognitive deficit compared to normative data as measured by a symbol coding test. The study design includes a 6-week pre-screening period (to assess AD plasma biomarker positivity), 4-week screening period, a 36-week treatment period, and a 4-week follow-up period. The primary efficacy endpoint is change from baseline to week 36 on a computerized, global cognitive composite including measures of attention, working memory, executive function, and episodic memory. The key secondary outcome, the CDR-SB, will assess integrated cognition and function. Other measures of cognition, function, and behavior will also be examined.
Results: The results of the XanaMIA Phase 2B trial are expected in 2025.
Conclusions: The XanaMIA Phase 2B trial is a robustly designed trial using a contemporary rationale to select validated and treatment-sensitive endpoints, and patient enrichment strategies to demonstrate the procognitive and disease-course modifying benefits of Xanamem.

A PHASE 3 CLINICAL PROTOCOL TO STUDY THE SAFETY AND EFFICACY OF NA-831 IN COMBINATION WITH LECANEMAB IN SUBJECTS WITH EARLY ALZHEIMER'S DISEASE

POSTERS: A03.J. DRUG DEVELOPMENT, CLINICAL TRIALS:NEW CLINICAL TRIAL DESIGNS; SIMULATION OF PROGRESS-DIGITAL TWINS

Lloyd Tran, Fern Vu, Markku Kurkinen
Biomed Industries, Inc., Neurosciences, San Jose, United States of America

Aims: The aim of the multi-centers, double blind, placebo controlled parallel Phase 3 trials is to evaluate the efficacy and safety of combination therapy of NA- 831 with Lecanemab for patients with Early Alzheimer's Disease.
Methods: Enrolment: 600 participants. Ages: 50 to 90 Years. All sexes are eligible for the study. Core Study: Participants will be divided in 3 groups, randomly assigned in a 1:1 ratio to receive a drug or a combination of two drugs or placebo. Group 1: will receive one 30 mg of NA-831 capsule orally once a day or placebo, Group 2: will receive and intravenous lecanemab (10 mg per kilogram of body weight every 2 weeks) or placebo. Group 3: will receive one 30 mg of NA-831 capsule orally once a day and intravenous lecanemab (5 mg per kilogram of body weight every 2 weeks) or placebo. Open Label Extension Phase: Participants completing the core study will receive one 30 milligram (mg) NA-31 capsule orally once a day, and intravenous lecanemab (5 mg per kilogram of body weight every 2 weeks)
Results: The study will be completed in 2025. I. Key Outcome Measures: Core Study: Change from Baseline in the CDR-SB at 18 Months [Time Frame: Baseline, 18 months] Extension Phase: Number of Participants Reporting One or More Treatment-emergent Adverse Events (TEAEs) [Time Frame: From first dose of study drug up to approximately 24 months (including 3 months follow up) for the extension phase] II. Secondary Outcome Measures: Core Study: Change from Baseline in Alzheimer Disease Assessment Scale - Cognitive Subscale 14 (ADAS-cog14) at 18 Months [Time Frame: Baseline, 18 months]
Conclusions: The results of the phase 3 study will be availlabe in 2025. The details of the Phase 3 methodology and protocol will be presented and discussed.

EFFECTS OF TRANSCRANEAL PULSE STIMULATION FOR THE TREATMENT OF ALZHEIMER´S DISEASE- SPANISH EXPERIENCE WITH A CONTROL GROUP STUDY

POSTERS: A03.K. DRUG DEVELOPMENT, CLINICAL TRIALS: NON-PHARMACOLOGICAL INTERVENTIONS

Cristina Guijarro-Castro[1], Miguel Ángel Fernández Blázquez[2], Rubén Sebastián-González[1], Lucía Fernández-Arana[1], Javier Martín[3], Karin Freitag[4]
[1]Clínica DKF, Neuroscience Department, Madrid, Spain, [2]Universidad Autónoma de Madrid, Department Of Biological And Health Psychology, Madrid, Spain, [3]Clínica DKF, R&d Department, Madrid, Spain, [4]Clínica DKF, Rheumatology Department, Madrid, Spain

Aims: Recent studies have shown that Transcranial pulsed stimulation (TPS; Neurolith®) may have beneficial effects on brain glucose metabolism and cognitive function in patients with Alzheimer's Disease (AD). In our study, we expect to confirm the usefulness of TPS on patients with AD at 3 months.
Methods: Fifteen patients (males and females aged 61 to 89) diagnosed with MCI due to AD or mild to moderate AD underwent TPS treatment. Also, to compare the effect of treatment with the natural course of the disease, data from 15 matched control patients who had not received TPS treatment were retrospectively included. The safety, tolerability, cognitive and clinical effects of the TPS therapy vs. control participants have been evaluated. Inclusion criteria: diagnosed of probable AD dementia or MCI due to AD, MMSE > 10, baseline MRI scan excluding other potential causes of dementia, Fazekas score ≤ 2, anticholinesterase drugs or memantine treatments were allowed. Cognitive impairment was screened using MoCA. A comprehensive neuropsychological evaluation was conducted for all patients, before and after treatment.
Results: After treatment, 47% of the patients presented higher scores at the 3-month follow-up, 40% showed no change and 13% manifested a slight worsening (MoCA test). In episodic memory, 45% showed improvement on the 3-month follow-up scores, another 45% remained invariable, and the remaining 10% worsened. Strikingly, no patient reported significant impairment of depressive symptomatology whereas 60% even improved; three patients showed indeed a relevant reduction. In comparison, during the same follow-up control patients showed a worsening in all domains evaluated.
Conclusions: Based on our findings, we can conclude TPS is a safe and effective therapeutic option for AD that benefits cognition and mood. Neurolith ® accompanies and complements currently available treatments.

WHAT DOES AMYLOID-BETA (AB) HAVE TO DO WITH ALZHEIMER'S DISEASE: A HISTORY OF FAILURE

POSTERS: A03.J. DRUG DEVELOPMENT, CLINICAL TRIALS:NEW CLINICAL TRIAL DESIGNS; SIMULATION OF PROGRESS-DIGITAL TWINS

Lloyd Tran, Zung Tran
Biomed Industries, Inc., Neurosciences, San Jose, United States of America

Aims: To review and analyze clinical data of major anti-Aβ monoclonal antibody drugs including recent FDA approved Aducanumab and Lecanemab for the treatment of Alzheimer's Disease.
Methods: We systematically searched, reviewed, and analyzed the clinical data of anti-Aβ monoclonal antibody drugs. We focused on two important outcome measures: CDR-SB and ADAS-Cog. Nearly all trials reported the difference between scores of the treatment relative to the placebo at the end of the trial. On a scale where a higher score is "worse," a negative (-) difference "favors" treatment (lower score – higher score = - value). We use the bootstrapping method, a statistical procedure that resamples a single dataset to create simulated samples. This resampling process allows for the calculation of means, median, standard errors, confidence intervals (CI), hypothesis testing, and other statistics. For our study, we estimated the mean and 95%CI of these published differences by performing 10,000 resamples.
Results: All the clinical trials analyzed were randomized, placebo controlled. Sample sizes varied for the phase 3 trials, from 253 to 1072 per arm (median=519 participants); trial lengths were from 76 to 105 weeks (median=78 weeks). The estimated bootstrap mean and 95%CI for differences between placebo and drug, for CDR-SB and for ADAS-Cog were: CDR-SB; mean (95%CI) = *-0.08* (-0.31 to +0.22), range of differences = -0.70 to 1.30; ADAS-Cog; mean (95%CI) = *-0.53* (-1.03 to +0.22), range of differences = -1.60 to +4.74.
Conclusions: The cumulative mean changes for CDR-SB were -0.08; for ADAS-Cog it was -0.53, with both 95%CI including zero. The score range for CDR-SB is 0 to 18; the range for ADAS-Cog is 0 to 70/90. These mean differences across the many trials conducted cannot be either clinically or statistically significant.

Aims: We have set up a novel protocol to study multimodal lifestyle intervention in mice to recapitulate recent successful clinical trials FINGER and LipiDiDiet. The protocol was developed to identify the biological mechanism underlying the positive findings of multimodal lifestyle interventions.
Methods: In the Lifestyle group, mice were given access to running wheels (voluntary exercise), Fortasyn Connect (healthy diet), and they were subjected to cognitive training in an IntelliCage environment. To separately investigate the effects of pharmacological vascular monitoring, a group of mice was given Atorvastatin and Enalapril in the diet (Pharma group). Control mice were housed in normal conditions. We included 12 wild-type female C57BL/J6 mice 6 months of age per group. The full intervention lasted for 8 weeks. Blood pressure was measured using a tail-cuff system at baseline and the end of the intervention. Additionally, all mice underwent a battery of behavioural testing after the eight weeks of intervention.
Results: During the intervention, the Lifestyle group demonstrated effective learning in the different cognitive training tasks and actively used the running wheels. At the end of the intervention, the Pharma and the Lifestyle groups showed a medication- and a lifestyle-induced lowering of blood pressure, respectively. Furthermore, the Lifestyle group displayed an improved short-term spatial working memory compared to the control group as assessed by the spontaneous alternation in the Y maze test.
Conclusions: The lifestyle protocol had both health and cognitive performance-enhancing effects in adult WT mice proving that the protocol can be back-translated from humans to mice. Now we will continue to determine the brain protein and lipid changes associated with these beneficial effects. The future steps involve studying animal models of cognitive decline, Alzheimer's disease and vascular/metabolic dysfunction.

COGNITO'S EVOKED GAMMA OSCILLATION TREATMENT AFFECTS CSF BIOMARKERS RELATED TO SYNAPTIC REGULATION, GLIAL FUNCTION AND IMMUNOLOGICAL RESPONSES IN MCI-AD

POSTERS: A03.K. DRUG DEVELOPMENT, CLINICAL TRIALS: NON-PHARMACOLOGICAL INTERVENTIONS

Mihaly Hajos[1], Duc Duong[2], Annabelle Singer[3], Monika Shpokayte[1], Zach Malchano[1], Ralph Kern[1], James Lah[4], Allan Levey[4], Nicholas Seyfried[2], Kiran Pandey[5]
[1]Cognito Therapeutics, R&d, Cambridge, United States of America, [2]Emory University School of Medicine, Department Of Biochemistry, Atlanta, United States of America, [3]Georgia Institute of Technology & Emory University, Coulter Dept. Of Biomedical Engineering, Atlanta, United States of America, [4]Emory University School of Medicine, Neurology, Atlanta, United States of America, [5]Emtherapro, Inc., R&d, Atlanta, United States of America

Aims: Evaluating mode of action of Cognito Therapeutics' medical device using unbiased proteomic analysis of cerebrospinal fluid (CSF) samples in participants with mild cognitive impairment (MCI) due to Alzheimer's disease (AD).
Methods: CSF samples were collected in the delayed-start FLICKER clinical trial (NCT03543878) at baseline, 4- and 8-weeks follow-up time points from participants with MCI (n=5 per arm) recruited from the Emory Goizueta Alzheimer's Disease Research Center (ADRC) who received 4 or 8 weeks of daily, one-hour treatment using Cognito Therapeutics medical device. Proteomic quantification and analysis were conducted using tandem-mass tag mass spectrometry (TMT-MS) of CSF samples. CSF proteome of FLICKER participants were compared to within-study pooled AD and healthy control CSF reference standards from the Goizueta ADRC to benchmark baseline protein levels of participants (Johnson et. al., 2022) and, to assess treatment effects, via differential expression analysis (one-way ANOVA; $p<0.05$).
Results: A total of 2,785 CSF proteins were analyzed across all CSF samples. Differential expression analysis of proteins from baseline (n=5) versus treatment (n=5, 8 weeks), normalized for baseline CSF proteomes, revealed 110 proteins that met the significance threshold ($p<0.05$, no FDR correction), with 60 proteins upregulated and 50 proteins downregulated as result of treatment. 52 of the significant proteins were classified into 12 brain-derived AD modules. Treatment had a significant impact on CSF proteins linked to AD pathologies represented by brain modules related to Synapse/Neuron (M1), Oligo/Myelination (M3), Post-Synaptic Density (M5), Complement-System/Acute Phase (M26), and Neurotransmitter Regulation (M36).
Conclusions: Unbiased CSF proteomic analysis in MCI-AD patients demonstrated that evoked gamma oscillation by Cognito Therapeutics medical device resulted in treatment-driven upregulation and downregulation of proteins associated with AD pathology, including effects on synaptic regulation, glial function and immunological responses.

DE-RISKING CLINICAL TRIAL DESIGN VIA MODEL-INFORMED DRUG DEVELOPMENT WITH THE CRITICAL PATH FOR ALZHEIMER'S DISEASE CONSORTIUM

POSTERS: A03.L. DRUG DEVELOPMENT, CLINICAL TRIALS: REGULATORY ASPECTS, OTHER

Sudhir Sivakumaran[1], Yashmin Karten[1], Nicholas Cullen[1], Corissa Lau[1], Eileen Priest[1], Hazel White[1], Michael Irizarry[2]
[1]Critical Path Institute, Critical Path For Alzheimer's Disease, Tucson, United States of America, [2]Eisai, Inc, Neurology Business Group, Nutley, United States of America

Aims: The Critical Path for Alzheimer's Disease (CPAD) consortium serves as a pre-competitive, neutral convenor to generate novel, regulatory endorsed quantitative drug development tools and solutions that are made freely available to the public. These tools accelerate drug development by de-risking key decisions in clinical trial planning.
Methods: Patient-level data from contemporary Phase II and III Alzheimer's disease (AD) clinical trials and observational studies make up the CPAD integrated database. This diverse collection of datasets is harmonized and relevant statistical model specifications (based on cognitive outcomes, biomarker modalities, study populations, etc.) are identified. Disease progression models are then fitted using subsets of the CPAD database matching these specifications. With the fitted disease progression models, clinical trial simulations are then developed by applying clinical trial dynamics such as treatment effect, placebo effect, and dropout. Finally, by altering key trial design parameters such as inclusion criteria, trial length, and visit frequency, we can better understand how trial design decisions affect clinical trial outcomes.
Results: As of August 2023, CPAD's data repository contains 73 studies with 100,812 individual anonymized patient records, with a rich source of key AD biomarkers (biofluids and imaging). Different mixed effects models have been developed with cognitive scales as outcome and different biomarker modalities (e.g., PET + MRI, CSF, and plasma) as baseline predictors. A comprehensive clinical trial simulation tool which builds on these disease progression models has been developed and made available. Additionally, harmonization of tau PET results and their impact on cognition along the Alzheimer's disease continuum have been evaluated.
Conclusions: The precompetitive collaboration pioneered by CPAD is fundamental to the generation of actionable tools for accelerating and advancing AD drug development.

PRESERVATION OF BRAIN STRUCTURE AND FUNCTION IN OLDER EXPERT MEDITATORS: LINKS TO COGNITION, PSYCHOLOGICAL AND LIFESTYLE FACTORS

POSTERS: A03.K. DRUG DEVELOPMENT, CLINICAL TRIALS: NON-PHARMACOLOGICAL INTERVENTIONS

Sacha Haudry[1], Brigitte Landeau[1], Julie Gonneaud[1], Antoine Lutz[2], Gaëlle Chételat[1]
[1]Normandie Univ, UNICAEN, Inserm, U1237, Phind "physiopathology And Imaging Of Neurological Disorders", Neuropresage Team, Cyceron, Caen, France, [2]CNRL, Lyon Neuroscience Research Center, Inserm U1028, CNRS UMR 5292, Rhône, Lyon, France

Aims: Objectives: Meditation is a mental training approach for stress reduction and attention and emotion regulation. It is expected to improve mental health and well-being in ageing, and reduce age-related decline in brain structural and functional integrity; altogether contributing to reduced risk for Alzheimer's disease. We hypothesize that long-term meditation will be associated with more preserved brain structure and function with age compared to meditation-naive controls.
Methods: Methods: 25 expert meditators (ExpMed) with > 20 years of meditation practice and 135 cognitively unimpaired meditation-naive older adults (HC) from the Age-Well cohort (all ≥65 years old) were included. All participants underwent neuroimaging, cognitive, psychological and lifestyle assessments. ExpMed were compared with HC on structural MRI and brain perfusion maps. Amongst regions showing significant between-group differences, stepwise regressions were conducted to assess i) which meditation composite score or lifestyle factor best predicted these differences and ii) which regions best predicted cognitive and psychological variables.
Results: Results: ExpMed had significantly higher volume in inferior frontal, orbitofrontal and posterior cingulate cortex as well as higher perfusion in temporo-occipito-parietal areas including the hippocampus, amygdala, temporal and angular gyrus. Higher meditation composite score and engagement in complex mental activities were associated with greater volume and perfusion in brain areas themselves associated with better working memory and attention performances and, higher self-compassion and emotion regulation.
Conclusions: Conclusions: Long-term meditation practice is associated with more preserved brain volume and perfusion in a fronto-parietal network as a result of attention, emotion regulation and introspection training. These brain changes have positive impact on cognition and psychological factors. Engagement in complex mental activities such as meditation practice could contribute to cerebral preservation in older adults.

CLINICIAN SPECIALTY AND LOCATIONAL VARIATIONS BASED ON PRESCRIPTION PATTERNS FOR US VETERANS WITH ALZHEIMER'S DISEASE

POSTERS: A03.L. DRUG DEVELOPMENT, CLINICAL TRIALS: REGULATORY ASPECTS, OTHER

Brant Mittler[1], Joel Reisman[2], Byron J Aguilar[2], Dan Berlowitz[3], Qinqing Li[4], Raymond Zhang[5], Amir Monfared[5], Quanwu Zhang[6], Weiming Xia[7]
[1]VA San Antonio Healthcare System, Geriatric Research and Clinical Center, Medicine/geriatrics, San Antonio, United States of America, [2]VA Bedford Healthcare System, Geriatric Research and Clinical Center, Center For Healthcare Organization & Implementation, Bedford, United States of America, [3]University of Massachusetts, Department Of Public Health, Lowell, MA, United States of America, [4]University of Edinburg, Department Of Mathematics, Edinburg, United Kingdom, [5]Eisai, Inc., Alzheimer's Disease And Brain Healthe, Nutley, United States of America, [6]Eisai, Inc., Alzheimer's Disease And Brain Healthe, Nutley, NJ, United States of America, [7]University of Massachusetts, Department Of Biological Sciences, Lowell, MA, United States of America

Aims: This study aims to determine if there are variations in access to specialty care over metropolitan locations based on prescription patterns among US Veterans with Alzheimer's disease.
Methods: A cohort of Veterans with probable AD who had received any prescription in the Veterans Affairs (VA) Healthcare System was evaluated based on the United States Census metropolitan areas: non-metropolitan, small-, medium-, large fringe-, and large central-metro areas. Clinician specialties were determined using information in the VA personnel records.
Results: There were 83,909 Veterans with AD who had ≥1 prescriptions for any drug from VA clinicians in 2019, and this number was not significantly changed from 2012 (83,350). During Fiscal Year 2019, 19%, 11%, 25%, 22% and 23% of AD patients resided in non-metropolitan, small-, medium-, large fringe-, and large central-metro regions, respectively. Among clinician types, 64.4% were primary care clinicians, 25.1% were psychiatrists, 5.5% were neurologists, and 5.0% were geriatricians. Thus, among the clinicians who serve Veterans with AD, only 35% were qualified to prescribe anti-amyloid therapy in the VA. The majority (74%) of prescriptions written by neurology, psychiatry, and geriatric specialists were generated in medium to large metropolitan areas as opposed to small-metro or non-metropolitan areas.
Conclusions: This study reveals variations in treatment access to clinician specialists over metropolitan areas among US Veterans with AD. Given that anti-amyloid treatment in the VA can only be prescribed by AD specialists, these variations may result in limited access to anti-amyloid treatments, especially in non-metro and small-metro areas.

IN ALZHEIMER'S DISEASE STUDY RECRUITMENT, SCHEDULING LAG IMPACTS PRE-SCREEN ATTENDANCE, CANCELLATION, AND NO-SHOW RATES

POSTERS: A03.L. DRUG DEVELOPMENT, CLINICAL TRIALS: REGULATORY ASPECTS, OTHER

Yu-Jay Huoh, Brenda Martinez, Elly Lee, Ralph Lee
Irvine Clinical Research, Irvine Clinical Research, Irvine, United States of America

Aims: In this study, we examined the impact of the number of days between when a prescreening appointment is created and the actual scheduled date (“scheduling lag”) on key recruitment metrics - attendance, cancellation, and no-show rates - in potential Alzheimer's Disease study participants.
Methods: Between January and August 2023, 2,322 potential Alzheimer's Disease study participants were scheduled for prescreening appointments. These potential participants were recruited through advertisements on Facebook, Instagram, and Google. After a brief phone screen for basic eligibility criteria, in-person prescreening appointments were scheduled. Reminder messages were sent in the days leading up to the appointment.
Results: The prescreening appointments were scheduled anywhere from same day up to 21 days in the future. Mean scheduling lag was 10.5 days (median 9 days, SD 5.9 days). Scheduling lag had a conclusively significant impact on nearly every performance metric - attend rate ($\beta = -0.034$, $P < 0.00001$), cancellation rate ($\beta = 0.035$, $P < 0.0001$), no show rate ($\beta = 0.038$, $P < 0.00001$). This was driven by sharp performance improvements for appointments scheduled within five to seven days.
Conclusions: Research sites are increasingly relying on advertising to recruit trial participants for traditionally difficult-to-recruit-for conditions, such as Alzheimer's Disease. Because of this shift, sites need to monitor how cost-effective these campaigns are. A key driver for successful recruitment is attendance rate (and a reduction in cancellation/no-shows), and sites can improve this by decreasing scheduling lag to less than seven days.

THE EVOLUTION OF RANDOMIZED CONTROLLED TRIALS IN ALZHEIMER'S DISEASE

POSTERS: A03.L. DRUG DEVELOPMENT, CLINICAL TRIALS: REGULATORY ASPECTS, OTHER

Joseph Therriault[1], Angela Kwan[1], Etienne Aumont[1], Joao Pedro Ferrari-Souza[2], Marcel Woo[1], Saman Arfaie[1], Serge Gauthier[1,3], Pedro Rosa-Neto[1]
[1]Translational Neuroimaging Laboratory, Mcgill University Research Centre For Studies In Aging, Alzheimer's Disease Research Unit, Douglas Research Institute, Montréal, Canada, [2]University of Pittsburgh, Psychiatry, Pittsburgh, United States of America, [3]McGill University, Neurology And Neurosurgery, Montreal, Canada

Aims: To describe the key features of RCT design for interventions in AD and their changes over time.
Methods: We performed a literature review to identify phase II and phase III RCTs of Alzheimer's disease in Pubmed, Scopus and Medline. Key features of RCT design, target population and funding were extracted from published reports. Key design features were analyzed with respect to time using regression and chi-square analyses.
Results: The study included 182 RCTs testing interventions in AD. The most common endpoint was the Clinical Dementia Rating Sum-of-Boxes. The average sample size of RCTs increased substantially over time (165% increase from 1992 to 2022), as did average trial duration (119% increase from 1992 to 2022). An increase in studies testing disease-modifying treatments was observed over time in contrast to symptomatic treatments. A substantial increase in the proportion of studies funded by the pharmaceutical industry was observed, with over 75% of RCTs in AD since 2007 being funded by the pharmaceutical industry.
Conclusions: This study noted substantial changes in the key features of AD clinical trials from 1992-2022. RCTs in AD are now larger and longer and are correspondingly powered to detect smaller clinical differences. The AD research community needs a better understanding of what constitutes clinically meaning changes.

INVESTIGATING AMYLOID PRECURSOR PROTEIN METABOLITES IN CSF IN RELATION TO NEUROIMAGING MARKERS

POSTERS: A04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Zina Abed Al Sattar[1], Emir Basic[1,2], Francesco Locatelli[1,2], Johan Svensson[3], Anders Wallin[1,2], Petronella Kettunen[1,2]
[1]University of Gothenburg, Neuroscience And Physiology, Gothenburg, Sweden, [2]Sahlgrenska University Hospital, Psychiatry, Cognition And Old-age Psychiatry, Mölndal, Sweden, [3]Sahlgrenska University Hospital, Internal Medicine And Clinical Nutrition, Gothenburg, Sweden

Aims: The Gothenburg Mild Cognitive Impairment (MCI) study is a mono-center study of patients seeking help for cognitive complaints at the memory clinic at Sahlgrenska University Hospital. Manifest dementia in patients, including Alzheimer's disease (AD), subcortical small-vessel disease (SSVD) and mixed AD/SSVD (MIX), is diagnosed based on medical history, MRI, checklists and instruments for cognitive symptoms, including scores for the Mini Mental State Examination and the Clinical Dementia Rating. Moreover, cerebrospinal fluid (CSF) AD biomarkers amyloid-β (Aβ) 1-42, total tau (t-tau) and hyperphosporylated tau (p-tau181), as well as Aβx-38, Aβx-40, Aβx-42, and soluble amyloid precursor protein (sAPP) α and β have been analyzed for the patients, although these are not used for diagnosis. In this project, we investigated the correlation between these CSF biomarkers and brain structure volumes in patients with preclinical and manifest disease.
Methods: Subjects included controls, subjective cognitive impairment (SCI), MCI, AD, MIX, SSVD. AD pathology was assessed for all patients according to the International Working Group for New Research Criteria for the Diagnosis of AD (IGW-2). The applied cut-offs indicating AD pathology in CSF were t-tau > 350 ng/L, p-tau181 > 59 ng/L, and Aβ1-42 < 530 ng/L. Correlations between brain volumes and biomarker levels were done using Spearman correlation and predictions were performed using linear regression with covariates.
Results: Our preliminary analysis showed that several of the CSF biomarkers analyzed correlated with volumetric MRI data in our cohort. For example, the ratios of Aβx-42/x-38 and Aβx-42/x-40 correlated with entorhinal cortex volumes, as well as hippocampal volumes.
Conclusions: Our findings confirms that CSF biomarkers can reflect the neurodegenerative processes in the brain as measured with MRI.

SEVERITY OF SLEEP DISORDERS IS ASSOCIATED WITH NEUROINFLAMMATION AND MEDIATES THE RELATIONSHIP BETWEEN GLYMPHATIC SYSTEM FUNCTIONING AND WHITE MATTER INTEGRITY

POSTERS: A04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Ariane Delgado Sanchez[1], Natalia Cullell[2], Giovanni Caruana[3], Andrea Elias[3], Nicola Ray[1], Sonia Correa-Muller[4], Jurek Krupinski[2]
[1]Manchester Metropolitan University, Department Of Psychology, Manchester, United Kingdom, [2]Fundació Docència i Recerca Mútua Terrassa, Stroke Pharmacogenomics And Genetics, Terrassa, Barcelona, Spain, [3]Fundació Docència i Recerca Mútua Terrassa, Department Of Radiology, Terrassa, Barcelona, Spain, [4]Manchester Metropolitan University, Department Of Life Sciences, Manchester, United Kingdom

Aims: Obstructive sleep apnoea (OSA) is associated with increased risk of developing Alzheimer's disease (AD). White matter (WM) changes due to neuroinflammation and/or neurodegeneration are suggested to be an early event in AD and have been detected in OSA. It is possible that integrity of the glymphatic system (a brain-wide waste clearance system that is activated during sleep) underpins these relationships. We therefore explore relationships between glymphatic health, severity of OSA and neurodegeneration and neuroinflammation in whole-brain WM.
Methods: 22 participants with mild cognitive impairment completed polysomnography, anatomical MRI and diffusion tensor imaging (DTI). OSA severity was measured via the number of apnoea/hypoapnoea episodes per hour. Glymphatic health was measured via the DTI-ALPS index (analysis along the perivascular space index). Neuroinflammation and neurodegeneration in WM were measured via free water (FW) volume and free water-corrected fractional anisotropy (cFA), respectively. Tract Based Spatial Statistics were computed to examine relationships between OSA severity and glymphatic health, and WM integrity.
Results: We did not observe a relationship between OSA severity and the ALPS index. However, OSA severity was correlated with FW volume, but not cFA across widespread WM regions. Conversely, the ALPS index was correlated with cFA, but not FW cross widespread white matter regions. In follow-up analyses, the relationship between ALPS and cFA was mediated by OSA severity.
Conclusions: OSA may increase neuroinflammation in WM, while structural degeneration in WM may depend on impaired glymphatic health. Whether OSA eventually leads to impaired glymphatic function and neurodegeneration in later disease stages is supported by the finding that OSA severity mediated the relationship between ALPS and cFA. These conclusions support the use of treatments for sleep disorders for prevention of neuroinflammation and neurodegeneration.

THE DEGENERATION OF LOCUS COERULEUS OCCURRING DURING ALZHEIMER'S DISEASE PROGRESSION: A NEUROIMAGING FOLLOW-UP INVESTIGATION

POSTERS: A04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Alessandro Galgani[1], Francesco Lomabrdo[2], Francesca Frija[2], Nicola Martini[2], Gloria Tognoni[3], Gabriele Siciliano[3], Nicola Pavese[4,5], Filippo Giorgi[1]
[1]University of Pisa, Department Of Translational Research And Of New Surgical And Medical Technologies, Pisa, Italy, [2]Fondazione Monasterio, Department Of Radiology, Pisa, Italy, [3]University of Pisa, Department Of Clinical And Experimental Sciences, Pisa, Italy, [4]Newcastle University, Translational And Clinical Research Institute, Newcastle, United Kingdom, [5]Aarhus University, Clinical Medicine - Department Of Nuclear Medicine And Pet, Aarhus N, Denmark

Aims: To assess the longitudinal evolution of Locus Coeruleus Magnetic Resonance Imaging (LC-MRI) parameters and their association with clinical progression in patients with Alzheimer's Disease (AD).
Methods: Twelve AD demented (ADD) patients and 45 Mild Cognitive Impaired (MCI) individuals underwent a baseline and a 2.5-year follow-up LC-MRI scan. MCI individuals were classified as converter (cMCI = 19) or non-converter (ncMCI = 26) ones at the end of the clinical follow-up, based on whether or not they converted to dementia. Using a standardized template-based approach, LC-MRI parameters were extracted, namely Locus Coeruleus Contrast Ratio (LC_{CR}) and Locus Coeruleus-belonging voxels (LC_{VOX}).
Results: Both LC-MRI parameters were reduced during follow-up across the whole population ($p<0.001$), and in all the diagnostic groups, apart from LC_{VOX} in the AD group. Linear mixed models (LMMs) analysis confirmed the reduction of LC-MRI parameters over time ($p<0.001$) and showed an association with the severity of the diagnosis. LMMs showed that both LC_{CR} and LC_{VOX} were more markedly reduced in ADD patients ($p = 0.022$ for LC_{CR} and $p = 0.006$ for LC_{VOX}) and cMCI individuals ($p = 0.002$ for LC_{CR} and $p= 0.001$ for LC_{VOX}) than in ncMCI ones. This trend was also found considering LC subregions, with the rostral LC and the left LC showing higher levels of statistical significance.
Conclusions: Our results show, for the first time in vivo in humans, the progressive degeneration the LC suffers from, during the progression of AD. They are also in line with previous neuropathological *post-mortem* data, and this supports the reliability of LC-MRI as a tool to explore the integrity of the central noradrenergic system in patients.

DATA-DRIVEN NEUROANATOMICAL SUBTYPE CLASSIFICATION IN NON-DEMENTED ELDERLY COHORT

POSTERS: A04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Na Young Shin[1], Woo Jung Kim[2], Jihye Choi[1]
[1]Yonsei University College of Medicine, Department Of Radiology, Seoul, Korea, Republic of, [2]Yongin Severance Hospital, Yonsei University College of Medicine, Psychiatry, Yongin, Korea, Republic of

Aims: Given the heterogeneous cognitive outcome of subjective cognitive decline (SCD) and mild cognitive impairment (MCI), this study aimed to identify neuroanatomical subtypes among non-demented elderly individuals using unsupervised, data-driven cluster analysis and to investigate the longitudinal trajectories of cognitive function.
Methods: A total of 148 community-dwelling non-demented elderly individuals (aged 62-79, control = 64, SCD = 60, MCI = 22) underwent 3-dimensional T1-weighted imaging, clinical assessments for SCD and depression, and neuropsychological assessments. Among them, 137 participants were followed up for an average of 2.33 ± 0.06 years. We conducted hierarchical cluster analysis on brain volumes of 84 regional areas and examined the cognitive and neuroanatomical characteristics of the identified subtypes. We employed linear mixed models to evaluate whether the proposed subtypes were more effective than the clinical diagnosis in predicting longitudinal changes in cognitive function.
Results: We identified three anatomical subtypes. Cluster 1 exhibited larger brain volumes and superior cognitive performance compared to the other clusters. Transitioning from Cluster 1 to Cluster 3, brain volumes and cognitive function gradually decreased. While Cluster 2 demonstrated intermediate cognitive performance, individuals in this subtype had the most severe SCD and depressive symptoms among the three clusters. Regarding cognitive changes, 40%, 60.4%, and 70% of Cluster 1, 2, and 3 experienced cognitive decline, respectively, while 67%, 64%, and 36% of control, SCD, and MCI individuals showed cognitive decline. The proposed subtypes (AIC = 36.525) showed a marginal improvement in predicting cognitive changes over a 2-year period compared to the clinical diagnosis (AIC = 41.053).
Conclusions: Our study suggests that the data-driven neuroanatomical subtype classification might be useful to reflect clinical and cognitive characteristics and predict future cognitive outcome in non-demented elderly population.

EVALUATING THE RELATIONSHIP BETWEEN OXYGEN EXTRACTION FRACTION (OEF), TAU AND AMYLOID PATHOLOGY, AND COGNITIVE STATUS IN ALZHEIMER'S DISEASE

POSTERS: A04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Seyyed Ali Hosseini[1], Stijn Servaes[1], Joseph Therriault[1], Cécile Tissot[1], Nesrine Rahmouni[1], Arthur Macedo[1], Firoza Lussier[2], Jenna Stevenson[1], Yi-Ting Wang[1], Jaime Fernandez Arias[1], Kely Quispialaya[1], Etienne St-Onge[1], Alyssa Stevenson[1], Serge Gauthier[1], Junghun Cho[3], David Rudko[1], Tharick A Pascoal[4], Pedro Rosa-Neto[1]
[1]Mcgill University, Neurology & Neurosurgery, Montréal, Canada, [2]University of Pittsburgh, Psychiatry, Pittsburgh, United States of America, [3]University at Buffalo, The State University of New York, Biomedical Engineering, New York, United States of America, [4]University of Pittsburgh, Department Of Psychiatry, Pittsburgh, United States of America

Aims: Oxygen Extraction Fraction (OEF) is a measure of the proportion of oxygen that is removed from the blood as it flows through the brain's vascular system. This study aims to explore the role of OEF in Alzheimer's Disease (AD) using Magnetic Resonance Imaging (MRI). We specifically focus on examining the relationships between OEF and cognitive status across different age groups.
Methods: A diverse cohort of 347 participants was analyzed, including young controls (Y: n=37), Cognitively-Unimpaired older adults (CU_{65+}: n=182), individuals with Mild Cognitive Impairment (MCI: n=80), and AD patients (n=48). All subjects underwent tau-PET, amyloid-PET, and 3D gradient-recalled echo sequence MRI scans. A pipeline for generating OEF maps was constructed using TRIAD cohort preliminary data. The OEF maps were subsequently registered to the Montreal Neurological Institute (MNI) space for Region-Of-Interest (ROI) and voxel-based analyses.
Results: We observed a marked decrease in OEF values across multiple brain regions when progressing from young controls to CU, MCI, and AD groups, distinctly highlighting the age effect (Figure1). This age-related decline was especially significant and consistent, suggesting that age serves as a strong modulator for OEF values in the brain. Age-related cortical differences were further substantiated, revealing that older age groups, particularly those with MCI and AD, showed more pronounced changes in OEF, suggesting an age-dependent vulnerability to cerebral metabolic disruptions (Figure2).

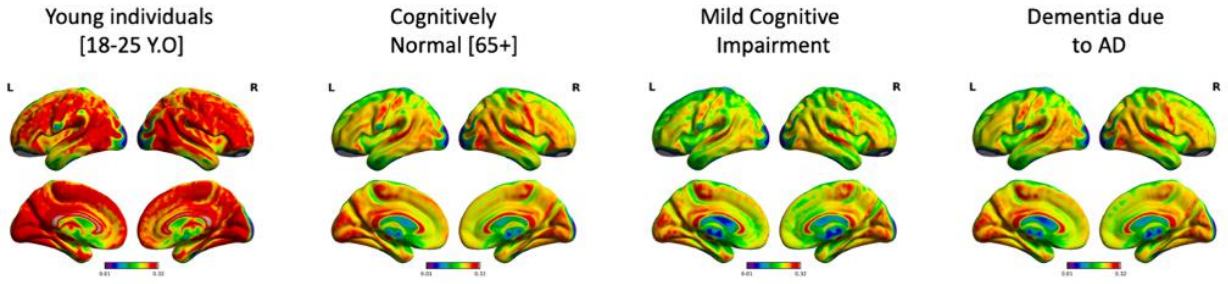

Figure1: Average OEF images

Model: OEF ~ tau + Amyloid + COV.

- COV : age, sex, Apoe4
- **(Y:** n=37), (CU_{65+}: n=182), (MCI: n=80), and (AD: n=48).
- T-statistical parametric maps were corrected for multiple comparisons using a random field theory cluster threshold of P < .001, overlaid on the Montreal Neurological Institute reference template.

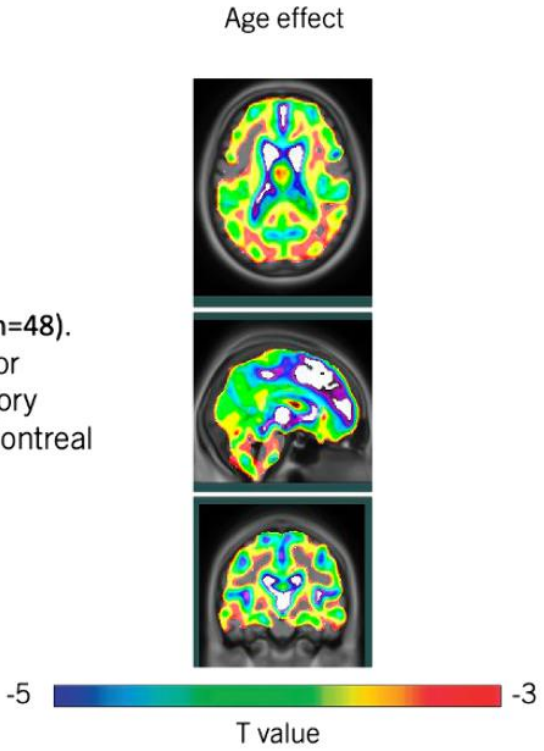

Figure2. AGE related cortical Differences

Conclusions: Our study emphasizes the potential of MRI-measured OEF as an age-sensitive marker for understanding Alzheimer's Disease. While no direct associations were identified between OEF and traditional pathological markers, our results point to the significant impact of age on OEF levels. This suggests that age may be a critical factor influencing cerebral metabolism and blood flow changes in AD.

EFFECTS OF DEFACING PROGRAMS ON THE REGIONAL BRAIN VOLUME SEGMENTATION

POSTERS: A04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Dongwon Yang[1], Chunghwee Lee[1], Jung Hee Cho[1], Dong-Woo Ryu[1], Yongsoo Shim[2], Yun Jeong Hong[3], Seonggyu Kim[4], Jong-Min Lee[5]
[1]The Catholic University of Korea, Neurology, Seoul, Korea, Republic of, [2]Eunpyeong St. Mary's Hospital, College of Medicine, The Catholic University of Korea,, Neurology, Seoul, Korea, Republic of, [3]Uijeongbu St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Neurology, Uijeongbu-si, Korea, Republic of, [4]Hanyang University, Electronic Engineering,, Seoul, Korea, Republic of, [5]Hanyang University, Biomedical Engineering, Seoul, Korea, Republic of

Aims: In brain MRI research, data sharing with collaborators can raise privacy concerns. Defacing allows for the dissemination of this data without compromising participants' identities. Brain MRI defacing, the process of obscuring facial features in these images for privacy protection, has been shown to potentially affect the accuracy of brain volume calculations in certain studies. In this study, we compared three available brain MRI defacing programs to evaluate their accuracy in volumetric analysis.
Methods: 3D T1 MRI scans from 10 subjects (age: 71.1±6.1) diagnosed with subjective cognitive decline were processed using defacing programs: FreeSurfer, BioImage Suite Web, and De-facer. Both the original non-defaced and defaced images from these programs were analyzed with the FreeSurfer and the Quick Brain Volumetry (QBraVo) program, based on SPM8 and MATLAB. The accuracy of brain segmentation was assessed by comparing the Total Intracranial Volume (TIV), Whole Brain Volume (WBV), Cortical Volume(CV), and Hippocampal Volume (HV) using the Intra-class Correlation Coefficient (ICC).
Results: The TIV for the non-defaced images, FreeSurfer, BioImage Suite Web, and De-facer were highly similar. The ICC for TIV across the four image datasets was 0.998($p<0.001$) for FreeSurfer and 0.999 ($p<0.0001$) for QBraVo. The WBV values for these datasets also demonstrated consistency, with an ICC of 0.997 ($p<0.0001$) and 0.999(p,0.001). HV displayed similar value trends, with ICCs of 0.993 ($p<0.0001$) for FreeSurfer and 0.992 ($p<0.0001$) for QBraVo, respectively.
Conclusions: All three defacing programs demonstrated successful defacing outcomes and delivered reliable volumetric results in FreeSurfer and QBraVo analysis. Among them, De-facer exhibited superior defacing image quality. While both FreeSurfer and De-facer operate on the Linux system, necessitating a prolonged training period, the BioImage Suite Web defacing program is designed for the Windows system and needs short training time.

MRI ASSESSMENT OF HEALTHY AGING TRAJECTORIES OF THE MARMOSET BRAIN

POSTERS: A04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Diego Szczupak[1], Rebecca Bhik-Ghanie[1], Bei Zhang[1], Daniel Papoti[1,2], Vinicius Campos[3], Lauren Dubberly[1], Thomas Hitchens[1], Frank Yeh[4], David Schaeffer[1], Stacey Sukoff Rizzo[1,5], Afonso Silva[1]

Aims: Objective: The common marmoset (C*allithrix jacchus*) is an important animal model in neuroscience and neurological diseases (e.g., Alzheimer's disease - AD), as they present primate-specific evolutionary features such as an expanded frontal cortex. Here, we aim to characterize healthy aging trajectories for a population of marmosets.
Methods: Methods: We imaged a cohort of 59 marmosets (45 males, 14 females) across the lifespan (8 to 150 months) using a dedicated 9.4T 30cm bore MRI scanner (Bruker BioSpin Corp, Billerica). The animals were anesthetized under isoflurane anesthesia. High-resolution (250 µm isotropic) T1-, T2-, and diffusion-weighted structural MRI were acquired. The brain images were aligned and registered to the Marmoset Brain Mapping V3 template, the brain was segmented into cortical (CTX) and subcortical (SUB CTX) grey matter, white matter (WM), and cerebral spinal fluid (CSF), and voxel-based-morphometry was used to quantify regional brain volume in the left and right hemispheres.
Results: Results: We discovered a decrease in grey matter volume in both males and females with age (Figure 1), reflected by the volume reduction in several cortical and subcortical brain regions in both sexes. Overall, we discovered that age affects female marmoset brains (38 CTX and 5 SUB CTX regions) more than males (15 CTX and 2 SUB CTX regions). We found no significant age-dependent changes in WM and CSF.
Conclusions: Conclusions: Our work is the first to thoroughly describe the normal aging of the marmoset brain, a valuable model for age-related neuropathologies (e.g., AD). This research will set the normal parameters for marmoset aging and will be vital for generating transgenic marmoset models for AD, which is the goal of the MARMO-AD consortium.

	WM	CTX	Sub CTX	CSF

LEVERAGING COMPREHENSIBLE CONVOLUTIONAL NEURAL NETWORKS TO DETERMINE AMYLOID POSITIVITY STATUS VIA MRI SCANS.

POSTERS: A04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Fedor Levin[1], Devesh Singh[1], Stefan Teipel[1,2], Martin Dyrba[1]
[1]Deutsches Zentrum für Neurodegenerative Erkrankungen e.V. (DZNE), Clinical Dementia Research, Rostock, Germany, [2]Rostock University Medical Center, Department Of Psychosomatic Medicine, Rostock, Germany

Aims: Despite recent advances in the development of antibody treatments targeting amyloid in Alzheimer's disease (AD), some questions still surround their application in a clinical setting, for example the need for the assessment of amyloid accumulation, typically done via amyloid PET or CSF biomarkers. In this study, we aim to apply convolutional neural networks (CNNs) to commonly available magnetic resonance imaging (MRI) scans to select patients at high risk for amyloid positivity for conducting additional clinical assessments.
Methods: Previously, we have developed a deep learning network that allowed detecting AD-related atrophy patterns in MRI scans and visualizing features of brain images that are relevant to the decision of the network. In the current study, we will use MRI scans from participants with subjective memory decline or mild cognitive impairment and available amyloid status data (PET, CSF) of the ADNI study to retrain the CNN models to predict amyloid positivity based on MRI. We will assess the accuracy of classification and examine the spatial distributions of relevance scores to identify brain regions that are key for detecting amyloid positivity status.
Results: The planned analyses will evaluate the feasibility of using CNNs with MRI data for detecting amyloid-positivity, as well as resulting accuracy. We will also assess relevance maps to report brain areas associated with amyloid positivity classifications.
Conclusions: Here, we present ongoing work aiming to use CNNs in combination with relevance maps to determine amyloid positivity using widely available MRI scans. This method may allow physicians to identify patients who will benefit from in-depth diagnostic assessments, such as amyloid PET or CSF analysis.

MICROSTRUCTURAL CHANGES WITHIN BRAINSTEM NUCLEI CORRELATE WITH REM SLEEP WITHOUT ATONIA IN ISOLATED REM SLEEP BEHAVIOR DISORDER: A PILOT STUDY

POSTERS: A04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Ambra Stefani[1], Stephan Grimaldi[2,3], Firdaus Fabrice Hannanu[3], Kavita Singh[3,4], Guadalupe Garcia-Gomar[3,5], Subhranil Koley[3], Aleksandar Videnovic[1], Marta Bianciardi[3]
[1]MGH, Harvard Medical School, Neurology, Boston, United States of America, [2]University Hospital La Timone, Neurology And Movement Disorders, Marseille, France, [3]Athinoula A. Martinos Center, MGH, Harvard Medical School, Radiology, Charlestown, United States of America, [4]National Institute on Aging, NIH, Multiscale Imaging And Integrative Biophysics Unit, Lbn, Baltimore, United States of America, [5]Universidad Nacional Autónoma de México, Escuela Nacional De Estudios Superiores Unidad Juriquilla, Juriquilla, Mexico

Aims: Isolated REM sleep behavior disorder (iRBD) is characterized by REM-sleep without atonia (RWA). Animal studies show that REM atonia is regulated by brainstem nuclei, in particular the sublaterodorsal/subcoeruleus nucleus and the medullary-reticular-formation. Yet, those mechanisms are understudied in living humans. Aim of this study was to investigate the microstructure of brainstem nuclei in iRBD patients, and to correlate it to RWA indices.
Methods: We acquired 7-Tesla 0.75mm isotropic-resolution T1-weighted MP2RAGE and T2*-weighted GRE in five patients with video-polysomnography-proven iRBD (4m/1f, 66.6±8.2 years). We applied the recently developed in-vivo probabilistic Brainstem Navigator atlas to identify the subcoeruleus nucleus and the inferior medullary-reticular-formation. Then, we calculated the mean signal intensity within these nuclei. RWA was quantified in the chin (phasic, “any” and tonic) and in the flexor digitorum superficialis (FDS) muscles bilaterally in 3-s mini-epochs, according to the Sleep Innsbruck Barcelona (SINBAR) criteria.
Results: Chin tonic activity correlated with T1-weighted values within the left inferior medullary-reticular-formation (r=-0.906, p=0.034) and the left subcoeruleus-nucleus (r=-0.925, p= 0.024). “Any” chin correlated with T1-weighted values within the left subcoeruleus-nucleus (r=-0.879, p=0.049). The SINBAR-index correlated with T1-weighted values within the subcoeruleus-nucleus bilaterally (r=0.943, p=0.016; r=-0.917, p=0.028; right and left, respectively), the in ferior medullary-reticular-formationbilaterally (r=0.891, p=0.043, and r=0.899, p=0.038, left and right), and with T2*-weighted values within the right inferior medullary-reticular-formation(r=0.882, p=0.048). The FDS index correlated with T1-weighted values within the inferior medullary-reticular-formation bilaterally (T1-weighted left r=0.998, p=0.002, right r=0.995, p=0.005; T2* weighted right r=0.986, p=0.014).
Conclusions: Correlation between microstructural changes in the subcoeruleus nucleus and the medullary reticular formation and RWA indices in iRBD support the role of these nuclei in regulation of motor activity during REM sleep, supporting the concept of RWA as biomarker of neurodegeneration.

CONDITIONAL DIFFUSION MODEL-BASED MRI SUPERRESOLUTION ENHANCES ALZHEIMER'S DISEASE CLASSIFICATION

POSTERS: A04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Youho Myong[1,2], Dan Yoon[3], Young Gyun Kim[3], Yongsik Sim[4], Byung-Mo Oh[2], Sungwan Kim[5]
[1]Seoul National University, Department Of Biomedical Engineering, Seoul, Korea, Republic of, [2]Seoul National University Hospital, Department Of Rehabilitation Medicine, Jongno-gu, Korea, Republic of, [3]Seoul National University, Interdisciplinary Program In Bioengineering, Jongno-Gu, Korea, Republic of, [4]Severance Hospital, Department Of Radiology, Seoul, Korea, Republic of, [5]Seoul National University, Department Of Biomedical Engineering, Jongno-Gu, Korea, Republic of

Aims: To evaluate a novel conditional diffusion model-based MRI superresolution (SR) offers superior image quality than conventional SR, and if they can enhance AI-based Alzheimer's disease (AD) classification performance.
Methods: Two networks were trained. Firstly, a U-Net-based network produced conventional SR images (c3T*). The network comprised two branches: dilated kernels for overall feature extraction and Hough Transformation for detailed feature extraction. The second network employed cDM, integrating U-shaped multi-stream networks with a multi-encoder to produce cDM-based SR images (d3T*) as in Figure 1. Both networks were trained on a subgroup (n=170) of Alzheimer's disease neuroimaging initiative data with both 1.5T and 3T T1WI from the same individuals taken at the same visit. The quality of source, c3T*, and d3T* images were evaluated using peak signal-to-noise ratio (PSNR), Structural Similarity Index (SSIM), Natural Image Quality Evaluator (NIQE), and Blind/Referenceless Image Spatial Quality Evaluator (BRISQUE). To determine if d3T* enhanced AD classification, a U-Net-based AD classifier was employed to classify healthy and AD brains. Classifier performance was evaluated using accuracy, precision, specificity, sensitivity, Matthews Correlation Coefficient (MCC), F1-score, and AUROC.

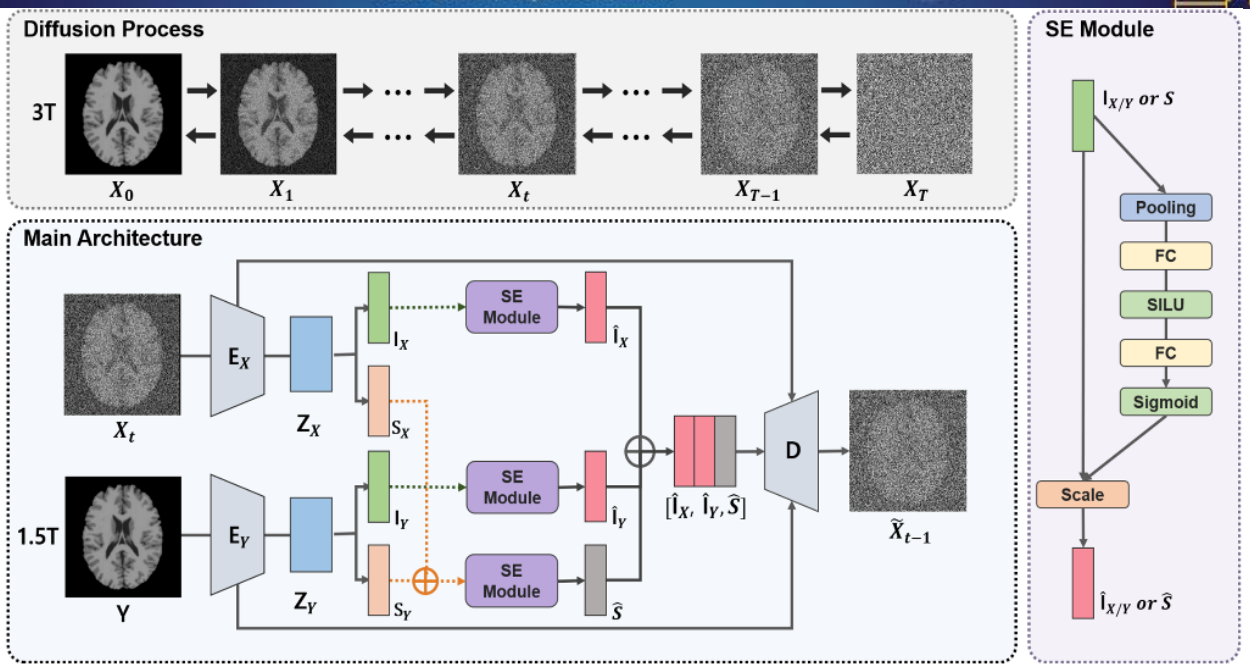

Figure 1. d3T* architecture

Results: Example source, c3T*, and d3T* images are shown in Figure 2. d3T* showed superior image quality than original source or c3T*, comparable to the 3T ground truth (Table 1, Figure 3). When given as input to AD classifier, d3T* MRI resulted in better classification performance than 1.5T images or c3T* counterparts (Table
2).

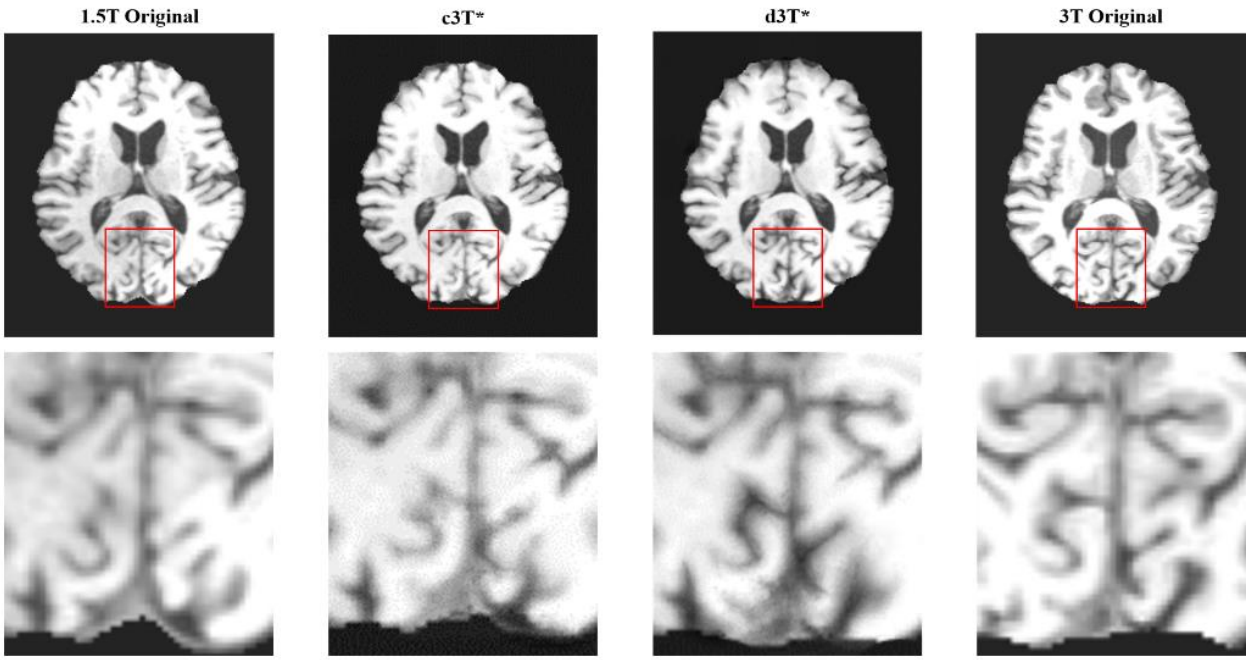

Figure 2. Example source and SR images

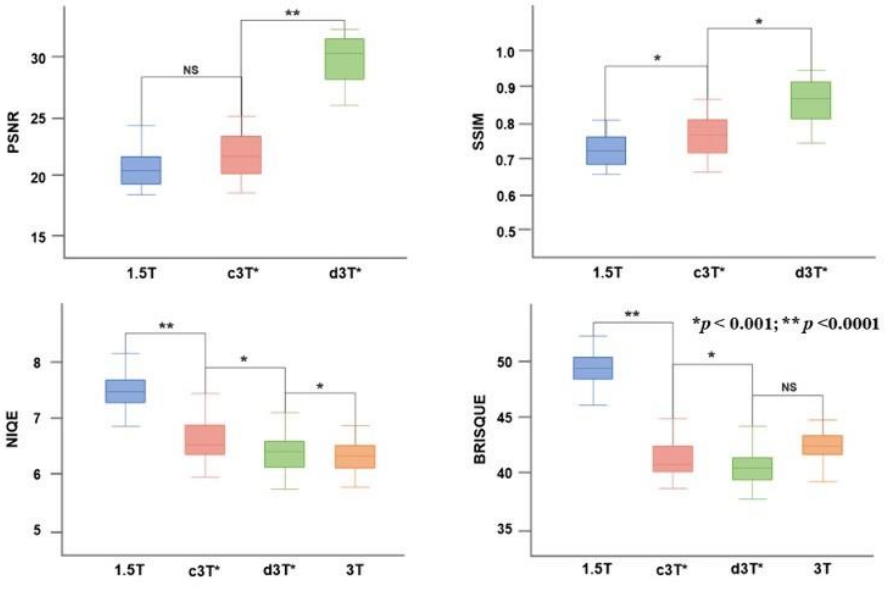
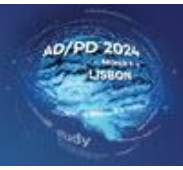


* For PSNR & SSIM, higher values mean better image quality; for NIQE & BRISQUE, lower values mean better quality.

Figure 3. Image quality metrics among source and SR images

Table 1. Alzheimer's Disease Classification Performance

Input	Accuracy	AUROC	Precision	MCC	F1 Score	Sensitivity	Specificity
1.5T	0.87	0.79	0.83	0.68	0.75	0.71	0.94
c3T*	0.83	0.84	0.67	0.63	0.75	0.86	0.81
d3T*	0.91	0.90	0.86	0.79	0.86	0.86	0.94



Conclusions: cDM-based MR SR may be a valuable tool to augment AI-aided AD diagnosis.

GENETIC RISKS OF ALZHEIMER'S BY APOE AND MAPT ON CORTICAL MORPHOLOGY IN YOUNG HEALTHY ADULTS

POSTERS: A04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Li Su
University of Cambridge, Psychiatry, Cambridge, United Kingdom

Aims: Genetic risk factors such as APOE ε4 and MAPT (rs242557) A allele are associated with amyloid and tau pathways and grey matter changes at both early and established stages of Alzheimer's disease, but their effects on cortical morphology in young healthy adults remain unclear.
Methods: 144 participants aged 18 to 24 underwent 3T MRI and genotyping for APOE and MAPT to investigate unique impacts of genetic risk factors in a cohort without significant comorbid conditions such as metabolic and cardiovascular diseases. We segmented the cerebral cortex into 68 regions and calculated the cortical area, thickness, curvature, and folding index. Then, we trained machine learning models to classify APOE and MAPT genotypes using these morphological features. In addition, we applied a growing hierarchical self-organizing maps algorithm, which clustered the 68 regions into 4 subgroups representing different morphological patterns. Then, we performed general linear model analyses to estimate the interaction between APOE and MAPT on cortical patterns.
Results: We found that the classifiers using all cortical features could accurately classify individuals carrying genetic risks of dementia outperforming each individual feature alone. APOE ε4 carriers had more convoluted and thinner cortex across the cerebral cortex. A similar pattern was found in MAPT A allele carriers only in the regions that are vulnerable for early tau pathology. With the clustering analysis, we found a synergetic effect between APOE ε4 and MAPT A allele i.e., carriers of both risk factors showed the most deviation of cortical pattern from the typical pattern of that cluster.
Conclusions: Genetic risk factors of dementia were associated with variations of cortical morphology, which can be observed in young heathy adults more than 30 years before pathology and 50 years before symptoms may begin.

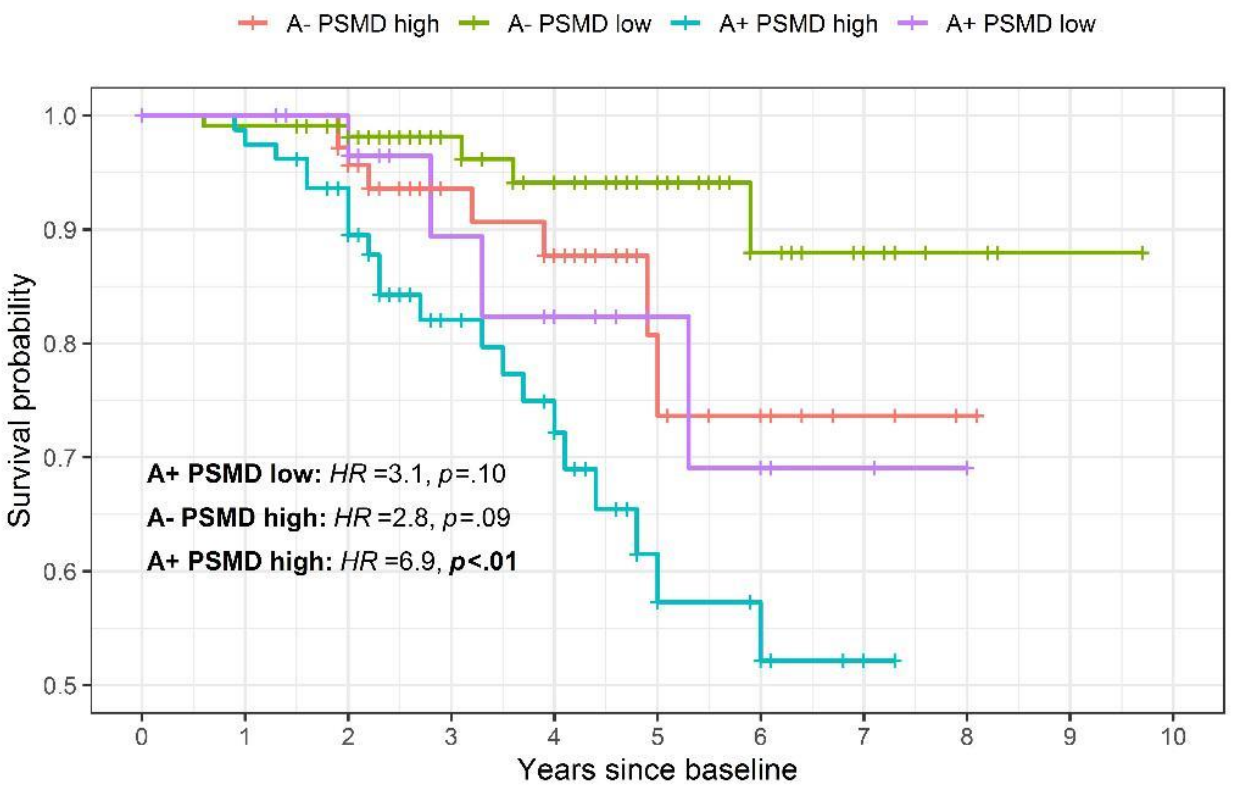
IMPROVING DEMENTIA PROGRESSION PREDICTION: THE ADDED VALUE OF PSMD BEYOND AMYLOID STATUS

POSTERS: A04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Sandra Tecelão[1], Bjørn-Eivind Kirsebom[1,2], Lene Pålhaugen[1,3], Atle Bjørnerud[4,5], Per Selnes[1,3], Tormod Fladby[1,3]
[1]Akershus University Hospital, Department Of Neurology, Lørenskog, Norway, [2]University Hospital of North Norway, Department Of Neurology, Tromsø, Norway, [3]Institute of Clinical Medicine, Campus Ahus, University Of Oslo, Lørenskog, Norway, [4]Department of Diagnostic Physics, Oslo University Hospital, Oslo, Norway, [5]Department of Physics, University Of Oslo, Oslo, Norway

Aims: Studies have shown the potential of Peak width of Skeletonized Mean Diffusivity (PSMD) as a neuroimaging marker for cerebral small vessel diseases (cSVD). Considering cSVD's significant role in vascular-related cognitive decline, this study aims to verify whether PSMD can predict the risk of MCI/dementia progression beyond amyloid (A) status.
Methods: 176 subjects from the Dementia Disease Initiation cohort (88 cognitively unimpaired (CU) and 88 with mild cognitive impairment (MCI) at baseline) underwent 1 to 5 evaluations, resulting in 462 observations. Baseline PSMD was computed from DTI images acquired on 5 different scanners. Scanner effect correction was done using ComBat harmonization in R, with age and sex as covariates. Harmonised baseline PSMD was divided into 'PSMD low' and 'PSMD high' for values below and above the median respectively. Baseline A status was determined from Amyloid PET or from Abeta42/40 ratio. Results were categorized as A- PSMD low, A- PSMD high, A+ PSMD low and A+ PSMD high. Survival function was performed using the "survival" package from R, with progression from CU to MCI/dementia as the event of interest. Hazard ratios were assessed with the Cox proportional-hazards model with age and A status/PSMD at baseline and sex as covariates.
Results: show that individuals with A+ PSMD high have a 6.9-fold higher risk of MCI/dementia progression compared to A- PSMD low ($p<0.01$). A+ PSMD low increases the risk by 3.1-fold ($p = 0.10$), while A- PSMD high results in a 2.8-fold higher risk ($p = 0.09$) (Figure 1).



Conclusions: These findings suggest that a combination of PSMD and A status has the potential to improve the prediction of MCI/dementia progression, and that a combination of these risk factors more than doubles the risk of progression.

WHOLE BRAIN BETA-AMYLOID DETECTION BY HIGH-RESOLUTION QUANTITATIVE SUSCEPTIBILITY MAPPING

POSTERS: A04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Nian Wang
Indiana University, Radiology And Imaging Sciences, Indianapolis, United States of America

Aims: To detect and quantify the beta-amyloid plaques through the whole mouse brain using high-resolution Quantitative susceptibility mapping (QSM).
Methods: Animal experiments were carried out in compliance with the local IACUC Committee. The B6, 5xFAD, 5xFAD^{P522R}, and 5xFAD^{M28L} mice were chosen for brain imaging. The specimens were scanned at 9.4T scanner using a modified 3D multi-gradient echo pulse sequence . The phase data from the MGRE acquisition was used to reconstruct QSM images using STI Suite. The magnetic susceptibility was then obtained from the local tissue phase by solving an inverse problem using the improved LSQR (iLSQR) method.
Results: Figure 1. The representative T2*-weighted images of both WT (B6) and AD (5xFAD) mice. Compared to B6, there are hyperintensities areas in 5xFAD
mice.

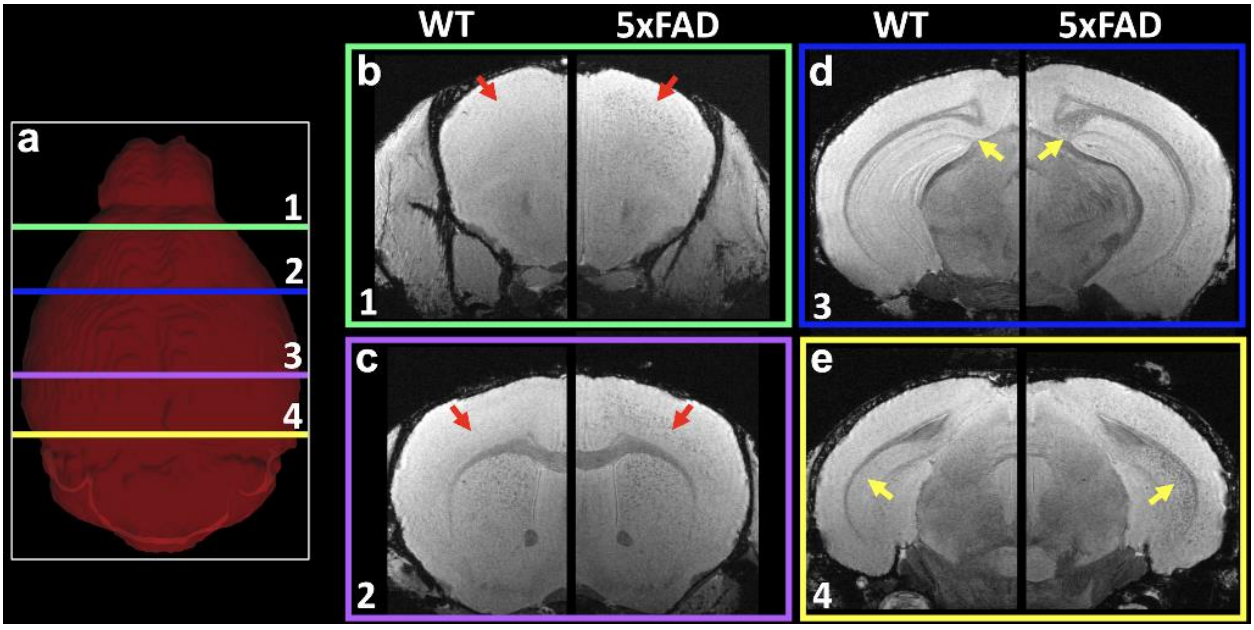

Figure 2. The plaque loading is comparable between QSM and conventional histology.

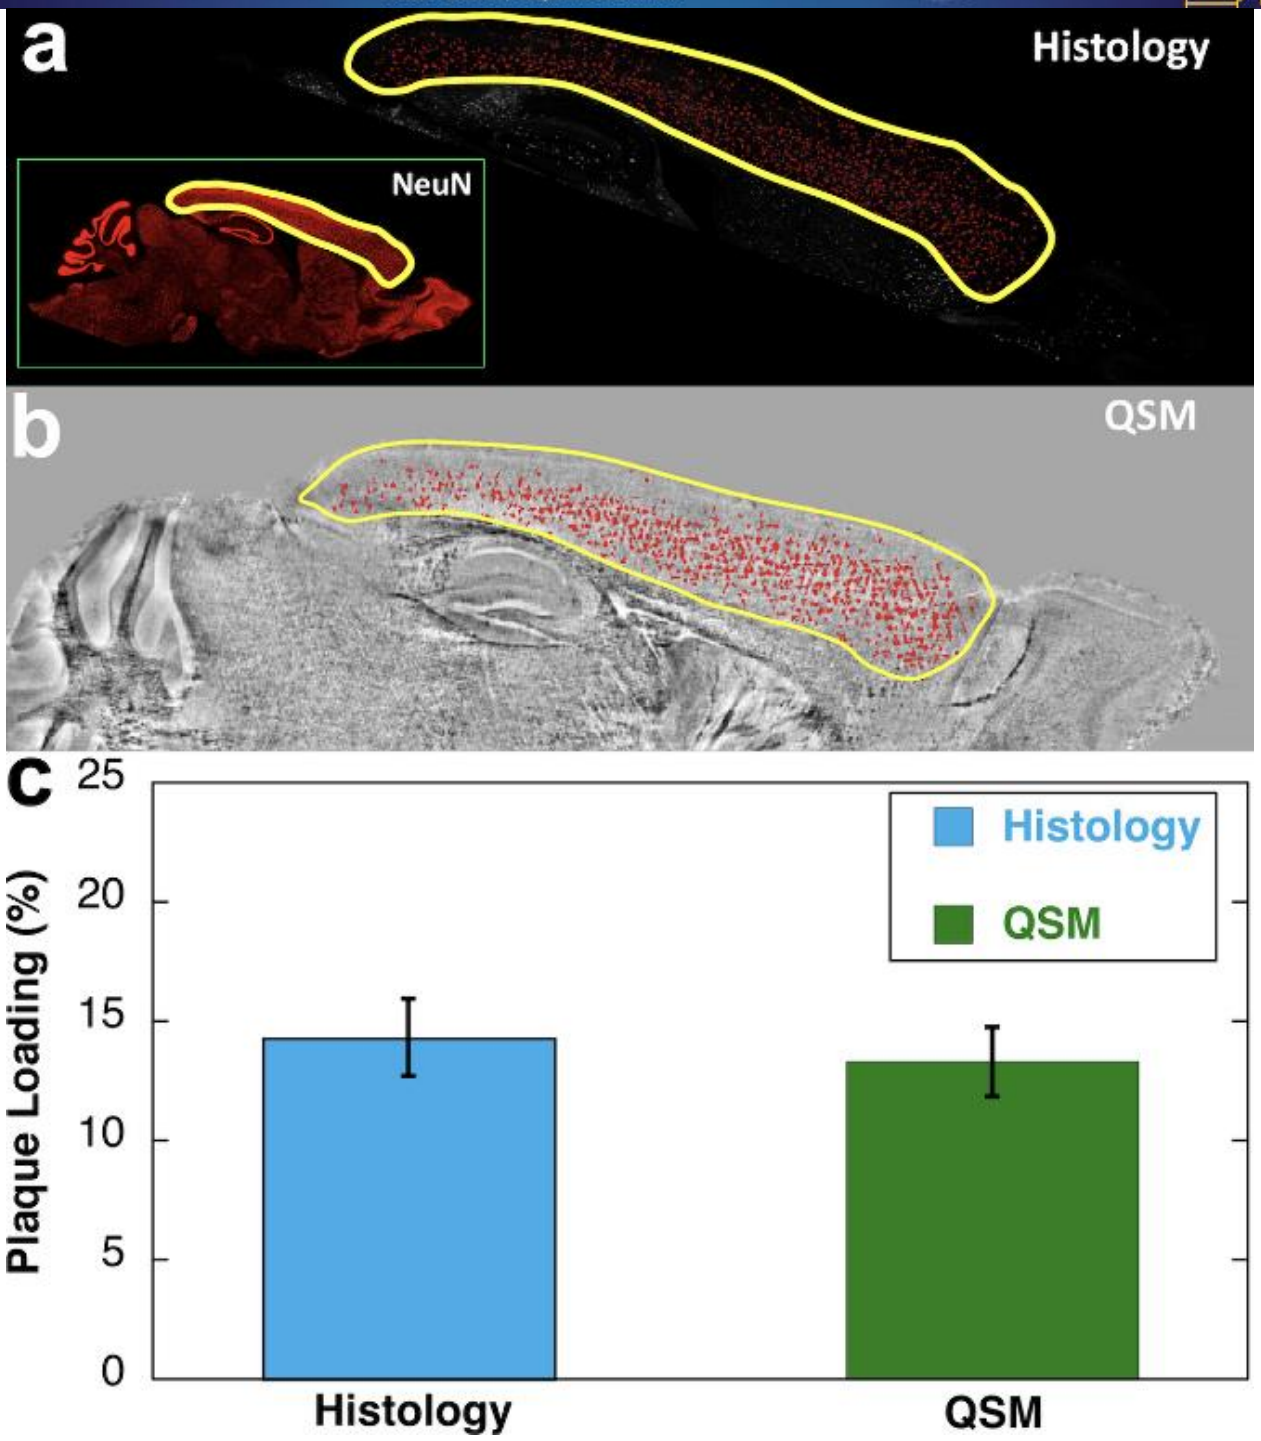

Figure 3. The QSM and T2* map of the 5xFAD mice.

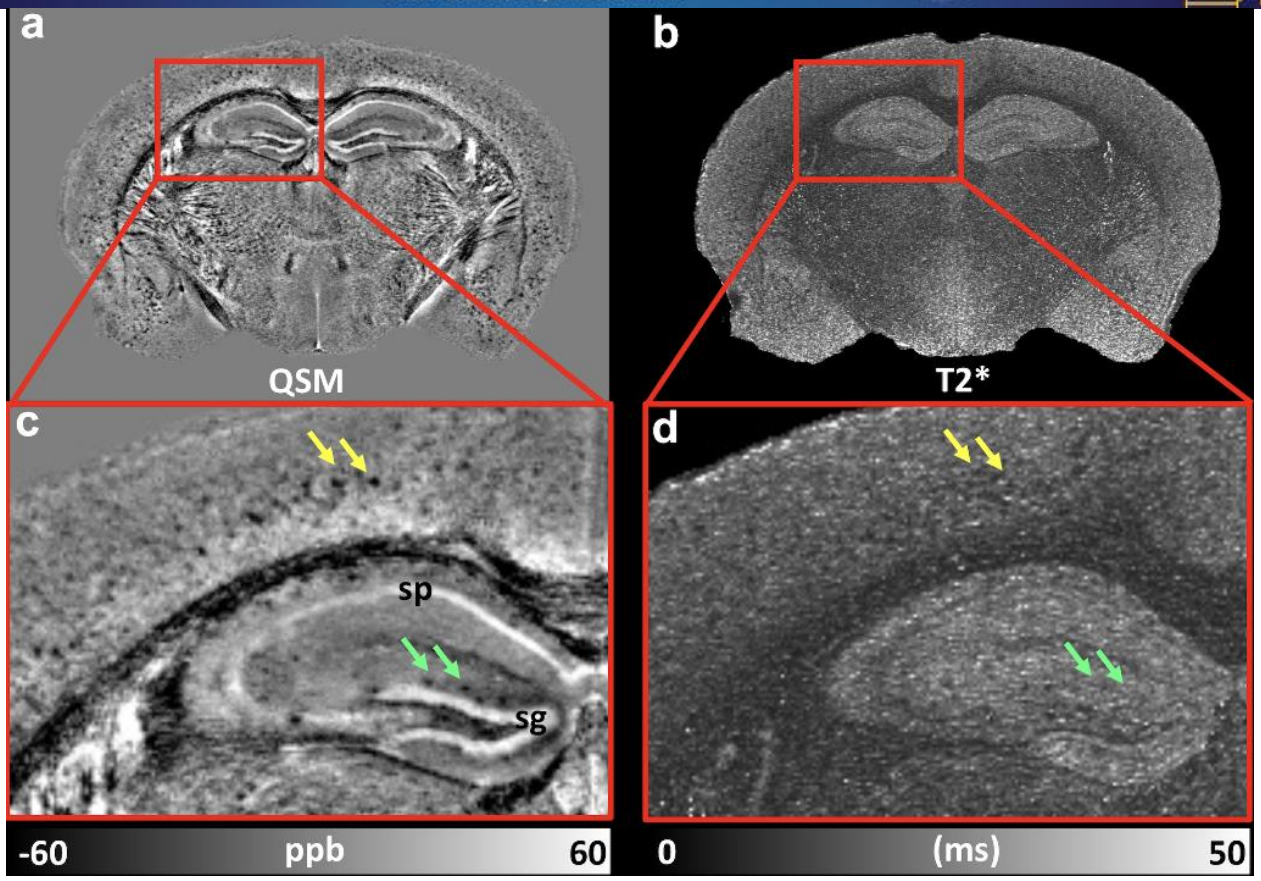

Figure 4. The plaque loading in 5xFAD, 5xFAD^{M28L}, and 5xFAD^{P522R}.

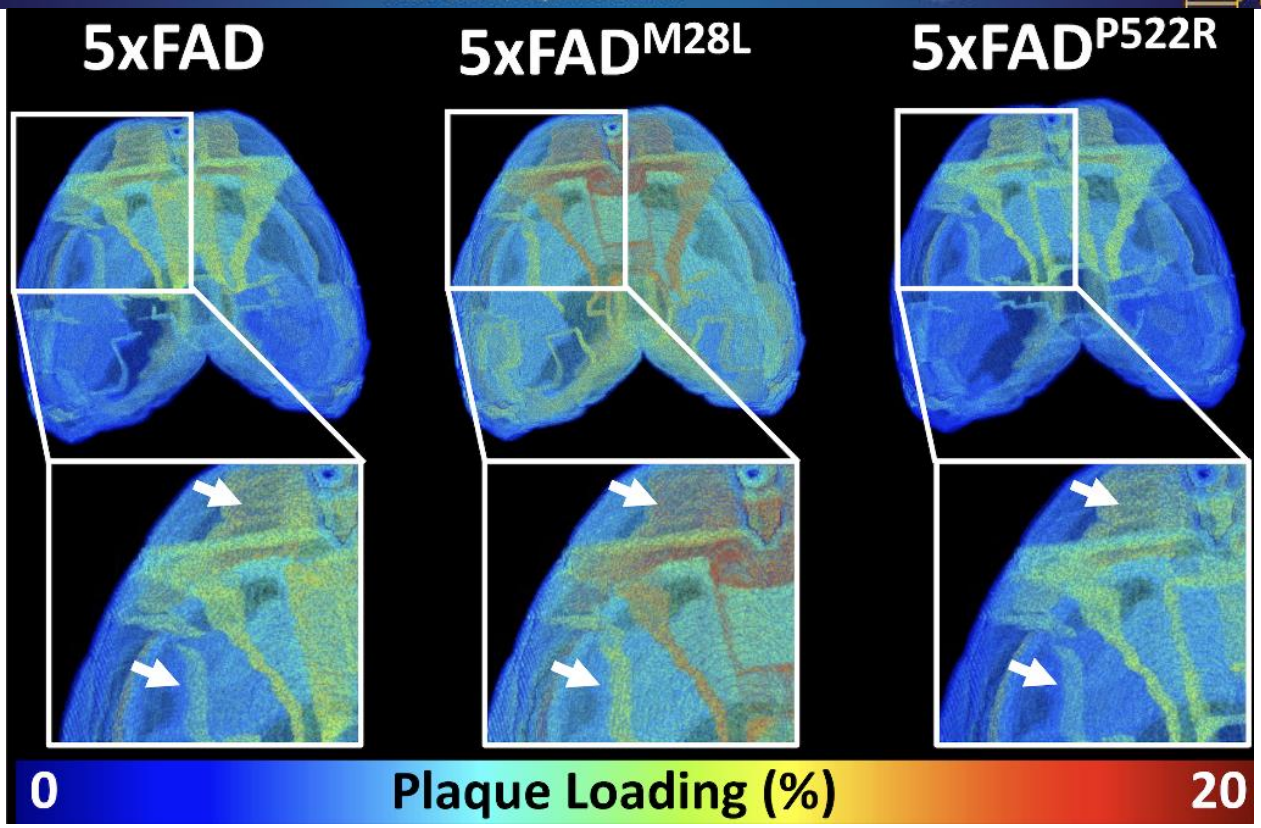

Conclusions: Although the cause of AD is not fully understood, clinical and neuropathological studies have hypothesized that the formation of beta-amyloid (Aβ) plaques and tau neurofibrillary tangles are crucial to the pathogenesis of AD. It has been reported that Amyloid plaque is one of the earliest hallmarks of AD and can occur up to 20 years before clinical diagnosis. In this study, we demonstrated that high-resolution QSM can be used to detect the individual beta-amyloid plaque through the whole mouse brain. We also showed that plaque loading is different in AD risk variant (M28L) mice and AD protective variant (P522R), which suggested that QSM may be a sensitive imaging-based biomarker to detect and monitor AD progression and understand the complicated mechanism of AD.

COGNITION AND BRAIN STRUCTURE IN COGNITIVELY ACTIVE PEOPLE

POSTERS: A04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Clara Iñesta, Javier Oltra-Cucarella, Esther Sitges-Maciá, Beatriz Bonete-López
Universidad Miguel Hernández de Elche, Departamento De Psicología De La Salud, Elche, Spain

Aims: Aging is associated with cognitive alterations that lead to dementia. The cognitive reserve hypothesis suggests that people with higher cognitive performance have a lower risk of developing cognitive decline or dementia. Therefore, it is important to study people with high cognitive reserve to identify protective factors against dementia. Previous works found that older people who attend university programs for Seniors are involved in more cognitively stimulating activities than people from the general population and might have better preserved cognitive function through an increased cognitive reserve. This work aims to analyze the association of cognition and brain structure in cognitively active older people through a neuropsychological battery and structural magnetic resonance imaging (MRI) data.
Methods: Data on brain structure and cognitive functioning of 40 people (30 women, 75%) over 55 years of age enrolled in university courses at the Miguel Hernández University of Elche are presented.
Results: The mean age was 68.9 (SD=6.14) and the mean educational level was 13.47 (SD=3.89). All participants were evaluated using a neuropsychological battery and underwent an MRI study to identify brain volume. In this sample, age was associated with the volume of the bilateral putamen, the bilateral accumbens, and the left hippocampus. Education was associated with the left pallidum and hippocampus. Left hemisphere brain volume and total brain volume were associated with processing speed, semantic memory, and naming, but not with episodic memory. Right brain volume was associated with semantic memory. Brain volume was not associated with the risk of presenting one or more low scores ($p = .150 - .273$)
Conclusions: A preserved processing speed could be key to preserving better cognitive functioning in older people, regardless of the brain volume of memory-related structures.

ALTERED BRAIN NETWORK DYNAMICS IN THE RESTING-STATE AND BEHAVIOURAL CORRELATIONS IN THE TGF344-AD RAT MODEL OF ALZHEIMER'S DISEASE

POSTERS: A04.B. IMAGING, BIOMARKERS, DIAGNOSTICS: FUNCTIONAL MRI

Sam De Waegenaere[1,2], Alya Al-Awlaqi[1,2], Lori Berckmans[1,2], Ignace Van Spilbeeck[1,2], Marleen Verhoye[1,2], Mohit Adhikari[1,2]
[1]University of Antwerp, μneuro Research Centre Of Excellence, Antwerpen, Belgium, [2]University of Antwerp, Bio-imaging Lab, Antwerpen, Belgium

Aims: A network-level perspective has gained prominence in Alzheimer's Disease (AD), besides the molecular approach, emphasizing dynamic brain region interactions. By evaluating these interactions, resting-state functional magnetic resonance imaging (rsfMRI) offers insights into AD's functional deficits. We studied AD's functional impact at different stages in the TgF344-AD rat model using rsfMRI functional connectivity (FC), transient co-activation patterns (CAPs), and behavioural readouts.
Methods: 15 TgF344-AD and 15 wildtype rats underwent anesthetised (isoflurane/medetomidine) rsfMRI scans at 4 (pre-plaque) and 10 (plaque stage) months using a 9.4T MRI-system. Post 10-month scans, we assessed learning and memory using a radial arm maze. After pre-processing the scans, regional and network-level FC was calculated. We obtained CAPs by concatenating pre-processed images from all scans and clustering individual volumes by spatial similarity. Group and age effects on FC, spatial and temporal properties of the CAPs were assessed using repeated measures ANOVA. Behavioural learning curves were analysed and correlated with FC. We evaluated the accuracy of CAP features to classify the animals according to genotypes and ages.
Results: We identified six CAPs (Fig.1A) and observed functional hyperactivation and hypoactivation in the TgF344-AD rats of the default mode-like network (DMLN), especially in the hippocampus and frontal DMLN regions, at the pre-plaque and plaque stages respectively in CAP 1 and 6 (Fig1D,E). Spatial properties of CAPs predicted the pre-plaque transgenic group most accurately and showed confusion between genotypes at the post-plaque stage (Fig2). Behaviourally, transgenic rats showed memory impairments correlating with FC changes in the lateral-cortical network (LCN) (Fig3).

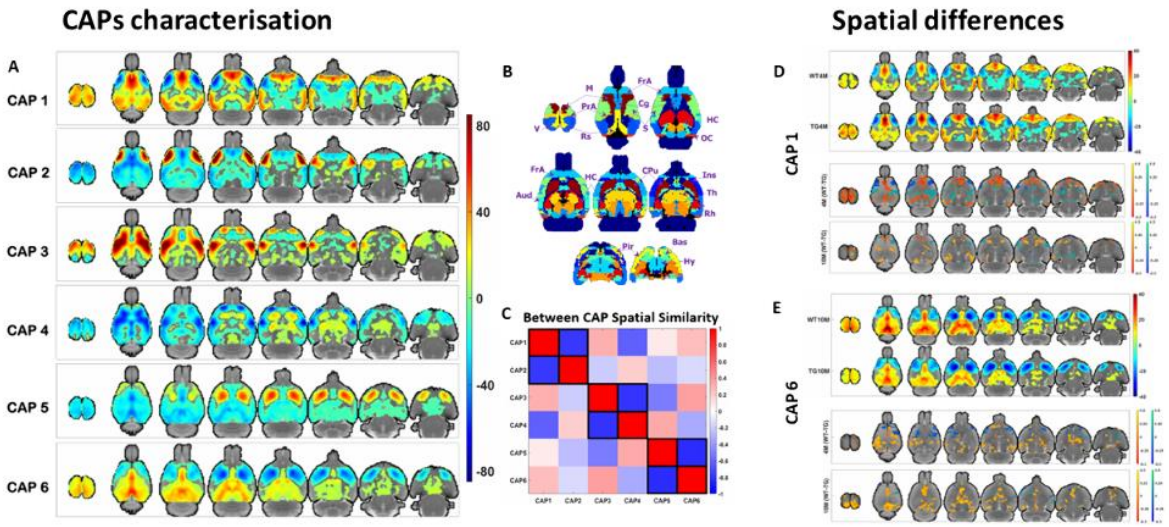

Figure 1. CAP spatial characteristics and differences. (A) Voxels with significant (de)activation levels ($p < 0.01$; Bonferroni corrected). **(B)** Anatomical reference atlas. **(C)** Correlation matrix showing distinct CAP anti-CAP pairs. **(D, E)** (Top panels) Age-wise genotype 1-sample t-tests and (bottom two panels) post-hoc comparisons after 2-way ANOVA between genotypes at pre-plaque and plaque stages (FDR corrected; $p < 0.05$)

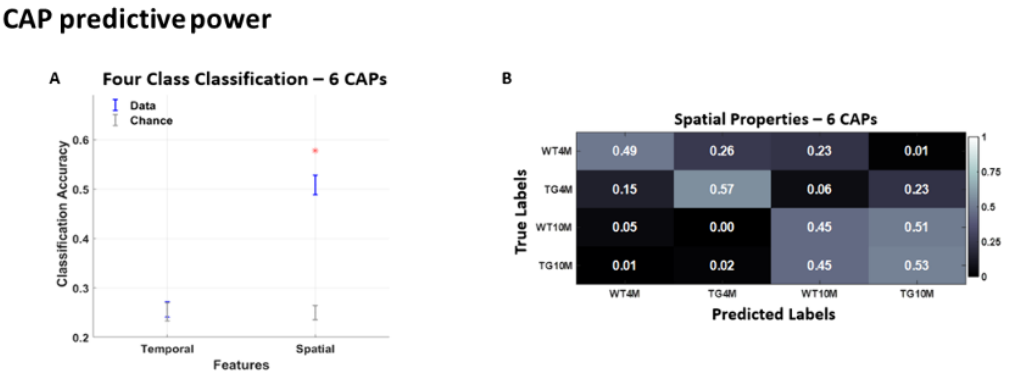

Figure 2. CAP classification analysis. (A) Classification accuracy for different CAP features (mean +/- SEM). Temporal features consist of CAP duration and occurrence rate, spatial features correspond to BOLD intensities of voxels whose activations within the corresponding group-level CAP were found to be significantly different from zero. Red asterisk: significantly higher than chance-level (FDR corrected, $p < 0.05$). **(B)** Confusion matrix using spatial properties.

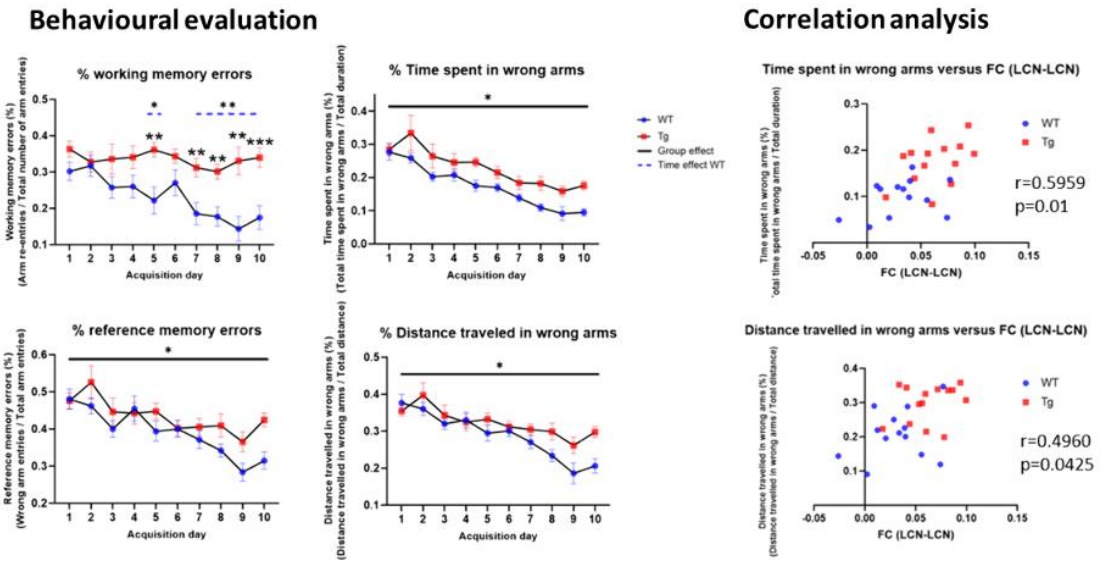

Figure 3. Behavioural evaluation through radial arm maze (RAM) test. (A-D) Learning curves of the RAM. Mean ± SEM is shown. *p ≤0.05, **p ≤0.01, ***p ≤0.001 (repeated measures 2-way ANOVA). **(E, F)** Scatterplots for behavioural parameters on day 10 that correlated significantly with the within LCN FC in 10-month-old rats.

Conclusions: Our findings demonstrate hyper- and hypo-activations of DMLN regions in transient brain-states at pre- and post-plaque stages respectively in transgenic animals. Behavioural readouts correlate with functional connectivity, emphasising a network perspective in AD understanding.

Aims: While promising blood biomarkers for brain Alzheimer's disease (AD)-type Aβ pathophysiology now exist, there is an unmet need for a biomarker that tracks neurodegenerative changes in AD. Neurofilament light chain (NfL) is a general marker of neurodegeneration/axonal injury across multiple disorders. Total-tau (t-tau) has very large overlaps between AD, non-AD dementias and control groups to be diagnostically useful. We recently presented a novel blood-based neurodegeneration biomarker brain-derived tau (BD-tau) that showed higher levels in biomarker-confirmed AD versus non-AD dementia and unaffected controls.
Methods: In the present study we examined plasma NfL, T-tau and BD-tau associations with longitudinal cognition and AD-signature atrophy rates in the Dementia Disease Initiation (DDI) cohort (n=364) which includes patients in early stages of the AD continuum. Longitudinal linear mixed models were fitted to assess associations between biomarkers at baseline and the pertinent dependent variable (cognition or MRI) over time
Results: Plasma BD-tau, but not plasma t-tau or NfL, was significantly associated with future AD meta-Region of Interest (ROI) atrophy (b=-0.06, p<0.01). Moreover, plasma BD-tau was associated with baseline performance on both the Consortium to Establish a Registry for Alzheimer's Disease (CERAD) memory recall and the Trail Making Test-B (TMT-B); b=-0.16, p<.001 and b=0.12, p<.01 respectively), as well as the longitudinal worsening in performance on both tests over up to 8 years later (b=-0.05, p<.05; b=0.04, p<.001 respectively). Plasma NfL was not associated with baseline cognitive performance on either CERAD memory recall or TMT-B.
Conclusions: Plasma BD-tau was the only marker associated with future AD meta-ROI atrophy and both baseline and cross-sectional performances on the CERAD and TMT-B. Together, these results show that plasma BD-tau associates with brain neurodegenerative signatures that interact with Aβ pathophysiology to synergistically drive cognitive decline.

VALIDATION OF THE AUTOMATED CENTILOID SCALE UTILIZATION IN MULTIPLE B-AMYLOID PET TRACER QUANTIFICATION

POSTERS: A04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - AMYLOID

Yeong Sim Choe, Hye Weon Kim, Min-Woo Lee, Hajin Kim, Jiyeon Lee, Zunhyan Rieu, Minho Lee, Donghyeon Kim, Regina Kim
NEUROPHET Inc., Research Institute, Seoul, Korea, Republic of

Aims: The Centiloid scale was introduced to standardize the quantification of β-amyloid PET tracers in Alzheimer's disease. However, the original method requires technical expertise and manual parameter calibration. An automated Centiloid scale that process results within 5 minutes is currently accessible, and we aimed to validate the feasibility of the automated Centiloid scale in comparison to the original method employed in the Centiloid Project.
Methods: We used 286 participants who underwent amyloid PET (^{11}C-PiB, ^{18}F-Florbetaben, ^{18}F-Flutemetamol, ^{18}F-Florbetapir, and ^{18}F-NAV4694) and 3D T1-weighted MRI scans obtained from GAAIN dataset (https://www.gaain.org/centiloid-project). We processed the SUVR calculation using SCALE PET (Neurophet Inc.) in global cortical regions (frontal, lateral parietal, lateral temporal, cingulate cortices, and striatal regions) with the cerebellum as the reference. Results were then converted to the Centiloid scale by PiB SUVR translation and compared to the original method using MATLAB R2018a (SPM12).
Results: Our results showed a strong correlation with the original method (slope = 1.00, intercept = 0.02 R^2 = 0.99). Individual tracers showed varying slopes when comparing their SUVR values to PiB SUVR. Notably, ^{18}F-NAV4694 showed a slope closest to 1.0 (0.997), while ^{18}F-Florbetapir showed a more distant value (0.51). After converting SUVR to the Centiloid scale, most tracers displayed high R^2 values (0.89 to 0.99), slopes (1.00 to 1.07), and intercepts (0.14 to 2.52) when compared to the original Centiloid scales. Except for ^{18}F-Florbetapir, which had a large intercept (2.52), other tracers affirmed their suitability as Centiloid scales by showing intercept below 2.0 (^{18}F-Florbetaben: 0.46, ^{11}C-PiB: 0.82, ^{18}F-Flutemetamol: 1.07, ^{18}F-NAV4694: 1.90).
Conclusions: The automated Centiloid scale has been validated for its applicability in comparison to the original method with various amyloid tracers, providing time-saving benefits and accessibility for various users.

SYNTHESIS AND PET IMAGING BIODISTRIBUTION STUDIES OF A NEW RADIOLABELED IODODIFLUNISAL, A TRANSTHYRETIN TETRAMER STABILIZER, CANDIDATE DRUG FOR ALZHEIMER'S DISEASE

POSTERS: A04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - AMYLOID

Gemma Arsequell[1], Sameer Joshi[2], Thomas Wilson[3], Zibo Li[4], Vanessa Gómez Vallejo[5], Veronique Gouverneur[3], Jordi Llop[5]
[1]Institute of Advanced Chemistry of Catalonia (IQAC-CSIC), Biological Chemistry, Barcelona, Spain, [2]The University of North Carolina at Chapel Hill, Department Of Radiology,, North Carolina, United States of America, [3]Chemistry Research Laboratory, Department Of Radiology, Oxford, United Kingdom, [4]Lineberger Comprehensive Cancer Center, The University of North Carolina at Chapel Hill, Department Of Radiology, North Carolina, United States of America, [5]CIC biomaGUNE, Basque Research and Technology Alliance (BRTA), Radiochemistry And Nuclear Imaging Lab, Donostia-San Sebastián, Gipuzkoa, Spain

Aims: Transthyretin (TTR) has a well-established role in neuroprotection in Alzheimer's Disease (AD). Iododiflunisal (IDIF), a TTR tetramer stabilizer, is a chemical chaperone enhancing TTR/Amyloid-beta peptide (Aβ) interactions. Previous studies with this potential disease modifying drug showed that IDIF enhances TTR blood brain barrier penetration and reduces brain amyloidosis *in vivo*. Here, we investigate different strategies for efficient radiolabeling of IDIF in different positions of the molecule for *in vivo* nuclear imaging studies.
Methods: Precursors of IDIF and derivatives of the NSAID diflunisal have been obtained by organic synthesis procedures. Different radioiodination and radiofluorination procedures have been assayed to achieve the synthesis of [^{123}I]IDIF and [^{18}F]IDIF. Dynamic 90-min positron emission tomography (PET) images have been acquired immediately after intravenous administration in mice.
Results: Two new radiolabeled IDIF derivatives, [^{123}I]IDIF and [^{18}F]IDIF, containing either the gamma emitter ^{123}I or the positron emitter ^{18}F, have been independently synthesized. Radioiodination of a pinacol ester (Bpin) of a diflunisal derivative was performed with Na^{123}I using a copper(II)-mediated radioiododeboronation reaction. Initial attempts for the copper-mediated radiofluorination of a labile pinacol ester (Bpin) of an IDIF derivative with [^{18}F]KF/K_{222} in the presence of *tetrakis*(pyridine)copper(II) triflate [$Cu(OTf)_2(py)_4$] were unsuccessful. However, [^{18}F]IDIF could be synthesized from IDIF by isotopic exchange using [^{18}F]KF/K_{222}. PET Biodistribution studies with [^{18}F]IDIF show slow blood clearance, prolonged retention in the liver, progressive elimination via urine and significant brain accumulation. The results are in good agreement with those previously described using [^{131}I]IDIF and dissection/gamma counting.
Conclusions: IDIF can be efficiently radiolabeled with ^{123}I and ^{18}F using copper(II)-catalyzed radioiododeboronation and isotopic exchange reactions, respectively. PET studies confirmed previous biodistribution results obtained with [^{131}I]IDIF, opening opportunities for future studies in larger species or humans.

STRIATUM INVOLVEMENT IS ASSOCIATED WITH MORE PRONOUNCED MEMORY IMPAIRMENT IN AMYLOID PET POSITIVE PATIENTS

POSTERS: A04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - AMYLOID

Jiri Cerman[1], Adela Skorvagova[1], Martin Vyhnálek[2], Jakub Hort[2]
[1]Charles University, 2nd Faculty Of Medicine, Prah, Czech Republic, [2]Second Faculty of Medicine, Charles University, Department Of Neurology, Prague, Czech Republic

Aims: Today, many tools are being investigated with the aim of refining the prognosis of patients with Alzheimer's disease (AD), but none has yet been introduced into clinical practice. One of these is amyloid PET, where recent work has shown that the involvement of subcortical structures, particularly the striatum, is associated with more rapid cognitive decline. Our aim was to build on this work using memory tests specific to AD.
Methods: From a cohort of 60 patients with positive amyloid PET and mild cognitive impairment or mild dementia who also underwent neurological and neuropsychological assessment, volumetric MRI and other tests, a total of 8 patients with negative striatal involvement were identified. These patients were matched for age, education and global cognition (MMSE) to 8 patients with positive striatal involvement from the same cohort and their results in Enhanced cued recall test (ECR; a short picture version of Free and Cued Selective Reminding Test) were compared. PET images were evaluated visually using the GM-EDGE method.
Results: Amyloid PET positive patients with striatal involvement had significantly worse performance on the ECR free recall test compared to patients with unaffected striatum ($p=0.027$; $F=6.089$), although performance on the global cognition test (MMSE) did not differ ($p=0.514$; $F=0.447$). There was no difference in ECR total recall possibly due to its ceiling effect ($p=0.238$; $F=1.554$).
Conclusions: Amyloid PET positive patients with MCI or mild dementia who also have striatal involvement have more pronounced impairment in free recall FCSRT compared to patients with negative striatal impairment. This is consistent with previous data. Further and also longitudinal data are however needed to evaluate the use of amyloid PET in prognostic assessment of AD patients.

ETHNIC DIFFERENCES IN AMYLOID PET POSITIVITY AND COGNITIVE TRAJECTORIES RELATED TO ALZHEIMER'S RISK FACTORS

POSTERS: A04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - AMYLOID

Min Young Chun[1,2,3], Hyemin Jang[1], Jihwan Yun[1], Jun Pyo Kim[1], Hee Jin Kim[1], Duk L Na[1], Sook-Young Woo[4], Sang Won Seo[1]
[1]Samsung Medical Center, Sungkyunkwan University School of Medicine, Department Of Neurology, Seoul, Korea, Republic of, [2]Yonsei University College of Medicine, Department Of Neurology, Seoul, Korea, Republic of, [3]Yongin Severance Hospital, Yonsei University College of Medicine, Department Of Neurology, ongin-si, Gyeonggi-do, Korea, Republic of, [4]Samsung Biomedical Research Institute, Biostatistics Team, Seoul, Korea, Republic of

Aims: Ethnic differences in amyloid-β (Aβ) marker characteristics and in cognitive trajectories related to Alzheimer's risk factors should be considered when recommending Aβ targeted therapies in various ethnic populations. We aimed to investigate the prevalence of Aβ (+) and cognitive trajectories related to Alzheimer's risk factors in two separate cohorts of Koreans and non-Hispanic whites (NHWs).
Methods: In the cross-sectional study, we included 3,785 Koreans from multiple centers in Korea and 914 NHWs from the Alzheimer's Disease Neuroimaging Initiative. In the longitudinal study, we followed 1,130 Koreans and 1,130 NHWs who were matched for cognitive stage and age between Koreans and NHWs using the Mini-mental State Examination (MMSE) scores. All participants underwent Aβ PET scans, and were categorized into three cognitive stages: cognitively unimpaired (CU), amnestic mild cognitive impairment (aMCI), and dementia of the Alzheimer type (DAT).
Results: In the cross-sectional study, in the CU stage, the odds of Aβ (+) in Koreans compared to NHWs were lower (odds ratio [OR], 0.521), while those did not differ in the aMCI and DAT stages. The effects of *APOE* ε4 on Aβ (+) seemed to be greater in NHWs (adjusted OR [aOR], 14.0) than in Koreans (aOR, 5.9) in the DAT stage, but not in the CU stage. In the longitudinal study, Aβ (+) Koreans showed a faster decline in MMSE compared to Aβ (+) NHWs ($p < 0.001$). Sex, *APOE*, and education levels had less pronounced impacts on cognitive trajectories in Aβ (+) Koreans than in Aβ (+) NHWs over time (p-for-interaction < 0.001).
Conclusions: Ethnic differences in the prevalence of Aβ (+) and in cognitive trajectories related to Alzheimer's risk factors highlight the consideration of ethnicity for developing the Aβ-targeted treatment strategy.

PREDICTING GLOBAL AND REGIONAL TAU TANGLES USING AMYLOID PET, PLASMA PTAU 181, AND COGNITIVE ASSESSMENTS

POSTERS: A04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - AMYLOID

Viswanath Devanarayan, Arnaud Charil, Pallavi Sachdev, Harald Hampel, Lynn Kramer, Shobha Dhadda, Michael Irizarry
Eisai, Inc., Clinical Evidence Generation, Nutley, United States of America

Aims: Objectives: This study aims to develop and validate prediction models for detecting whole cortical and regional Tau tangles, facilitating clinical and research studies lacking Tau-PET scans, and minimizing screen failures.
Methods: Methods: We analyzed MK6240 Tau-PET SUVR data from a clinical trial training cohort of 354 amyloid-positive early AD patients. Global and Braak stage-specific Tau positivity thresholds were established using 52 cognitively unimpaired individuals from the Lantheus/Cervaux cohort through robust one-sided 95% upper confidence limits. Bayesian models were built to predict global Tau positivity and Tau tangles across Braak stages 1-6. Predictors included amyloid-PET Centiloid (CL), cognitive assessments (sub-scores and composites of CDR-SB, ADAS-Cog-13, and MMSE), and plasma pTau181, alongside demographics and ApoE4 status. Prediction performance was evaluated via internal cross-validation (IV) within the training cohort and external validation (EV) using an independent ADNI cohort of 243 subjects with the Flortaucipir tracer.
Results: R**esults:** Global Tau positivity prediction with amyloid-PET CL achieved AUROCs of 81% (IV) and 80% (EV). This matched performance obtained by combining cognitive assessments and plasma pTau181 (AUROCs: IV 77%, EV 81%) and surpassed individual predictors. For Braak stage prediction, a separate model using amyloid-PET CL effectively distinguished earlier from later stages (Braak 0-2 vs. 3-6; AUROCs: IV 90%, EV 87%) and performed well in advanced Braak-6 stage (AUROCs: IV 79%, EV 83%). The combination of pTau181 and cognitive assessments also accurately predicted Tau across Braak 0-2 versus 3-6 (AUROCs: IV 88%, EV 80%) and Braak-6 (AUROCs: IV 74%, EV 72%).
Conclusions: Conclusion: Global Tau presence and Braak-staging can be predicted accurately using amyloid-PET CL, plasma pTau181, and cognitive assessments. Validated across different Tau-PET tracers, these models enhance the efficiency of Tau-PET screening, benefiting clinical and research endeavors.

AN AUTOMATED PIPELINE FOR CENTILOID QUANTIFICATION OF AMYLOID-B USING MULTIPLE 11C-PIB-PET AND 18F- PET TRACERS

POSTERS: A04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - AMYLOID

Elizabeth Gordon, Ayoub Gueddou, Mathilde Borrot, Luca Villa, Thomas Jubault, Nicolas Guizard
Qynapse, Clinical Science, Paris, France

Aims: To develop and validate a single and fully automated Centiloid quantification pipeline for multiple amyloid PET compounds in support of standardizing multi-site investigations.
Methods: QyScore®'s fully-automated pipeline was validated on ^{11}C-PiB-PET images from the Centiloid project (https://www.gaain.org/centiloid-project): 34 young controls [age=31.5±6.3 years] and 47 AD patients [age=67.5±10.5 years; CDR= 0.5–1]. ^{18}F tracers included Florbetapir (FBP, N=46), Florbetaben (FBB, N=35), Flutemetamol (FTM, N=74) and NAV4694 (NAV, N=55) validation datasets from the project. PET/MR image pairs were co-registered to MNI template space. The standardized uptake value ratio (SUVr) was computed as the ratio of the mean signal in the grey matter composite (target) and the whole cerebellum (reference) (Figure 1). Linear regression analyses investigated replication of the original validation Centiloid cohort; concordance of QyScore®'s ^{11}C-PIB and ^{18}F tracer SUVr values; and the concordance between QyScore®'s SUVr results with published validation cohorts. Equations for converting QyScore®'s ^{18}F-SUVr to Centiloid values were derived using the Centiloid project recommended validation process.
Results: QyScore®'s fully-automated quantitative pipeline produced SUVr's closely matching the Centiloid method (SUVr_AD-100=2.08+/-0.2; SUVr_YC-0=1.01+/-0.05; R^2=0.99; slope=1.00; intercept=-0.44). R^2 for QyScore®'s ^{18}F SUVr with paired ^{11}C-PiB SUVr were high across all tracers: 0.91, 0.95, 0.95 and 0.99 (Figure 2). ^{11}C-PiB SUVr correlation coefficients with published values were all above 0.98 (Figure 3) and QyScore®'s Centiloid conversions, (using the following equations) showed clear differentiation between AD and healthy controls across all tracers (Figure 4). **Centiloid conversion equations:** Centiloid=233.39 x SUVr_FBP – 243.48 Centiloid=160.57 x SUVr_FBB – 183.35 Centiloid=136.94 x SUVr_FTM – 156.18 Centiloid=94.67 x SUVr_NAV – 98.72

Figure 1: Example of a PET/MR image pairs co-registered and normalized in the MNI template space with the regions of interest (ROI) segmentations produced using QyScore® displayed.

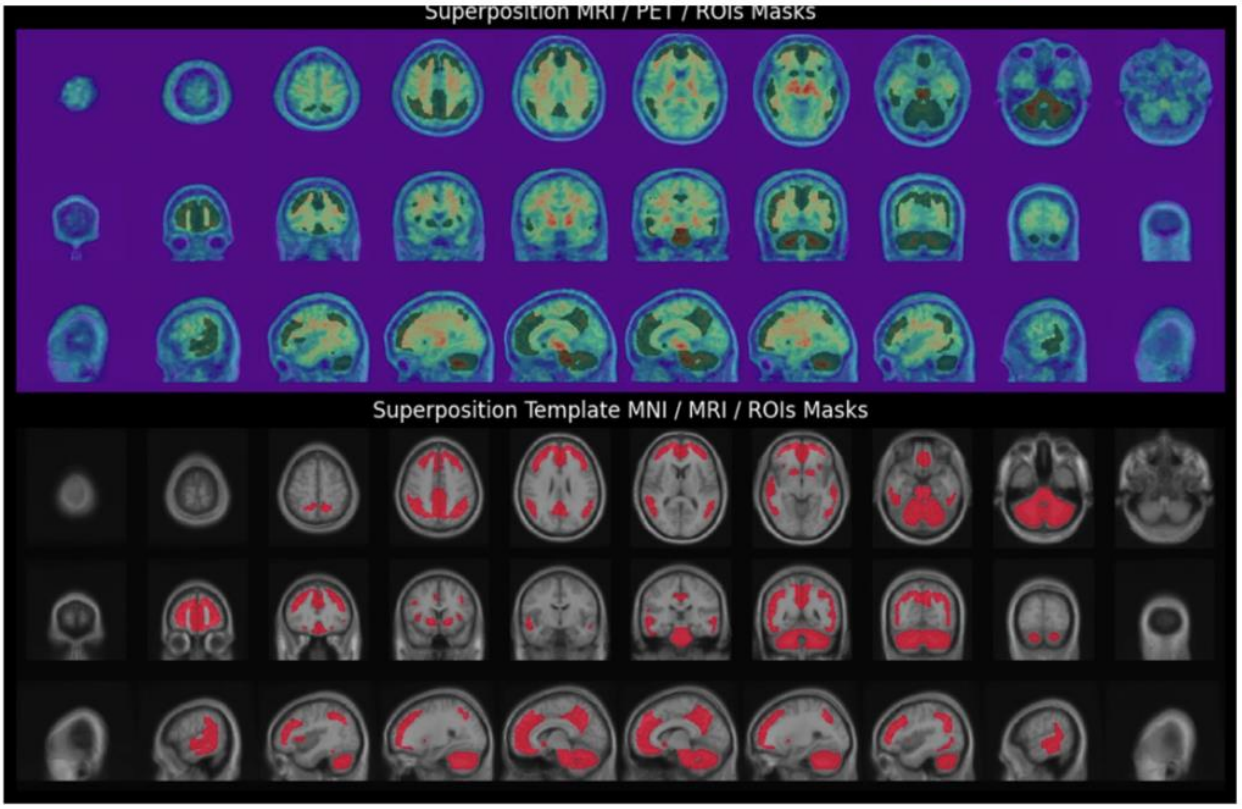

Figure 2. Correlation between each ^{18}F tracer and paired ^{11}C-PIB SUVr produced using QyScore®'s fully automated quantitative PET pipeline

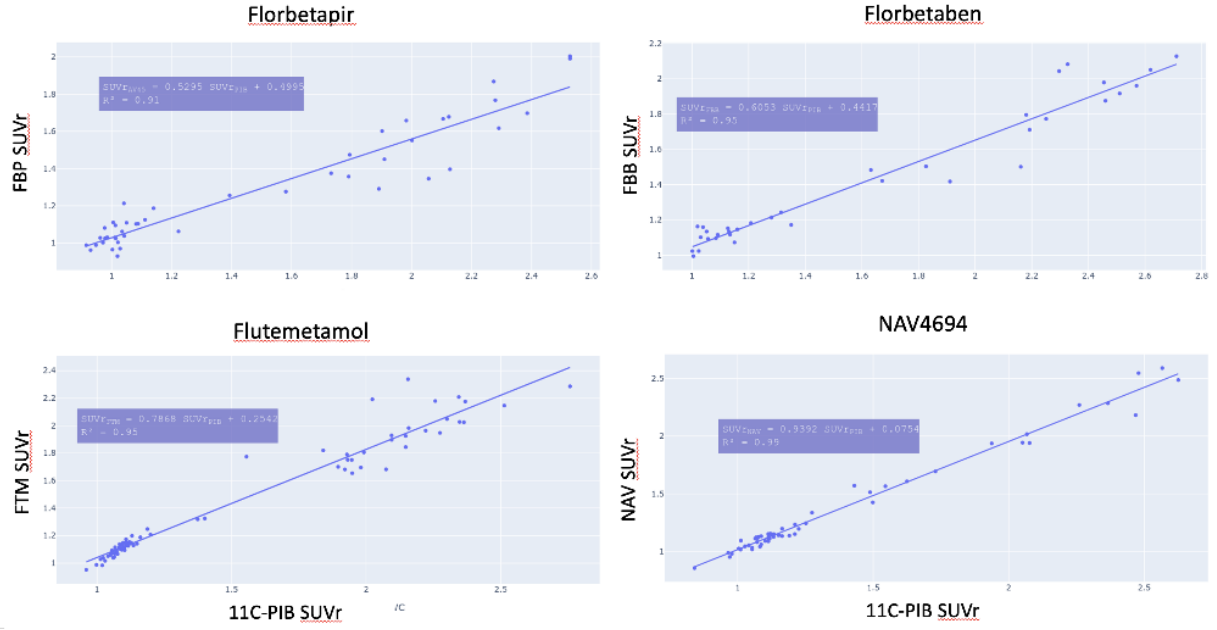

Figure 3. Correlation between QyScore®'s ^{18}F tracer SUVr with the Centiloid GAAIN validation gold-standard SUVr

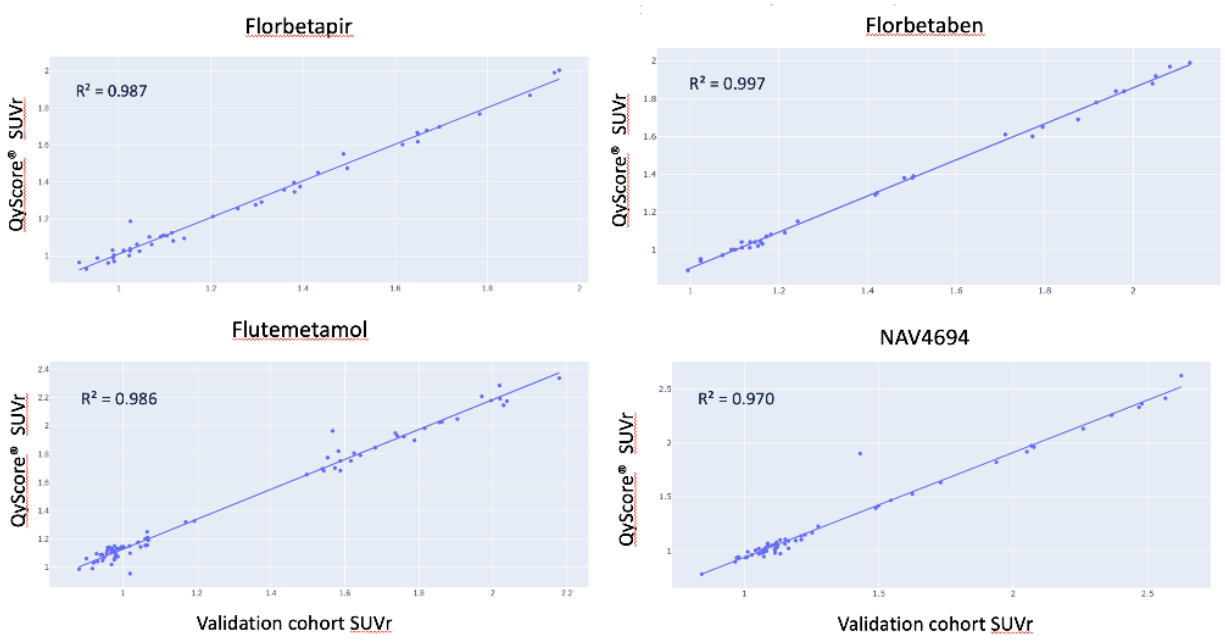

Figure 4. QyScore®'s converted Centiloid results for Heathy Controls (HC) and Alzheimer's Disease (AD) patient amyloid-PET quantification across all four ^{18}F tracer validation datasets

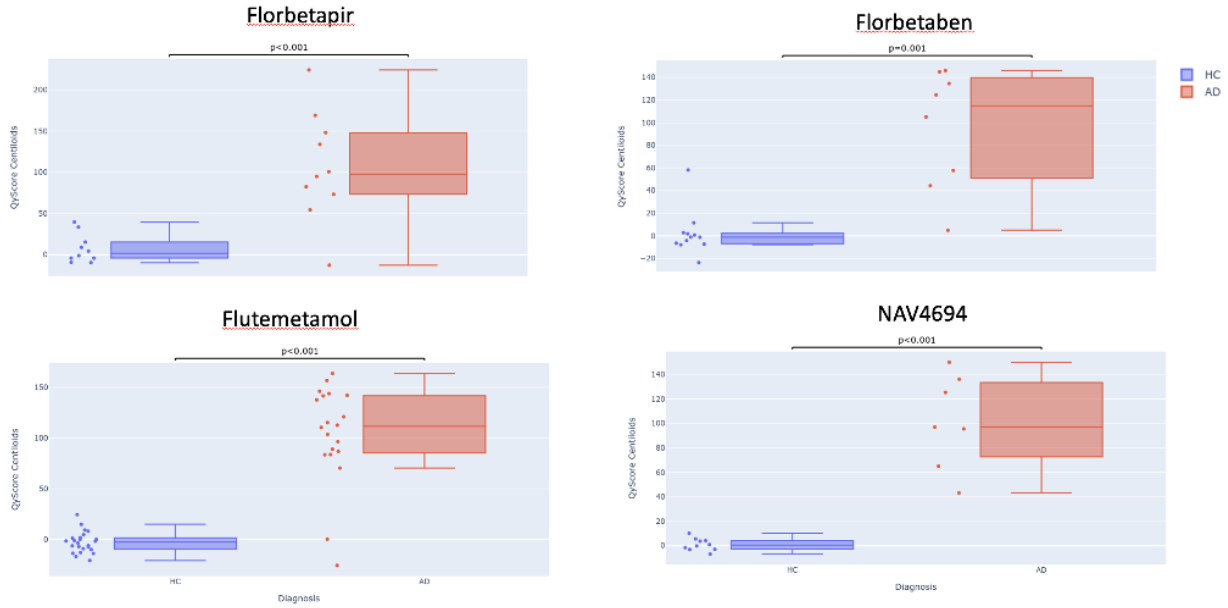

Conclusions: We demonstrate the strong performance of QyScore®'s fully-automated amyloid-PET pipeline for analysing multiple amyloid-PET compounds (^{11}C-PiB and ^{18}F) and validated conversion to the standardized Centiloid scale suitable for multi-site clinical trials.

INCREASED CEREBRAL PERFUSION PROXY WITH INCREASED BETA-AMYLOID BURDEN IN THE PRECLINICAL PHASE OF ALZHEIMER'S DISEASE: EVALUATION USING DUAL-PHASE 18F-FLORBETABEN PET

POSTERS: A04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - AMYLOID

Jee Hyang Jeong[1], Geon Ha Kim[2], Hai-Jeon Yoon[3], Hae Ri Na[4]
[1]Ewha Womans University Seoul Hospital, Neurology, Seoul, Korea, Republic of, [2]Ewha Womans University College of Medicine, Neurology, Seoul, Korea, Republic of, [3]Ewha Womans University College of Medicine, Nuclear Medicine, Seoul, Korea, Republic of, [4]Bobath Memorila Hospital, Neurology, Seongnam, Korea, Republic of

Aims: This study aimed to investigate the earliest change in cerebral blood flow (CBF) in preclinical Alzheimer's disease using early-phase ^{18} F-florbetaben (FBB) PET scans. Additionally, the relationship between CBF and β-amyloid (Aβ) burden, measured by delayed-phase FBB PET scans, was examined in cognitively normal (CN) subjects.
Methods: A total of thirty-six subjects, including 19 with Aβ-negative normal cognition (AβNC) and 17 with Aβ-positive NC (Aβ+NC) were enrolled. A dynamic PET scan was obtained in the early phase (0-10 min, eFBB) and delayed phase (90-110 min, dFBB), which were then averaged into a single frame, respectively. In addition to the averaged eFBB, an R1 parametric map was calculated from the eFBB scan based on a simplified reference tissue model (SRTM). Between-group regional and voxel-based analyses of the images were performed. Correlations between eFBB PET-derived CBF proxies and dFBB PET-derived Aβ burden were analyzed.
Results: The eFBB revealed hyper-perfusion in the superior frontal, mid frontal, and postcentral cortices ($p < 0.005$). R1 revealed hyper-perfusion in the precentral, superior motor, paracentral lobule, postcentral, cuneus, superior occipital, and superior temporal pole cortices ($p < 0.005$). There was a significant positive correlation between R1 and dFBB in the frontal (rho = 0.373, p = 0.025), posterior cingulate and precuneus (rho = 0.409, p = 0.013), and lateral parietal (rho = 0.388, p = 0.020) cortices.
Conclusions: To our knowledge, this is the first study to utilize a dual-phase FBB PET protocol for investigating preclinical AD. The results reveal an increase of CBF and positive correlation between CBF and amyloid pathology. These findings may indicate a potential compensatory hemodynamic mechanism that offers protection against pathology during the very early stages of AD.

EXPERIENCES FROM CLINICAL RESEARCH AND ROUTINE USE WITH NEURACEQ AMYLOID PET DURING 10 YEARS POST-AUTHORISATION – PRIMED FOR THE FUTURE

POSTERS: A04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - AMYLOID

Aleksandar Jovalekic, Santiago Bullich, Nuria Roe-Vellve, Floriana Elsholz, Mariana Lagos-Quintana, Rossella Gismondi, Audrey Perrotin, Andre Mueller, Andrew Stephens, Norman Koglin
Life Molecular Imaging, Clinical R&d, Berlin, Germany

Aims: The amyloid positron emission tomography (PET) tracer Neuraceq® (florbetaben F18) obtained approval in Europe and the US in 2014 following a histopathology study. This abstract presents integrated real-world evidence gathered recently, including outcomes from two post-authorization safety studies (PASS) conducted within the EU.
Methods: The data encompass three key aspects: first, evaluating the efficacy of the approved visual assessment method in the routine clinical practice (PASS1 study, EUPAS12145); second, elucidating prescribing patterns of Neuraceq® in routine clinical practice (PASS2, EUPAS13366); and third presenting quantification results of an extended dataset to underscore reliability and the additional value of quantification.
Results: The PASS1 results confirmed that both experts and naïve readers comprehend SmPC risk-minimization measures, accurately assess Neuraceq® PET scans, and maintain these abilities over time (correct assessments: 96% at baseline and 92% at 6 months follow-up). The PASS2 results revealed that the majority of referring physicians adhered to SmPC specifications in all aspects of their practice, i.e. of the evaluated 126 patient reports only 4 patients (3.2%) were categorized “off-label”. Quantitative methods, employing both CE-marked software and widely available processing tools, consistently demonstrated robust and homogeneous performance, offering valuable support for visual assessments.
Conclusions: Since its approval, Neuraceq® has undergone additional validation across diverse settings in the US and Europe, with effective and enduring reader training, robust quantification for image interpretation, and alignment with clinical selection practices. The presented data are in line with results presented from larger real-world studies, such as AMYPAD, IDEAS, ABIDE or NEUUS. Neuraceq® PET imaging significantly contributed to the advancement of AD drug development and is now primed for use in the forthcoming era of approved disease-modifying AD drugs.

CAIDE DEMENTIA SCORE RELATES TO INCREASED RISK OF COGNITIVE DECLINE IN HEALTY ELDERLY POPULATION: A NEUROIMAGING STUDY

POSTERS: A04.B. IMAGING, BIOMARKERS, DIAGNOSTICS: FUNCTIONAL MRI

Andras Horvath, Katalin Farkas, Dalida Berente
National Institute of Mental Health, Neurology and Neurosurgery, Neurocognitive Research Center, Budapest, Hungary

Aims: The CAIDE (Cardiovascular Risk Factors, Aging, and Incidence of Dementia) Dementia Risk Score is an established tool to identify late-life dementia risk (20 years later), based on midlife vascular risk and epidemiological factors. The aim of our study was to investigate the utility of CAIDE score in relation to objective biomarkers of cognitive impairment in an elderly population.
Methods: Seventy participants were enrolled from the AlzEpi Cohort Observational Library (ACOL database) of the National Institute of Mental Health, Neurology and Neurosurgery, Budapest, Hungary. Every participant of this study is classified as a healthy elderly control individual (age>65, no cognitive impairment with neuropsychological tests, negative neurological status and brain MRI). All participant underwent a comprehensive cognitive test tool including neuropsychology, structural MRI, resting state fMRI. Subjects were divided into high risk (CAIDE>6) and low risk individuals (CAIDE<7). Intergroup comparisons with covarietes were performed on psychological test results, neural volumes, cortical thickness, global functional connectivity and intranetwork connectivity of default mode network (DMN).
Results: Patients with low CAIDE score had significantly better cognitive performance (e.g., TMT-A test time for low risk group is 34+/−11.9 vs 39.84+/−11.32 in high risk group, $p<0.001$). Reduced brain volumes in entorhinal cortex and precuneus were demonstrated in the high risk population (p:0.011). Subjects with high CAIDE score showed reduced global connectivity indexes, and significant disconnection between the medial prefrontal cortex and posterior cingulate gyrus of the DMN ($p<0.001$).
Conclusions: Our observations reinforce the application of CAIDE score in the prediction of cognitive decline. It also shows that CAIDE score system could be useful even in the risk assessment of healthy elderly since high CAIDE values associate with changes of objective biomarkers related to cognitive deterioration.

Aims: This study evaluates the classification performance of Alzheimer's Disease (AD) and Mild Cognitive Impairment (MCI) using Amyloid PET images and mini-mental state examination (MMSE) scores. Incorporating transfer learning, we compared the 3D Densely Connected Convolutional Networks (DenseNet) using only Amyloid PET images to the Graph Convolutional Networks (GCN) employing both modalities.
Methods: 282 patients from Dong-A University Hospital, comprising 158 with AD and 124 with MCI, underwent Amyloid PET scans and MMSE. The Amyloid PET images were preprocessed using techniques including realignment, cerebellar region-based count normalization, skull stripping, pixel normalization, and trilinear interpolation. The 3D DenseNet first classified MCI and AD using only these images. Then, employing transfer learning, Amyloid PET images and MMSE scores were integrated into graph data for the GCN. Each node represents a patient, and the feature vector of the node utilized the feature extraction results from the 3D DenseNet. Edges connected patients based on image and MMSE score similarities. Various edge assignment methods were tested. The two models' performances were then compared using nested stratified 5-fold cross-validation.
Results: In the classification of MCI and AD using nested stratified 5-fold cross-validation, the 3D DenseNet achieved an accuracy of 0.71, precision of 0.72, recall of 0.80, F1-score of 0.76, and AUC of 0.76. Conversely, the GCN, using multimodal data, recorded better scores: accuracy of 0.79, precision of 0.80, recall of 0.83, F1-score of 0.82, and AUC of 0.83.
Conclusions: Utilizing feature extraction techniques with transfer learning, the GCN approach using multimodal data exhibited better performance in classifying MCI and AD than the 3D DenseNet using only Amyloid PET images. Future studies might explore additional clinical indicators for further enhancement.

ALZHEIMER'S DISEASE PLASMA BIOMARKER COMPARISON STUDY

POSTERS: A04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - AMYLOID

Anna Mammel
Neurocode USA Inc., Neurology, Bellingham, United States of America

Aims: Novel high-sensitivity biomarkers based diagnostic platforms of Alzheimer's disease (AD) have facilitated a movement toward the biological definition of AD. While measurement of amyloid β 42 /40, total Tau, p-Tau, and neurofilament light chain (NfL) in Cerebrospinal fluid (CSF) can distinguish AD from other neurodegenerative disorders. The feasibility of phosphorylated tau biomarkers (pTau181 & pTau217) and neurofilament light chain (NfL) in blood makes them valuable biomarkers for AD diagnosis. Our blood-based biomarker panel can accurately predict the course of cognitive decline in the mild and moderate AD.
Methods: The performance of plasma pTau 181 vs. plasma pTau 217 was studied on EDTA plasma samples of normal controls, amyloid positive (PET+) and negative (PET-) cohorts. The concentrations of plasma p-tau181 were measured by SIMOA on the Quanterix HD-X platform. The levels of plasma pTau217 were measured using a novel commercial plasma based Simoa assay which has been developed by ALZpath. NfL samples were original ran on the HD-X platform (Gothenburg) and were evaluated using the Lumipulse blood assay (Bellingham, WA).
Results: We compared the clinical performance of the two pTau SIMOA assays ran on the same HD-X plate form. pTau217 had a higher AUC (0.92) compared to pTau181 (AUC = 0.81), suggesting a pTau217 has a high predicative values compared to pTau181. NfL levels were compared for healthy controls (N = 98), non-pathological (N = 23), and pathological (N = 20) EDTA-plasma samples. A between platform comparison was performed for the Quanterix HD-X and Fujirebio Lumipulse, with a pearson correlation coefficient of 0.96.
Conclusions: Plasma pTau 217 is more accurate than pTau 181 to rule out other neurodegenerative diseases and diagnosis AD. NfL Lumipulse blood assay had a similar performance to the NfL HD-X.

CENTILOID-BASED PREDICTION FROM STANDARD CLINICAL ASSESSMENTS FOR AMYLOID PET TRIAGE

POSTERS: A04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - AMYLOID

Chris Page, Jan Wolber
GE HealthCare, Pharmaceutical Diagnostics, Chalfont St Giles, United Kingdom

Aims: Deposition of B-amyloid in the brain is a hallmark of Alzheimer's Disease. Demand for robust detection of amyloid presence, such as positron emission tomography imaging, is expected to rise with the advent of anti-amyloid therapies. We propose a model to predict amyloid plaque levels using routine information from early diagnostic workup. The model could help optimise both diagnostic and clinical trial workflows by identifying mild cognitive impairment patients to prioritise for confirmatory amyloid assessments.
Methods: Regression models were trained and evaluated on baseline data from the ADNI-GO/ADNI2, AIBL, BioFINDER-1, and GE Healthcare-sponsored Vizamyl™ ([^{18}F]flutemetamol) Phase 3 and Japanese extension studies, where amyloid PET imaging provides the standard of truth. The models use MRI volumetrics, neuropsychological test scores, patient demographics and APOE genotype to estimate the centiloid (CL) score. An exhaustive data-driven approach to model and feature selection, and hyperparameter tuning, was used to train the models. Use of a synthetic population to further optimise models for a target population was assessed.The models were evaluated as classifiers of negative/uncertain/positive amyloid status by applying thresholds of CL=15 and CL=50 to the predicted score.
Results: A general model for amyloid status prediction trained using five independent studies was built. Use of centiloids allowed the model to leverage dynamic range information instead of the standard dichotomous rating. The model showed classification accuracy for each category of 74-76%. The synthetic population model increased accuracies by ~2%.
Conclusions: The resulting models allow quantitative estimation of amyloid plaque levels in the brain, based on standard demographic, neuropsychological, genetic, and structural imaging measures. Further work using blood-based biomarkers and more granular neuropsychological tests is expected to improve performance.

DYNAMIC RECONFIGURATION OF METABOLIC BRAIN CONNECTIVITY DURING PROGRESSION FROM MCI TO ALZHEIMER'S DISEASE DEMENTIA

POSTERS: A04.D. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - GLUCOSE

Silvia Paola Caminiti[1], Alice Galli[2], Arianna Sala[3], Marianna Inglese[4], Luca Presotto[5], Cristina Tassorelli[6], Daniela Perani[7]
[1]University of Pavia, Department Of Brain And Behavioral Sciences, Pavia, Italy, [2]University of Brescia, Neurology Unit, Department Of Clinical And Experimental Sciences, Brescia, Italy, [3]Giga Coma Group, University Of Liege, Liege, Belgium, [4]Department of Biomedicine and Prevention, University Of Rome Tor Vergata, Rome, Italy, [5]Università degli Studi Milano-Bicocca, Dipartimento Di Fisica "giuseppe Occhialini", Milano, Italy, [6]University of Pavia, Department of Brain and Behavioral Sciences, Irccs Mondino Foundation, Pavia, Italy, [7]Vita-Salute San Raffaele University, Division Of Neuroscience, Milano, Italy

Aims: To investigate brain connectivity reconfigurations along the progression from mild cognitive impairment (MCI) to Alzheimer's disease (AD) dementia, using a unique longitudinal design based on metabolic information provided by FDG-PET at three time points.
Methods: We longitudinally analyzed the FDG-PET images of patients with AD according to ATN-classification in the stages of MCI (AD-MCI, N=31), mild dementia (mild-AD, N=31) and full-blown dementia (AD-D, N=20). A group of age/sex-matched healthy controls (HC) was longitudinally evaluated for comparison. We evaluated between-group metabolic connectivity changes at each time point by applying a z-test to the correlation coefficients. Extent of connectivity changes for each region was quantified trhough summary indices indicating hypo and hyperconnectivity. The obtained indices also served as input for a k-means (KM) cluster analysis: KM1)each time point was considered individually to assess the specific hallmark of the disease stage; KM2)three time points analyzed as a single event, to exploit the patterns of connectivity reconfiguration in the AD course.
Results: In AD-MCI, fewer alterations observed compared to mild-AD and AD-D stages. KM1)At AD-MCI stage, "alteration cluster" encompassed subcortical and limbic regions, occipito-parietal cortices, and cerebellum. In mild-AD and AD-D stages, this cluster predominantly involved occipito-parietal cortices and the cerebellum. KM2)Four clusters emerged: Cluster1)Including frontal cortex, insula, and basal ganglia nodes, remained unaffected throughout disease; Cluster2)Prevalent hyperconnectivity in cortical occipito-temporo-parietal nodes; Cluster3)Prevalent hypoconnectivity in subcortical and limbic regions; Cluster4)Featured both hypo and hyperconnectivity in the precuneus throughout disease course.
Conclusions: The current study describes metabolic connectivity changes along the disease course from prodromal to full-blown dementia. Connectivity alterations started from subcortical and AD-prototypical cortical regions. Then, connectivity changes mostly involved cortical associative regions and cerebellum. The precuneus represents a mediator between hyperconnected and hypoconnected hubs.

[18F]-FDG-PET/CT ANALYSIS OF GLUCOSE METABOLISM IN A MOUSE MODEL OF ALZHEIMER'S DISEASE WITH C456R MUTATION IN NOTCH3

POSTERS: A04.D. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - GLUCOSE

Leila Letica, Sang Ho Choi, Diego Szczupak, Jung Eun Park, David Schaeffer, Afonso Silva
University of Pittsburgh, Neurobiology, Pittsburgh, United States of America

Aims: This work aims to evaluate cortical glucose metabolism in a novel, double-transgenic mouse model of familial Alzheimer's disease (FAD) and cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL). The mouse model, referred to as 5xFAD/Notch3C456R, was created by crossing the well-characterized 5xFAD mouse with a knock-in mouse harboring the CADASIL-causing C456R mutation in Notch3, to evaluate the contributions of vascular pathology to AD onset and progression.
Methods: 18F-FDG was delivered to awake mice via a tail vein injection, with an average dose of 18.5 MBq. The mice were fasted for a minimum of 2 hours prior to 18F-FDG administration. PET and CT acquisitions were completed after a 30-minute 18F-FDG circulation period using a Bruker Si78 instrument. Static datasets were analyzed for standard uptake values relative to the brainstem (SUVr) and corrected for glucose levels (SUVglc). Statistical tests performed include unpaired t-test and 1-way ANOVA using GraphPad Prism 9.
Results: Blood glucose levels taken prior to ligand injection showed an age-dependent decrease in WT mice. 12-month-old 5xFAD/Notch3C456R mice presented decreased baseline blood glucose levels and lower whole-brain SUVglc values than age-matched WT controls. ROI analysis revealed the following regions in 5xFAD/Notch3C456R mice exhibited decreased SUVglc levels: Striatum, Cortex, Hippocampus, Thalamus, Cerebellum, Basal Forebrain Septum, Amygdala, Central Gray Matter, Olfactory Bulb, Midbrain, Superior & Inferior Colliculi.
Conclusions: Decreased 18F-FDG uptake across cortical brain regions of 5xFAD/Notch3C456R mice provides evidence of cortical glucose metabolism disruption in a novel double-transgenic mouse model of Alzheimer's Disease with CADASIL Notch3C456R mutations, suggesting that vascular pathology contributes to the etiology and disease progression in AD. We are currently preforming western blot analysis to describe changes in expression of glucose transporter proteins such as GLUT-1,3,4 due to Notch3C456R mutation.

Aims: To compare the performance of plasma p-tau217 and visual assessments of [^{18}F]FDG-PET to diagnose atypical presentations of Alzheimer's disease
Methods: We conducted a retrospective analysis of individuals with atypical and/or early-onset dementia who were assessed at a specialized memory clinic. All participants underwent CSF evaluations to measure Aβ42, phosphorylated tau (P-tau181), and total tau levels, brain [^{18}F]FDG-PET scans, and plasma p-tau217. The [^{18}F]FDG-PET data were visually examined by two nuclear medicine experts to determine whether they were indicative of AD and CSF biomarker results were categorized as either AD biomarker positive or negative. Contingency analysis was performed to assess the relationships between the PET scan interpretations and CSF biomarker groupings. CSF biomarker groupings were treated as the reference standard.
Results: 75 subjects with early-onset or atypical dementia had CSF AD biomarker evaluations, [^{18}F]FDG-PET ratings, and plasma p-tau217 assessments. Both [^{18}F]FDG-PET and plasma p-tau217 had high levels of agreement with reference standard CSF AD biomarkers ([^{18}F]FDG-PET: 69%; plasma p-tau217:81%). Although both biomarkers had similar specificity for AD ([^{18}F]FDG-PET: 67%, plasma p-tau217 70%), plasma p-tau217 had higher sensitivity for abnormal CSF AD biomarkers (97%). Overall accuracy was also higher for plasma p-tau217 (AUC=83%, 95%CI = 0.74- 0.83). The same pattern of results was observed when using amyloid-PET as the reference standard.
Conclusions: Our study provides evidence that plasma p-tau217 has excellent diagnostic performance for AD in individuals with early-onset or atypical dementia evaluated in specialized settings. The topographical information from [^{18}F]FDG-PET may give complementary information.

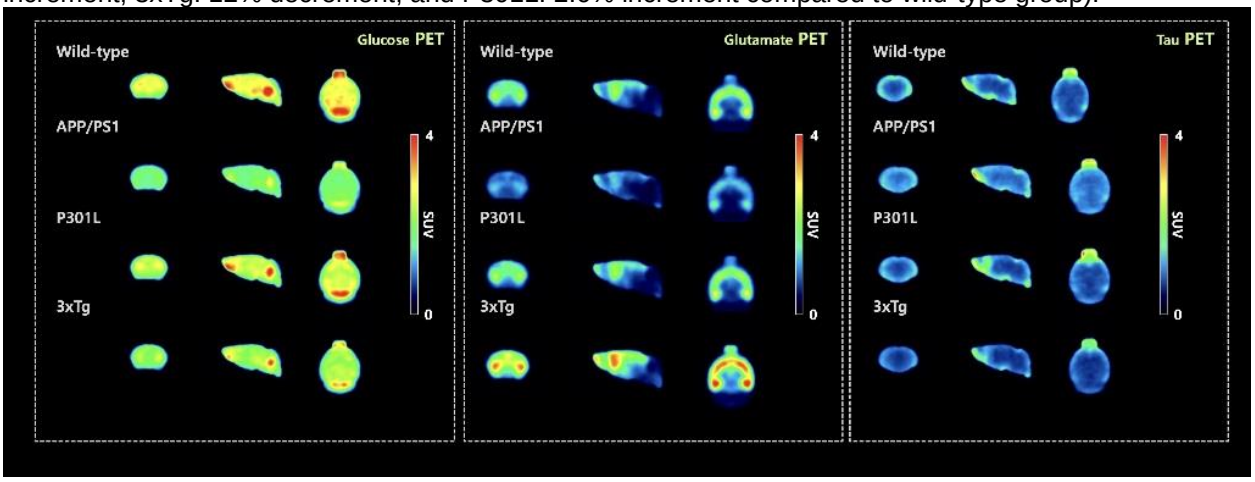
EVALUATION OF THE NEURONAL CHANGES OF VARIOUS ALZHEIMER'S ANIMAL MODELS BY PET

POSTERS: A04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - OTHER

Sang Jin Han[1], Se Jong Oh[1], Sungsu Lim[2], Kyung June Kang[1], Kyung Rok Nam[1], Yun Kyung Kim[2], Jae Yong Choi[3]
[1]Korea Institute of Radiological & Medical Sciences, Division Of Applied Ri, Seoul, Korea, Republic of, [2]Korea Institute of Science and Technology, Brain Science Institute, Seoul, Korea, Republic of, [3]Korea Institute of Radiological & Medical Sciences, Division Of Applied Ai, Seoul, Korea, Republic of

Aims: Alzheimer's disease (AD) is a representative senile neurodegenerative disease and its prevalence is gradually increasing. Many researchers have used animal models to elucidate the pathophysiology of AD, but there are still few animal models in vivo that reflect the progress of AD in clinical practice in a non-invasive way. Therefore, the aim of the present study is to examine neuronal changes in vivo using various AD animal models.
Methods: In this study, the various transgenic AD mice models, including APP/PS1(female, n = 2), 3xTg (female, n = 3), P301L (female, n =4), and age-matched wild-type mice (female, n = 3) were used for positron emission tomography (PET) studies. At 17 months of age, neuroPET studies were formed using [18F]FDG, [18F]FPEB, and [18F]Av-1451 for evaluation of glucose metabolism, glutamate system, and tau pathology, respectively.
Results: In glucose PET, brain uptakes in APP/PS1 mice decreased from 15.6 to 35% compared to wild-type groups, 3xTg and P301L mice showed 9.3 to 26.8%, and 2.9 to 15.8% reduced uptakes, respectively. In glutamate PET, brain uptakes in APP/PS1 mice decreased by 31-42% compared to the wild-type group, and the uptakes in 3xTg mice were increased by 52-54%. However, the uptakes in P301L mice showed similar to wild-type (0.9-2.8% decrement compared to wild-type). In tau PET, there was no significant difference between the transgenic mice and the wild-type group (APP/PS1: 6.7% increment, 3xTg: 12% decrement, and P301L: 2.6% increment compared to wild-type group).



Conclusions: From this study, we demonstrated AD animal models showed overall hypometabolism in glucose PET, but glutamate PET showed different uptake patterns depending on the group, and tau PET showed no significant difference from wild-type.

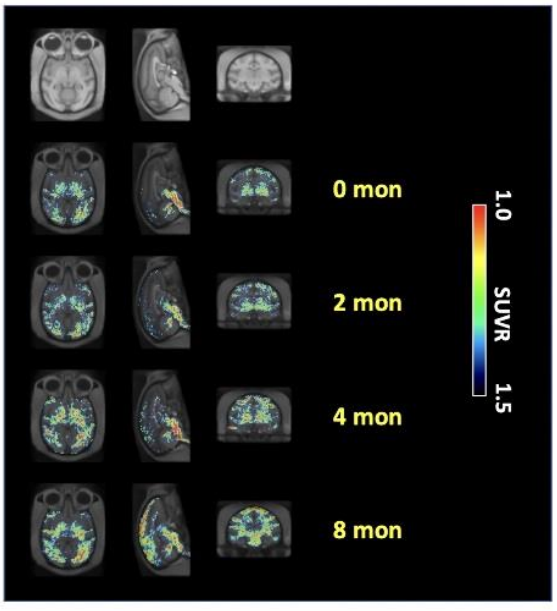
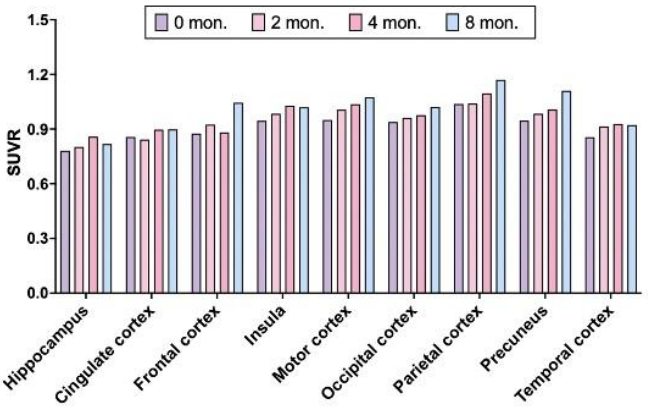
LONGITUDINAL AMYLOID PET IN PRIMATES ALZHEIMER'S MODELS USING AB OLIGOMERS

POSTERS: A04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - OTHER

Kyung Rok Nam[1], Junghyung Park[2], Jinyoung Won[2], Kyung Seob Lim[2], Chang-Yeop Jeon[2], Yu Gyeong Kim[2], Seung Ho Baek[2], Youngjeon Lee[2], Jae Yong Choi[3]
[1]Korea Institute of Radiological & Medical Sciences, Division Of Applied Ri, Seoul, Korea, Republic of, [2]Korea Research Institute of Bioscience and Biotechnology, National Primate Research Center, Cheongju, Korea, Republic of, [3]Korea Institute of Radiological & Medical Sciences, Division Of Applied Ai, Seoul, Korea, Republic of

Aims: Alzheimer's disease is the most common neurodegenerative disease, and its prevalence is increasing as society becomes aging, but there are no fundamental therapeutic drugs until now. Therefore, preclinical studies, especially non-human primate experiments, are important to understand the pathophysiology of AD. In the present study, we would like to introduce a longitudinal amyloid PET in the non-human primate AD model
Methods: In the present study, we used two adult rhesus female monkeys (13 years old), and baseline amyloid PET scans were performed before Aβ oligomer injection. After Aβ oligomer administration (100μg/dose x 12 times) in artificial cerebrospinal fluid, subsequent amyloid PETs were obtained a total of 4 times every 2 months from 2 months of age. Here, [18F]florbetaben was used as a specific radiotracer to detect amyloid-β plaques. For quantitative comparison, a standardized uptake value ratio (SUVR) was used with the cerebellum as the reference region.
Results:





When evaluating the distribution of brain uptakes by dividing the early (0-20 min, p.i), mid (20-60min, p.i.), and late time windows (60-120 min) in dynamic PET, the late time zone generated the clear distinction between white and gray matter. Therefore, we used this time window as SUVR estimation. Overall, brain uptakes in cortical and sub-cortical areas gradually increased over time. In particular, PET uptake has steadily increased in motor, occipital, parietal cortices, and precuneus. At 8 months of age, brain uptakes

in these areas showed an increase of 8.7-19.2% compared with baseline PET (the rate of increase, motor cortex: 13.1%, occipital cortex: 8.7%, parietal cortex: 12.8%, precuneus: 17.8%)

Conclusions: From this study, we demonstrated that in vivo amyloid pathology in a non-human primate AD model produced by injecting amyloid oligomers increased over time.

BRAIN HYPOMETABOLISM AND ERRORS ON THE CLOCK DRAWING TEST PREDICT CONVERSION FROM MILD COGNITIVE IMPAIRMENT TO ALZHEIMER'S DEMENTIA

POSTERS: A04.D. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - GLUCOSE

Giacomo Tondo[1], Fabiola De Marchi[2], Federico Menegon[3], Martina Filippone[1], Silvia Caminiti[4], Roberta Matheoud[5], Gian Mauro Sacchetti[6], Daniela Perani[7], Cristoforo Comi[1]
[1]Neurology Unit, Sant'Andrea Hospital, Vercelli, University Of Piemonte Orientale, Vercelli, Italy, [2]University of Piemonte Orientale, Department Of Neurology, Novara, Italy, [3]University of Piemonte Orientale, Department Of Translational Medicine, Novara, Italy, [4]University of Pavia, Department Of Brain And Behavioral Sciences, Pavia, Italy, [5]University Hospital "Maggiore della Carità", Medical Physics Department, Novara, Italy, [6]Nuclear Medicine Department, University Hospital Maggiore Della Carità, Novara, Italy, [7]University Vita Salute San Raffaele, In Vivo Imaging Unit, Milan, Italy

Aims: Mild Cognitive Impairment (MCI) is associated with increased risk of developing dementia, especially Alzheimer's dementia (AD). Several markers have been explored as conversion predictors from MCI to AD. The clock drawing test (CDT) is a screening test revealing executive, working memory and visuospatial deficits. Brain FDG-PET is a neuroimaging technique underlining specific hypometabolism patterns reflecting neuronal dysfunction. We aimed to correlate CDT errors and FDG-PET hypometabolism patterns in MCI, evaluating the combination of different CDT errors and brain hypometabolism pattern in predicting conversion to AD.
Methods: We included 65 MCI (Petersen,2004) with a baseline CDT and FDG-PET scan. CDT errors were qualitatively classified (Parsey,2011) in stimulus-bound (STIMULUS), conceptual (CONCEPTUAL), spatial (VISUOSPATIAL), and perseveration (PERSEVERATION) errors. FDG-PET images were analyzed with a validated SPM method (Perani,2014) to obtain single-subject brain hypometabolism maps using a large dataset of controls for comparison (Caminiti,2021). MCI subjects were longitudinally evaluated and classified according to the diagnosis at follow-up in stable MCI, AD, frontotemporal dementia, or Lewy bodies dementia.
Results: MCI subjects performing correctly to the CDT showed a normal metabolism (NORMAL). The PERSEVERATION and the VISUO-SPATIAL error groups showed hypometabolism in temporoparietal regions, posterior cingulate, and precuneus (corresponding to typical AD pattern). The STIMULUS error group showed left hypometabolism in frontotemporal cortices. The CONCEPTUAL error group was characterised by widespread hypometabolism (frontotemporal, parietal, occipital cortices). At follow-up, none of the NORMAL MCI converted to dementia. Conversely, in PERSEVERATION group, 85% of MCI converted to dementia. An AD hypometabolism pattern in PERSEVERATION error group predicted AD conversion with high accuracy (AUC=85%).
Conclusions: Combining CDT qualitative errors and semi-quantitative analysis of brain FDG-PET accurately predicts conversion to AD or other dementia conditions, aiding, at the baseline, a clinical stratification of MCI subjects.

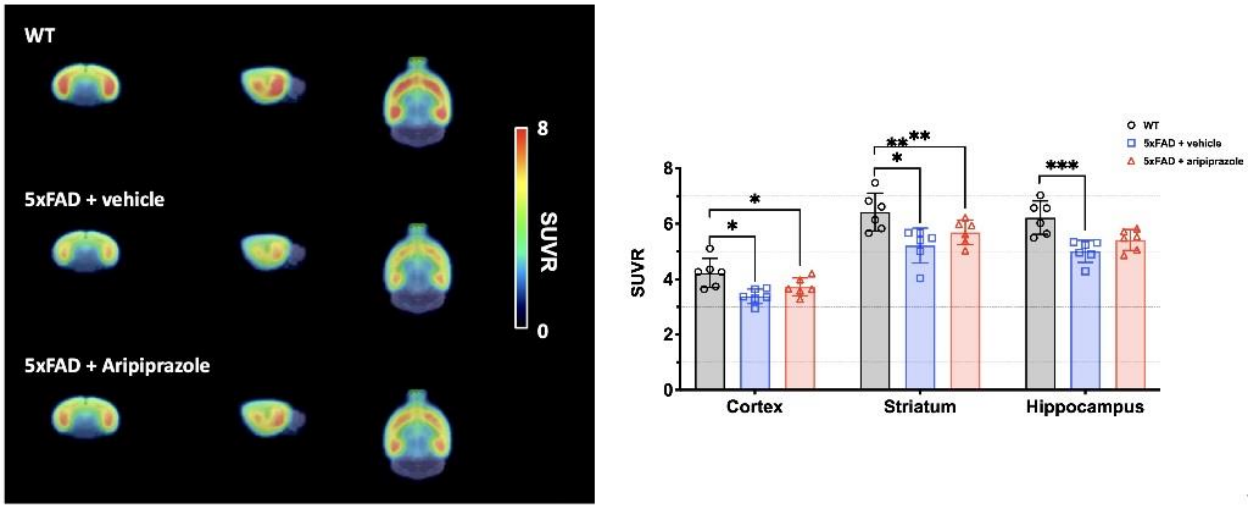
EVALUATION OF THE EFFECTS OF ARIPIPRAZOLE ADMINISTRATION ON THE BRAIN GLUTAMATE SYSTEM

POSTERS: A04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - OTHER

Hae-June Lee[1], Hyun-Yong Kim[1], Se Jong Oh[2], Yeonghoon Son[1], Kyung June Kang[2], Kyung Rok Nam[2], Jae Yong Choi[3]
[1]Korea Institute of Radiological & Medical Sciences, Division Of Radiation Bioscience, Seoul, Korea, Republic of, [2]Korea Institute of Radiological & Medical Sciences, Division Of Applied Ri, Seoul, Korea, Republic of, [3]Korea Institute of Radiological & Medical Sciences, Division Of Applied Ai, Seoul, Korea, Republic of

Aims: The main clinical symptom of Alzheimer's disease (AD) is cognitive impairment, and it is well-known that this cognitive dysfunction is closely related to the prevalence of psychotic symptoms. In addition, the glutamate system in the central nervous system plays an important role in learning and memory. To date, however, studies on the effects of anti-psychotic drugs on the glutamate system have been limited. The aim of the current study is to investigate the effect of aripiprazole on the glutamate system in an AD animal model using functional molecular imaging.
Methods: In this study, the transgenic 5xFAD mice were used as an AD animal model. At the age of 5 months, the female mice were classified into a wild-type, a vehicle control group, and an aripiprazole-treated group (n = 6 for each group). In addition, from 5 months to 7 months of age, the aripiprazole-treated group administered aripiprazole intraperitoneally at a dose of 1 mg/kg every day, and the vehicle group administered only solvents. At 8 months of age, glutamate PET images were acquired using a specific radiotracer for a metabotropic glutamate receptor 5 (mGlur5).
Results: A vehicle-treated 5xFAD mice showed a 19-20% reduction of brain uptakes compared to the wild-type group. However, the aripiprazole-treated 5xFAD group displayed 11-13% lowered brain uptake values compared to the wild-type. The available mGluR5 binding was 7-8% higher in the aripiprazole-treated 5xFAD group than that in the vehicle-treated group. In the immunohistochemistry experiments, aripiprazole administration resulted in decreased mGluR5 damage in the hippocampus compared to that in the vehicle group.



Conclusions: From this study, we demonstrated that the administration of aripiprazole plays a role in preventing glutamate damage.

A DEEP LEARNING FRAMEWORK FOR CLINICAL TRIAL ENRICHMENT IN ALZHEIMER'S DISEASE

POSTERS: A04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Luis Peraza Rodriguez, Robin Wolz, Colm Mcginnity, Richard Joules
IXICO, Research & Development, London, United Kingdom

Aims: Selection of participants at risk of cognitive decline in clinical trials, trial enrichment, increases the probability of trial success. Here we present a deep-learning (DL) framework for trial enrichment that uses a combination of imaging and clinical/demographic variables as input, and has built-in redundancy allowing the system to work effectively with missing inputs.
Methods: We employed T1w and amyloid-PET images from ADNI (CN=270, MCI=595, AD=59), OASIS-3 (CN=367, MCI=20, AD=67) and AMYPAD (CN=808, MCI=4) repositories. Images were pre-processed by validated pipelines for volumetric and SUVR estimation. Training-set participants were labelled as stable or decline through hierarchical clustering, where a stable participant experienced no significant decline within a 36-month period. Our framework comprises two phases: first, Siamese convolutional neural networks (CNN) were trained with decline/stable targets and neuroimages as inputs. Then, a battery of random forest classifiers were trained with CNN outputs, neuroimaging derivatives, and demographics/clinical data inputs and decline/stable targets.
Results: When using complete inputs, our framework reached mean accuracy of 93% and a positive predictive value (PPV) of 87% in test sets, and a mean accuracy of 90%, with 86% PPV in cross-dataset validations (e.g., train on ADNI, test on OASIS-3, AMYPAD and so on). The best predictor of decline was baseline CDR-SB score, followed by CNN-PET, CNN-MRI, hippocampal volume, and SUVR. In the absence of PET data, our framework reached a mean accuracy of 88% and 87% PPV in cross-dataset validations. In the absence of baseline CDR-SB, our framework reached 87% mean accuracy and 80% mean PPV in cross-dataset validations, with CNN-PET becoming best predictor.
Conclusions: Our trial enrichment framework showed high accuracy when predicting future cognitive decline. The DL models highly contributed to the prediction of decline which guarantees further research.

HIPPOCAMPAL SYNAPTIC DENSITY ESTIMATED WITH 11C-UCB-J PET AND ITS ASSOCIATION WITH COGNITIVE PERFORMANCE IN HEALTHY ELDERLY APOE4 CARRIERS

POSTERS: A04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - OTHER

Anniina Snellman[1], Jouni Tuisku[1], Laura Ekblad[1], Mikko Koivumäki[1], Saara Wahlroos[2], Mira Karrasch[3], Juha Rinne[1]
[1]University of Turku, Turku Pet Centre, Turku University Hospital, Turku, Finland, [2]University of Turku, Turku Pet Centre, Turku, Finland, [3]Åbo Akademi University, Department Of Psychology, Turku, Finland

Aims: Synaptic loss is one of the pathological features of Alzheimer's disease (AD). Here, we investigated **i)** differences in hippocampal synaptic density *in vivo* using ^{11}C-UCB-J positron emission tomography (PET) in cognitively unimpaired individuals with varying number of *APOE4* alleles and risk for sporadic AD, **ii)** association between hippocampal synaptic density, brain Aβ load and cognitive performance in the whole study sample.
Methods: 46 individuals (*APOEε4ε4* n=14; *APOEε4ε3* n=16; *APOEε4ε4* n=16) from the ASIC-E4 study participated in ^{11}C-UCB-J PET, brain MRI and cognitive testing using CERAD and APCC batteries during years 2020-2022. Amyloid PET was performed 21 months (median, interquartile range 19-22) earlier with ^{11}C-PiB. Hippocampal ^{11}C-UCB-J standardized uptake value ratios (SUVr) were calculated using centrum semiovale as a reference region, and hippocampal volumes obtained by FreeSurfer. Differences between the *APOE* genotypes were tested with ANOVA, and subsequent sensitivity analysis was performed by further adjusting for age, sex, education and hippocampal volume. Associations with Aβ and cognitive variables were tested with Spearman's correlation.
Results: Significant difference in hippocampal ^{11}C-UCB-J binding was present between the *APOE4* groups (p_{ANOVA}=0.016), *APOEε4ε4* showing lower SUVrs (mean 2.90, SD 0.30) compared to *APOEε3ε3* (mean 3.33, SD 0.35, p=0.013). Significant difference was also present between *APOE4* carriers and non-carriers (p=0.010), but not between Aβ-positive and Aβ-negative individuals (p=0.11). Statistically significant findings remained unchanged when adjusted for age, sex, education and hippocampal volume. Hippocampal SV2A binding did not correlate with CERAD total score (r=-0.052, p=0.74), APCC score (r=0.17, p=0.28) or global ^{11}C-PiB uptake (r=-0.10, p = 0.50) in our sample.
Conclusions: Our data suggests that hippocampal synaptic loss is an early event in the AD continuum, and measurable *in vivo* already in cognitively unimpaired at-risk individuals.

ULTRASOUND-GUIDED DRY NEEDLING FOR VERTIGO MANAGEMENT IN A COMBAT PATIENT WITH SKULL TRAUMA: A NOVEL CASE REPORT

POSTERS: A04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Rostyslav Bubnov[1], Lev Kalika[2], Zbigniew Pilecki[3], Grzegorz Pilecki[3]
[1]Clinical hospital `Pheophania`, Ultrasound, Kyiv, Ukraine, [2]New York Dynamic Neuromuscular Rehabilitation & Physical Therapy, Rehab, New York, United States of America, [3]Center of Sport Medicine, Orthopedics, Zabrze, Poland

Aims: To investigate the efficacy of US-guided dry needling in managing vertigo symptoms associated with musculoskeletal issues following skull trauma. To explore the neurophysiological responses and potential mechanisms of action of US-guided dry needling in treating vertigo. To emphasize the importance of careful assessment and multidisciplinary collaboration in tailoring treatment for combat patients with skull trauma.
Methods: Case Diagnosis: A 30-year-old male combat patient with a history of skull trauma presenting with vertigo and neck pain. Ultrasound diagnosis revealing multiple trigger points in the neck and shoulders. Application of US-guided dry needling to suboccipital muscles, including m. rectus capitis post major and m. obliquus capitis inf., with one needle incidentally touching the dura mater. Assessment of extralong needle grasp pattern and referred pain in the occipital area.
Results: Immediate relief from vertigo symptoms and elimination of neck pain observed after US-guided dry needling. The technique's effectiveness attributed to its impact on trigger points and specific neurophysiological responses. Caution emphasized due to the complexity of the procedure, necessitating expertise and careful patient evaluation, particularly in combat patients with skull trauma.
Conclusions: US-guided dry needling demonstrates promise as a potential intervention for managing vertigo associated with musculoskeletal issues post-skull trauma. The technique's efficacy may be linked to its influence on trigger points and neurophysiological responses. In cases involving intracranial needling, only experienced practitioners should perform the procedure, with thorough patient assessment to ensure safety and suitability. A multidisciplinary approach is essential for tailoring individualized management plans, thereby enhancing treatment outcomes.

ASSOCIATIONS BETWEEN NEUROINFLAMMATION AND BRAIN BETA-AMYLOID ACCUMULATION IN AN ELDERLY POPULATION – A 5-YEAR FOLLOW-UP STUDY WITH [11C]PBR28 AND [11C]PIB PET IMAGING

POSTERS: A04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Laura Ekblad[1], Teemu Kipinoinen[1], Anniina Snellman[1], Matti Viitanen[2], Semi Helin[1], Antti Jula[3], Sini Toppala[1], Jouni Tuisku[1], Juha Rinne[1]
[1]University of Turku, Turku Pet Centre, Turku, Finland, [2]University of Turku, Department Of Geriatrics, Turku, Finland, [3]Finnish Institute for Health and Welfare, Public Health And Wellbeing, Turku, Finland

Aims: Neuroinflammation appears to participate in the Alzheimer's disease (AD) pathogenesis, but the temporal course of neuroinflammation across the disease stages remains unclear. In this 5-year follow-up study we aimed to evaluate if neuroinflammation predicts Aβ accumulation by examining dementia-free elderly individuals at baseline and at follow-up using [^{11}C]PBR28 positron emission tomography (PET) scans for TSPO availability (neuroinflammation) and [^{11}C] Pittsburgh compound B ([^{11}C]PiB)-PET scans for beta-amyloid (Aβ) accumulation.
Methods: We examined 40 volunteers (median age at follow-up 74.2, 55% women, 50% APOEε4 carriers) in 2014-2016 and 2019-2021 with [^{11}C]PBR28 and [^{11}C]PiB PET. [^{11}C]PBR28 and [^{11}C]PiB binding was quantified for a cortical composite region-of-interest using standardized uptake value ratio (SUVR) with respect to cerebellar cortex. We employed a linear regression model adjusted to age, sex and TSPO genotype to examine associations between [^{11}C]PBR28 binding and [^{11}C]PiB binding at baseline and follow-up. Associations were further evaluated based on baseline Aβ-positivity (cut-off for positivity [^{11}C]PiB SUVR = 1.5).
Results: In the model adjusted for age, sex and TSPO genotype, baseline [^{11}C]PBR28 did not predict follow-up [^{11}C]PiB binding (β=-0.59, p=0.72), and baseline Aβ status did not modify this association (β=1.01, p=0.23 for Aβ-negative; slope=3.85, p=0.072 for Aβ-positive). However, in cross-sectional analyses with Aβ-negative individuals, [^{11}C]PBR28 binding was associated with Aβ accumulation both at baseline (β=1.43, p=0.018) and at follow-up (β=0.68, p=0.032).
Conclusions: Neuroinflammation measured with [^{11}C]PBR28 PET showed no association with Aβ accumulation in prospective design. However, concurrent assessment revealed an association between neuroinflammation and amyloid accumulation at both timepoints in the participants who were still amyloid negative. Our results suggest that neuroinflammation might be important in the earliest phases of Aβ accumulation. However, baseline neuroinflammation does not predict Aβ accumulation during a 5-year follow-up.

UK BIOBANK IMAGING IN A MEMORY CLINIC POPULATION: ASSOCIATIONS BETWEEN IMAGING-DERIVED PHENOTYPES AND COGNITIVE DOMAINS IN THE OXFORD BRAIN HEALTH CLINIC

POSTERS: A04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Grace Gillis[1,2], Gaurav Bhalerao[1], Clare O'Donoghue[1,2], Jasmine Blane[1,2], Robert Mitchell[1,2], Lola Martos[1,2], Vanessa Raymont[1,2], Clare Mackay[1], Ludovica Griffanti[1,2]
[1]University of Oxford, Psychiatry, Oxford, United Kingdom, [2]Oxford Health NHS Foundation Trust, Warneford Hospital, Oxford, United Kingdom

Aims: The Oxford Brain Health Clinic (BHC) has seen over 200 NHS memory clinic patients. In addition to high-quality cognitive and lifestyle assessments and opportunities for research participation, patients receive a clinical MRI scan (T1-weighted, T2-FLAIR, and SWI) and can consent to additional research scans (dMRI, rfMRI, and ASL) aligned to the UK Biobank. We aimed to automatically extract imaging-derived phenotypes (IDPs) and explore associations with cognition and diagnoses in this real-world memory clinic population.
Methods: Scans from 213 BHC patients, 122 of whom completed all additional research scans, were processed using the UK Biobank pipeline with previously described modifications and supplementary quality control. Using the ACE-III, cognition was assessed across the following domains: memory, attention, language, verbal fluency, and visuospatial abilities. We performed regression analyses to test associations of IDPs with cognitive scores (N=203) and subsequent diagnoses (dementia, MCI, no dementia-related diagnosis; N=184). Results were controlled for age, sex, head size, and corrected for multiple comparisons.
Results: Out of 4100 IDPs of interest, 47 and 49 IDPs significantly associated with ACE-III scores and diagnoses, respectively (Benjamini-Yekutieli correction; Figures 1-2). While many associations align with known dementia-related atrophy patterns, others are less well-established. Memory sub-scores associated with 52 IDPs including many temporal lobe volumes, while visuospatial sub-scores associated with 10 IDPs mainly clustered in the occipital and parietal lobules. Language sub-scores associated with 16 IDPs, 13 of which were left-localised. **Fig1**: Associations between IDPs and ACE-III total scores.

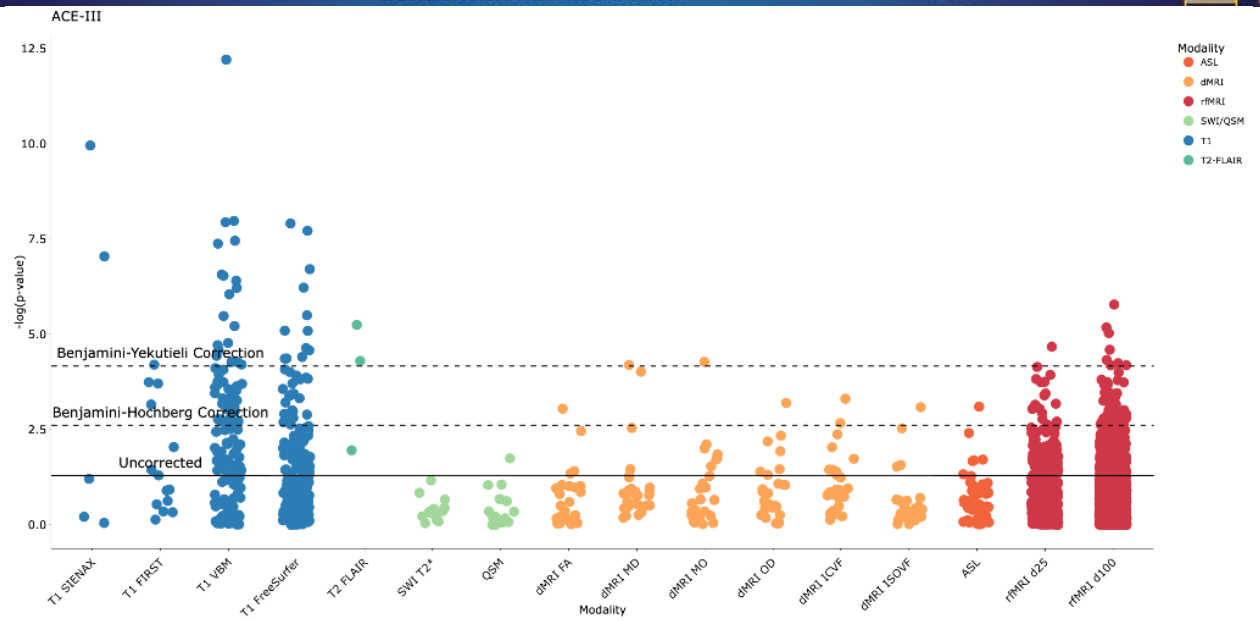

Fig2: Associations between IDPs and diagnoses.

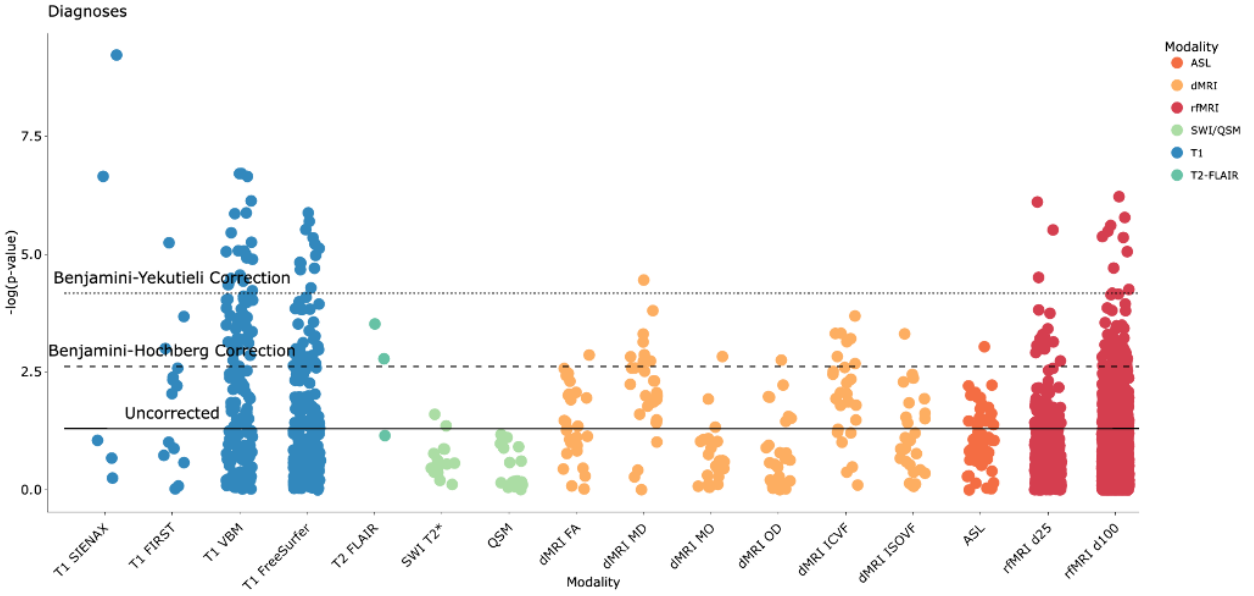

Conclusions: By using an unselected memory clinic population, this work provides real-world validation of associations well-established in research, while also supporting specific patterns of changes associated with cognitive domains. This represents a key step towards integrating research-quality imaging in memory clinics.

EXPLORING THE ROLE OF BRAIN MRI IN THE MEMORY CLINIC PATHWAY FOR THE DEPLOYMENT OF DISEASE MODIFYING THERAPIES FOR AD

POSTERS: A04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Ludovica Griffanti[1,2], Grace Gillis[1,2], Pieter Pretorius[3], Robert Mitchell[2], Vanessa Raymont[1,2], Lola Martos[1,2], Clare Mackay[1,2]
[1]University of Oxford, Department Of Psychiatry, Oxford, United Kingdom, [2]Warneford Hospital, Oxford Health Nhs Foundation Trust, Oxford, United Kingdom, [3]Oxford University Hospitals NHS Trust, Neuroradiology, Oxford, United Kingdom

Aims: We explored the role of brain MRI for diagnosis and screening eligibility to receive monoclonal antibodies in a real-world UK memory clinic population from the Oxford Brain Health Clinic (BHC).
Methods: 237 people referred to the BHC (O'Donoghue et al., 2023 BMJOpen) received a 3T brain MRI scan which was reported using a standardised template (Griffanti et al., 2022 Neuroimage:Clinical). Information about diagnosis was obtained after the memory clinic appointment. Psychiatrists were asked to report on their confidence in diagnosis (0-5 scale, consensus of 2 clinicians) on a subset of 12 BHC patients (receiving advanced assessments including MRI) and 14 patients seen in memory clinic but who did not attend the BHC. From the MRI report, we extracted the type and amount of brain anomalies that would meet an exclusion criterion for Lecanemab or Aducanumab, according to published Appropriate Use Recommendations.
Results: Out of the 237 consecutive patients, 95 (40%) were diagnosed with MCI or mild AD (IC10 codes F06.7, F00.0, F00.1 or F00.9 and ACE-III 60-100). Psychiatrists reported increased confidence in diagnosis for BHC patients (average score 4.04 vs 3.29 for non-BHC patients) and an evaluation on a bigger sample is currently ongoing. 22 MCI/mild AD patients (23%) had one or more brain anomalies that would make them ineligible for Lecanemab or Aducanumab (N=3 with more than 4 microhemorrhages; N=10 periventricular or deep Fazekas score greater than 3; N=9 infarcts; N=1 hemorrhage; N=2 superficial siderosis or hemosiderin deposit; N=1 meningioma).
Conclusions: MRI performed in the memory clinic diagnostic pathway and reported using a standard template can increase confidence in diagnosis and be used for screening eligibility for monoclonal antibodies, potentially saving around 20% of amyloid investigations (PET or CSF).

MASS SPECTROMETRY IMAGING REVEALS REGION-SPECIFIC ALTERATIONS OF BRAIN LIPIDS INDUCED BY PARKINSONISM AND L-DOPA-INDUCED DYSKINESIA

POSTERS: A04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Ibrahim Kaya[1], Theodosia Vallianatou[1], Anna Nilsson[1], Patrik Bjärterot[1], Dominika Luptáková[1], Yachao He[2], Reza Shariatgorji[1], Per Svenningsson[2], Erwan Bezard[3], Per Andrén[1]

Aims: The aim of the study is to comprehensively map different molecular species (spatial omics), such as neurotransmitters, neuropeptides, and lipids in specific brain regions, using brain samples from an experimental Parkinson's disease (PD) model (MPTP, *Macaca mulatta*) with L-DOPA-induced dyskinesia (LID).
Methods: We employed matrix-assisted laser desorption ionization mass spectrometry imaging (MALDI-MSI) methods for the visualisation of neurotransmitters, neuropeptides and lipids within several brain regions of the coronal brain tissue sections within this project. For this study, all of the MALDI-MSI experiments for lipid imaging were performed in both negative and positive ionization modes on the same tissue sections using a MALDI-FTICR (7T solariX XR-2ω, Bruker Daltonics) mass spectrometer equipped with a Smartbeam II 2 kHz laser.
Results: We previously observed abnormal elevations of L-DOPA and its metabolite, 3-O-methyldopa, in the whole brain of LID animals. This resulted in increased dopamine and downstream metabolites in all brain regions, except putamen and caudate. Furthermore, we found that the abundance of selected neuropeptides was associated with L-DOPA concentrations in the putamen, emphasizing their sensitivity to L-DOPA. In this study, we conducted extensive imaging of various lipid species, enabling the detection of specific distributions of hydroxylated and non-hydroxylated sulfatide lipids within the same individual brains. Hydroxylated sulfatides were abundant within several basal ganglia brain regions, whereas long-chain hydroxylated sulfatides were depleted in motor-related regions, with non-hydroxylated showing an elevation. When comparing individuals with LID to those without dyskinesia, we observed a decrease in plasmalogen phosphatidylcholines and an increase in polyunsaturated fatty acid-containing glycerophospholipids specifically in the internal segment of globus pallidus. These changes were significantly correlated with the LID scores of the animals.
Conclusions: This MALDI-MSI study provides valuable insights into signaling system dynamics during PD and its treatment.

OPTICAL DIFFERENTIATION OF PROTEIN AGGREGATES IN DIFFERENT TYPES OF ALZHEIMER´S DISEASE AND ALPHA-SYNUCLEINOPATHIES USING THIOPHENE-BASED LIGANDS

POSTERS: A04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Therése Klingstedt[1], Linnea Björk[1], Hamid Shirani[1], Martin Ingelsson[2,3,4], Ruben Vidal[5], Bernardino Ghetti[5], Peter Nilsson[1]
[1]Linköping University, Department Of Physics, Chemistry And Biology, Linköping, Sweden, [2]Uppsala University, Department Of Public Health And Caring Sciences, Uppsala, Sweden, [3]University Health Network, Krembil Brain Institute, Toronto, Canada, [4]University of Toronto, Tanz Centre For Research In Neurodegenerative Diseases, Toronto, Canada, [5]Indiana University School of Medicine, Department Of Pathology And Laboratory Medicine, Indianapolis, United States of America

Aims: The aim of this study was to investigate binding of a variety of thiophene-based ligands to amyloid-β (Aβ) deposits in Alzheimer´s disease (AD), as well as to α-synuclein (α-syn) inclusions in α-synucleinopathies.
Methods: For Aβ, cases of sporadic and inherited AD were included. For this study, inherited AD consisted of mutation carriers of the *APP* or *PSEN1* genes; α-synucleionopathies consisted of Parkinson's disease (PD) or multiple system atrophy (MSA). Brain tissue sections from each case were stained with combinations of thiophene-based ligands such as HS-276 and LL-1. The ligand staining patterns were compared using hyperspectral imaging and ligand specificity was confirmed by immunohistochemistry.
Results: When applying different dual staining protocols with specific thiophene-based ligands, distinct staining patterns of Aβ deposits were revealed for sporadic versus inherited AD. For example, with a combination of ligands HS-276 and LL-1, HS-276 was most prominent in sporadic AD, whereas LL-1 was most prominent in an *APP* E693G case. In addition, within the group of inherited AD, a difference in ligand staining could be seen. Differential staining patterns were also observed in the analysis of α-syn inclusions in PD versus MSA.
Conclusions: Dual staining protocols with different thiophene-based ligands allow a more precise differentiation of Aβ deposits in sporadic and inherited AD, as well as α-syn inclusions in PD and MSA. This study also highlights the importance of having a toolbox of ligands to enable detection and differentiation of the entire spectrum of disease-associated Aβ or α-syn pathologies. Hence, a variety of ligands is probably essential for an early and accurate diagnosis of different types of AD and α-synucleinopathies, as well as for monitoring disease progression and evaluating potential treatment strategies for these diseases.

Aims: We aimed to i) assess differences in blood and imaging biomarkers of neurodegeneration among cognitively unimpaired *APOE* ε4 homozygotes, heterozygotes, and non-carriers and ii) to determine how different cerebral pathologies (Aβ deposition, medial temporal atrophy, and cerebrovascular pathology) contribute to blood biomarker concentrations.
Methods: Sixty *APOE* ε4 homozygotes (n = 19), heterozygotes (n = 21), and non-carriers (n = 20) ranging from 60–75 years, were recruited. Participants underwent Aβ-PET ([^{11}C]PiB), structural brain MRI, and blood sampling for measuring neurofilament light chain (NfL), total tau (t-tau), N-terminal tau fragments (NTA-tau) and glial fibrillary acidic protein (GFAP). [^{11}C]PiB standardized uptake value ratio was calculated for different brain regions. MRI images were analysed for regional volumes, atrophy scores, and volumes of white matter hyperintensities. Differences in biomarker levels and associations between blood and imaging biomarkers were tested using uni- and multivariable linear models.
Results: NfL concentration was increased in *APOE* ε4 homozygotes compared with non-carriers (mean 21.4 pg/ml vs. 15.5 pg/ml, p = 0.013), whereas other blood biomarkers did not differ between the groups (p > 0.077 for all). Hippocampal volume was decreased in *APOE* ε4 homozygotes compared with non-carriers (6.71 ml vs. 7.2 ml, p = 0.029). In the whole sample, blood biomarker levels were differently predicted by the cerebral pathologies; NfL concentration was associated with cerebrovascular pathology and medial temporal atrophy, NTA-tau associated with medial temporal atrophy. GFAP showed significant association with both medial temporal atrophy and Aβ pathology. T-tau concentration did not associate with any of the measured pathologies.
Conclusions: Only increased NfL concentrations and decreased hippocampal volume was observed in cognitively unimpaired APOEε4 homozygotes compared to non-carriers. In the whole population the blood biomarkers were affected in distinct ways by different pathologies.

Aims: The primary goal of this project is to combine hyperspectral confocal imaging and SIMOA to probe the chemical and structural aspects of neurofibrillary tau pathology in Alzheimer's Disease.
Methods: Herein we devised a hyperspectral chemical imaging approach to stratify Tau aggregation and biochemical Tau profiles in postmortem brain across different phases of disease progression. We further correlate those profiles with blood and CSF biomarker patterns collected antemortem in a unique paired longitudinal cohort. Using fluorescent probes and hyperspectral, fluorescent microscopy we characterized and annotated distinct stages of Tau aggregation and maturation in the brain.
Results: Correlative immunohistochemistry identified ptau 217 deposition across structurally distinct Tau aggregates including pretangles (PT), neurofibrillary tangles (NFT), ghost tangles (GT), neuropil threads (NPT) and axonal and dystrophic neurites associated with amyloid pathology. Finally, we show that pTau217 levels within hippocampal tangle pathology correlate with both pTau 217 CSF and Braak stages.
Conclusions: These results provide new insights into the continuum of polymorphic Tau aggregation and how pTau biomarkers relate to brain pathology at the microscale.

HIPPOCAMPAL SUBFIELD VOLUMES AT 7T IN MILD COGNITIVE IMPAIRMENT

POSTERS: A04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Michela Pievani[1], Federica Ribaldi[2], Ileana Jelescu[3], Jorge Jovicich[4], Valentina Garibotto[5], Giovanni Frisoni[6]
[1]IRCCS Istituto Centro San Giovanni di Dio Fatebenefratelli, Lab Alzheimer's Neuroimaging & Epidemiology, Brescia, Italy, [2]University of Geneve, Laboratory Of Neuroimaging Of Aging (lanvie), Geneve, Switzerland, [3]Lausanne University Hospital (CHUV) and University of Lausanne (UNIL), Dept Of Radiology, Lausanne, Switzerland, [4]University of Trento, Center For Mind/brain Sciences (cimec), Rovereto, Italy, [5]Laboratory of Neuroimaging and Innovative Molecular Tracers (NIMTlab), Geneva University Neurocentre, Faculty of Medicine, University of Geneva, Division Of Nuclear Medicine And Molecular Imaging, Geneva, Switzerland, [6]University of Geneva (UNIGE and Geneva University Hospital (HUG), Department Of Rehabilitation And Geriatrics, Geneva, Switzerland

Aims: Hippocampal subfields play a key role in memory and are affected early in Alzheimer's disease (AD). In this study, we used 7T MRI to assess hippocampal subfield volumes in patients with mild cognitive impairment (MCI) and their relationship with memory deficits and AD pathology.
Methods: Thirty-nine participants were recruited at the Geneva Memory Center: n=22 cognitively unimpaired participants (CU; MMSE: 29±1) and n=17 MCI patients (MMSE: 27±3). Participants underwent 7T MRI (Siemens), including T2-weighted and structural MRI, at the EPFL in Lausanne. A subsample of participants underwent amyloid PET and tau PET. Hippocampal subfields (subiculum, CA1, CA2, CA3, dentate gyrus (DG), hippocampal tail) and extra-hippocampal areas (entorhinal and parahippocampal cortex) were segmented using Automated Segmentation of Hippocampal Subfields (ASHS) package. Differences between groups in hippocampal subfields were assessed with analysis of variance adjusting for age, sex and education. Correlations between hippocampal subfields, memory, amyloid and tau were assessed with Spearman's correlation test.
Results: MCI showed smaller volumes than CU in all hippocampal subfields ($p<0.05$), except for the DG that showed a trend ($p=0.087$). CA1, DG, and hippocampal tail volumes were positively associated with episodic memory in MCI (FCSRT immediate and delayed recall, $p<0.05$), while CU showed a significant association between memory and DG volume ($p=0.03$). In the whole sample, tau uptake in the hippocampus showed a negative correlation with CA1 volume ($p=0.05$), tau uptake in the inferior temporal cortex with parahippocampal volume ($p=0.02$), and tau uptake in the parahippocampus with DG volume ($p=0.03$). Amyloid levels were not associated with hippocampal subfield volumes.
Conclusions: These results suggest that hippocampal subfield markers may be sensitive to cognitive deficits in MCI, and confirm that tau but not amyloid pathology is associated with subfields neurodegeneration.

NOVEL DUAL MODALITY IMAGING AGENTS FOR DIAGNOSTIC APPLICATIONS IN ALZHEIMER'S DISEASE

POSTERS: A04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Liviu Mirica
University of Illinois, Chemistry, Urbana, United States of America

Aims: Metal radiotracers exhibit beneficial properties that can improve *in vivo* positron emission tomography (PET) imaging over traditional radionuclides, such as longer half-lives, facile last-stage radiolabeling steps, and the potential for dual imaging-therapy applications. Among such radionuclides, ^{64}Cu exhibits a longer half-life ($t_{1/2}$ = 12.7 h) that allows for later PET imaging times and the ability to distribute ^{64}Cu imaging agents to facilities that do not have an on-site cyclotron.
Methods: The employed approach uses a bifunctional chelator with two Aβ-interacting fragments that dramatically improves the Aβ-binding affinity and lipophilicity for favorable blood-brain barrier (BBB) penetration, while the use of optimized-length spacers between the Cu-chelating group and the Aβ-interacting fragments further improves the *in vivo* Aβ-binding specificity and brain uptake of the corresponding ^{64}Cu PET imaging agent.
Results: Herein, we report to the best of our knowledge the first ^{64}Cu PET imaging agent that shows appreciable *in vivo* brain uptake and exhibits high specific affinity for beta-amyloid aggregates, leading to the successful PET imaging of amyloid plaques in the brains of 5xFAD mice versus those of WT mice.
Conclusions: ^{64}Cu PET imaging agents can be used for *in vivo* imaging of beta-amyloid aggregates.

A VISUAL SCALE TO RATE AMYGDALAR ATROPHY ON MRI

POSTERS: A04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Francesca Benedetta Pizzini[1], Federica Ribaldi[2], Valerio Natale[3], Giovanni Frisoni[2,4], Max Scheffler[5]
[1]University of Verona, Department Of Engineering For Innovation Medicine, Verona, Italy, [2]University of Geneve, Laboratory Of Neuroimaging Of Aging (lanvie), Geneve, Switzerland, [3]Radiology, University of Verona, Dept. Of Diagnostic And Public Health, Verona, Italy, [4]University of Geneva (UNIGE and Geneva University Hospital (HUG), Department Of Rehabilitation And Geriatrics, Geneva, Switzerland, [5]University of Geneve, Radiology And Medical Informatics, Geneve, Switzerland

Aims: Visual scales are routinely used in clinical radiology to assess brain atrophy, but no scoring system specifically addresses amygdala atrophy. Recently, a highly prevalent neurodegenerative condition called TDP-43 age-related predominant limbic encephalopathy (LATE), characterized by early and severe atrophy of the amygdala, has been described. The purpose of this study is to develop and validate a visual assessment scale of amygdalar atrophy (AAS).
Methods: We evaluated: inter/intra-rater reliability (Hypothesis 1-H1), convergent validity of AAS versus volumetry (H2) and its association with autopsy-confirmed LATE neuropathologic change (LATE-NC–H3) For *H1,* we randomly selected 100 patients from Geneva Memory Centre (GMC) cohort stratified by medial temporal atrophy based on Scheltens' scale (MTA 0-1, 1.5-2, 2.5-3, 3.5-4) to represent the variability observed in clinical cohorts. AAS criteria were operationalized for no, mild/moderate, and severe amygdalar atrophy. AAS was scored by three independent expert neuroradiologists (R1, R2, R3) on 3D T1 acquisitions. Weighted Cohen's Kappa (wK) assessed intra- and inter- rater reliability.
For *H2,* we used the entire GMC cohort (N=2008) with available 3D T1 scans. We assessed the association of AAS scores with amygdalar volumes with a Kruskal–Wallis test. For *H3* we used ADNI cohort (N=96) and assessed the association of LATE-NC with AAS score with a test for trend.
Results: Intra- and inter- rater agreement for AAS demonstrated very good reliability (mean wK 0.79, range 0.71-0.93). Significant amygdalar volume differences were observed between individuals with no atrophy, mild atrophy and severe atrophy, regardless of the rater ($p \leq 0.0001$). There was a trend towards increasing percentage of LATE-NC in the amygdala with severity of amygdalar atrophy ($p=0.057$).
Conclusions: AAS scale proves to be a reliable and valid tool to assess amygdalar atrophy in clinical routine.

RELATIVE POWER FOR LONGITUDINAL CHANGES OF CORTICAL MICROSTRUCTURE, CORTICAL THICKNESS, TAU PET AND COGNITION IN MILD COGNITIVE IMPAIRMENT

POSTERS: A04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Ged Ridgway[1], Ritobrato Datta[2], Mario Torso[1], Michele Valotti[1], Ziad Saad[2], Hartmuth Kolb[2], Steven Chance[1], Adni Alzheimer'S Disease Neuroimaging Initiative[1]
[1]Oxford Brain Diagnostics Ltd, Obd, Oxford, United Kingdom, [2]Janssen R&D, Johnson & Johnson, Neuroscience Biomarkers And Global Imaging, La Jolla, United States of America

Aims: To compare longitudinal rates of decline in cognition and function, microstructural and macrostructural neurodegeneration, and tau pathology, in the Mild Cognitive Impairment (MCI) stage of Alzheimer's Disease (AD).
Methods: Data comprised all available ADNI diffusion MRI and tau PET scans acquired within 100 days of each other, having two or more time-points on the same MRI scanner model, diagnosed as MCI at time of first scan, yielding 99 scans from 43 subjects (19 female), summarised in Table 1. Cortical thickness was derived using FreeSurfer; dMRI were processed using FSL, and proprietary software produced a minicolumn-associated measure of cortical microstructure (PerpPD^{+}; Torso et al., 2022; PMID:36281682). Measures were averaged over all cortical regions (whole-brain [WB]) and over AD signature regions (Ridgway et al., CTAD2022). Tau PET SUVR (using cerebellar gray reference region) was averaged over all cortical regions (WB) and a Braak4 meta-ROI (Therriault et al., 2022; PMID:37118445). Longitudinal imaging data were summarised by annualised percentage change from baseline, alongside absolute annualised change for MMSE and CDR-SB.

Table 1 Clinical and demographic characteristics

	Mean	SD
Age at first scan (years)	73.398	7.651
MMSE at first scan	27.698	2.435
CDR at first scan	0.477	0.106
CDR-SB at first scan	1.291	0.861
MRI timespan (years)	1.996	0.723
PET timespan (years)	1.916	0.731

Results: Longitudinal changes are summarised in Figure 1. Following Wang et al., (2016; PMID:27010616), we report mean-to-standard deviation ratio (MSDR) and relative sample size (RelSS, proportional to inverse square MSDR) compared to the best method (Table 2). PerpPD+ signature performed best, followed by Tau PET Braak4 (9% higher RelSS), followed by cortical thickness signature (approx. twice as many subjects). These three best imaging metrics are related to MMSE and CDR-SB in Figure 2; the strongest association is between MMSE and PerpPD+ signature.

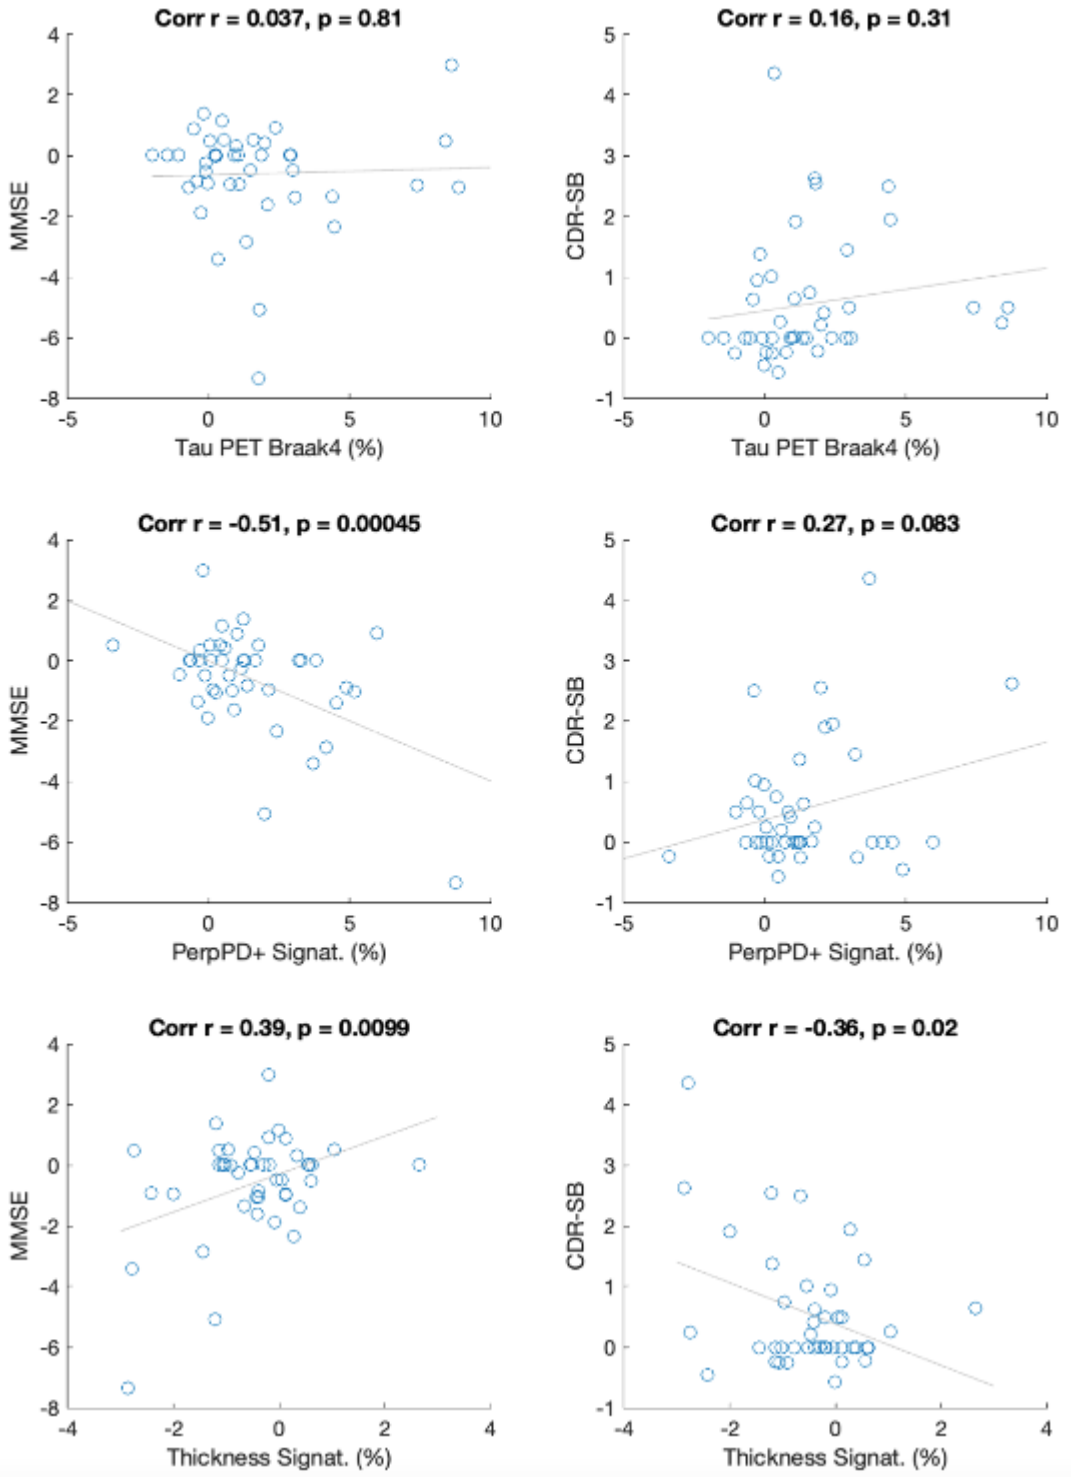
Table 2 Annualised longitudinal change from baseline (percentage where indicated)

Metric	Mean	SD	MSDR	RelSS
MMSE	-0.599	1.704	-0.351	3.657
CDR-SB	0.547	1.019	0.537	1.563
Tau PET WB (%)	1.215	2.262	0.537	1.564
Tau PET Braak4 (%)	1.658	2.581	0.642	1.094
PerpPD+ WB (%)	1.238	2.469	0.502	1.792
PerpPD+ Signat. (%)	1.477	2.199	0.672	1
Thickness WB (%)	-0.373	1.088	-0.343	3.839
Thickness Signat. (%)	-0.490	1.058	-0.463	2.101

Figure 2



Conclusions: Cortical microstructure assessed using dMRI can quantify longitudinal change in MCI, better than cortical macrostructure, and similarly to tau PET. Future work will explore additional cortical microstructural measures, tau PET measures, and their interrelations.

EXPLORING THE FEASIBILITY OF DETECTING PROTEIN AGGREGATIONS IN SPINAL CORDS OF ALZHEIMER'S DISEASE MOUSE MODELS THROUGH MULTIMODAL HIGH-RESOLUTION IMAGING

POSTERS: A04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Valeriia Skoryk[1], Pablo De Castro Mínguez[1], Stephen Hall[2], Oxana Klementieva[1]
[1]Faculty of Medicine, Lund University, Experimental Medical Science, Lund, Sweden, [2]Faculty of Engineering, Lund University, Solid Mechanics, Lund, Sweden

Aims: Early detection of amyloid plaque is an important task to be resolved for early Alzhiemer's desease (AD) diagnosis. High-resolution X-ray tomography (HR-XT) can reveal protein aggregates in tissue based on density variations, yet the exact composition and structure of these aggregates remain elusive.
Methods: To validate HR-XT as label free tool for early plaque detection, we performed three-dimensional HR-XT imaging and immunolabeling of amyloid plaques in spinal cords of two AD mouse models, 5xFAD and hAPP^{NL-G-F}knock-in. The comprehensive approach involved visualizing various protein epitopes using different antibodies, followed by three-dimensional reconstruction. These methods enabled us to visualize components like amyloid-β and α-synuclein within protein aggregations in a three-dimensional context.
Results: We acquired HR-XT data through two techniques: 1) laboratory X-ray microtomography, 4D Imaging Lab, Lund University; 2) synchrotron X-ray phase-contrast tomography, Anatomix beamline, SOLEIL. After reconstructing the data into 3D representations, we identified small, condensed areas in the second dataset. Comparison between the tomography- and immunolabeling-based 3D-models revealed a partial overlap between the condensed areas and amyloid-β. This is significant result, suggesting the presence of components within the aggregates missed by immunolabeling.
Conclusions: Therefore, to have a greater understanding of protein aggregation related to AD pathology the use of multimodal imaging approach is an imperative. Furthermore, to augment our methodology we are incorporating another label-free technique: structure sensitive high-resolution optical infrared spectroscopy, as a downstream imaging procedure, followed by multiplex immunolabeling. This provides a 3D depiction of small protein aggregates, elucidating their structure and composition. The following comparison of the 3D models from the different approaches may help us to characterise better the components within the aggregates missed by immunolabeling and to, thus, identify potential proteins depositions even at an early stage.

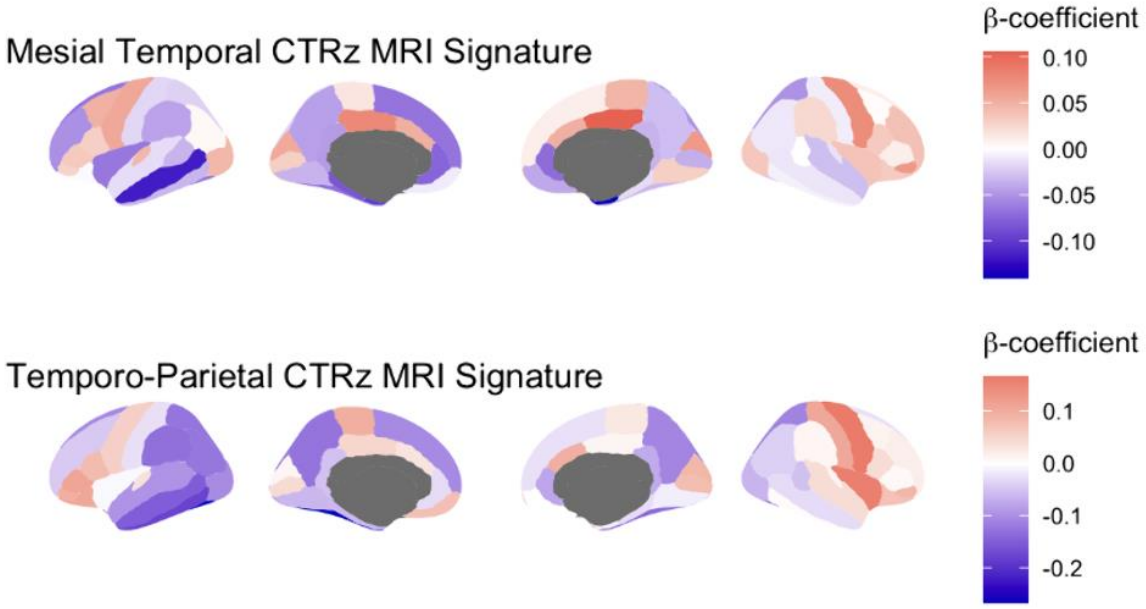
STRUCTURAL CONNECTOME-INFORMED MRI-BASED SIGNATURES PREDICT TAU BIOLOGICAL STAGES OF ALZHEIMER'S DISEASE

POSTERS: A04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Clara Sorensen, Duygu Tosun
University of California - San Francisco, Radiology And Biomedical Imaging, San Francisco, United States of America

Aims: In light of recent clinical trials for Alzheimer's disease (AD), the newly proposed NIA-AA staging has extended biological stratification by including tau proteinopathy stages. Our goal was to develop predictive models for tau stages in the absence of tau positron emission tomography (PET). To accomplish this, we analyzed demographic, clinical, and imaging data from the Alzheimer's Disease Neuroimaging Initiative (ADNI) study.
Methods: Structural magnetic resonance imaging (MRI) signatures were trained on a cohort of 469 participants from the Alzheimer's Disease Neuroimaging Initiative (ADNI) to identify patterns of atrophy associated with tau PET burden ($CenTauR_z$ values) in mesial temporal (MTL) and temporo-parietal (TP) regions separately, using regularized linear regression constrained by the average structural connectome of 80 healthy controls. Tau positivity for MTL and TP stages were defined at $CenTauR_z>2$. Nested ordinal logistic regression models were trained on an independent cohort of 118 ADNI subjects to predict the MTL and TP tau stage positivity. These models incorporated independent variables of demographic and clinical data, amyloid centiloid, and MTL and TP MRI signatures, both separately and jointly.
Results: MRI signatures associated with MTL and TP tau burden (R^2 of 0.44 and 0.40, respectively) are shown in Fig1. Employing 5-fold cross validation, the top-performing model achieved a multiclass AUC of 0.76, incorporating both MTL and TP MRI signatures, CDR-SOB, MMSE, APOE e4 status, and amyloid centiloid value. In contrast, using demographic data as predictors alone yielded an AUC of 0.5, while combining demographic and clinical data resulted in an AUC of 0.67.

Fig. 1 Structural MRI Signatures



Conclusions: Our study highlights the potential of leveraging intrinsic brain properties to construct MRI signatures as a promising and effective approach to significantly improve the accuracy of tau staging in AD.

APOE4-RELATED WHITE MATTER IMPAIRMENT CORRELATES WITH INCREASED BETA-AMYLOID DEPOSITION IN HEALTHY ELDERLY ADULTS

POSTERS: A04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Claudia Tato-Fernández[1], Laura Ekblad[1], Elina Pietilä[1], Virva Saunavaara[1], Semi Helin[1], Riitta Parkkola[2], Juha Rinne[1,3], Anniina Snellman[1,4]
[1]University of Turku, Turku Pet Centre, Turku, Finland, [2]Turku University Hospital, Department Of Radiology, Turku, Finland, [3]University of Turku, Inflames Research Flagship Center, Turku, Finland, [4]Institute of Neuroscience & Physiology, The Sahlgrenska Academy, University of Gothenburg, Department Of Psychiatry And Neurochemistry, Gothenburg, Sweden

Aims: *APOE4* is a genetic risk factor for late-onset Alzheimer's disease. In this study, we evaluated whether i) white matter impairment measured by DTI differs between healthy individuals with different number of *APOE4* alleles; ii) white matter impairment associates with Aβ load measured by positron emission tomography (PET).
Methods: Our sample included 96 participants (*APOE4/4*, *N* = 20; *APOE4/3*, *N* = 39; *APOE3/3*, *N* = 37), with mean (SD) 68 (8) years, 64.9% females. All underwent magnetic resonance imaging, including diffusion tensor imaging sequences, and ^{11}C-PiB amyloid PET. We conducted hypothesis-driven region-of-interest (ROI) analysis in the cingulum, corpus callosum and uncinate fasciculus. Fractional anisotropy (FA) and mean diffusivity (MD) were calculated within each ROI and compared between the *APOE* groups using ANCOVA, with sex and age as covariates. A voxel-weighted average of FA and MD was calculated for each subject to evaluate correlation with Aβ load, estimated as ^{11}C-PiB composite standardized uptake value ratio, using Spearman's rank correlation.
Results: A significant difference between groups in regional MD was present in the body of corpus callosum ($p = 0.039$, ANCOVA) where *APOE4/4* carriers exhibited higher MD than *APOE4/3* ($p = 0.0053$) and *APOE3/3* ($p = 0.026$). On the contrary, no regional differences were detected for FA ($p > 0.13$ for all). High brain Aβ load was associated with elevated MD ($r = 0.29$, $p = 0.0063$) in the whole sample, driven by *APOE4/3* carriers ($r = 0.42$, $p = 0.011$).
Conclusions: Cognitively unimpaired *APOE4/4* carriers showed increased MD in the body of corpus callosum. This indicator for neurodegeneration positively correlated with ^{11}C-PiB uptake, suggesting that Aβ deposition and white matter damage are related in subjects with high risk for Alzheimer's disease.

A MULTIMODAL STRATEGY FOR PREDICTING COGNITIVE AND FUNCTIONAL IMPAIRMENTS THROUGH WHITE MATTER DATA

POSTERS: A04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Nishant Chauhan[1], Hyun Woong Roh[2], Sang Son[2], Chang Hyung Hong[2], Dongha Lee[1]
[1]Korea Brain Research Institute, Cognitive Science Research Group, Daegu Metropolitan City, Korea, Republic of, [2]Ajou University School of Medicine, Psychiatry, Suwon, Korea, Republic of

Aims: Neurodegenerative disorders, marked by the accumulation of pathological proteins in the brain, often lead to cognitive impairment and disability. Accurate diagnosis of cognitive decline and functional independence in these conditions poses clinical challenges. White matter, housing vital neural circuits and glial cells, can sustain damage, resulting in clinical symptoms that affect daily life independence. Recent advances in imaging have made brain MRI and amyloid PET examinations more accessible. While these tests traditionally focused on grey matter, this study highlights the significance and potential of white matter in neurodegenerative disease diagnosis.
Methods: This study examined data from 455 participants in the Biobank Innovations for Chronic Cerebrovascular Disease with Alzheimer's Disease Study (BICWALZS), encompassing individuals with subjective cognitive decline (SCD), mild cognitive impairment (MCI), Alzheimer's disease (AD), and vascular dementia (VD). The dataset was categorized into two groups: cognitive impairment (SCD vs. MCI, AD, VD), which involves individuals experiencing cognitive deficits, and functional disability (SCD, MCI vs. AD, VD), which pertains to individuals facing limitations in their daily functioning. Amyloid PET and MRI data were collected, and white matter information from these scans was integrated to create an ensemble dataset.
Results: The classification was performed using a support vector machine (SVM) on multimodal datasets, which included T2-FLAIR, amyloid PET, and ensemble data. The ensemble model achieved significantly higher accuracy in classifying cognitive impairment (89.25%) compared to individual T2-FLAIR (85.29%) and amyloid PET models (84.20%). In the classification of functional disability, the ensemble model (77.58%) outperformed T2-FLAIR (70.77%) and amyloid PET models (73.17%), with no significant difference between T2-FLAIR and amyloid PET models.
Conclusions: This study showcases the potential of white matter data to enhance diagnostic accuracy in neurodegenerative diseases.

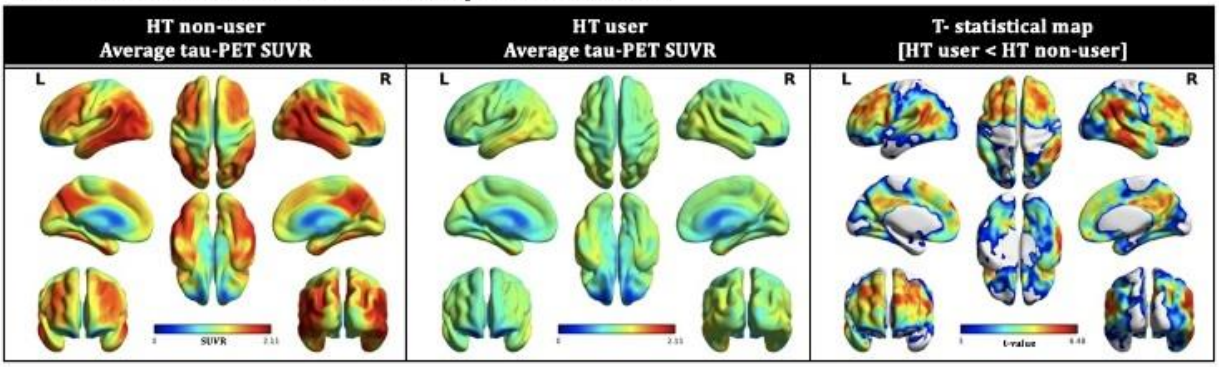
Aims: Postmenopausal females represent approximately 70% of the Alzheimer's disease (AD) cases. Previous literature proposes a connection between the decreased estrogen levels during menopause and an increased risk of dementia. However, the outcomes of administrating hormone therapy (HT) as a preventive strategy against AD in peri/post-menopausal females have been inconclusive. The goal of the present study was to examine the impacts of HT on AD biomarker-informed pathologies.
Methods: This cross-sectional study assessed post-menopausal female individuals from two cohorts: the TRIAD cohort and the ADNI cohort. Participants underwent magnetic resonance imaging (MRI), amyloid-β (Aβ) and tau positron emission tomography (PET), and biofluid collection. Voxel-based t-tests were performed to assess the differences in Aβ and tau neurofibrillary tangles (NFTs) loads between post-menopausal females without HT history (HT-) and post-menopausal females who were using HT (HT+). Linear regression models with interaction terms were conducted to examine the effects of the interaction between HT and Aβ-PET on regional tau-PET and tau fluid biomarkers.
Results: HT+ females demonstrated significantly lower tau-PET standardized uptake value ratio (SUVR) in Braak I-II ROIs ($P < 0.05$, Hedges' $g = 0.73$), Braak III-IV ROIs ($P < 0.0001$, Hedges' $g = 0.74$) and Braak V-VI ROIs ($P < 0.0001$, Hedges' $g = 0.69$) compared to HT- females (Fig 1). HT+ females also showed significantly lower CSF p-tau$_{181}$ ($P < 0.001$) and plasma p-tau$_{181}$ ($P < 0.0001$) concentrations. Additionally, results from linear regression models indicated that HT use interacts with cortical Aβ and mitigates regional NFT formation (Table
1).

Figure 1. Hormone therapy mitigates tau tangle aggregation in post-menopausal females

A) Results from voxel-based Welch's t-test showed that HT+ females presented significantly lower tau-PET SUVR in multiple brain regions as demonstrated in the t-statistical map. B) ROI-based linear regression models showed that with similar Aβ load, HT+ females demonstrated less NFT aggregation compared to HT- females, suggesting HT use modulated the relationship between cortical Aβ and regional NFT load.

A. HT+ females had lower tau-PET SUVR compared to HT- females



B. HT modulated the relationships between cortical Aβ and regional NFT load

Table 1. Hormone therapy interacts with cortical Aβ and mitigates regional tau-PET load

Multivariate linear regression models were performed to understand how the interaction between Aβ and HT influenced regional tau-PET. The results showed that HT interacted with neocortical Aβ-PET and predicted lower tau-PET in Braak ROIs. The findings remained significant after correcting for age, education, *APOE ε4* carriage status and clinical diagnosis. Interaction plots are demonstrated on the right side of the table.

Braak I - II

Variable	Est. (95% Conf. Int.)	t-stat	P-value

Aims: Plasma p-tau217 can differentiate Alzheimer's disease (AD) cases with significant brain pathology from non-AD cases. In addition, plasma p-tau217 starts to increase earlier than other p-tau variants and shows an increase during preclinical AD. Data strongly suggests that while both plasma p-tau181 and p-tau217 are accurate markers to predict the future development of AD in symptomatic patients with either MCI or subjective cognitive decline (SCD), plasma p-tau217 is slightly better for AD diagnosis due to its sizable increase in the earlier stage of AD. In this study, we validated the diagnostic accuracy of p-tau217 in differentiating AD from non-AD pathology.
Methods: In this study, we conducted diagnostic validation to assess the analytical performance of plasma p-tau217 using EDTA plasma samples from individuals with β amyloid PET-positive (n=121) and β amyloid PET-negative (n=35) status. Plasma p-tau217 levels were quantified using an innovative commercial plasma-based Simoa assay developed by ALZpath, employing an exclusive proprietary monoclonal p-tau217 capture antibody.
Results: The mean plasma p-tau217 levels were 1.25 ± 0.54 ng/L in PET+ cases and 0.49 ± 0.42 ng/L in PET-negative cases. ROC analysis demonstrated an AUC of 0.92, with a Youden's Index of 0.73 pg/mL, indicating a specificity of 92.9% and a sensitivity of 86.4%. Notably, when considering an upper limit cut-off of 0.63 pg/mL, specificity remained at 82% while sensitivity increased to 92.2%. Conversely, employing a lower limit cut-off of 0.40 pg/mL resulted in a specificity of 53.6% but a notably higher sensitivity of 99%.
Conclusions: The specific analytic findings of plasma p-tau 217 validation showed good promise. However, establishing a potentially practical clinical cut-off for the AD diagnosis, particularly as a clinical screening tool, requires further validations through clinical studies conducted within memory clinics.

Aims: In the last decade, biomarker research in the field of Alzheimer's Disease(AD)using body fluids has moved toward the blood-based biomarker concept to ease sample handling decrease cost and facilitate disease management.In this regard, measurements of AD biomarkers in urine matrix would be even more patient-friendly practical,and cost-effective.Therefore we aimed to profile Aβ40Aβ42 GFAP NfL and p-tau231 in the paired spot urine and plasma samples of AD patients along the AD continuum in a proof-of-concept approach.
Methods: We included 634 longitudinally collected urine samples from the TRIAD,which was representative of the AD continuum.All paired plasma and urine samples were measured for Aβ42 Aβ40 GFAP and NfL with a commercial Simoa N4PE kit and p-tau231 using in-house Simoa technology at the University of Gothenburg.Plasma and urine creatinine and urine albumin concentrations were determined using a Cobas c501.Glomerular barrier function was assessed based on albumin-creatinine ratio(ACR) and eGFR calculation.
Results:

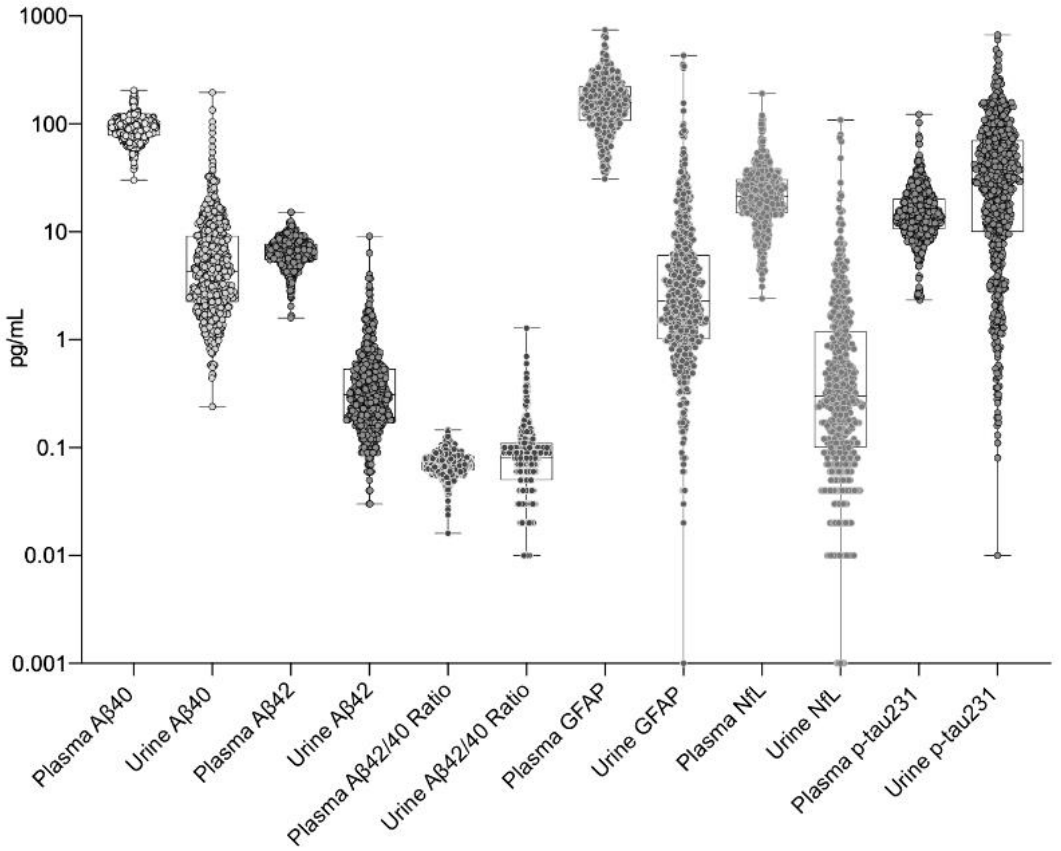

Figure 1. The box-and-whisker plots show plasma vs. urine concentrations of biomarkers. For the box-and-whisker plots, the horizontal bar shows the median, and the upper and lower boundaries show the 25th and 75th percentiles, respectively.

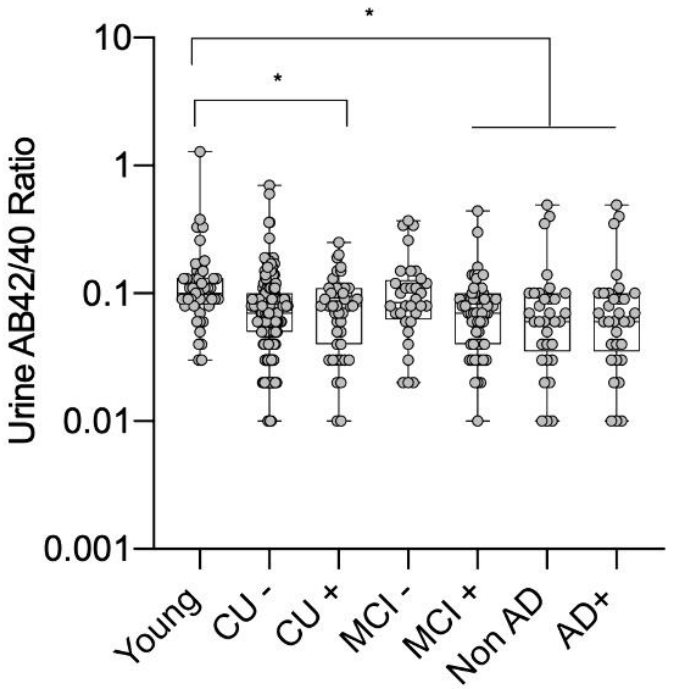

Figure 2. The box-and-whisker plots show urine Aβ42/40 ratio across groups. For the box-and-whisker plots, the horizontal bar shows the median, and the upper and lower boundaries show the 25th and 75th percentiles, respectively. *p <0.001

The quantitative measurability of urine biomarkers(n,%),respectively,were Aβ40(623 98.26%)Aβ42(611 96.37%)GFAP(618 97.47%)NfL(521 82.17%)p-tau231(626 98.73%).The median absolute concentrations of biomarkers in plasma samples were significantly higher than urine concentrations,except for p-tau231 which was higher in urine(Figure1).Across groups along the ADcontinuum only urine Aβ42/40 was significantly higher in young participants(Figure2).

Conclusions: In contrast to few publications a large percentage of five investigated AD blood biomarkers were detectable in the urine matrix.While urine biomarkers correlated between themselves we found no significant change of AD markers in urine across the ADcontinuum.We also did not find a relationship between plasma and urine in patients with impaired glomerular barrier.As a result of this study urine seems not to be a reliable matrix for the determination of AD pathology.However the wide range of values of such biomarkers in urine warrants further investigate for mechanistic understanding.

MAPPING THE TEMPORAL COURSE OF CSF GAP-43 IN ALZHEIMER'S DISEASE

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Prithvi Arunachalam[1], Alexis Moscoso[1], Nicolai Franzmeier[1,2,3], Michael Schöll[1,4,5]
[1]1University of Gothenburg, The Sahlgrenska Academy, Institute of Neuroscience and Physiology, Department Of Psychiatry And Neurochemistry, Mölndal, Sweden, [2]LMU Munich, Institute For Stroke And Dementia Research, Munich, Germany, [3]LMU Munich, Munich Cluster For Systems Neurology (synergy), Munich, Germany, [4]University of Gothenburg, Wallenberg Centre For Molecular And Translational Medicine, Gothenburg, Sweden, [5]Institute of Neurology, University College London, Dementia Research Centre, London, United Kingdom

Aims: Synaptic dysfunction has been proposed as one of the earliest events in Alzheimer's Disease (AD) pathogenesis, strongly correlating with cognitive decline. Changes in the pre-synaptic protein Growth-associated protein 43 (GAP-43) in the cerebrospinal fluid (CSF), which plays a crucial role in synaptogenesis, have been linked to the detection of cognitive impairment. Several studies have further linked changes in CSF GAP-43 to pathological changes in markers of AD. However, the biomarker lacks longitudinal validation. In this work, we have mapped the temporal trajectory of CSF GAP-43 across the AD spectrum and investigated, when in the disease course, its levels turn abnormal.
Methods: We included longitudinal Ab PET scan (either with [^{18}F]Florbetapir; FBB, [^{18}F]Florbetaben) from 1480 ADNI participants, baseline CSF GAP-43 from 673 ADNI subjects (i.e., cognitively normal (CN) Ab-, n=138; CN Ab+=77; cognitively impaired (CI) Ab-=164; CI Ab+=294). To estimate the population-based shape of AD-specific timeline of Ab accumulation, we fitted a nonlinear mixed effects model based on longitudinal Ab PET measures. Similar models were used to model baseline and longitudinal levels of available biomarkers (including CSF GAP-43) as a function of time since Ab positivity.
Results: The findings indicated an increase in CSF GAP-43 levels in the presence of Ab pathology at baseline (**Figure 1**). The longitudinal analysis demonstrated a consistent upward trend with the earliest CSF GAP-43 changes manifesting ~6.5 years before the onset of Ab pathology. Finally, it was estimated that CSF GAP-43 is the first AD biomarker to reach abnormal levels (**Figure 2**).

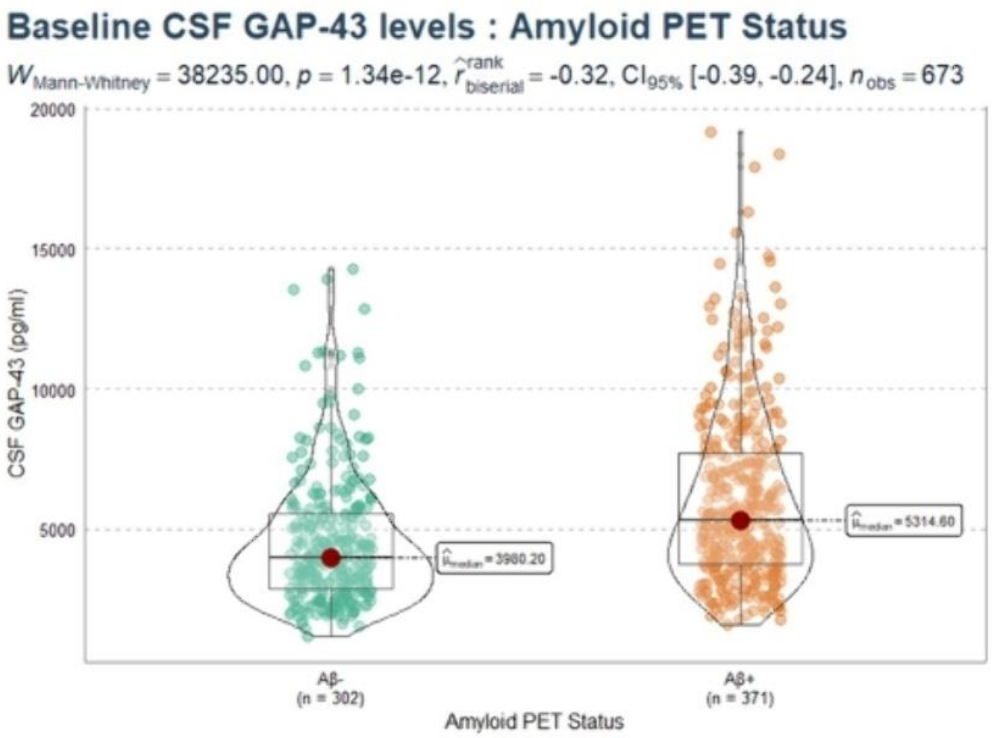

Figure 1. Group comparisons represented by violin plots for baseline CSF GAP-43 levels based on Ab positivity. The CSF GAP-43 concentration in Ab+ was higher than in Ab-. Boxes show the median and first and third quartiles. Dots represent individual observations. Abbreviations: Ab-, Ab PET negative group; Ab+, Ab PET positive group.

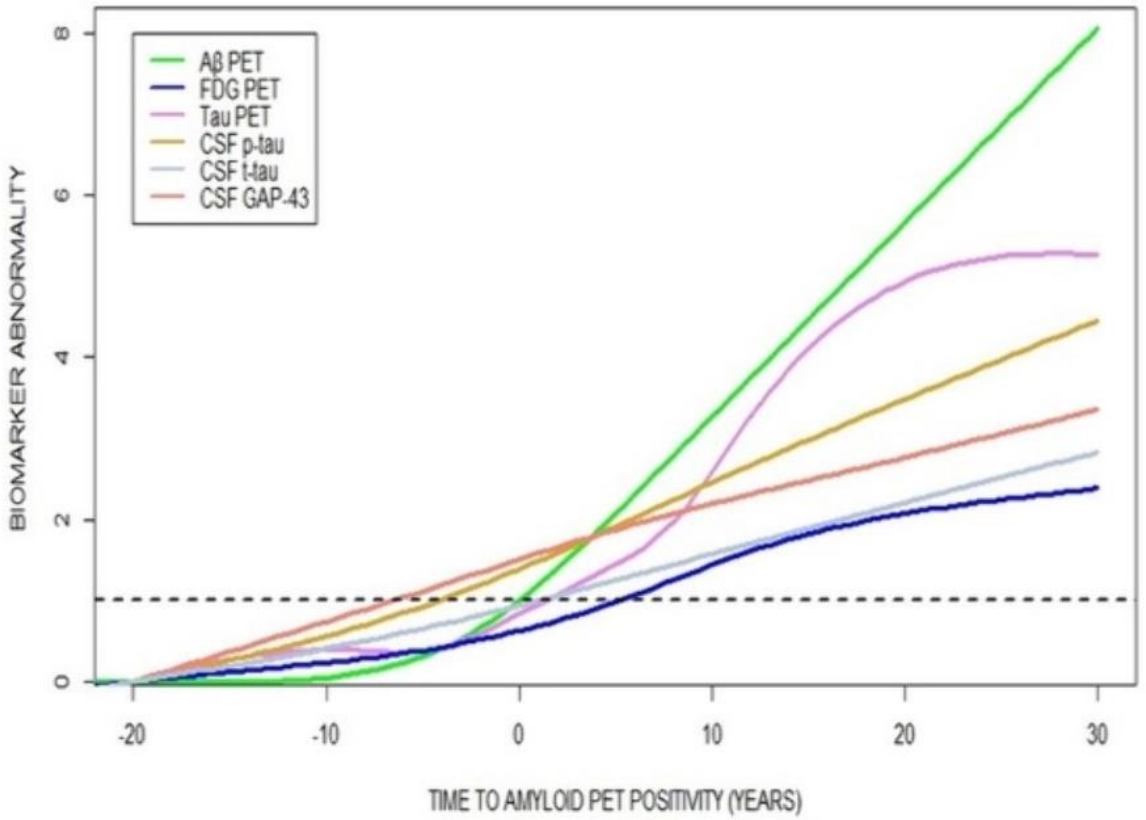

Figure 2. Combined biomarker trajectories of CSF GAP-43, Ab PET, Tau PET, FDG, and other CSF biomarkers as a function of time since Ab PET positivity in AD. The different biomarkers analyzed are color-coded as per the legend. Each biomarker measurement was normalized to its cut-off value to represent all biomarkers on a common scale where biomarker abnormality was recorded when the biomarker trajectory crosses the horizontal dashed line anchored at one (*i.e.*, cut-off value) on the y-axis.

Conclusions: These findings indicate that CSF GAP-43 increases before other investigated pathologic AD biomarkers, suggesting its potential significance for the early detection of aberrant synaptic activity in response to initial events during AD pathogenesis.

THE ROLE OF YRNAS AND YRNA FRAGMENTATION IN THE DEVELOPMENT AND PROGRESSION OF ALZHEIMER'S DISEASE (AD)

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Ingrid Lovise Augestad, Ingrun Alseth
Oslo University Hospital, Department Of Microbiology, Oslo, Norway

Aims: Despite intense research efforts over the past decades, the exact causes underlying AD is unknown and there is still no effective treatment or cure. In order to develop AD therapies, we need reliable and non-invasive biomarkers for diagnosis and disease progression. Therefore, it is crucial to investigate underlying pathophysiological mechanisms. The role of exosomes, a subgroup of extracellular vesicles, has recently gained a lot of attention for their potential as diagnostic biomarkers. Most cells in the body release exosomes, which are important for maintaining cell homeostasis and in cell-to-cell communication. We are interested in cytoplasmic (y) RNA, that are found enriched in exosomes. The fact that yRNAs are found in higher levels in exosomes suggest a highly selective packaging process. Our main hypothesis is that AD has a specific exosomal yRNA profile that can be used as biomarker. Further, we hypothesize that EndoV is instrumental for exosomal packaging of yRNAs and is involved in regulating inflammation.
Methods: Blood plasma will be collected from wildtype, AD mice (5XFAD), *EndoV*$^{-/-}$ and 5XFAD/*EndoV*$^{-/-}$ mice at different timepoints before (1-month- old) and during (2.5-, 4.5- and 9-month-old) the progression of AD. Exosomes will be isolated using size exclusion chromatography columns and exosomal yRNA levels and fragmentation will be analyzed with RT-qPCR. Neuronal and glial markers will be used to analyze brain tissue for neurodegeneration and inflammation.
Results: Previous work from our group has shown that yRNA bind to the human ribonuclease Endonuclease V (EndoV) and that deletion of EndoV in mice leads to milder disease in three different disease models.
Conclusions: We expect to generate new knowledge about AD and to our knowledge this is the first time yRNAs and EndoV in AD will be studied.

Aims: NfL and GFAP are promising blood-based biomarkers for Alzheimer's disease. However, few studies have explored plasma GFAP in the prodromal and preclinical stages of AD. In our cross-sectional study, our aim is to investigate the role of these biomarkers in the earliest stages of AD.
Methods: We enrolled 40 patients (11 SCD, 21 MCI, 8 AD dementia). All patients underwent neurological and neuropsychological examinations, analysis of CSF biomarkers ($A\beta_{42}$, $A\beta_{42}/A\beta_{40}$, p-tau, t-tau), Apolipoprotein E (*APOE*) genotype analysis and measurement of plasma GFAP and NfL concentrations. Patients were categorized according to the ATN system as follows: normal AD biomarkers (NB), carriers of non-Alzheimer's pathology (non-AD), prodromal AD, or AD with dementia (AD-D).
Results: GFAP was lower in NB compared to prodromal AD (p=0.003, d=1.463) and AD-D (p=0.002, d=1.695). NfL was lower in NB patients than in AD-D (p=0.011, d=1.474). NfL demonstrated fair accuracy (AUC=0.718) in differentiating between NB and prodromal AD, with a cut-off value of 11.65 pg/mL. GFAP showed excellent accuracy in differentiating NB from prodromal AD (AUC=0.901) with a cut-off level of 198.13 pg/mL.
Conclusions: GFAP exhibited excellent accuracy in distinguishing patients with normal CSF biomarkers from those with prodromal AD. Our results support the use of this peripheral biomarker for detecting AD in patients with subjective and objective cognitive decline.

Aims: To define whether a quantitative assessment of amyloid (A+) and tau (T+) cerebrospinal fluid (CSF) biomarkers can predict Alzheimer's (AD) phenotype and severity. To assess the effect of Lewy body (LB) co-pathology on AD presentation.
Methods: We evaluated 420 consecutive subjects with documented cognitive decline and CSF profile A+/T+ (Aβ42/40 ratio <0.68; phospho-tau181 >57 pg/ml). Participants were stratified twice in tertile groups according to Aβ42/40 ratio and phospho-tau values. Additionally, all cases were tested for the alpha-synuclein seeding activity by the real-time-quaking induced conversion assay in the CSF.
Results: CSF phospho-tau181 and Aβ42/40 ratio were negatively correlated (rho=-0.489). Higher phospho-tau181 levels were associated with younger age at onset (highest tertile 67.4±8.5 vs. lowest 71.0±9.3 years, p=0.0004; onset <65 years 48.9% vs. 29.8%, p=0.001), higher CSF total-tau (1049 [871-1334] vs. 466 [412-563] pg/ml, p<0.0001) and NfL (1513 [1140-1871] vs. 1039 [798-1700] pg/ml, p=0.003) levels, and a trend toward lower MMSE scores (19.8±6.4 vs. 21.4±5.7). By contrast, no significant differences were detected by comparing A+ tertiles. NfL levels in CSF and plasma, but not phospho-tau181, were significantly correlated (rho=0.514). LB co-pathology was found in 17.8% of patients; it was associated with a higher frequency of at least one clinical core feature of dementia with LB (28.6% vs. 12.5%, p<0.001), later onset (>65 years, 70.4% vs. 58.4%, p=0.04) and older age at CSF collection (71.2±9.4 vs. 68.9±9.0 years, p=0.03).
Conclusions: Higher CSF phospho-tau181 but no lower Aβ42/40 ratio levels are associated with a more severe AD phenotype, because of the younger age at onset, the worse performance at neuropsychological testing, and the significant increase of CSF biomarkers of neurodegeneration (N+). LB co-pathology influences the clinical presentation independently from phospho-tau181 and Aβ42/40 ratio levels.

OLIGOMERS COUNT.

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Oliver Bannach[1], Marlene Pils[1], Fabian Rehn[1], Sandra Kienast[1], Dieter Willbold[1,2]
[1]attyloid GmbH, Research And Development, Düsseldorf, Germany, [2]Forschungszentrum Jülich, Ibi-7, Jülich, Germany

Aims:

re in neurodegenerative diseases is the formation of toxic protein oligomers, which include amyloid-beta, alpha-synuclein, and Tau proteins ut also potent biomarkers for early diagnosis and drug development. However, accurately measuring these oligomers in biological fluids lik technical challenge, requiring extreme sensitivity and specificity.

Methods: We have introduced a technology called surface-based Fluorescence Intensity Distribution Analysis (sFIDA), which offers unparalleled sensitivity and specificity for quantitative detection of oligomers and other soluble aggregates. By integrating the precision of immunoassays with digital fluorescence microscopy, sFIDA enables the counting of individual oligomers.

Results: This presentation will offer an updated overview of our most recent findings, including novel data on quantifying oligomers in blood samples from the DELCODE cohort as well as in fecal samples. These insights are valuable not only for diagnostic applications but also for enhancing our understanding of key disease mechanisms, such as the clearance of oligomers from the brain.

Conclusions: In the realm of drug development, sFIDA serves as a crucial tool for validating the efficacy of drugs designed to dismantle oligomers. This technique can be applied in vitro, in animal models, and in ex vivo tissue samples. Furthermore, sFIDA proves invaluable as a biomarker assay for patient selection, stratification, and monitoring, as well as for evaluating drug-target engagement and therapeutic efficacy.

DAY-TO-DAY SLEEP VARIABILITY AND HIGHER PLASMA P-TAU231: INTERACTION BY MILD COGNITIVE IMPAIRMENT CONVERTING STATUS

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Andrée-Ann Baril[1], Cynthia Picard[2], Anne Labonté[2], Erlan Sanchez[3], Bery Mohammediyan[2], Catherine Duclos[1], Nicholas Ashton[4], Henrik Zetterberg[5], Kaj Blennow[5], John Breitner[2], Sylvia Villeneuve[2], Judes Poirier[2]
[1]Université de Montréal, Medecine, Montreal, Canada, [2]Douglas Mental Healthy University Institute, Stop-ad, Montreal, Canada, [3]Sunnybrook Research Institute, Research Center, Toronto, Canada, [4]University of Gothenburg, Neurochemistry, Gothenburg, Sweden, [5]University of Gothenburg, Department Of Psychiatry And Neurochemistry, Molndal, Sweden

Aims: Day-to-day variability might reveal unstable sleep-wake cycles reflecting neurodegenerative processes. Elevated plasma p-tau231 is an early event when correlated with AD post-mortem neuropathology, and may increase already at subtle levels of Ab deposition prior to amyloid positivity. We evaluated the association between plasma p-tau231 with sleep day-to-day variability.
Methods: In the PREVENT-AD cohort, 203 dementia-free participants (age:68.3±5.4, 78M) with a parental history of sporadic AD were tested with actigraphy, plasma p-tau231 (Simoa) and $A\beta_{42}$ (LC-MS) assays, as well as with longitudinal RBANS cognitive testing for mild cognitive impairment (MCI) adjudication. Day-to-day variability (standard deviations in sleep metrics over a week of actigraphy) was assessed for sleep midpoint, duration, efficiency, and nighttime activity count.
Results: Higher plasma p-tau231/$A\beta_{42}$ was associated with higher day-to-day variability of sleep duration and nighttime activity count (b=0.221, FDR p=0.020; b=0.333, FDR p<0.001). These associations were still significant when adjusting for body mass index, retirement status, and psychoactive medications. The exact same finding was observed when looking at higher plasma p-tau231 alone (and not in a ratio with $A\beta_{42}$) with higher sleep duration variability and nighttime activity count variability (p=0.002; p<0.001). MCI converter status significantly interacted with plasma p-tau231/$A\beta_{42}$ (p=0.037), where higher plasma p-tau231/$A\beta_{42}$ was associated with higher sleep duration variability only in those that converted to MCI (b=0.662, p<0.001).
Conclusions: Sleep day-to-day variability was associated with the novel plasma p-tau231 in at-risk individuals, suggesting that unstable sleep promotes neurodegeneration or, conversely, that AD neuropathology disrupts sleep-wake cycles.

TRACING CHANGES IN BLOOD CELL TRANSCRIPTOMIC LANDSCAPE DURING THE ALZHEIMER'S DISEASE CONTINUUM

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Viktoriia Bavykina, Mariano Avino, Adrien Zimmer, Hugo Parent-Roberge, Usma Munawara, Mohammed Amir Husain, Abdelouahed Khalil, Marie A. Brunet, Tamas Fülöp, Benoit Laurent
Université de Sherbrooke, Department Of Biochemistry And Functional Genomics, Sherbrooke, Canada

Aims: Alzheimer's disease (AD) is the most common form of dementia with the symptoms gradually worsening over the years, ultimately leading to death. However, the driving pathological processes occur well before the appearance of symptoms. It has been observed that AD patients display signs of systemic inflammation, suggesting that it could precede well-established AD hallmarks such as the deposit of Aβ plaques and neurofibrillary tangles. Our goal is to characterize changes in gene expression in monocytes and lymphocytes isolated from patients' blood at different stages of AD progression and validate potential RNA biomarkers for a better AD prognosis and diagnosis.
Methods: We collected blood from three groups of patients: healthy subjects, Mild Cognitive Impairment (MCI) and AD patients n=9 for each group). We purified monocytes and lymphocytes from each sample and performed a whole transcriptome analysis by RNA-seq. We established differentially expressed genes (DEGs) per cell type of AD patients compared to those of healthy individuals and cross-correlated them to identify universal biomarkers across blood cells.
Results: We observed that the majority of DEGs are mainly involved in chemokine activity and cytokine-mediated signaling pathways. We further confirmed several RNA biomarkers by quantitative PCR and showed that they are often deregulated at pre-clinical stages of the disease (MCI stage). We finally confirmed the alteration of these candidates at the protein level, opening the possibility of detecting these biomarkers via different diagnostic methodologies.
Conclusions: Our findings provide evidence that we can detect the pre-clinical stage of AD in blood cells using a specific set of RNA biomarkers, highlighting the importance of studying the early immune response in neurodegenerative diseases. Blood-based RNA biomarkers have the potential to revolutionize AD diagnostic and prognostic.

EVALUATION OF NOVEL MID-REGION AND C-TERMINAL-SPECIFIC CSF B-SYNUCLEIN ELISAS FOR ALZHEIMER'S DISEASE DIAGNOSIS

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Sherif Bayoumy[1], Julie Goossens[2], Charlotte De Rocker[2], Wiesje Van Der Flier[3,4], Inge Verberk[1], Charlotte Teunissen[1], Eugeen Vanmechelen[2]
[1]Amsterdam UMC, Laboratory Medicine, Amsterdam, Netherlands, [2]ADx Neurosciences, Neurosciences, Ghent, Belgium, [3]Amsterdam UMC, Alzheimer Center Amsterdam, Neurology, Amsterdam, Netherlands, [4]Neurodegeneration, Amsterdam Neuroscience, Amsterdam, Netherlands

Aims: Elevated cerebrospinal fluid (CSF) β-synuclein levels measured with an N-terminal-targeted ELISA has emerged as a potential specific biomarker for Alzheimer's disease (AD) [1, 2]. The N-terminus is more conserved across synuclein variants, potentially leading to assay cross-reactivity [3]. This suggests potential improved diagnostic efficacy of assays targeting the more β-synuclein-specific mid and C-terminal regions, which we aimed to assess here.
Methods: We developed two novel CSF ELISAs targeting mid and C-terminal β-synuclein independently, and set-up the N-terminal assay previously described [2]. We validated the precision, sensitivity and selectivity of the ELISAs. Next, we validated the diagnostic performance of the ELISAs by analyzing 44 routine CSF samples (22 AD and 22 control with CSF Aβ42 and p-tau181 profiles).
Results: All three assays detected β-synuclein in all clinical samples with mean intra-assay precisions below 10%CV (Figure 1). The β-specific-synuclein capture-antibody used for both the mid-region and C-terminal assays did not react with recombinant α-synuclein. In contrast, the capture antibody of the N-terminus assay did show reactivity with α-synuclein protein. CSF β-synuclein levels measured with all three ELISAs significantly discriminated AD from controls (Figure 2, all: $p<0.05$). Fold-change differences in median values were 2.3 (N-terminus), 1.6 (mid-region), and 2.2 (C-terminus). Age and sex-corrected ROC analyses showed comparable diagnostic performance across the assays (AUCs: N-terminus: 0.75 (95%CI: 0.60-0.90), mid-region: 0.69 (95%CI: 0.51-0.86) and C-terminus: 0.81 (95%CI: 0.67-0.95).
Conclusions: The novel β-synuclein-specific ELISAs have robust analytical performance, and promising diagnostic accuracy to reliably distinguish AD from control CSF samples. Further validation of these ELISAs across various clinical AD stages is underway to assess their full diagnostic and prognostic utility and to determine if our specific assays have improved diagnostic accuracy compared to the N-terminal assay.

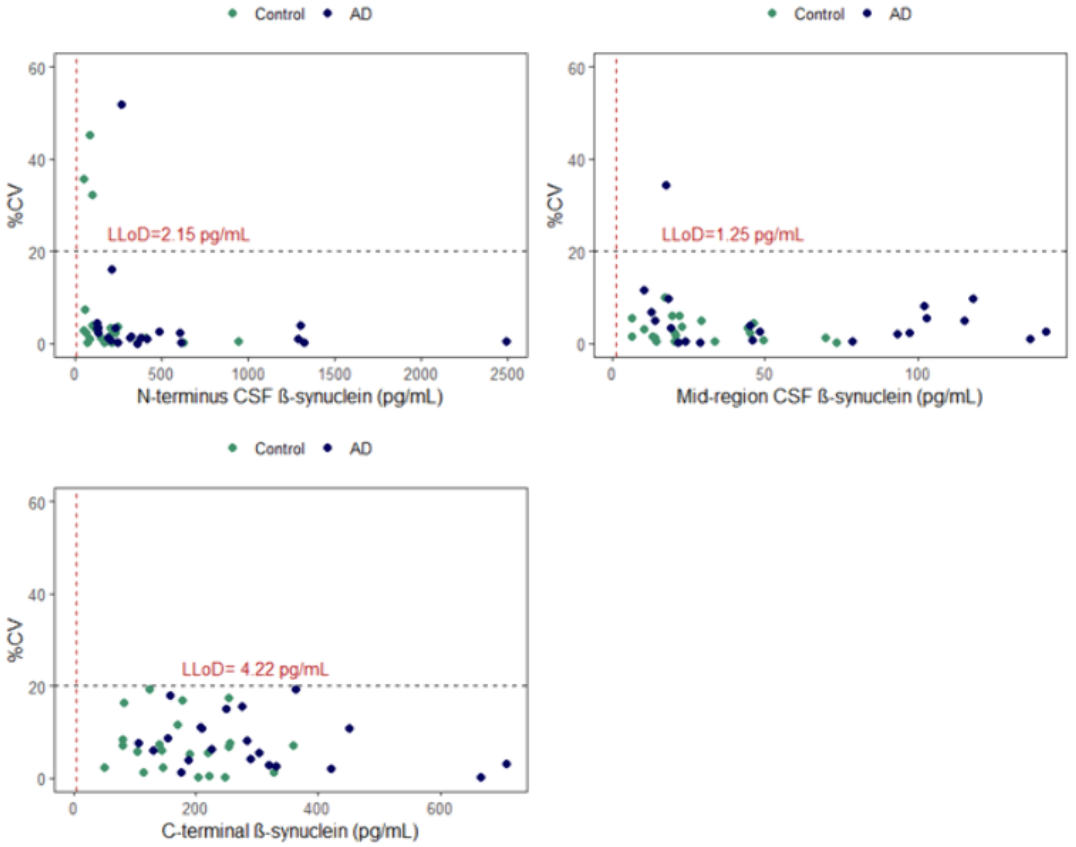

Figure 1. Precision plots of the novel CSF β-synuclein ELISAs. The plots demonstrate β-synuclein concentrations for each assay on the x-axis against the variation of duplicate measurements as percentage coefficient of variation (%CV) on the y-axis. The clinical samples were color-coded per group as AD (mean age 69.8±7.1 years: 55% F) and control (68.8 ±7.4 years: 20%F). The vertical dashed lines represent the lowest limit of detection (LLoD) (i.e., mean of 16 blanks*10x standard deviation of the blanks), and the horizontal dashed lines represent a CV of 20% for each assay.

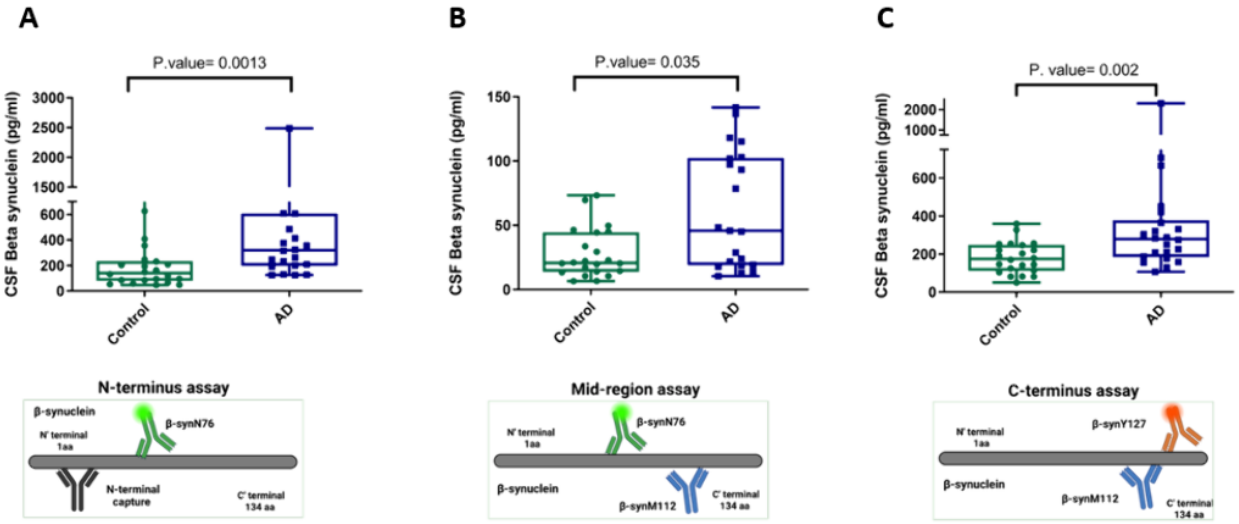

Figure 2. A) Box plots of the novel CSF β-synuclein ELISAs. A) N-terminal-β-synuclein ELISA, B) mid-β-specific-synuclein ELISA, C) C-terminal-β-specific-synuclein ELISA. Group differences were calculated using non-parametric Mann-Whitney U Tests, and results are shown with p-values within the boxplots. All assays showed significant differences between the groups with p-values of <0.05.

Aims: Fully-automated platforms offer standardized and cost-effective plasma biomarker measurements for the molecular diagnosis of Alzheimer's disease (AD). Analyzing the concordance between plasma and CSF biomarkers can expedite their clinical implementation.
Methods: Two independent cohorts (UNIPG and AMS) were included. UNIPG cohort consisted of n=450 paired CSF/plasma samples with a CSF biomarker profile of A-/T- (n=126), A-/T+ (n=50), A+/T- (n=48), and A+/T+ (n=226). This cohort considered subjects belonging to the whole AD continuum, controls, and patients affected by other neurodegenerative diseases. AMS cohort was composed of n=40 paired CSF/plasma AD samples (A+/T+) and plasma of n=40 controls. Plasma and CSF Aβ1-42, Aβ1-40, and p-tau181 levels were measured with Lumipulse® assays. For these assays we evaluated analytical performance, impact of renal dysfunction and blood-brain-barrier permeability, and diagnostic performance.
Results: High plasma p-tau181 values optimally reflected CSF A+/T+ profile in AD dementia and prodromal AD, but not in asymptomatic AD. Plasma Aβ42/40 showed similar sensitivities and specificities in all clinical stages, well reflecting the CSF A status. Cutoffs and probability-based classification models (Figure 1) for A+ and A+T+ obtained in UNIPG well performed in

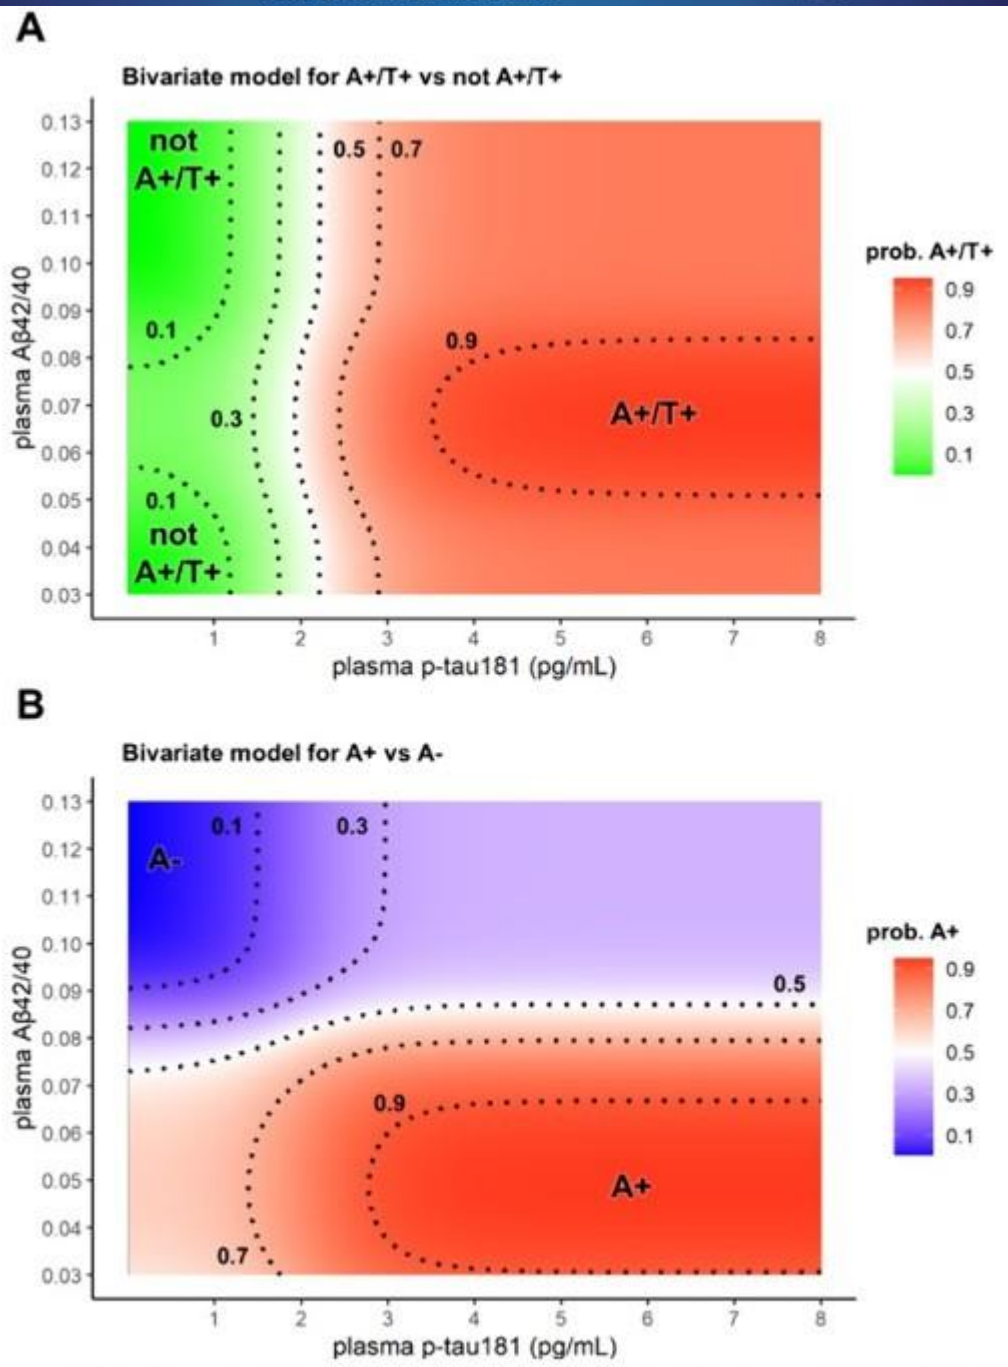

Figure 1. Bivariate probability models. The 2D probability plots for A+ vs A- (A) and for A+/T+ vs not A+/T+ (B) were built by combining 1D probabilities calculated for plasma Aβ42/40 and p-tau181. The optimal combination constant for each of the two models was chosen by maximizing the average accuracy on the training set by 100-fold cross-validation. Isoprobability dotted lines for $p = 0.1, 0.3, 0.5, 0.5$ and 0.9 are displayed.

AMS.

Conclusions: Automated plasma Aβ42/40 and p-tau181 assays showed high concordance with CSF AD biomarkers. Here we propose cutoff values and algorithms that may allow to bypass CSF collection in presence of cognitive deficits and in absence of kidney dysfunction

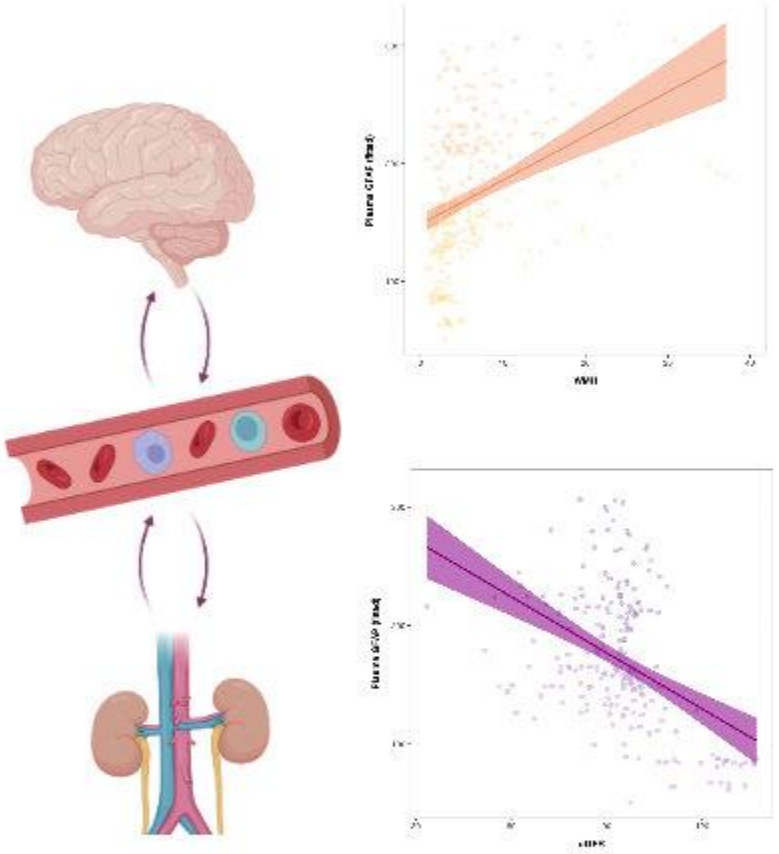
Aims: It is increasingly recognized the association between kidney function and brain health. Studies investigating the "Kidney-Brain Axis" suggest that poor renal function is linked to cerebrovascular changes and cognitive decline. Several mechanisms for that are being suggested, including vascular damage, inflammation and others. Given that the blood is the main pathway linking the kidney and the brain, it is important to evaluate how protein concentrations in the peripheral circulation affect/are affected by these factors. Thus, we aimed at investigating the association between brain vascular damage, renal function and plasma biomarkers.
Methods: Cross-sectional data from the TRIAD cohort was available for 370 participants classified according to clinical and amyloid status (Young=35, CU-=140, CU+=38, MCI-=28, MCI+=50, AD=50, Non-AD dementia=29) who had quantified white matter hyperintensities (WMH) as well as plasma biomarkers (GFAP, NfL, pTau217, sTREM2). Renal function was measured by estimated Glomerular Filtration Rate (eGFR). Amyloid status was indexed by [^{18}F]AZD469 PET. Spearman correlations and linear models tested the association between plasma biomarkers and WMH or eGFR, adjusting for age, sex and diagnostic groups.
Results: All plasma biomarkers correlated with WMH and eGFR. When linear regression models accounted for covariates, only plasma GFAP was associated with both WMH (P=0.04) and eGFR (P=0.02). No other plasma biomarker was associated with WMH. Higher NfL levels were associated with reduced eGFR (P=0.0001), but no association was found between eGFR and pTau217 (P=0.37) or sTREM2 (P=0.05).



Conclusions: Preliminary results suggest that plasma GFAP levels might be specifically linking kidney function and brain vascular damage, which was not observed for other biomarkers. Coming analysis should further investigate these associations and suggest possible mechanisms connecting these findings.

Aims: Plasma biomarkers are on the verge of being introduced into screening of individuals at risk for Alzheimer's disease (AD). Yet, previous studies yielded contradictory results regarding their association with established biomarkers of AD pathology. This study aims to investigate the specific relationship between core AD biomarkers, such as amyloid PET and CSF pTau, and the novel plasma biomarkers.
Methods: We analyzed plasma pTau181, pTau217, pTau231 and GFAP, CSF pTau181, and Aβ-PET scans in a cohort of memory clinic patients (N=139) who underwent a comprehensive clinical assessment at the the Memory Clinic, Karolinska University Hospital, Stockholm,Sweden. We utilized methods based on multiple linear regression to model and evaluate the distinct contributions of Aβ-PET and CSF pTau in explaining the variance of plasma biomarkers, while also considering demographic variables.
Results: We found significant positive associations between Aβ-PET and all plasma biomarkers (R^2=0.14-0.56); highest associations were observed for pTau217. Similarly, significant positive associations of lower magnitude were observed between plasma biomarkers and CSF pTau(R^2=0.09-0.26). After accounting for the influence of Aβ-PET on plasma biomarkers and CSF pTau, only pTau217(R^2=.049) and pTau231(R^2=.024) remained significantly associated with CSF pTau. Dominance analysis showed that Aβ-PET had the highest relative importance in predicting plasma biomarkers values, followed by CSF pTau. Aβ-PET and CSF pTau explained the larger portion of variance in plasma pTau217 levels(~60%) compared to that explained in plasma GFAP (~30%),pTau181(~17%), and pTau231(~18%) levels.
Conclusions: Amyloid burden was the main predictor of levels of all plasma biomarkers. The effect of CSF pTau on GFAP and pTau181 was attenuated by the effect of Aβ-PET, while pTau231 and pTau217 also reflected subtle effects of CSF pTau. Variance in plasma pTau217 levels appeared to be well explained by AD-related pathological changes.

Aims: Background & Objective: Plasma biomarkers need of further research to translate them as a realistic option in the clinical practice. However, many studies to date have assessed them in research cohorts. Here we evaluated the clinical value of plasma pTau181 as a predictive marker of AD dementia risk in a real-world memory clinic cohort.
Methods: Methods: The ACE cohort encompass 1649 patients with subjective cognitive decline (SCD), mild cognitive impairment (MCI), AD dementia and other dementias, with paired CSF and plasma samples. CSF Aβ42, Aβ40, pTau181 and tTau, and plasma pTau181 were measured using the Lumipulse G1200 automatic platform (Fujirebio Inc.). Complete cohort were divided in the Testing cohort (n=1000) and Validation cohort (n=649).
Results: Results: plasma pTau181 significantly correlated (P<0.0001) with CSF pTau181 in MCI, AD dementia and other dementias, but not in SCD. Specifically for MCI patients, ROC curve of MCI A+T+ *vs* MCI A-T- showed and AUC=0.8874 and P<0.0001. A cut off value of 1.300 pg/ml exhibited a 93.6% sensibility and only 8.3% of false negatives in MCI patients. Hazard ratio of survival of conversion analysis showed that MCI patients above to this cut off value exhibited a 7.3 higher risk to convert to AD dementia than MCI under the cut off value. Validation cohort confirmed these findings.
Conclusions: Conclusion: plasma pTau181 could be useful as a pre-screening biomarker of MCI patients with high risk to progress to dementia. Positive patients will also require a confirmatory test. Plasma pTau181 by itself does not present a suitable biomarker for SCD. Another biomarker or a combination of biomarkers would be needed to this population. Further studies are need to obtain more clinical data and improve the knowledge to finally substitute CSF/PET biomarkers.

BIOSENSOR FOR DETECTION OF AN ALZHEIMER'S DISEASE BIOMARKER

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Pedro Carneiro[1,2], Joana Loureiro[1], Simone Morais[2], Maria Carmo Pereira[1]

Aims: The identification and detection of cerebrospinal fluid (CSF) and blood biomarkers has been gaining increasing relevance in the clinical diagnosis of Alzheimer's disease (AD). Although, pathophysiological hallmarks of AD can be identified through CSF or imaging techniques, its early diagnosis is still challenging due to the invasiveness and high cost associated with these methods. This way, the goal of this work was to develop a more cost-effective immunosensor for the sensitive detection of amyloid beta 42 in plasma samples by electrochemical sensing.
Methods: The proposed immunosensor consists of an indirect sandwich assay with a screen-printed carbon electrode (SPCE) modified with graphene oxide (GO) as the electrochemical transducer. The detection process is generated through an enzymatic degradation of H_2O_2 by horseradish peroxidase (HRP) converting the TMB substrate into its oxidative state. The capture antibodies specific for amyloid beta 42 were immobilized on the GO modified SPCE surface through covalent bonding to ensure the formation of a stable layer of the biorecognition elements. Moreover, this stage was accompanied with the addition of bovine serum albumin to minimize the occurrence of non-specific bindings. To conclude the detection process, a monoclonal antibody specific to amino acids 1-17 of human Aβ followed by a secondary antibody labelled with HRP were sequentially added.
Results: The electrochemical signal was generated by chronoamperometry, where under optimal conditions an analytical curve was attained using the current increase (%) observed after exposure of the developed immunosensor to different concentrations of amyloid beta 42.
Conclusions: The developed immunosensor enables a successful and highly sensitive detection of amyloid beta 42.

SALIVARY DISTURBANCES IN INFLAMMATORY, IMMUNOLOGICAL AND ANTIMICROBIAL DEFENSE RESPONSES IN PATIENTS WITH ALZHEIMER'S DISEASE

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Eva Carro, Desiree Antequera, Laura Carrero, Cristina Municio
Carlos III Health Institute (ISCIII), Neurobiology Of Alzheimer's Disease Unit, Majadahonda, Spain

Aims: Lactoferrin is an antimicrobial protein present in saliva and associated with host defense against oral pathogens. Salivary lactoferrin plays an important role in regulating the oral microbiota and the inflammatory state of the oral mucosa contributing to the maintenance of oral symbiosis. In our previous studies, we found that salivary lactoferrin correlates with AD status. Saliva samples from mild cognitive impairment (MCI) and Alzheimer's disease (AD) patients showed decreased levels of lactoferrin when compared with controls. Since lactoferrin displayed proteinase inhibitory activity against oral bacteria including *Porphyromonas gingivalis* (*P. gingivalis*), we propose that low salivary levels of lactoferrin, as seen in AD patients, lead *P. gingivalis* proliferation and subsequently, and infection-mediated inflammatory responses. Our study aimed to evaluate components of oral dysbiosis, including *P. gingivalis*-related manifestations, lactoferrin levels, and inflammatory profile, in the saliva of AD patients.
Methods: We performed a cross-sectional study including patients with (MCI) and AD, comparing with healthy controls. Diagnosis was based on detailed clinical assessment, neuropsychological study, neuroimaging and amyloid-Positron-Emission Tomography (PET) scan results. Non-stimulated saliva samples were collected and processed from all subjects as described previously, and biochemical analysis were performed to determine lactoferrin levels, inflammatory profile and gingipain expression.
Results: As we expected, we found significant reduction in salivary lactoferrin levels in MCI and AD patients, as well as in anti-inflammatory cytokines such as IL-1ra, IL-10. On the contrary, pro-inflammatory cytokines such as IL-6, IL-7, and IL-23 were up expressed in MCI and AD patients. We also found reduced levels of SDF-1α, MIP-1β, IP-10 and VEGF in saliva of AD patients compared to healthy control subjects.
Conclusions: Taken together, these finding suggest an inflammatory condition, compatible with oral dysbiosis, in the saliva of AD patients.

NEURODEGENE: A GENETIC PANEL FOR THE PROGNOSIS AND EARLY-DETECTION OF MULTIPLE FORMS OF NEURODEGENERATIVE DISEASES

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Miguel Casanova, Swann Ruyter, Seval Kul, Louis Chauvière, Ramiro Magno, Dany Mukesha, Lucas Pham-Van, Stéphanie Boutillier, Hüseyin Firat
Firalis, Amoneta, Huningue, France

Aims: Current diagnostic solutions for neurodegenerative disorders (NDs) are insufficient. We developed a novel target enrichment genetic panel, as an aid for early and differential diagnosis of NDs, their prognosis and better characterization of these patients, and of target populations enrichment for drug development studies.
Methods: Using multiple genetic disease and proprietary databases, we selected the most relevant coding and non-coding gene variants associated with NDs. These variants were used to create a target enrichment capture panel, NeuroDeGene, which was used to sequence 963 whole blood samples from the ADDIA (NCT03030586) and ADDKIT cohorts using the Illumina NovaSeq 6000 DX platform. The genomic data was analyzed with interdependent approaches: polygenic risk score to quantify individual susceptibility to disease; unsupervised analysis to stratify and extract patterns from the population; and machine learning to predict disease diagnosis.
Results: Using AD as a case study, we confirm that variants in *APOE* are amongst those with the strongest genetic risk. Interestingly, we identify other variants showing either an increased or decreased association with AD. Harnessing the genotyping information from these variants, we are able to cluster AD patients subjects into genomic profiles. Finally, our modelling approach allows predicting disease group with high performance (AUC ~0.80).
Conclusions: NeuroDeGene is an innovative precision medicine tool aiming to develop a clinically applicable, single risk prediction test for multiple NDs. It provides a panel of genetic variants covering many essential genes, but also many non-coding functional regions that are often overlooked. It will prove an invaluable tool to aid on the diagnosis of neurodegenerative disorders, prognostic applications and for supporting clinical trials in early dementia populations.

A SENSITIVE DIGITAL BIOASSAY FOR SERUM-BASED DIAGNOSIS OF NEURODEGENERATIVE DISEASE

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Matthew Cheetham[1], Dorothea Böken[1], Emre Fertan[1], Zengjie Xia[1], Jeff Lam[1], Elizabeth English[1], Henrik Zetterberg[2], David Klenerman[1]
[1]University of Cambridge, Yusuf Hamied Department Of Chemistry, Cambridge, United Kingdom, [2]University of Gothenburg, Department Of Psychiatry And Neurochemistry, Molndal, Sweden

Aims: To develop an aggregate-specific assay that is compatible with the SIMOA platform, and sufficiently sensitive to detect the presence of amyloid-beta and alpha-synuclein aggregates in serum samples and other biofluids.
Methods: The SIMOA platform uses antibody coated magnetic beads to capture biomarkers from the sample. A biotinylated detector antibody, and streptavidin conjugated enzyme are added to form an immunocomplex on the beads, which are then loaded into an array of microwells large enough to fit only a single bead. Resorufin conjugates are then added to this array, and any wells containing an immunocomplex exhibit fluorescence. The analyte concentration is then obtained from the fraction of beads in the "on" state, giving a significantly higher sensitivity than a typical ELISA. The standard use of SIMOA is to detect monomers, however since we are specifically interested in aggregates as biomarkers of disease, we developed our assays using the same antibody (6E10 or SC211) for both the capture and detection – that way monomeric amyloid-beta and alpha-synuclein are excluded as they only have single epitopes.
Results: The assays were highly sensitive, with limits of detection seen for in-vitro aggregates ~100 fM. The assays were also shown to be highly specific, not detecting monomers or other proteins. We also tested a cohort of serum and CSF samples and demonstrated that the assays are capable of detecting aggregates in these samples.
Conclusions: We have developed an ultra-sensitive and highly specific assay for amyloid-beta and alpha-synuclein aggregates. Further studies of early-onset disease vs control groups will enable us to explore the use of this assay to distinguish between the two, with the potential to offer early diagnosis to the patient based on the results of a routine blood test.

MULTIOMIC ANALYSES OF PLASMA PROTEOMIC BIOMARKERS OF DEMENTIA SUGGESTS A DIVERGENT BRAIN AGING TRAJECTORY

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Loet Coenen[1,2], Elga De Vries[1], Jinte Middeldorp[2]
[1]Amsterdam UMC location Vrije Universiteit Amsterdam, Molecular Cell Biology And Immunology, Amsterdam, Netherlands, [2]Biomedical Primate Research Centre, Neurobiology & Aging, Rijswijk, Netherlands

Aims: Aging is the main risk factor for neurodegenerative diseases such as Alzheimer's disease and other dementias (ADOD). Both aging and dementia leave a molecular signature in the plasma proteome. Understanding how the Dementia Plasma Proteome (DPP) diverges from the Aging Plasma Proteome provides insights in pathological changes in dementia patients, or resilience mechanisms in cognitive healthy individuals.
Methods: Using publicly available datasets such as the Human Protein Atlas, GTEx, and the Aging, Dementia and TBI study, we link changes observed in the plasma to age-associated changes in the brain. We provide a broad overview and evidence across multiple biological levels using methods such as Mendelian Randomization (MR), enrichment analysis, linear modeling and permutation tests.
Results: We compiled a DPP of 712 proteins shown to be changed in the plasma of ADOD patients with their corresponding protein quantitative trait loci (pQTLs). These pQTLs are enriched in brain-related phenotypes and phenotypes linked to dementia such as soluble TREM2 levels and lipoprotein levels. MR prioritizes proteins enriched with functions related to peripheral inflammation in ADOD. Proteins mostly expressed in the brain are shown to reflect a strong cortical signature and are more expressed in brain regions known to be vulnerable to ADOD. Permutation tests across brain regions show that DPP genes are more subjective to age-associated transcriptional changes than other genes. Comparing transcriptomic changes between ADOD patients and non-demented controls indicate both age-associated and pathology-associated differences in the brain transcriptome.
Conclusions: These results contribute to understanding the molecular signature of dementia in blood plasma and to the identification of novel biomarkers of brain pathology. Further validation in tissue is needed to link results from the DPP to pathology in the brain.

ALZHEIMER'S DISEASE PLASMA BIOMARKERS FOLLOW AGE-RELATED TRAJECTORIES IN COGNITIVELY HEALTHY OLDEST OLD

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Jennifer Cooper[1], Sophie Stukas[1], Mohammad Ghodsi[1], Stephen Leach[2], Angela Brooks-Wilson[2], Cheryl Wellington[1]
[1]University of British Columbia, Pathology And Laboratory Medicine, Vancouver, Canada, [2]BC Cancer, Canada's Michael Smith Genome Sciences Centre, Vancouver, Canada

Aims: To investigate how ageing modifies plasma levels of amyloid beta 42/40 (Aβ42/40), phosphorylated tau-181 (p-tau-181), neurofilament light (NfL), and glial fibrillary acidic protein (GFAP) in a normative, epidemiologically representative Canadian population and in cognitively healthy seniors over 80 years of age.
Methods: Biomarkers were analysed on the Quanterix Simoa HD-X analyzer using Neurology 4-plex E and p-tau-181 assays. N=900 Canadian Health Measures Survey plasma specimens were analyzed as a normative population. Using smoothed quantile regression, the 5th, 50th and 95th percentiles from ages 3-79 years were determined. N=480 plasma specimens were analyzed from cognitively healthy Super Seniors Study participants with a median age of 88 years old (IQR= 87-90y), who had never been diagnosed with dementia, cancer, diabetes, cardiovascular or major pulmonary disease.
Results:

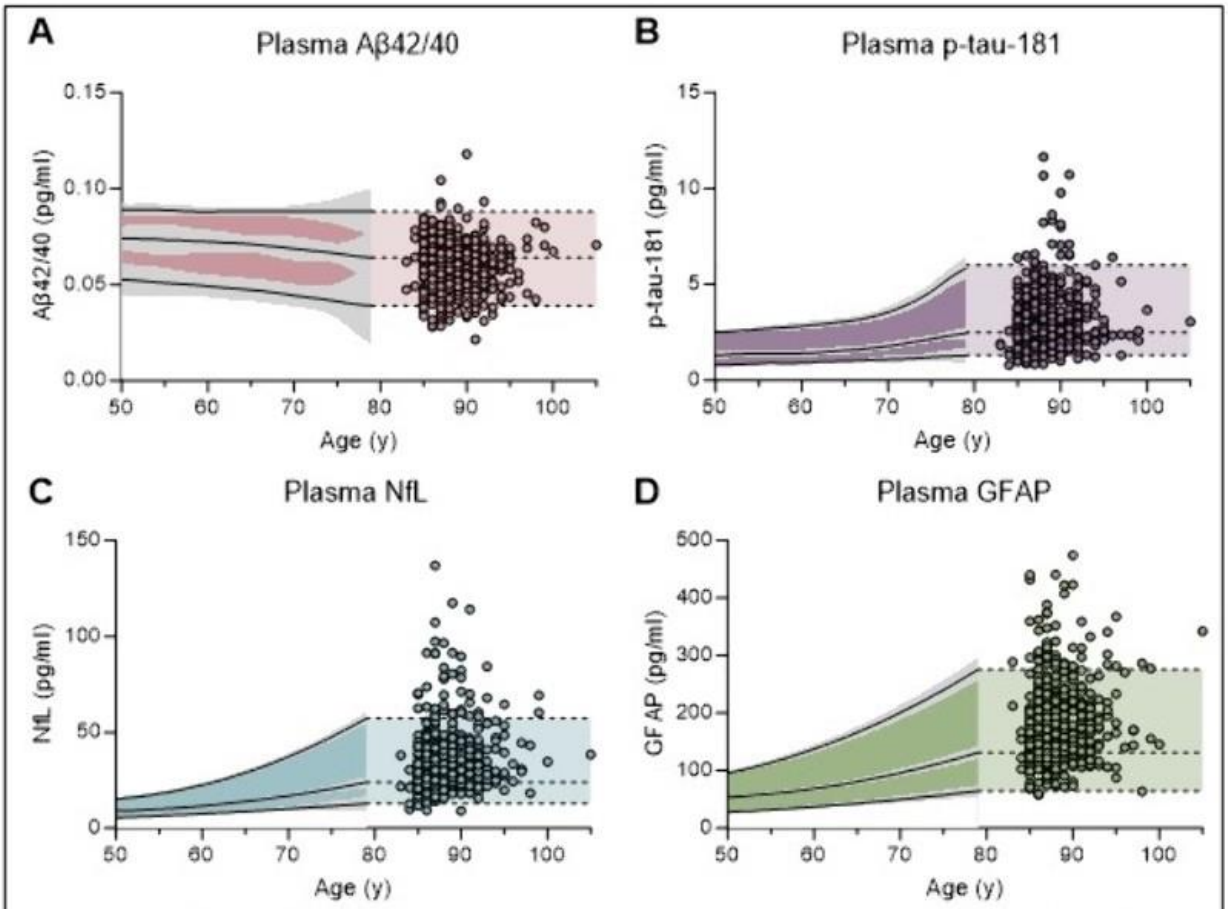

Figure 1. Plasma Aβ42/40 (A), p-tau-181 (B), NfL (C), and GFAP (D) in normative and healthy populations. N=243 specimens from normative participants from age 50 to 79 years old were used to generate percentiles of population normal concentrations. The 95th, 50th, and 5th percentiles are indicated by the solid black lines. The gray shaded regions indicate the 95% CI of each percentile. Dark shaded regions indicate the reference ranges (5th to 95th percentiles) for each biomarker form the age of 50 to 79 years old. Beyond 80 years old, the dashed black lines indicate the 95th, 50th, and 5th percentiles of 79-year-olds, with the light shaded region indicating the corresponding reference range. Coloured circles represent data from N=480 cognitively normal, Super Seniors.

In the normative population, the 50th percentiles of p-tau-181, NfL, and GFAP increased by 3-4% per year and the 95th percentile increased by 4-5% per year between 60-80 years of age. For Aβ42/40, both the 5th and 50th percentiles decreased by 1% per year. After age 80, biomarker levels in Super Seniors mimicked the levels of normative 79-year-olds. In Super Seniors, 93% of Aβ42/40, 90% of p-tau-181, 89% of NfL, and 87% of GFAP data points fell within the 5th and 95th percentiles of normative 79-year-olds. Within this reference range, a higher proportion of Super Seniors fell above the 50th percentile for p-tau-181 (59%), NfL (78%), and GFAP (75%), or below the 50th percentile for AB42/40 (60%), indicating a continuation of the trajectories observed in the normative population.

Conclusions: Cognitively healthy seniors over 80 years have similar plasma biomarker distributions as normative 79-year-olds, indicating that age, regardless of cognitive status, modifies biomarker concentrations over the age of 80 years.

Aims: In humans, neuroinflammation is thought to be a contributing factor to Alzheimer's Disease. We have previously shown that canine aging is linked to several biomarker changes, including age-related increases in NfL chain levels in CSF of Beagle dogs and decreases in %Aβ42 with age. The current study sought to further characterize inflammatory biomarker changes in the aged dog by investigating whether concentrations in CSF and plasma of the cytokines, TNFα, IL-2, IL-6, and IL-8, varied by age and with amyloid fluid biomarkers.
Methods: Concentrations of the biomarkers in CSF and plasma from three age groups of dogs were quantified using a commercially available canine multiplex cytokine kit and analyzed by the MESO QuickPlex SQ. Data were analyzed using the GraphPad Prism 9 statistical software.
Results: There was a significant effect of age group on concentrations of IL-2 and IL-6 but no significant differences in TNFα and IL-8 levels in CSF. Similar results were found in plasma. Increases in IL-2 and IL-6 were negatively correlated with %Aβ42.
Conclusions: The current results support the hypothesis of increased neuroinflammation in the aged dog and suggests that increased inflammatory biomarkers are correlated with increased brain amyloid load. Additional studies will need to be conducted to determine how these changes affect cognitive function and other clinically relevant biomarker changes previously reported in the aged Beagle dog.

Aims: Ultra-sensitive immunoassays allowed the development of blood biomarkers for Alzheimer's disease (AD). However, current methods are often limited by their ability to measure only few analytes simultaneously. Here we report the results from the novel nucleic acid linked immunoassay (NULISA) platform, which offers attomolar sensitivity and high multiplexing abilities, through which we measured and compared 100+ proteins in plasma and CSF of AD patients and controls.
Methods: The NULISA platform implements a proximity ligation (PL) assay concept using oligonucelotides conjugated to antibodies and, through sequential capture and wash steps, it minimizes background noise. A PL creates a library of DNA barcodes that can be sequenced and relatively quantified on a next-generation sequencer (Fig.1). We utilised the NULISAseq CNS Disease Panel in plasma and CSF from 40 patients (n=25 AD; n=15 non-AD) provided by University College London. Presence of AD pathology was assessed by CSF Aβ42/40 and p-tau181 on the LUMIPULSE-G1200.

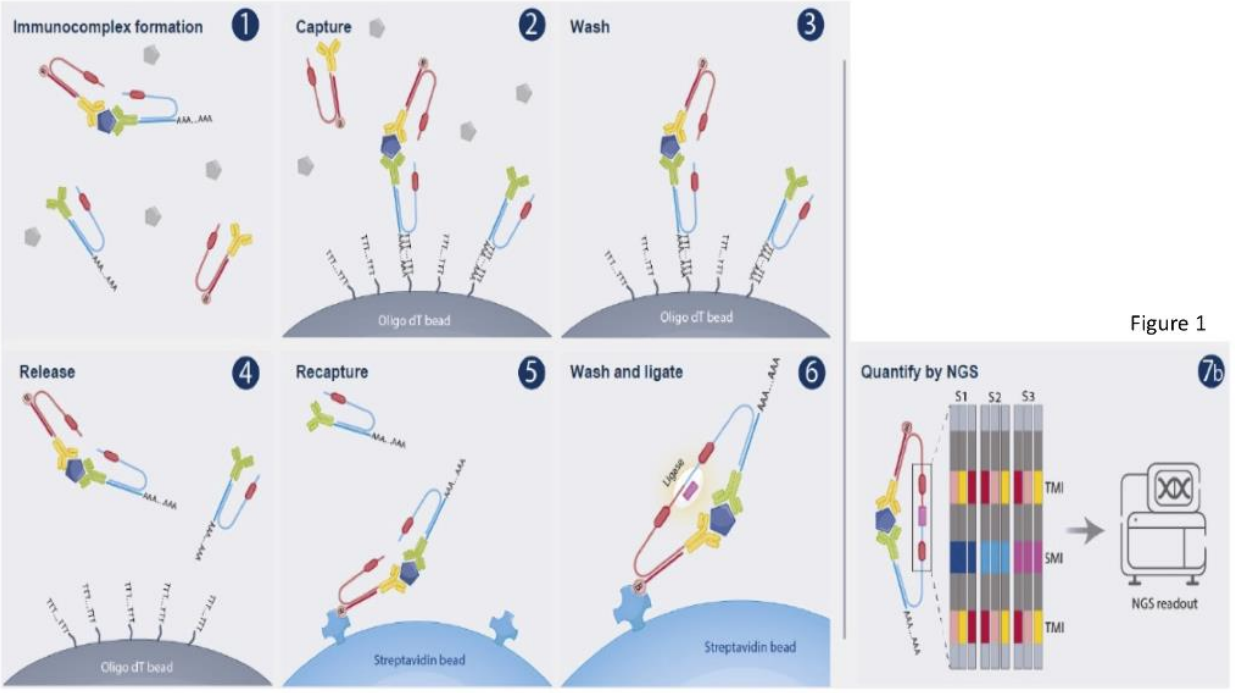

Figure 1

Results: Overall, 114/116 (98.4%) targets in the panel were detectable in plasma and 102/116 (87.9%) in CSF. FDR adjusted p-values from linear model analysis demonstrated 12 upregulated and 1 downregulated protein in CSF of AD patients (Fig.2). In plasma, 3 upregulated targets in AD were observed (Fig.3) and further targets were identified with more relaxed statistical thresholds (Fig.3) (e.g., BACE-1, BASP1,
CCL2).

Conclusions: In this pilot study, the NULISA CNS Disease panel was demonstrated to be a powerful tool to profile blood and CSF proteome. In the context of AD, this combines detection of known targets (e.g., p-tau217), along with an array of exploratory targets that can all be measured with ultra-high sensitivity. This approach will be fundamental in assessing response after anti-amyloid removal therapies and exploring novel complementary drug targets for AD.

M6A MODIFIED RNA TARGETS AS NOVEL BIOMARKERS FOR AD

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Sophie Van Der Spek[1], Alejandro Rondón Ortiz[2,3,4], Sambhavi Puri[1], Jenna Libera[4], Benjamin Wolozin[4,5,6,7,8]
[1]Boston University, Anatomy And Neurobiology, Boston, United States of America, [2]Boston, Biology, Boston, United States of America, [3]Boston University, Center For Network Systems Biology, Boston, United States of America, [4]Boston University, Pharmacology And Experimental Therapeutics, Boston, United States of America, [5]Boston University, Center For Systems Neuroscience, Boston, United States of America, [6]Boston University, Center For Neurophotonics, Boston, United States of America, [7]Boston University, Department Of Neurology, Boston, United States of America, [8]Boston University School of Medicine, Anatomy & Neurobiology, Boston, United States of America

Aims: The study of methylated RNA has offered a wide range of biomarkers and therapeutic avenues in the field of oncology, and holds similar potential to the field of neurodegeneration. Our lab recently discovered increased levels of methylated RNA (m6A) of about 4-fold in brains of Alzheimer's disease (AD) patients, in a stage dependent manner. This suggests the possibility that m6A-RNA may also be increased in human CSF. Here we aimed to determine abundance of specific m6A-RNA transcripts in CSF of AD patients.
Methods: To test our hypothesis, we developed a RIP-qPCR assay (termed M6RA): RNA is pulled down from CSF with anti-m6A antibody, then specific transcripts are amplified using Taqman probe-based qPCR. We first focused on m6A S18 ribosomal RNA (rRNA) because it is highly abundant and known to be methylated. We opted to target particular transcripts (rather than measuring total m6A) because we felt that quantifying particular RNA species would be more informative, this strategy has proven successful.
Results: Using U2OS human cells, we observed successful pull-down and detection of m6A-rRNA from <100 pg of total RNA. We proceeded with m6A-RNA capture from CSF. To compensate for low rRNA abundance in ante-mortem CSF we used 400 pg total RNA as assay input. The M6RA assay revealed a 4.2-fold increase in AD samples compared to healthy controls ($p<0.02$).
Conclusions: This first study shows great promise for M6RA to determine differential m6A-rRNA levels in CSF. M6RA is currently being validated and optimized towards a plate assay using avi-tagged YTH domain protein for m6A-capture. Future work includes extension of the assay to other transcripts based on m6A-transcriptomics. Together we anticipate the assay to be a powerful diagnostic platform for AD (and ADRDs in future studies).

Aims: Blood-brain barrier (BBB) integrity is crucial for brain homeostasis and maintenance. Aquaporin-4 (AQP4) has been implicated in BBB maintenance. Therefore, in this pilot study, we investigated the levels of cerebrospinal fluid (CSF) AQP4 for assessing BBB integrity.
Methods: CSF samples were collected from 56 participants (20 [35.71%] female and 36 males [64.28%]; mean [SD] age, 71 [10.8] years). Participants were stratified according to their CSF/serum albumin concentration ratio (Q-Alb); intact BBB (Q-Alb <9, n = 15), mild BBB damage (Q-Alb 9-14, n = 15), modest BBB damage (Q-Alb 14-30, n = 14), and severe BBB damage (Q-Alb >30, n = 12). AD CSF biomarkers (p-Tau181, total-Tau, Aβ42/40 ratio) was assessed by LUMIPULSE G1200. AQP4 levels were quantified using Cusabio ELISA Kit. Correlation analyses were conducted between AQP4 levels and albumin CSF/serum ratios with GraphPad Prism 9 (one-way ANOVA test was performed).
Results: CSF AQP4 was significantly higher in individuals with severe BBB damage (Fig.1). No significant difference between modest and mild BBB damage was observed. A positive correlation between AQP4 and Q-Alb (r = 0.6697, P <0,0001) was found, while none with AD and neurodegeneration biomarkers was
observed.

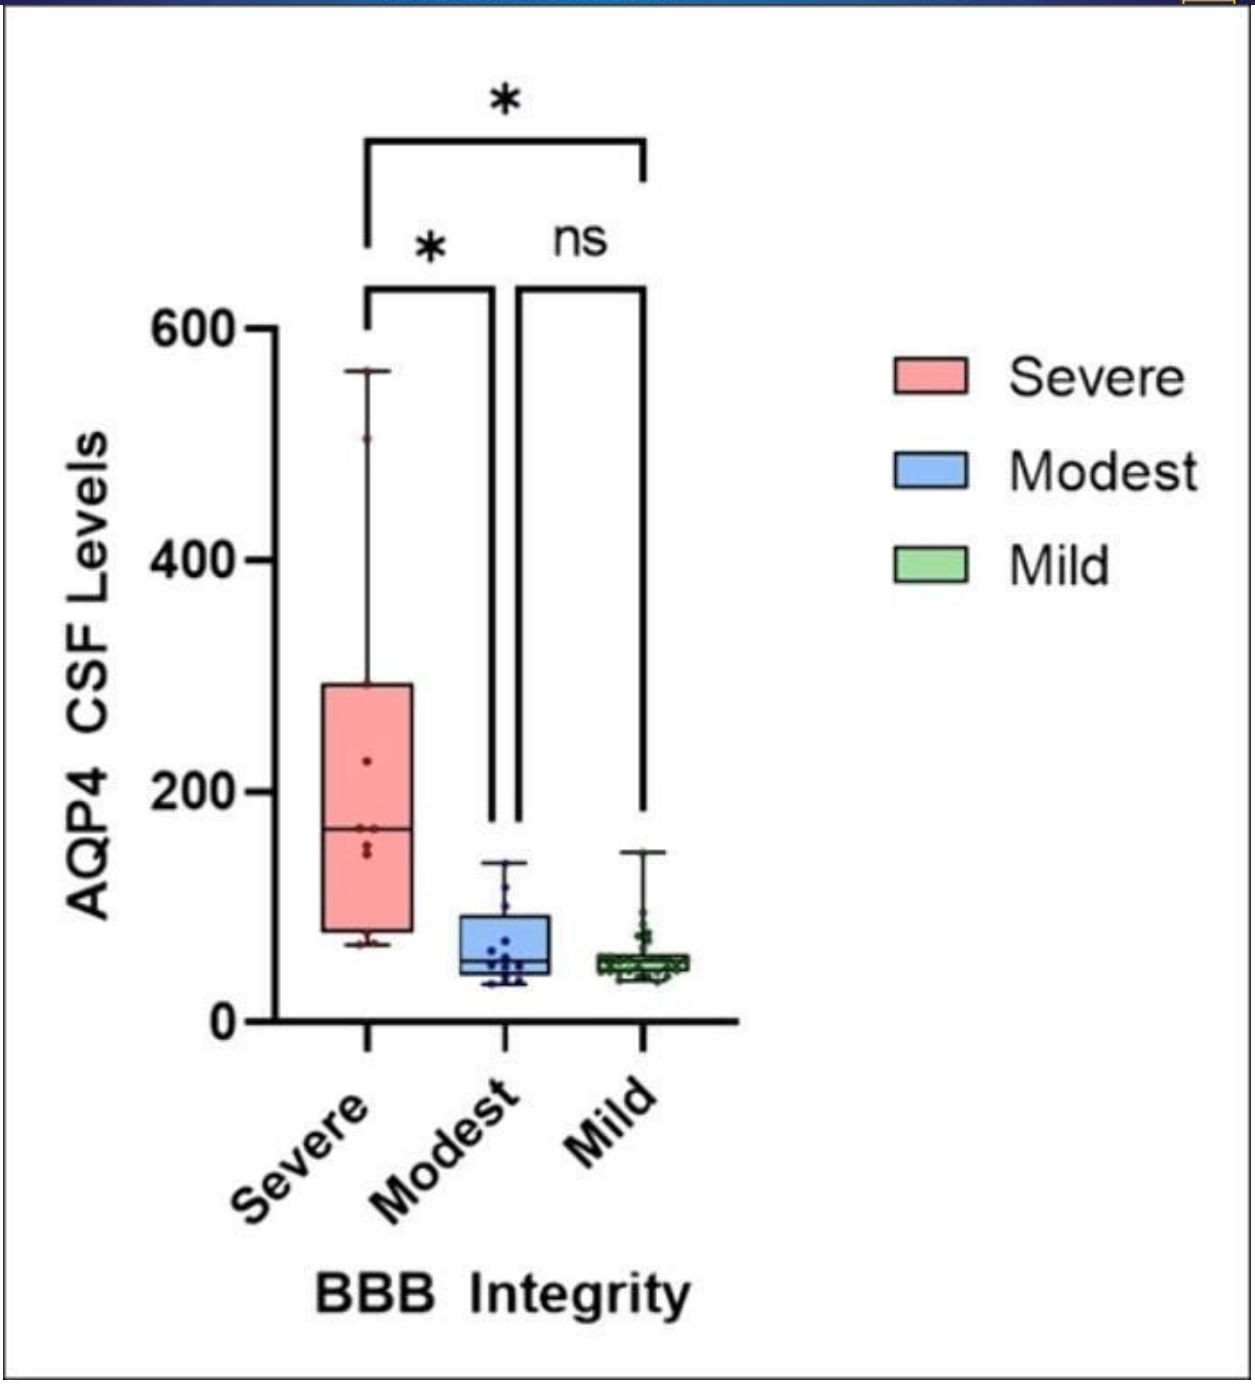

Figure 1. CSF Aquaporin-4 (AQP4) levels in individuals with severe, modest and mild blood-brain barrier damage.

Conclusions: In this pilot study, we show that CSF AQP4 concentration increases with severity of BBB damage. This highlights the potential of AQP4 as a novel biomarker for monitoring BBB integrity. Importantly, AQP4 may offer insights into a broader spectrum of neurodegenerative processes characterized by BBB dysfunction.

Aims: Glial fibrillary acidic protein (GFAP) is a marker of cerebral astrogliosis and occasionally elevated in patients with dementia. GFAP in cerebrospinal fluid (CSF), is routinely requested in referrals to neurochemistry laboratories; however, its ability to differentiate dementias and diagnostic capability is unclear. Our aim was to elucidate this, using two large datasets.
Methods: First, GFAP data measured since 2015 was retrieved from the database of the Clinical Neurochemistry Laboratory at the Sahlgrenska University hospital. We then cross-referenced with the Swedish dementia registry (SveDem). Here, information on ten different diagnoses such as early onset AD (EAD [<65 years]), late onset AD (LAD [≥65 years]), Parkinson disease with dementia (PDD), vascular dementia (VaD) and frontotemporal dementia (FTD), each with specific diagnostic criteria, were retrieved. The GFAP data was log_{10}-transformed, followed by an analysis of covariance (ANCOVA) and a subsequent post-hoc Tukey's test, with GFAP as dependent variable, diagnosis as independent variable and sex and age as covariates.
Results: In total, 1912 individuals (mean [SD] age, 71.9 [8.2] years; 52% male), were included. Lower log_{10}-transformed GFAP concentrations were seen in PDD (mean [SD], 2.68, [0.28] pg/mL), than in EAD, LAD, VaD and FTD; here, mean concentrations of 2.76 (0.24), 2.89 (0.23), 2.88 (0.32) and 2.76 (0.25) pg/mL were observed, respectively. In the post hoc analysis, GFAP differentiated VaD from EAD ($p<0.001$). PDD concentrations were significantly different from VaD ($p<0.001$) and LAD ($p<0.001$). Further, it also differentiated FTD from VaD ($p=0.006$) and LAD ($p=0.001$).
Conclusions: CSF GFAP could on a group level help differentiate VaD from EAD, FTD and PDD. Also, it could differentiate PDD from LAD. These results bear potential clinical relevance, where clinicians in some uncertain cases could use this marker as a differential tool.

IDENTIFICATION OF CANDIDATE PREDICTIVE BIOMARKERS OF PLASMA EXCHANGE WITH ALBUMIN REPLACEMENT TREATMENT EFFICACY IN MILD-TO-MODERATE ALZHEIMER'S DISEASES

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Chunmiao Feng[1], Ricardo Gonzalo[2], Carla Minguet[2], Isabel Bravo[2], Scott Lohr[1], Merce Boada Rovira[3], Oscar Lopez[4], Antonio Paez[2], Steven Braithwaite[1], Montserrat Costa[2], Benoit Lehallier[1]
[1]Alkahest, Sio, San Carlos, United States of America, [2]Grifols, Sio, Barcelona, Spain, [3]Ace Alzheimer Center Barcelona, Research Center And Memory Clinic, Barcelona, Spain, [4]University of Pittsburgh School of Medicine, Department Of Neurology, Pittsburgh, United States of America

Aims: Alzheimer's disease (AD) is a highly heterogenous disease, requiring precision treatment for individual patients. Here we aim to identify plasma proteins that will predict patients who will benefit the most from PE-Alb treatment (Plasma exchange with albumin replacement) based on the AMBAR clinical trial (Alzheimer's Management By Albumin Replacement), where PE-Alb significantly improved cognitive functions in patients with mild-to-moderate AD, especially based on CDR-sb measurement (Clinical Dementia Rating Sum of Boxes)
Methods: Baseline levels of plasma proteins were measured using the SomaScan assay (SomaLogic, Boulder, CO, USA) and were examined using Spearman correlation (rho) to identify single protein and/or protein ratios with strong association with CDR-sb changes in the treated group at end-of-study (n=88). ROC (Receiving Operating Characteristics) curves and AUC (Area Under the Curve) were calculated to estimate the predictive powers of these identified candidate biomarkers.
Results: One single protein and 4 protein ratios at baseline plasma were identified with significant and strong association with CDR-sb change at end-of-study (rho=-0.552 for single protein and ranging from -0.606 to -0.645 for protein ratios, adjusted p-values<0.05), with mean AUC>77% for single protein and mean AUCs ranging from 80% to 87% for 4 protein ratios. The relevance of these proteins was further supported by results in randomly selected samples of AMBAR study and by significant associations with ADAS-Cog (AD Assessment Scale-Cognitive Subscale) in AMBAR study. Interestingly, this single protein was a Notch ligand and found in two of the four protein ratios identified.
Conclusions: One plasma protein and 4 protein ratios were identified with high prediction power of CDR-sb improvement after PE-Alb treatment in mild-to-moderate AD patients. They deserve further investigation and validation for developing AD precision medicine.

EXPLORING ANGIOGENIC FACTORS IN PATIENTS WITH MANIFEST DEMENTIA

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Francesco Locatelli[1,2], Emir Basic[1,2], Sasha Hobson[3], Erik Erhardt[4], Johan Svensson[5], Gary Rosenberg[3], Anders Wallin[1,2], Petronella Kettunen[1,2]
[1]University of Gothenburg, Neuroscience And Physiology, Gothenburg, Sweden, [2]Sahlgrenska University Hospital, Psychiatry, Cognition And Old-age Psychiatry, Mölndal, Sweden, [3]University of New Mexico, Nm Center For Memory And Aging, Albuquerque, United States of America, [4]University of New Mexico, Mathematics And Statistics, Albuquerque, United States of America, [5]Sahlgrenska University Hospital, Internal Medicine And Clinical Nutrition, Gothenburg, Sweden

Aims: Alzheimer's disease (AD), subcortical small-vessel disease (SSVD) and mixed AD/SSVD (MIX) represent the most prevalent cognitive disorders, although limited knowledge exists about the involvement of angiogenic processes in their pathology. Consequently, this study aimed at assessing the contribution of angiogenic factors to the development of various dementia diagnoses. To this end, we investigated a panel of angiogenesis biomarkers in participants from the Gothenburg Mild Cognitive Impairment study, i.e. a longitudinal mono-center study of patients seeking help for cognitive complaints at the memory clinic at Sahlgrenska University Hospital.
Methods: First, we divided our subjects into 40 AD, 45 MIX, 25 SSVD and 41 controls according to the clinical diagnosis. Second, we re-diagnosed or confirmed all the patients' diagnoses using the International Working Group (IWG) for New Research Criteria for the Diagnosis of AD (IWG-2). The applied cut-offs indicating AD pathology were t-tau > 350 ng/L, p-tau181 > 59 ng/L, and Aβ1-42 < 530 ng/L. The proteins Flt1, PlGF, Tie-2, VEGF-D were analysed using the MSD Angiogenesis Panel 1 in both CSF and plasma.
Results: Our preliminary analysis showed that the endothelial growth factor Flt-1 appeared to be higher in AD and MIX than in SSVD and controls in CSF. The CSF placental growth factor PlGF was higher in MIX and SSVD compared to AD and controls. Levels of plasma angiogenesis factorsTie-2 and VEGF-D were lower in AD and SSVD compared to MIX and controls.
Conclusions: Our findings suggest that angiogenic processes play a significant role in the pathology of cognitive diseases, especially in individuals with the dual amyloid and vascular pathology, i.e. in mixed AD/SSVD.

MULTIOMIC BLOOD-BASED BIOMARKERS EXHIBIT HIGH SPECIFICITY IN PREDICTING ALZHEIMER'S DISEASE FROM PREDEMENTIA

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Benoit Souchet[1], Alkéos Michail[1], Maud Heuillet[2], Aude Dupuy-Gayral[2], Eloi Haudebourg[2], Catherine Pech[2], Antoine Berthemy[2], François Autelitano[2], Baptiste Billoir[1], Kimiko Domoto-Reilly[3], Christopher Fowler[4], Thomas Grabowski[3], Suman Jayadev[3], Colin Masters[4], Jerome Braudeau[1]
[1]AgenT, Paris, France, [2]Evotec, Toulouse, France, [3]University of Washington, Uw Adrc, Seattle, United States of America, [4]The Florey Institute of Neuroscience and Mental Health, University of Melbourne, Clinical Research Group, Melbourne, Australia

Aims: Diagnosing prodromal or demented Alzheimer's patients relies on cognitive assessments and amyloid plaques presence. However, these criteria have demonstrated an high sensitivity but a low specificity (Ritchie et al., 2014; Kokkinou et al., 2021; Martinez et al., 2017), leading to up to 25% false positives. **The aim of this study was to address this specificity limitation.**
Methods: We developed mass spectrometry assays for 81 blood-based biomarkers (45 proteins, 36 metabolites) identified in AAV-AD rats (Audrain et al, 2018). We analyzed samples from 345 cognitively impaired participants (193 MCI, 152 dementia), at blood draw and clinically followed for up to 13 years. The participants' diagnoses, either AD or another brain disorder, were clinically determined at their last clinical assessments. 82.9% had baseline amyloid data. We developed predictive machine learning (ML) models with high specificity for identifying AD participants (including 123 with prodromal AD and 126 with AD dementia) within the group of patients with non-AD brain disorders (comprising 96 participants). The training dataset (70%) was used to select the biomarkers, trained the algorithm, and set the cutoff, while the test dataset (30%) validated the model robustness.
Results: Combining 19 blood biomarkers and age, the ML model distinguished AD patients (41 prodromal AD and 43 AD dementia) from non-AD patients (25 individuals) with **92% specificity** and 52.4% sensitivity **on the test dataset** (AUROC=71.8%, p=0.001). When the ML model was associated with the amyloid status, we achieved **100% specificity** along with 39.7% sensitivity.
Conclusions: Our multiomics blood-based biomarkers exhibited an high specificity in identifying AD patients within the cognitively impaired population, minimizing false positives. They have the potential to not only enable earlier diagnosis but also **facilitate swift therapeutic interventions** and more effective clinical trials monitoring.

A NOVEL LIQUID BIOPSY PLATFORM FOR DEMENTIA PATIENTS USING CIRCULATING CELL FREE DNA AND CHIMERIC RNAS AS BIOMARKERS

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Milana Frenkel-Morgenstern[1], Eitan Okun[2]
[1]Bar-Ilan University, Azrieli Faculty Of Medicine, Safed, Israel, [2]Bar-Ilan University, The Mina And Everard Goodman Faculty Of Life Sciences, Ramat Gan, Israel

Aims: Alzheimer's Disease (AD), the most common age-associated neurodegenerative disorder, is a polygenic disease, is characterized by the presence of extracellular aggregates of amyloid plaques and intracellular tangles comprised of the Tau protein. The aim of this study was to establish a novel liquid biopsy approach that comprises a simple blood test and genomic analysis of cell-free RNA (cfRNA) and cell-free DNA (cfDNA) from tissues and liquid biopsies from patients with an early stage of mild-cognitive impairment (MCI) or AD.
Methods: Blood samples from 30 patients and 30 healthy controls, as well as 10 brain samples from AD patients and 10 samples from non-AD postmortem brains were obtained. The samples were subjected to deep sequencing and analyzed for genomic RNA (gRNA) and DNA (gDNA) data.
Results: We observed unique chimeric RNAs that have not been found in the gDNA data, particularly, sense-antisense chimeras (SAS) of *apolipoprotein E (APOE)* and *amyloid-precursor protein (APP)* genes. Moreover, we have uncovered more than 200 chimeric RNAs that are expressed in post-mortem brains as well as identified in the cfRNA of individuals with AD due to trans-splicing production. For the identification of cfDNA we mapped them specifically to the chimeric junction sites pre-computed by us from a previously developed database (ChiTaRS). Interestingly, the transcriptional chimeras of APOE and APP were associated uniquely with AD as they have not been found in the non-AD cohorts. We observed unique copy number variations on chromosomes 5 and 8. Finally, all the genes involved in chimeric transcripts tangled in cellular pathways connected to the release of dopamine and/or serotonin as well as to the function of acetylcholine.
Conclusions: These results indicate that chimeric RNAs might serve as biomarkers for the AD early diagnostics.

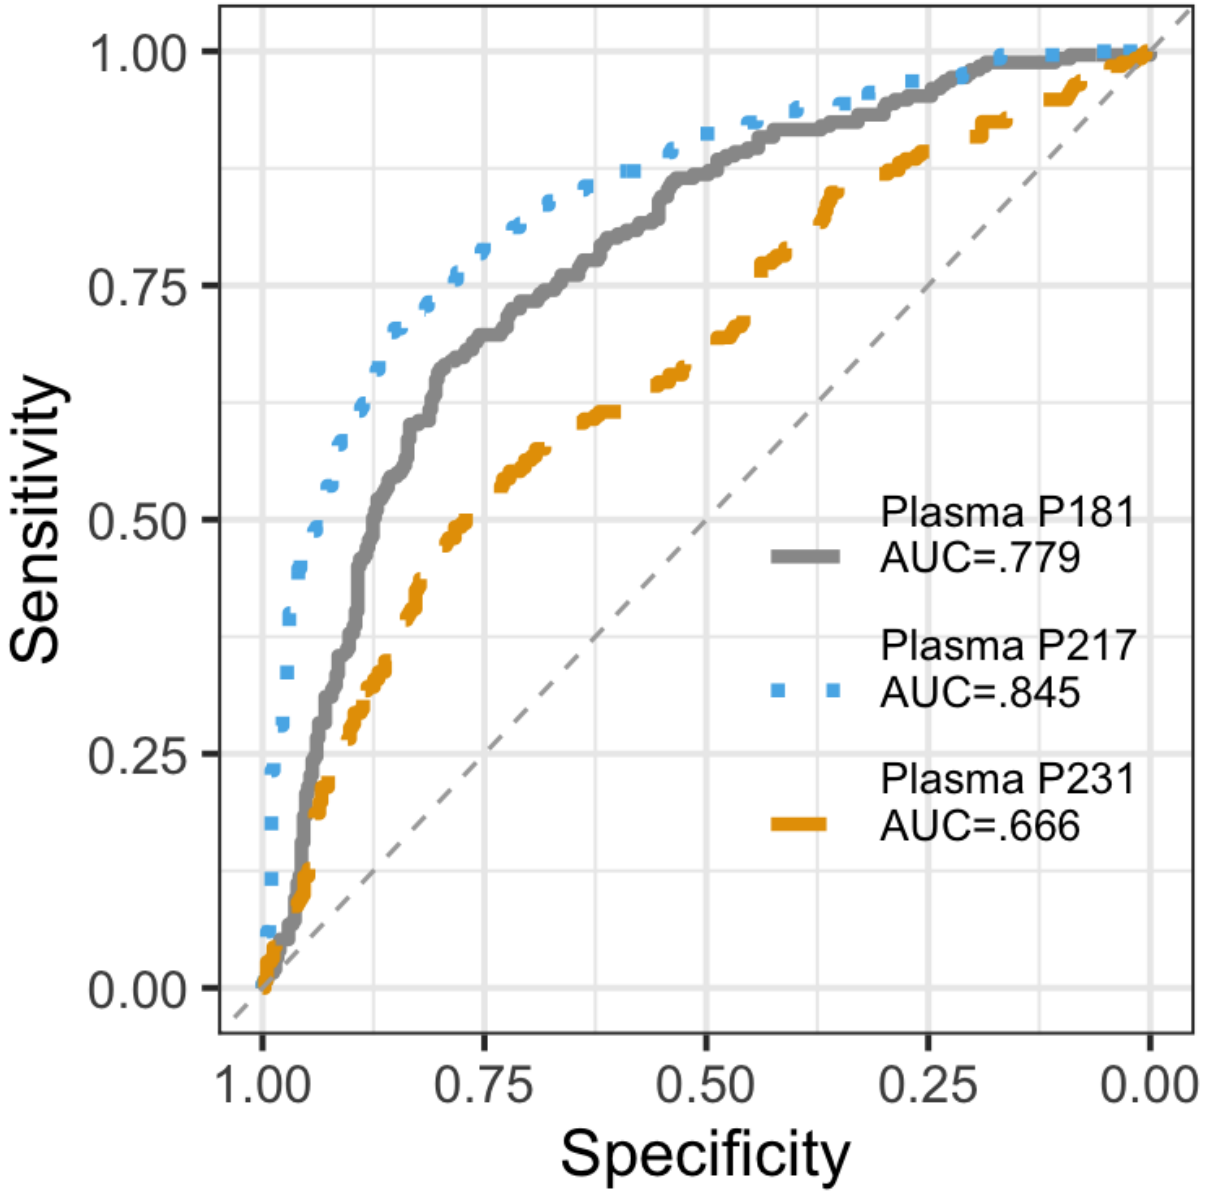
PLASMA P-TAU217 PREDICTS COGNITIVE DECLINE AND MRI CHANGES IN COGNITIVELY UNIMPAIRED INDIVIDUALS AND EARLY ALZHEIMER'S DISEASE

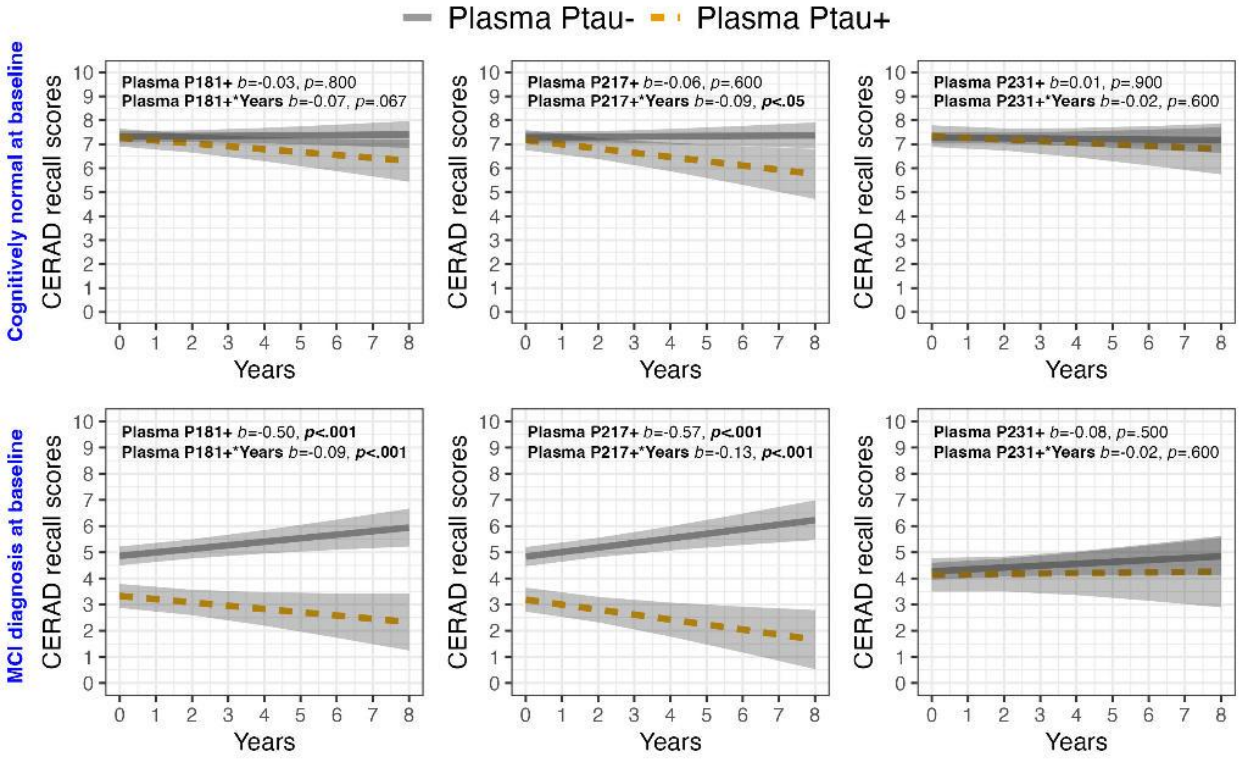
POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Fernando Gonzalez-Ortiz[1], Bjørn-Eivind Kirsebom[2], Sandra Tecelão[2], Thomas Karikari[3], Kaj Blennow[1], Tormod Fladby[4]
[1]Gothenburg University, Psychiatry And Neurochemistry, Göteborg, Sweden, [2]Akerhus University Hospital, Neurology, Lørenskog, Norway, Norway, [3]University of Gothenburg, Psychiatry And Neurochemistry, Göteborg, Sweden, [4]Akerhus University Hospital, Neurology, Oslo, Norway

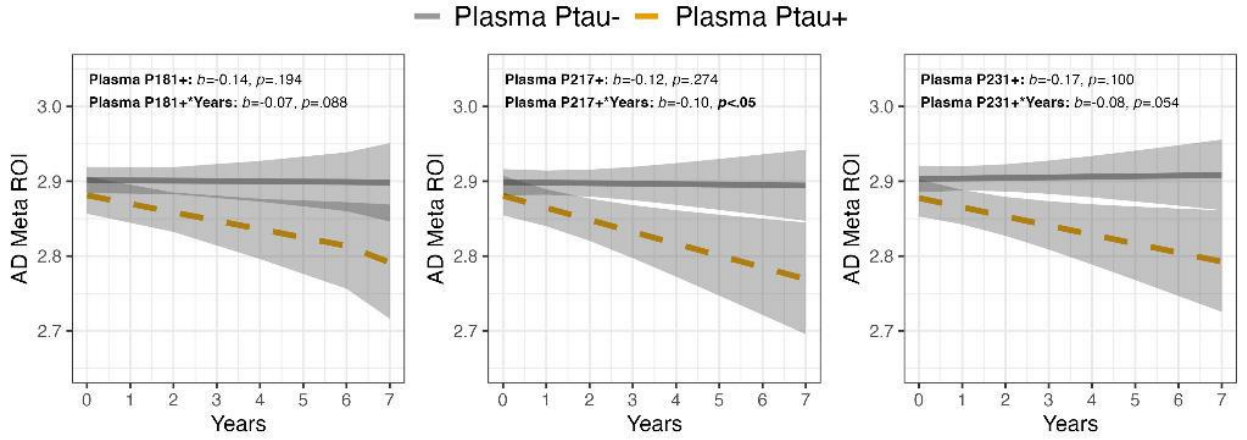
Aims: Detection of Alzheimer's disease (AD) pathophysiology among cognitively unimpaired individuals and those in the early stages of the disease continuum remains clinically challenging. Here, we aim to explore the diagnostic and prognostic value of plasma p-tau181, p-tau217 and p-tau231 by assessing baseline and longitudinal changes in cognition and AD meta-ROI in cognitively normal (CN) individuals and in those with mild cognitive impairment (MCI).
Methods: Participants from the Dementia Disease Initiation multicentre cohort (n=655) comprising CN (n=270) or MCI (n=378) cases were included. Area Under Curve (AUC) for the plasma ptau markers were determined using CSF Aβ42/40 ratio (<.077) as the standard of truth. Linear mixed models with random intercept for subject and random slopes for time were used to determined associations between the plasma ptau status (positive/negative) and future cognitive decline (n=555 subjects, 1226 observations over time, mean years = 3.41) and MRI AD Meta-ROI (n=377 subjects, 638 observations over time, mean years = 2.85).
Results: Plasma p-tau217 had the best diagnostic performance (AUC: 0.84) among the p-tau markers.



Plasma p-tau217 was the only marker associated with performance in the Consortium to Establish a Registry for Alzheimer's Disease (CERAD) test overtime in CN individuals (b=-0.09, p<0.05). In participants with MCI, plasma p-tau217 was associated with performance in CERAD at baseline and overtime (b=-0.57, p<0.001 and b=-0.13, p<0.001, respectively).



In the whole cohort, plasma p-tau217 was the only p-tau marker significantly associated with future AD meta-ROI atrophy (b=-0.10, p<.05).



Conclusions: Plasma p-tau217 can be an easily accessible and efficient way to screen and monitor patients with suspected AD pathophysiology. Moreover, p-tau217 associations with future cognitive decline and prediction of AD meta-ROI signature changes support its use as a diagnostic and prognostic marker in AD.

CEREBROSPINAL FLUID YKL-40 AS AN EARLY PREDICTOR OF COGNITIVE DECLINE IN AMNESTIC MILD COGNITIVE IMPAIRMENT DUE TO ALZHEIMER'S DISEASE

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Aims: Ongoing Alzheimer's disease (AD) research has unveiled a promising range of fluid biomarkers with diagnostic and prognostic potential. Among these, neuroinflammation biomarkers such as soluble-Triggering-receptor-expressed-on-myeloid-cells-2 (sTREM2), chitinase-3-like-1-protein (YKL-40), and glial-fibrillary-acidic-protein (GFAP) have emerged as promising candidates, which will be soon incorporated as "non-specific biomarkers relevant in AD pathogenesis" within the revised NIA-AA criteria. This study aims to investigate the role of these biomarkers in predicting cognitive decline in individuals with amnestic mild cognitive impairment (aMCI) due to AD.
Methods: Fifty-nine subjects diagnosed with aMCI due to AD underwent a comprehensive clinical evaluation, an extensive neuropsychological assessment, and CSF biomarkers quantification (Aβ42/40 ratio, p-tau181, t-tau, NfL, sTREM2, YKL-40 and GFAP). After a one-year follow-up, subjects were categorized as "fast-decliners" (n=21) or "slow-decliners" (n=38) based on the degree of MMSE score reduction. Comparisons between groups and binomial logistic regression models were performed.
Results: The two groups exhibited no significant differences in terms of age, literacy and MMSE score at baseline. When comparing CSF biomarker levels between the cohorts, only concentrations of p-tau181, t-tau, and YKL-40 were significantly higher in the "fast-decliners" group. Notably, YKL-40 emerged as the most robust predictor of MMSE decline after one year in a binomial logistic regression model.
Conclusions: Our findings confirmed the importance of tauopathy in AD progression and contribute to the growing evidence regarding the role of neuroinflammation in AD pathogenesis. YKL-40 was revealed as a predictor of cognitive decline since the early stages of AD. Further research should focus on validating these findings in larger cohorts, exploring YKL-40's potential role in refining diagnostics, prognostics, and treatment, also investigating the therapeutic potential of interventions targeting astrocytosis in AD.

Aims: To determine the ability of plasma amyloid-β (Aβ)42/40, p-tau181, GFAP and NfL to detect Aβ pathology in cognitively unimpaired (CU) individuals at risk of AD.
Methods: Plasma biomarkers were measured using the plasma NTK panel (Roche Diagnostics International Ltd, Rotkreuz, Switzerland), a panel of robust prototype assays, in CU participants of the ALFA+ study. We studied their differences between AT groups (defined by CSF Aβ42/40 and p-tau181).

Next, we assessed their performance for detecting Aβ positivity (as defined by CSF Aβ42/40 or amyloid PET) by using ROC analysis. Finally, we simulated how introducing random variability to each biomarker value impacted their detection performance**.**

Results: The study included 403 CU participants (49.3 - 73.6 yo). Among them, 135 (33.5%) were CSF amyloid positive (A+). A subset (n=345) also had amyloid PET available (Table 1).

Table 1. Participants' characteristics of the ALFA+ study cohort stratified by CSF Aβ42/40 status.

Variable	N	CSF A-, N = 268	CSF A+, N = 135	p-value
Age (years), Median (IQR)	402	60.5 (57.5, 64.1)	62.9 (58.6, 66.0)	0.001[1]

Education (years), Median (IQR)	403	12.0 (11.0, 17.0)	12.0 (11.0, 17.0)	0.3[1]
Plasma Aβ42/40, Median (IQR)	399	0.138 (0.132, 0.144)	0.118 (0.112, 0.127)	<0.001[1]

All plasma biomarkers, except for NfL, were significantly different in the A+T- and A+T+ groups compared to the A-T- one. However, only p-tau181 and GFAP were significantly increased in a stepwise manner from A-T- to A+T+ (Fig. 1).

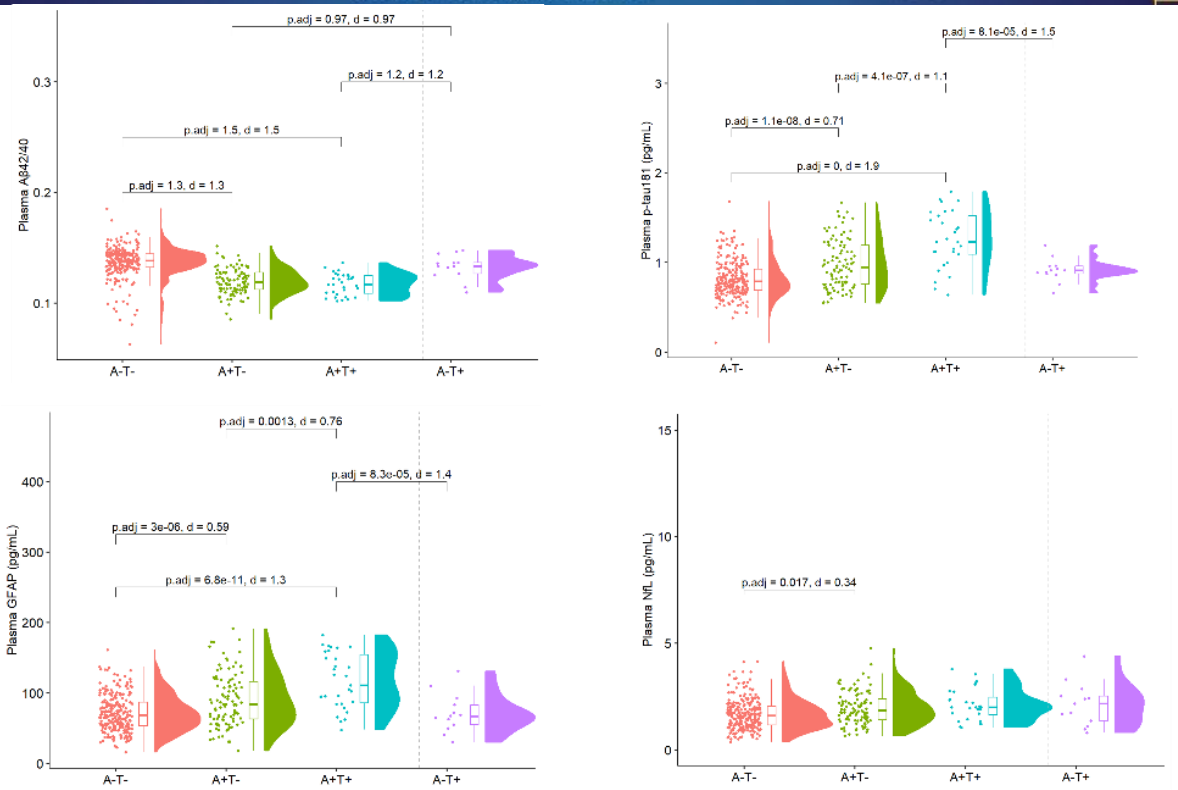

Figure 1. Raincloud plot of plasma NTK biomarkers levels by AT groups. A/T positivity was defined by CSF Aβ42/40 < 0.071 and CSF p-tau181 ≥ 24 pg/mL respectively. The p-value of Tukey HSD test and Cohen's d are reported for the significant comparisons.

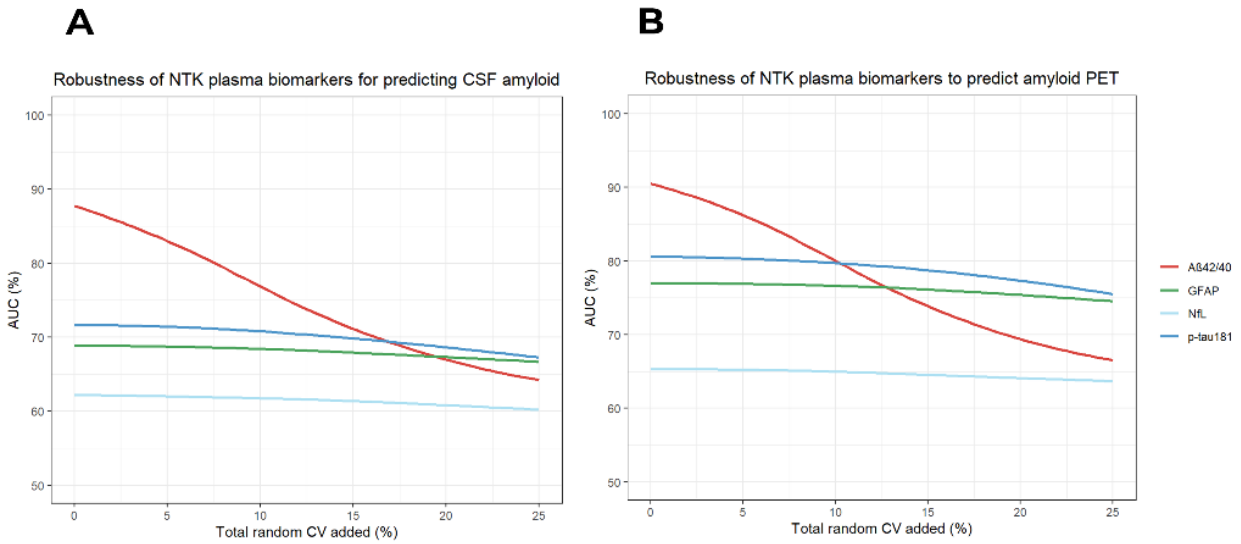
Plasma Aβ42/40 had the highest performance for Aβ positivity discrimination (CSF, AUC: 0.87; PET, AUC: 0.90), followed by p-tau181 (CSF, AUC: 0.72; PET, AUC: 0.81). Adding the plasma NTK ApoE4 measurement, rendered an AUC ranging 0.79-0.81 for p-tau181 and GFAP (Table 2). Plasma Aβ42/40 was the most sensitive biomarker to the addition of random variability, while the others remained moderately stable (Table 2 and Fig.
2).

Table 2. Summary table of the ROC analyses conducted to assess the performance of plasma NTK biomarkers for Aβ positivity discrimination. The model was assessed by the biomarker alone and then compared to a model with the addition of plasma ApoE4.

	CSF Aβ42/40 (A+ <0.071)			Amyloid PET (A+ ≥12 Centiloids)		
Model	**AUC**	**AUC (+ApoE4)**	**Improves w/ ApoE4**	**AUC**	**AUC (+ApoE4)**	**Improves w/ ApoE4**
Demog. (Age + Sex)	0.60 (0.54-0.66)	-	-	0.69 (0.61-0.76)	-	-
Aβ42/40	0.87 (0.83-0.91)*	0.88 (0.84-0.91)*	No	0.90 (0.86-0.93)*	0.90 (0.87-0.93)*	No
p-tau181	0.72 (0.66-0.77)*	0.80 (0.75-0.84)*	Yes	0.81 (0.73-0.88)*	0.81 (0.75-0.88)*	No
GFAP	0.69 (0.63-0.75)*	0.79 (0.75-0.84)*	Yes	0.77 (0.69-0.85)	0.79 (0.72-0.86)*	Yes
NfL	0.62 (0.56-0.68)	0.74 (0.69-0.79)*	Yes	0.65 (0.57-0.74)	0.68 (0.60-0.76)	Yes

* represent a corresponding AUC significantly higher (as determined by DeLong's test) than the one of the base demographics model (Age + Sex).

Figure 2. Robustness plots assessing the performance and stability of NTK plasma biomarkers for Aβ positivity discrimination. The line plot shows the AUC for each individual biomarker at each random CV variations, ranging from up to and including 0 to 25% variations of the original biomarker measurements (represented here at 0%). The results can be seen for two different amyloid standards of truth, CSF Aβ42/40 (A; cut-off: 0.071). and amyloid PET (B; cut off: 12 Centiloids). Abbreviations: AUC, area under the curve; CV, coefficient of variation.



Conclusions: Plasma Aβ42/40 decreased and p-tau181 and GFAP increased in early stages of the Alzheimer's preclinical *continuum*, namely in CU A+T- individuals. Plasma Aβ42/40 had the best performance to detect Aβ pathology but was more sensitive to measurement variability compared to p-tau181, GFAP and NfL.

Aims: Plasma biomarkers showed great potential in identifying and monitoring amyloid and tau pathology related to Alzheimer's disease (AD). Associations between longitudinal changes of plasma biomarkers and magnetic resonance (MR)-based parameters remain to be examined. We aimed to put the plasma biomarkers into better context and hypothesized that 1) they can track AD-related MR-based brain changes and that 2) they are related to pathologic distribution patterns (amyloid predominantly in frontal/parietal areas, tau predominantly in medial temporal lobes) or mechanisms (neuroinflammation, neuronal integrity).
Methods: In a cohort ranging from healthy controls (HC) to dementia due to suspected AD (total n=127, age range 55-84), we examined associations between longitudinal plasma amyloid-beta (Aβ)42/40 ratio, phosphorylated tau (p-tau181), glial fibrillary acidic protein (GFAP) and neurofilament light chain (NfL), and 7T parietal cortical thickness, hippocampus volume, resting-state default mode network and salience (Sal) connectivity, MR spectroscopy myo-inositol and N-acetylaspartylglutamic acid, and cognition. We used linear mixed models to explore cross-sectional and longitudinal associations.
Results: First, decreasing Aß42/40 was associated with increasing p-Tau181 in participants with subjective cognitive decline (SCD) but not HC. Second, of all examined plasma biomarkers, increasing p-Tau181 and GFAP showed most robust associations with 7T MR-based parameters, particularly measurements in frontal and parietal areas (decreasing parietal cortical thickness and Sal connectivity) or neuroinflammation (increasing MRS myo-inositol measured in the PCC/precuneus).
Conclusions: We contributed to the evidence that the potential of plasma Aß42/40 is limited to individuals in earliest stages of AD. Plasma p-Tau181 and GFAP seem to track disease progression in terms of continuously worsening MR-based measures and cognition. The fact that p-Tau181 and GFAP were more closely related to brain changes in regions of amyloid pathology and neuroinflammation and less tau accumulation warrants further investigation.

A COMPREHENSIVE INVESTIGATION OF PRE-ANALYTICAL SAMPLE HANDLING FACTORS AND THEIR IMPACT ON BLOOD-BASED BIOMARKERS FOR ALZHEIMER'S DISEASE

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Mariam Gouda[1], Daniel Antwi-Berko[1], Mardou Van Leeuwenstijn[2], Bram Bongers[1], Erik Stoops[3], Andreas Jeromin[4], Rebecca Edelmayer[5], Sjors In'T Veld[1], Charlotte Teunissen[1], Inge Verberk[1]
[1]Amsterdam UMC, Laboratory Medicine, Amsterdam, Netherlands, [2]Amsterdam UMC, Alzheimer Center Amsterdam, Neurology, Amsterdam, Netherlands, [3]ADx NeuroSciences, R&d, Gent, Belgium, [4]ALZPath, Inc, Alzpath, Inc, Carlsbad, United States of America, [5]Alzheimer's Association, Alzheimer's Association, Chicago, United States of America

Aims: Pre-analytical sample handling can significantly affect the clinical utility of blood-based Alzheimer's disease (AD) biomarkers, and thus affect their implementation. The Global Biomarker Standardization Consortium of the Alzheimer's Association has established a standardized operating procedures (SOPs) primarily based on amyloid-beta 1-40 (Aβ1-40) and 1-42 (Aβ1-42) assays. We aim to refine these SOPs by extending experimental conditions and evaluating additional blood-based biomarkers, including pTau isoforms.

Methods: We conducted 11 pre-analytical experiments on blood samples of 166 volunteers. Each experiment included a reference condition and 3-4 experimental conditions (Figure 1). Neurofilament light (NfL), glial fibrillary acidic protein (GFAP), Aβ1-42, Aβ1-40 and phosphorylated Tau (pTau) isoforms were measured on Simoa using the Neurology 4-plex E Quanterix, pTau181 Quanterix, and ALZpath pTau 217 assays. Recovery% was calculated by comparing experimental condition to their reference condition. Clinically relevant changes were defined as a median recovery change of ±10% or increased measurement variation.

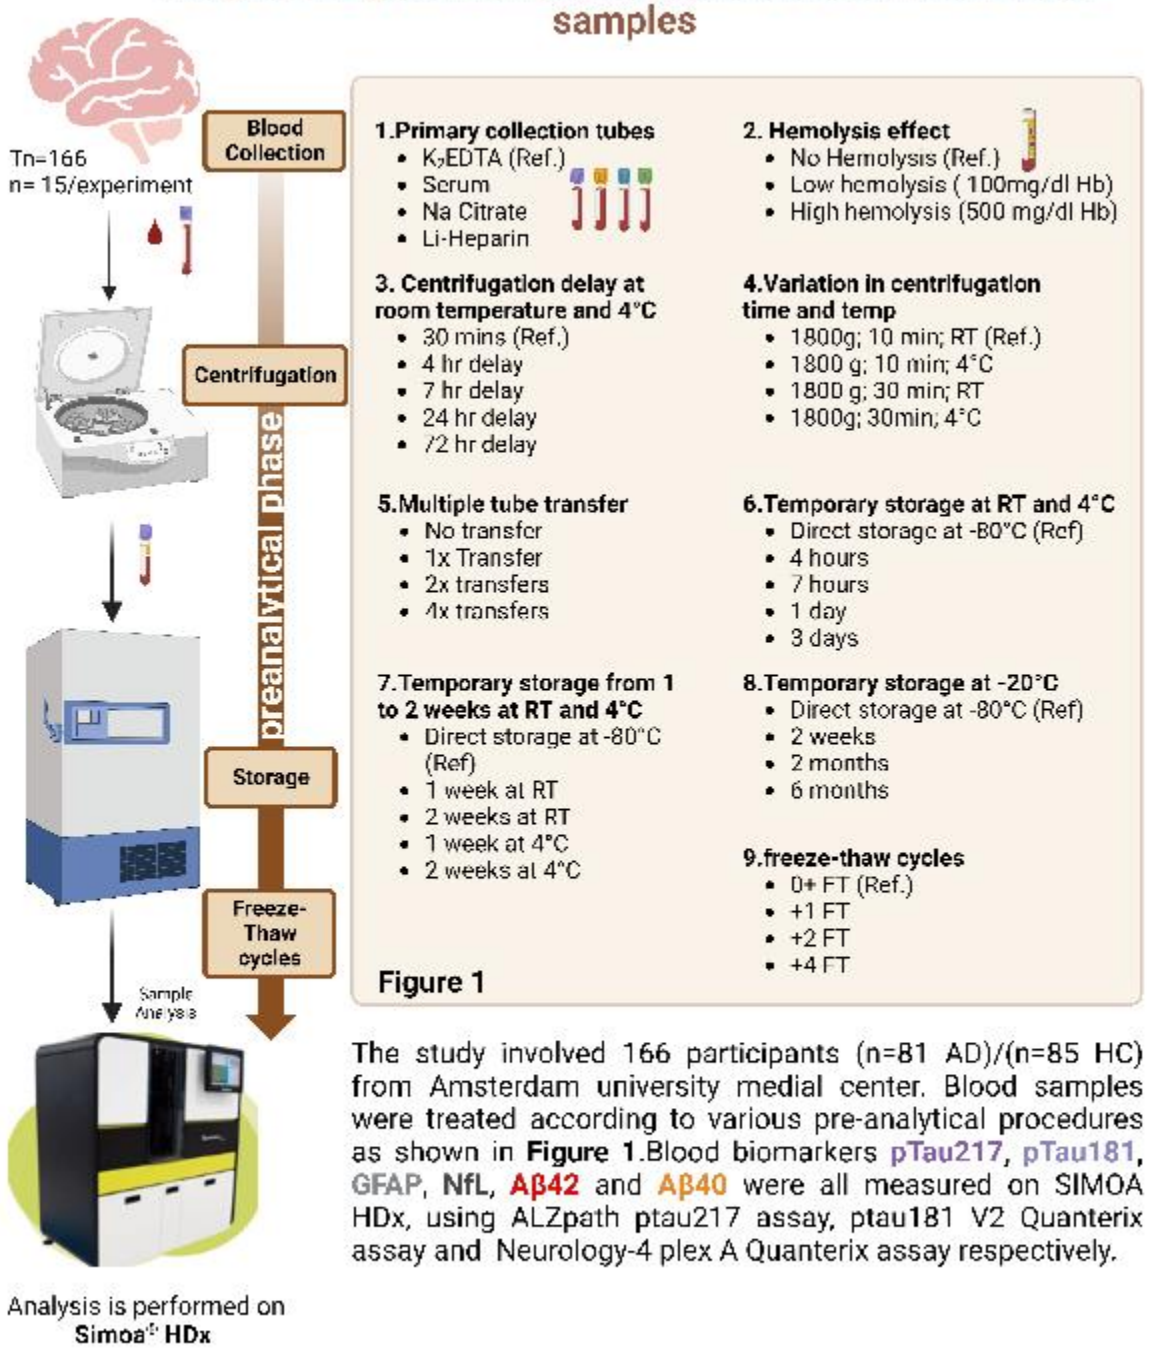

Figure 1

The study involved 166 participants (n=81 AD)/(n=85 HC) from Amsterdam university medial center. Blood samples were treated according to various pre-analytical procedures as shown in **Figure 1**.Blood biomarkers **pTau217**, **pTau181**, **GFAP**, **NfL**, **Aβ42** and **Aβ40** were all measured on SIMOA HDx, using ALZpath ptau217 assay, ptau181 V2 Quanterix assay and Neurology-4 plex A Quanterix assay respectively.

Results: Figure 2 summarizes the results. Primary collection tube types influenced the levels of all biomarkers. Aβ1-42 and Aβ1-40 were sensitive to prolonged centrifugation delays, -80°C storage delays, and high levels of hemolysis, resulting in reduced levels. The Aβ1-42/Aβ1-40 ratio partially mitigated these effects, except under extreme storage delays conditions (1-2 weeks at RT). pTau isoforms remained generally stable against experimental conditions, though pTau217 showed increased measurement variation with tube transfers. NfL and GFAP levels increased with prolonged storage delays at RT, in the fridge or at -

20°C, as well as, with sample freeze-thaw cycles

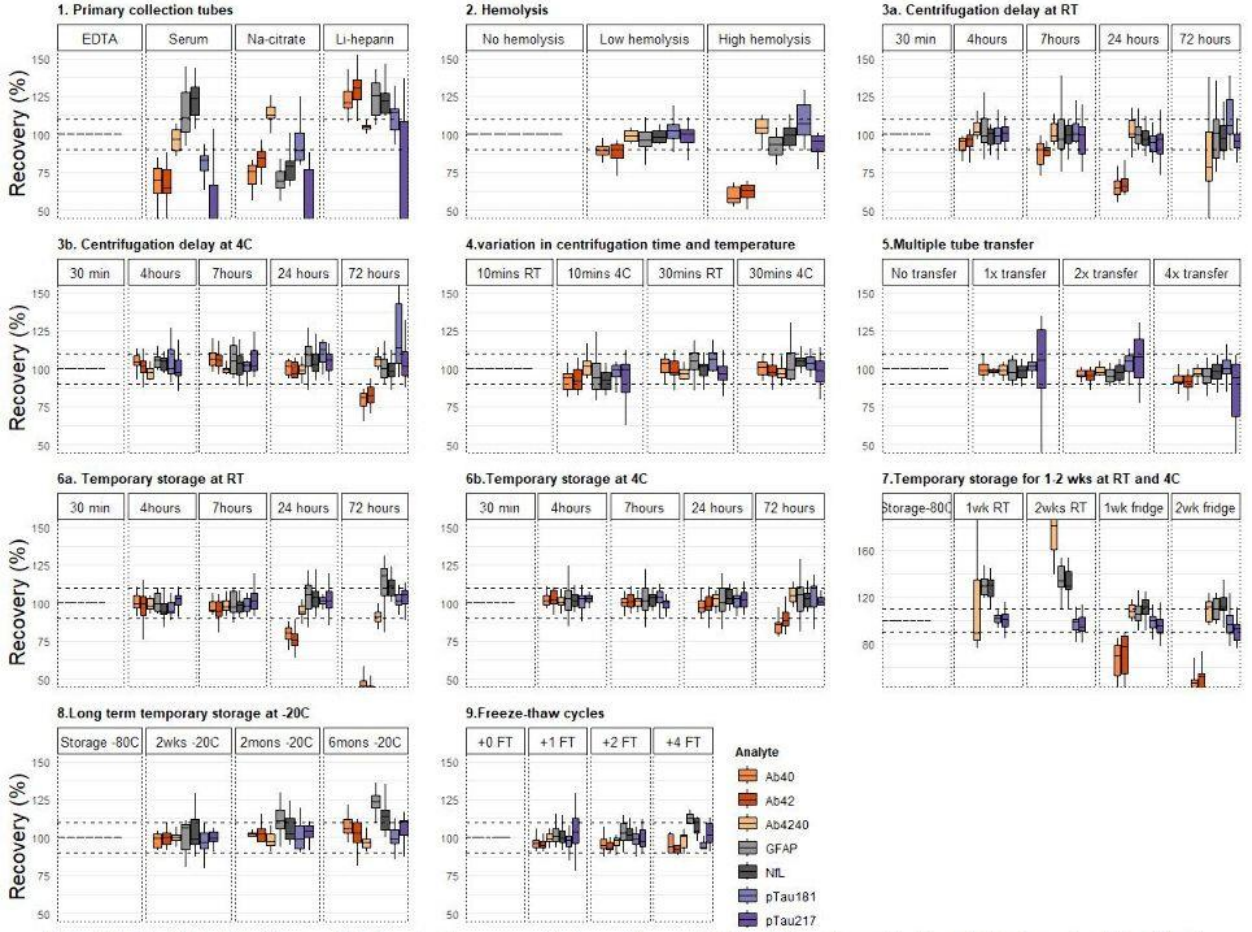

Figure 2: Results obtained from 11 pre-analytical experiments are presented. Recovery% was calculated as follows: Recovery%= (Concentration in experimental condition / Concentration in reference condition) * 100. Clinically relevant changes were defined as median recovery change of ± 10%, or visually increased measurement variability represented by the interquartile range.

Conclusions: Our findings allow refining the established SOP to counteract the impact of pre-analytical sample handling on biomarker measurement reliability. Notably, our results highlight the remarkable stability of pTau isoforms, even under extreme pre-analytical conditions.

Hussman Institute For Human Genomics, Miami, United States of America, [2]Wake Forest University School of Medicine, Maya Angelou Center For Health Equity, Winston-Salem, United States of America, [3]Instituto Nacional de Ciencias Neurológicas, Neurogenetics Research Center, Lima, Peru, [4]Universidad Central Del Caribe, Department Of Internal Medicine, Bayamon, Puerto Rico, [5]Case Western Reserve University, Department Of Population & Quantitative Health Sciences, Cleveland, United States of America

Aims: Plasma phosphorylated Tau (pTau181) and amyloid beta (Aβ42/Aβ40) are biomarkers for differential and preclinical diagnosis of Alzheimer disease (AD). Measurement of these biomarkers has been mostly from non-Hispanic, European individuals . Thus, we evaluated the practicality and generalizability of plasma pTau181 and Aβ42/Aβ40 in discriminating AD from cognitively intact (CI) individuals in diverse cohorts.
Methods: Plasma from was isolated, and two aliquots stored at -80°C and others at -20°C. After two, four, and six weeks, aliquots were moved from -20°C to -80°C. pTau181 and Aβ42/Aβ40 were measured with Simoa chemistry. We performed these assays on 642 African Americans (162 AD, 480 CI), 906 Puerto Ricans (385 AD, 521 CI), 149 Peruvians (49 AD, 100 CI), and 60 Cubans (26 AD, 34 CI). Differences across AD status and diagnostic performance and receiver operator characteristic curves were analyzed using logistic regression models.
Results: After six weeks at -20°C, the average change in pTau181 and Aβ42/Aβ40 across all samples was less than 10%. pTau181 was increased in AD compared to CI taking into account all individuals and in each cohort. There was no difference in the plasma Aβ42/Aβ40 ratio, however there was a trend towards decreasing concentration in AD. pTau181 was more accurate at predicting status than Aβ42/Aβ40 ratio, but classification improved when biomarkers were combined. The accuracy varied with AUC from 0.845 for African Americans to 0.683 for Peruvians.
Conclusions: These data suggest that locations lacking infrastructure of -80°C can utilize -20°C equipment and maintain biomarker fidelity, allowing for biomarker studies from low- and middle- income countries Furthermore, AD plasma biomarkers are generalizable across ancestries. Combining genomic and biomarker data will increase understanding of genetic risk and refine clinical diagnoses in individuals of diverse ancestries.

Aims: To compare Alzheimer's disease (AD) plasma immunoassays within a memory clinic population, stratified by age, and understand potential variances. To test a novel commercially available ALZpath plasma phosphorylated tau217 (p-tau217) Single Molecule array (Simoa) immunoassay.
Methods: 96 participants with cognitive complaints were categorized into two groups Alzheimer's disease (AD) and non-AD cerebrospinal fluid (CSF) profiles based on their CSF amyloid beta 42 (Aβ42) and phosphorylated tau181 (p-tau181) levels and evenly represented across the age ranges of 55-79 years. We conducted a direct comparison of seven plasma Single Molecule array (Simoa) Quanterix assays and determined their accuracy to discriminate between the two CSF profiles.
Results: There were 96 participants included in analysis (mean [SD] age, 65.3 [6.6] years; 42 females [43.8%]). Plasma p-tau217 (area under the curve [AUC] = 0.972) and the p-tau217/ Aβ42 ratio (area under the curve [AUC] = 0.972) provided high accuracy in discriminating between AD CSF and non-AD CSF and there were significant differences between participants at all ages. There were also significant differences using plasma p-tau181 between participants up to the age of 74 years, and Aβ42 and glial fibrillary acidic protein (GFAP) up to the age of 70 years.
Conclusions: Both the novel commercial Alzpath plasma p-tau217 assay and the p-tau217/ Aβ42 ratio provided the best discrimination between CSF profiles at all ages. These plasma biomarkers may have utility as a diagnostic tool in a memory clinic population. Further work is required to investigate the influence of age on plasma ptau concentrations.

Aims: Objectives Parkinson's Disease (PD) is a multi-factorial degenerative disease resulting in physical dysfunction and thereby hampering normal living. Furthermore, PD increases the risk of development dementia as a complication. Currently, PD is detected in the later stages when neurons have degenerated completely, and treatment options are limited. Thus, blood-based biomarkers are essential for the early detection and as such for increasing the probability for successful treatment.
Methods: Methods Biomarkers detecting fragments of the brain-specific proteins Tau, GFAP, and Neurocan were measured in 16 PD patients, and 11 age and gender matched healthy donors by ELISAs, to determine their potential as blood-based tools for diagnosis, prognosis and monitoring of pharmacodynamic effects in PDI. Mean age was 73.7 years and 50% male for the PD patients, and 70.8 years, 63.6% male for the healthy donors.
Results: Results Levels of the caspase-3 generated Tau fragment Tau-C, which previously has shown a relation to dementia progression, were significantly elevated in PD patients ($p<0.0001$). Importantly, the levels observed in PD were very high, reaching those in subjects with Traumatic Brain Injuries, clearly indicating a pathological relevance. Importantly, when used assays detecting GFAP and Neurocan fragments, no such elevation was observed ($p=0.570$ and $p=0.278$, respectively), conferring specificity of the finding to the Tau-processing.
Conclusions: Conclusions In conclusion, Tau-C levels measured in serum samples from PD patients are highly elevated. Such blood-based biomarker may be useful for monitoring PD development and response to therapy.

DEVELOPMENT AND VALIDATION OF A NOVEL PANEL OF CSF BIOMARKERS FOR ALZHEIMER'S DISEASE

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Yanaika Hok-A-Hin[1], Bram Bongers[1], Katharina Bolsewig[1], Lynn Boonkamp[1], Daimy Ruiters[1], Afina Lemstra[2], Wiesje Van Der Flier[2], Yolande Pijnenburg[2], Marta Del Campo Milán[1,3,4], Charlotte Teunissen[1]
[1]Amsterdam UMC, Department Of Laboratory Medicine, Amsterdam, Netherlands, [2]Amsterdam UMC, Alzheimer Center Amsterdam, Amsterdam, Netherlands, [3]Barcelonabeta Brain Research Center (BBRC), Pasqual Maragall Foundation, Barcelona, Spain, [4]Universidad San Pablo-CEU, CEU Universities, Departamento De Ciencias Farmacéuticas Y De La Salud, Facultad De Farmacia, Madrid, Spain

Aims: Using proximity extension proteomic arrays (PEA), we previously identified a CSF protein panel reflecting different biological processes associated to Alzheimer´s disease (AD), that efficiently discriminated AD from non-AD dementias (i.e., dementia with Lewy bodies (DLB) and Frontotemporal dementia (FTD)). We aimed to translate this CSF differential diagnostic panel into immunoassays for large-scale analysis, and assess its discriminative performance in an independent cohort.
Methods: In-house or commercial immunoassays measuring five out of nine proteins identified (THOP1, NSE, DDC, ITGB2, and MMP7) were developed and analytically validated. To verify analytical performance, CSF samples (n=206) were compared between custom-PEA and Ella immunoassays. Clinical validation was performed in controls (cognitively unimpaired; n=55), patients with mild cognitive impairment having amyloid pathology (MCI-Aβ+; n=39), AD (n=47), and non-AD dementia (including 54 DLB and 50 FTD).
Results: Strong correlations between analytical platforms were observed (Figure1). THOP1 and NSE concentrations were higher in AD compared to controls and MCI-Aβ+ groups, and NSE was higher in AD compared to non-AD. However, not all differences survived a correction for multiple testing. ITGB2 concentrations were higher, and DDC concentrations were lower in AD compared to non-AD (Figure2). THOP1, ITGB2, and NSE had strong correlations with pTau and tTau (*Rho's* >0.49). The CSF panel discriminated AD from non-AD dementia with moderate accuracy (AUC=0.72, 95%CI: 0.63–0.81), which was lower compared to our previous study including the same proteins (AUC=0.84, 95%CI: 0.77–0.94).
Conclusions: We successfully developed immunoassays for novel AD biomarkers, covering multiple biological processes underlying AD pathophysiology. This panel might have added value when detecting AD subgroups with a specific pathophysiological background. While our differential diagnostic panel showed lower performance, trends are consistent with our discovery study highlighting the need for external cohorts
validation.

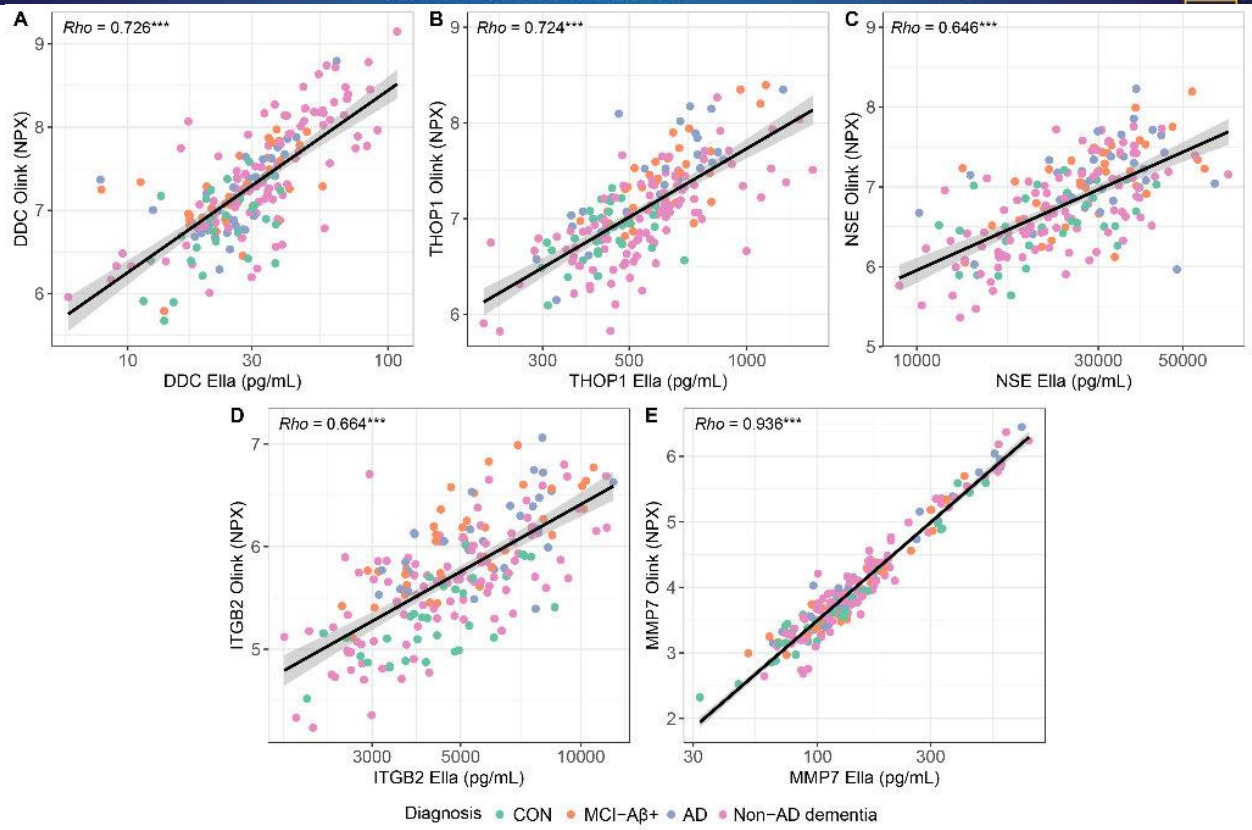

Figure 1. All Ella immunoassays significantly correlated with protein levels measured by Olink.
Protein levels were measured by custom-PEA assays (Olink) and with Ella immunoassays. Associations between platforms were determined by Spearman Rho's correlation analysis, which showed that all assays had a moderate-strong correlation between analytical platforms.

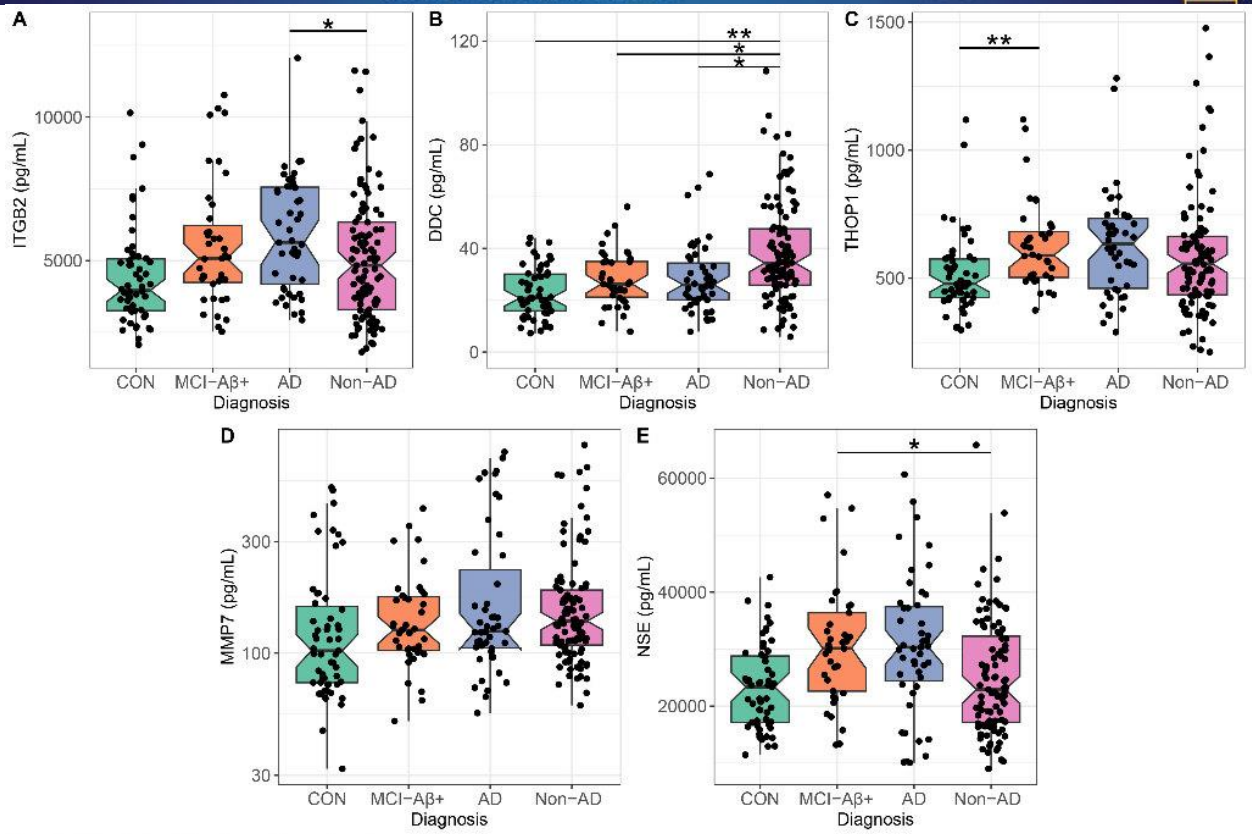

Figure 2. CSF proteins of the diagnostic panel are dysregulated
CSF protein concentrations of (A) ITGB2, (B) DDC, (C) THOP1, (D) MMP7, and (E) NSE were sequentially measured on the Ella platform.
CSF concentrations of ITGB2 and DDC are dysregulated between AD and non-AD group.

Aims: Blood-based biomarkers can provide a low-invasive and accessible way to identify neurodegenerative disease before clinical onset of dementia. We aimed to develop individualized predictions for risk of developing any-cause dementia and Alzheimer's disease (AD) dementia, in a memory clinic population of individuals with mild cognitive impairment (MCI), using plasma phosphorylated-tau-181 (pTau181), amyloid beta1-42/1-40 (Aβ42/40), glial fibrillary acidic protein (GFAP) and/or neurofilament light (NfL).
Methods: From the Amsterdam Dementia Cohort we included 250 individuals with MCI (age 65±7 years, n=89(36%) female, MMSE 27±2), who had annual follow-up visits for re-evaluation of diagnosis (average follow-up duration:2.7±1.7 years.) Plasma biomarkers were measured using a Simoa HD-X and concentrations were Z-transformed for analysis. We evaluated the biomarkers individually, and as a panel, added to a model including age, sex and MMSE score, and assessed model discrimination (C-index) and accuracy (Brier score). We generated parsimonious models using backward selection based on the Akaike information criterion. These models were used to calculate 1-year, 3-year and 5-year probabilities for progression, which were visualised in an interactive interface.
Results: During follow-up, 99 individuals developed dementia (91 AD dementia, 8 other dementia types). High baseline GFAP and pTau181, but not NfL or Aβ42/40, were associated with an increased risk of any-cause or AD dementia when entered into the prognostic models individually (Table 1). The parsimonious model using conversion to any-cause dementia as outcome included basic demographics and GFAP. Both GFAP and pTau181 were selected in the parsimonious model using AD-dementia as outcome, and individualised risk profiles can be obtained from these models (Figure

	Hazard Ratio	*P* Value	C-index	1-year Brier score	3-year Brier score	5-year Brier score
Model 1 – Baseline demographics only						
Age	1.00 (0.97 – 1.03)	0.983	0.607	0.0314	0.201	0.220
Sex	1.64 (1.09 – 2.46)	0.017				
MMSE Score	0.90 (0.83 – 0.99)	0.024				
Model 2 - Baseline demographics + NfL						
Age	0.99 (0.96 – 1.02)	0.565	0.619	0.0313	0.198	0.220
Sex	1.72 (1.14 – 2.59)	0.010				
MMSE Score	0.90 (0.83 – 0.99)	0.025				
NfL	1.16 (0.92 – 1.46)	0.205				
Model 3 - Baseline demographics + Aβ42/40						
Age	1.00 (0.97 – 1.03)	0.991	0.615	0.0314	0.199	0.226
Sex	1.54 (1.01 – 2.34)	0.043				
MMSE Score	0.89 (0.82 – 0.98)	0.016				
Aβ42/40	0.85 (0.64 – 1.11)	0.238				
Model 4 - Baseline demographics + GFAP						
Age	0.97 (0.93 – 1.00)	0.029	0.683	0.0299	0.192	0.191
Sex	1.59 (1.06 – 2.40)	0.025				
MMSE Score	0.89 (0.81 – 0.97)	0.011				
GFAP	1.95 (1.49 – 2.54)	<0.001				
Model 5 - Baseline demographics + pTau181						
Age	0.99 (0.96 – 1.02)	0.496	0.656	0.0310	0.193	0.216
Sex	1.72 (1.14 – 2.58)	0.009				
MMSE Score	0.90 (0.82 – 0.98)	0.019				
pTau181	1.47 (1.19 – 1.81)	<0.001				
Model 6 – Baseline demographics + the panel of all four plasma biomarkers						
Age	0.97 (0.94 – 1.00)	0.074	0.698	0.0300	0.189	0.195
Sex	1.47 (0.96 – 2.26)	0.079				
MMSE Score	0.88 (0.80 – 0.96)	0.006				
NfL	0.86 (0.65 – 1.14)	0.285				
Aβ42/40	0.88 (0.67 – 1.16)	0.364				
GFAP	1.89 (1.37 – 2.59)	<0.001				
pTau181	1.21 (0.95 – 1.54)	0.131				

Table 1: Associations of model variables with risk of clinical progression to any-cause dementia and evaluation of model performances in individuals with mild cognitive impairment. The table displays hazard ratio (95% CI) for all variables in each model. Biomarker values were natural log-transformed and standardized as Z scores for comparability of effect sizes. The point at which clinical progression occurred was defined as the first visit at which dementia was diagnosed. Harrell's C-index is used to assess prognostic discrimination and ranges from 0 to 1, with a score of 0.5 indicating risk score predictions are no better than a random prediction, and a score of 1 indicating perfect model prediction. The Brier score is used to assess the accuracy of probabilistic predictions at a given time, and ranges from 0 to 1, with a score closer to 0 indicating greater accuracy. MMSE= mini-mental state examination. pTau181= phosphorylated-tau-181. Aβ42/40 = Amyloid β42/40. GFAP = glial fibrillary acidic protein. NfL = neurofilament light.

1).

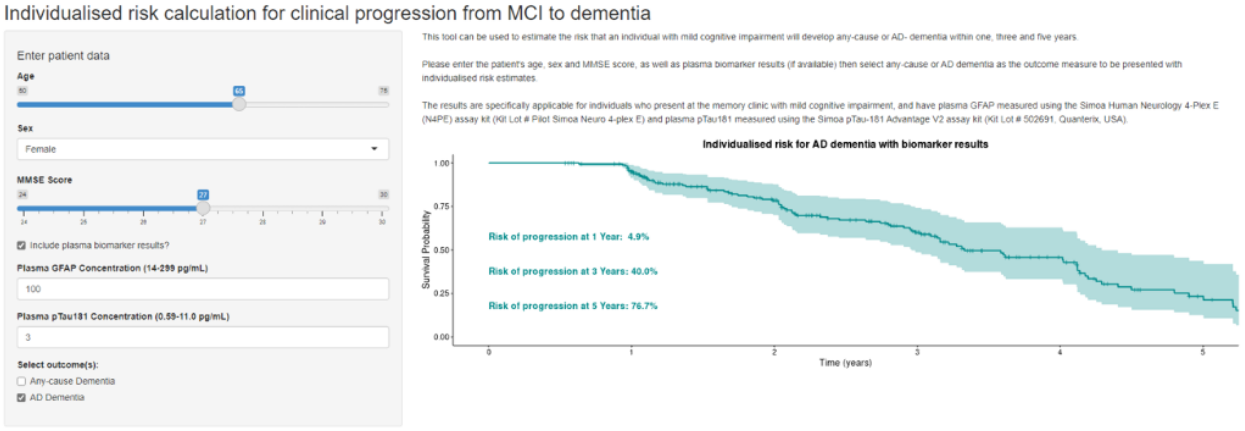

Figure 1: Screenshot of the interactive interface to estimate the risk that an individual with mild cognitive impairment will develop any-cause or AD- dementia within one, three and five years. The demographics-only prognostic model including age, sex and MMSE score is used to calculate the risk probabilities in the absence of biomarker results. The parsimonious models utilising plasma GFAP (for any-cause dementia as outcome), or both plasma GFAP and pTau181 (for AD dementia as outcome) are used to calculate the risk probabilities upon entering the biomarker results of an individual. MMSE= mini-mental state examination. pTau181= phosphorylated-tau-181. GFAP = glial fibrillary acidic protein. The interface is accessible through the link: https://gfapbiomarker.shinyapps.io/BiomarkerPredict/

Conclusions: Plasma biomarkers, particularly plasma GFAP and pTau181, can be utilized to provide prognostic risk information about progression to dementia for individuals presenting at a memory clinic.

FOOD INTAKE AFFECTS PROTEINS RELATED TO NEUROBIOLOGICAL PROCESSES AND ALZHEIMER'S DISEASE – A PILOT STUDY IN OBESE ADULTS

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Hanna Huber[1], Anna Donkers[2], Nicholas Ashton[1], Kaj Blennow[1], Alina Schieren[2], Peter Stehle[3], Henrik Zetterberg[1], Marie-Christine Simon[2]
[1]University of Gotheburg, Neurochemistry, Mölndal, Sweden, [2]University of Bonn, Nutrition And Microbiota, Bonn, Germany, [3]University of Bonn, Nutrition Physiology, Bonn, Germany

Aims: Recent findings suggested that food intake affects plasma biomarkers related to Alzheimer's disease (AD)[1]. We investigated the impact of a single meal on markers of neurobiological processes involved in neurological diseases.
Methods: 44 cognitively healthy participants (60±7y, 24 females, BMI 30±3kg/m^2) ingested a standardized meal. The Olink Target96 Neurology panel was measured in fasting and non-fasting serum samples (60- and 180-min post-meal). Fasting vs. non-fasting protein expressions were compared using mixed models for time effect adjusted for age, sex, BMI, and multiple testing (Benjamin-Hochberg correction).
Results: We replicated our previous findings in this cohort[1]: neurofilament light, glial fibrillary acidic protein, amyloid-β 42/40, phosphorylated tau 181 and 231, and total tau changed significantly over time post-meal (all p_{adj}<.05). Further, meal ingestion significantly affected the expression of 15 out of 89 measured panel proteins. E.g., tenascin-R (p_{adj}<.00001), FLRT2 (p_{adj}=.05), and Dkk-4 (p_{adj}=.02) decreased continuously post-meal. Among others, brevican (p_{adj}<.00001) as well as of SPOCK1 (p_{adj}=.001) decreased immediately after food intake and returned to baseline at 180min. The observed effects were independent of age, BMI, and sex (p for interaction >.05).
Conclusions: The extracellular matrix proteins tenascin-R and brevican (brain-specific) are involved in brain development, repair, and synaptogenesis and might contribute to AD[2]. SPOCK1 may play a role in blood-brain-barrier regulation, axonal regeneration and the aggregation of Aβ-precursor proteins[3]. FLRT2, and Dkk-4 may be implicated in AD and cognitive decline[4,5]. To conclude, we showed that a single test meal might affect proteins related to neurobiological processes associated with brain development, synaptic function, and AD. The fact that brain-specific proteins (brevican) were affected by food intake reveals a possible direct involvement of the CNS. Aims: Early detection of Alzheimer's disease (AD), particularly during the mild cognitive impairment (MCI) stage, is crucial for effective intervention and treatment. However, existing diagnostic methods, through cognitive assessments, brain imaging, or cerebrospinal fluid profiling, are subjective, expensive or invasive. We previously showed that the plasma proteome is altered in AD, suggesting the feasibility of utilizing blood biomarkers for AD detection. Therefore, to develop a blood test for early screening and staging of AD, it is important to identify blood biomarkers associated with MCI/early AD and the features of AD progression.
Methods: We conducted a comprehensive profiling of the plasma proteome of MCI by measuring 1,160 proteins in a Hong Kong Chinese cohort, to identify novel blood biomarkers for MCI/early AD. We further developed a biomarker panel based on the identified MCI/AD-associated blood biomarkers and validated its performance in an independent amyloid-PET-defined cohort.
Results: We identified 496 proteins that were dysregulated in MCI plasma, and these proteins, involved in different biological processes, exhibited distinct dysregulating patterns with disease progression. We further categorized these proteins into different groups based on their dysregulating patterns. By performing co-expression network analysis, we identified a 18-protein panel that captures the profile changes of plasma proteome in MCI and AD. This panel achieves accurate classification of MCI (AUC = 0.913-0.925) and AD (AUC = 0.970-0.993) in two independent cohorts. Moreover, this panel correlates with cognitive decline and the development of Aβ pathology in the brain, which outperforms plasma Aβ42/40, NfL, p-Tau181, and p-Tau217.
Conclusions: This study comprehensively profiled the MCI plasma proteome and demonstrates the feasibility of a blood-based biomarker assay for early detection and staging of MCI and AD, potentially facilitating early screening, monitoring, and intervention in future clinical settings.

Aims: Neurogranin (Ng) is a cerebrospinal fluid biomarker for synaptic dysfunction at early stage of Alzheimer's disease (AD). It has been reported that some truncated forms from Ng is increased in AD brain tissue. However, the clinical significance of Ng forms in plasma has remained unclear. In this study, we applied the immunoprecipitation combined with matrix-assisted laser desorption ionization time-of-flight mass spectrometry (IP-MALDI-MS) to investigate blood-based biomarkers for neurodegeneration.
Methods: Plasma samples were obtained from cognitively normal (CN), mild cognitive impairment (MCI), Alzheimer's dementia (AD) and non-Alzheimer's dementia (non-AD) individuals in National Center for Geriatrics and Gerontology. These subjects were classified as Aβ positive and negative based on PET with PIB tracer. Plasma Ng forms were immunoprecipitated from the samples spiked by stable isotope-labeled (SIL) Ng peptides and analyzed by MALDI-MS.
Results: We calculated intensity ratio of a Ng form-to-other Ng form (Ng ratio) in all combinations of peaks corresponding to mass of Ng forms. Five Ng ratios were significantly higher in the Aβ positive AD and Aβ negative non-AD groups than the CN group. In ROC analyses, AUC values greater than 0.80 were found in discriminating the Aβ positive AD or Aβ negative non-AD group from the CN group. Furthermore, the Ng ratios were significantly correlated with MMSE ($\rho<-0.400$).
Conclusions: Some Ng forms cleaved at or nearly the IQ domain have been found in the AD brain, which suggests the function loss of Ng in synaptic plasticity. The five plasma Ng ratios may be biomarker candidates for synaptic dysfunction involved in the change of Ng forms in the brain.

Aims: The propensity for beta-amyloid (Aβ) oligomerization was substantially increased in the plasma of Alzheimer's disease (AD) patients when synthetic Aβ was introduced. This discovery led us to the development of a blood-based AD diagnostic tool called AlzOn. However, the molecular mechanisms underlying the phenomena have not been investigated. To elucidate the diagnostic activity, the protein interactome of Aβ and blood plasma albuminome was analyzed.
Methods: To investigate differences in albuminome compositions between individuals with AD patients and healthy controls, we isolated the plasma albuminome from patients' blood samples. Subsequently, we utillized LC-MS/MS techniques to anlyze the plasma albuminome and its correlation with the Aβ interactome.
Results: By eliminating the albuminome, we observed a loss of diagnostic specificity of AlzOn AD diagnostic kit. Remarkably, LC-MS/MS data demonstrated substantial differences between AD patients and control subjects. Additionally, our findings revealed a significant overlap between the albuminome and the Aβ interactome exclusively within AD patients.
Conclusions: This report presents evidence supporting the pivotal role of Aβ oligomerization in the plasma of AD patients, as well as the impact of the albuminome and the Aβ interactome on the diagnostic specificity of AD.

Aims: To explore the underlying mechanism of the AlzOn test, a blood-based diagnostic tool for Alzheimer's disease (AD), we conducted a plasma proteome analysis on subjects with varying levels of oligomeric Aβ after administering exogenous Aβ to identify factors influencing AlzOn test results.
Methods: Using SOMAscan technology, we quantified approximately 7,000 proteins from plasma samples collected from subjects exhibiting either a high or low AlzOn signal (n=~20 per group). Pearson's correlation coefficients were computed to determine the association between individual proteins and AlzOn results. Differences in protein levels between the two groups were assessed using t-tests. Additionally, we examined the enrichment of gene sets associated with Alzheimer's disease and annotations from the Gene Ontology database.
Results: We identified a total of 221 proteins that exhibited significant correlations with the AlzOn signal. Within the group showing a high AlzOn signal, we observed an enrichment of gene sets associated with Alzheimer's disease, synapse, and immune response. On the other hand, in the group displaying a low signal, we found an enrichment of gene sets related to purine biosynthetic processes and autophagy.
Conclusions: This study revealed a correlation between the AlzOn signal and elevated levels of inflammation, disruption of the blood-brain barrier, as well as reduced purine biosynthesis and protein clearance.

CEREBROSPINAL FLUID REFERENCE PROTEINS INCREASE ACCURACY AND INTERPRETABILITY OF BIOMARKERS FOR BRAIN DISEASES

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Linda Karlsson[1], Jacob Vogel[1], Ida Arvidsson[2], Kalle Åström[2], Shorena Janelidze[1], Kaj Blennow[3], Sebastian Palmqvist[1], Erik Stomrud[1], Niklas Mattson-Carlgren[1], Oskar Hansson[1]

Aims: Cerebrospinal fluid (CSF) biomarkers reflect brain pathophysiology and are used extensively in translational research and in clinical practice for diagnosis of neurological diseases, e.g., Alzheimer's disease (AD). However, CSF biomarker concentrations may be influenced by non-disease related mechanisms that vary between individuals. Here we use a data-driven approach to demonstrate the existence of confounding inter-individual variability in CSF protein levels. To adjust for this variation, we identify and evaluate high-performing reference proteins that improved the diagnostic accuracy of key AD biomarkers and reduced the risk of false positive findings.
Methods: We used measurements of 2944 CSF proteins in the Swedish BioFINDER-2 cohort (n=830, 80% train and 20% test). Reference protein candidates were identified in a data-driven manner using t-distributed stochastic neighbor embedding (t-SNE) and a semi-supervised K-means clustering algorithm. The final candidate proteins were evaluated in logistic regression models, using CSF P-tau181 and CSF Aβ42 as main predictors of PET and conversion to dementia. Results were validated in the Swedish BioFINDER-1 cohort (n=904).
Results: Most proteins were associated with an individual's average protein level (Fig 1). A cluster of proteins with superior reference protein characteristics was identified and in it, single reference protein candidates were nominated. These candidates increased biomarker performance in multiple models and cohorts (Fig 2). We also show that reference proteins could explain AT(N) grouping discordance between CSF and PET (Fig 3), and that many reported CSF biomarker correlations may have been exaggerated or false positive findings due to this confounding
factor.

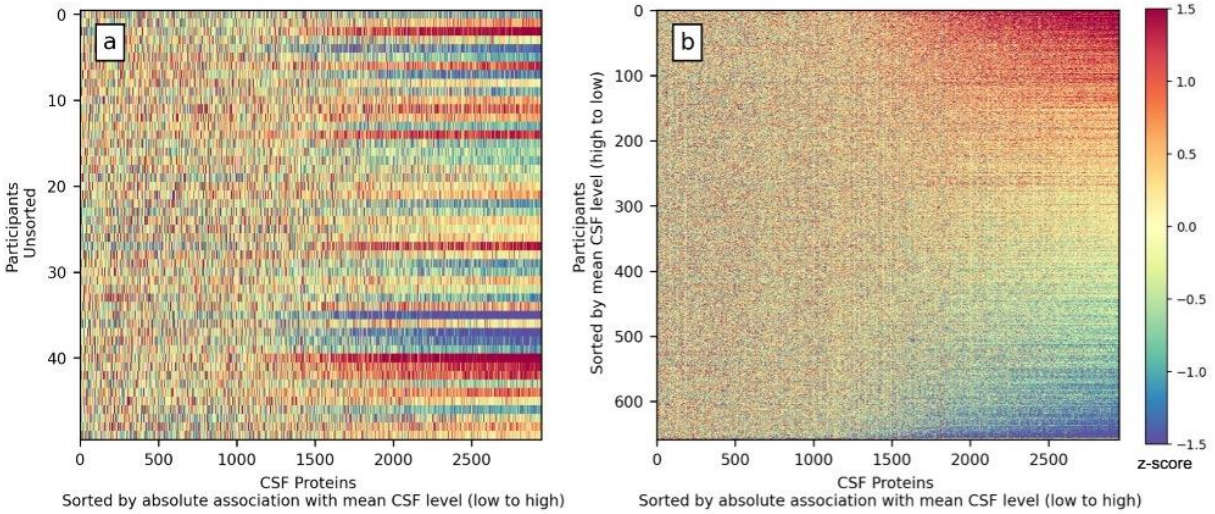

FIGURE 1: **Many CSF proteins vary in concordance with an individual protein level.** For each participant (row), the standardized concentration of 2,944 CSF proteins, sorted by increasing absolute association with the mean CSF protein level, is displayed. Systematic blue horizontal lines can be seen for individuals with consistently low values across most proteins, and correspondingly red horizontal lines for individuals with high values across most proteins (all relative to the total sample). **a)** a subset of 50 randomly selected participants. **b)** all 658 participants sorted by mean CSF level.

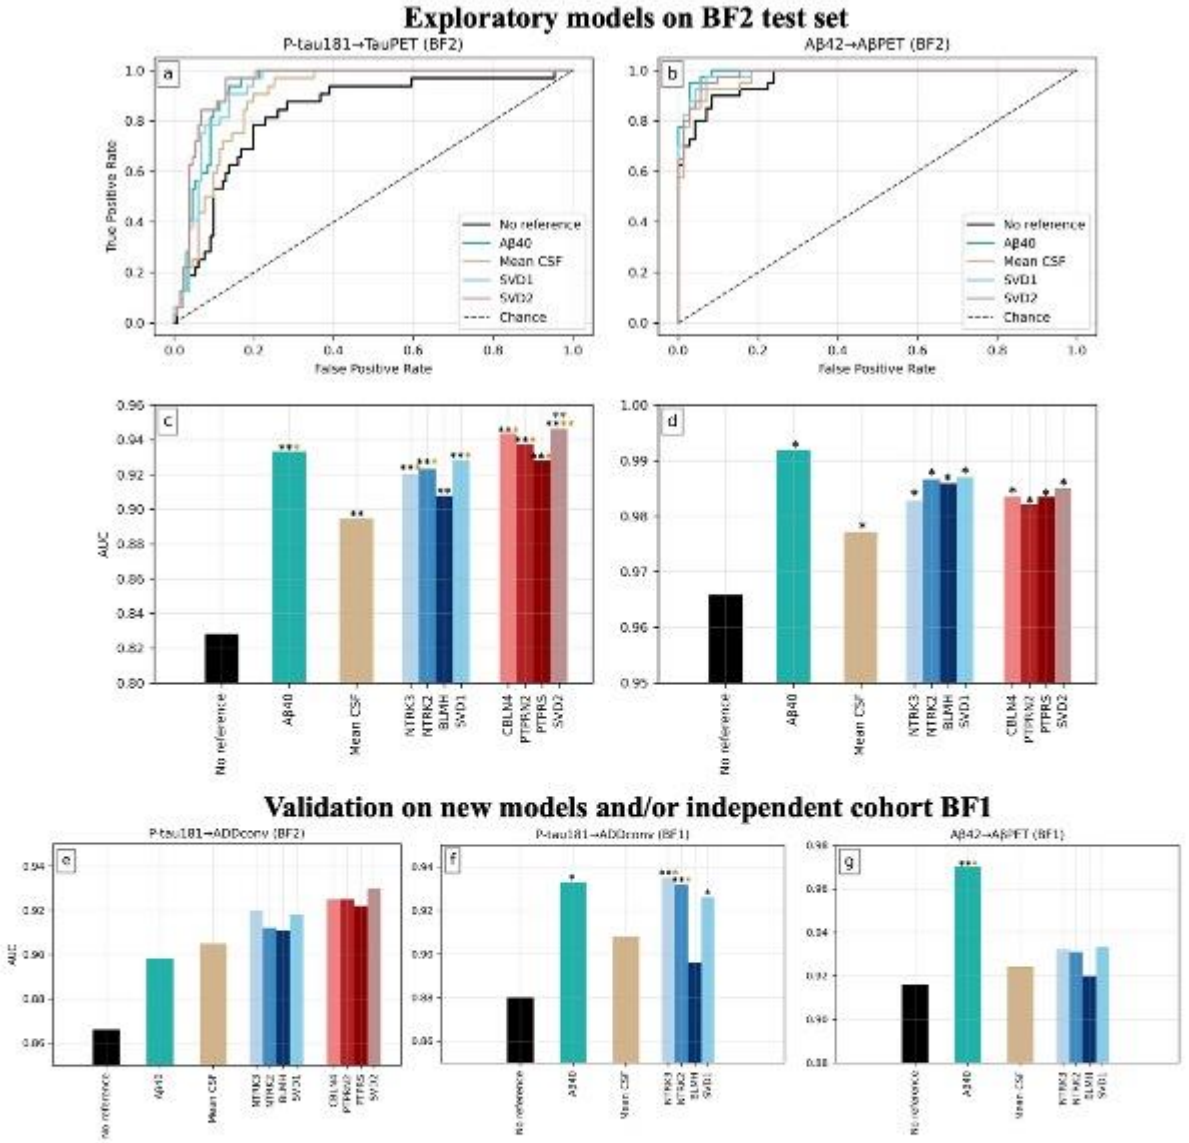

FIGURE 2: Performance evaluation of all models with and without references. ROC curves in **a)** and **b)**, and corresponding AUCs in **c)** and **d)**, for the two models **P-tau181→TauPET** and **Aβ42→AβPET**, evaluated on the BF2 test dataset. AUCs for **e)** model **P-tau181→ADDconv** on the training dataset BF2, **f)** model **P-tau181→ADDconv** on BF1 and **g)** model **Aβ42→AβPET** on BF1. No reference corresponds to the model without use of a reference protein, consistently outperformed by all tested references: Aβ40, mean CSF level, NTRK3, NTRK2, BLMH, SVD1, CBLN4, PTPRN2, PTPRS and SVD2. Quantitative details can be found in Supplementary Tab. 2. For visualization purposes, the ROC curves do not show all protein candidates but solely the corresponding SVDs.
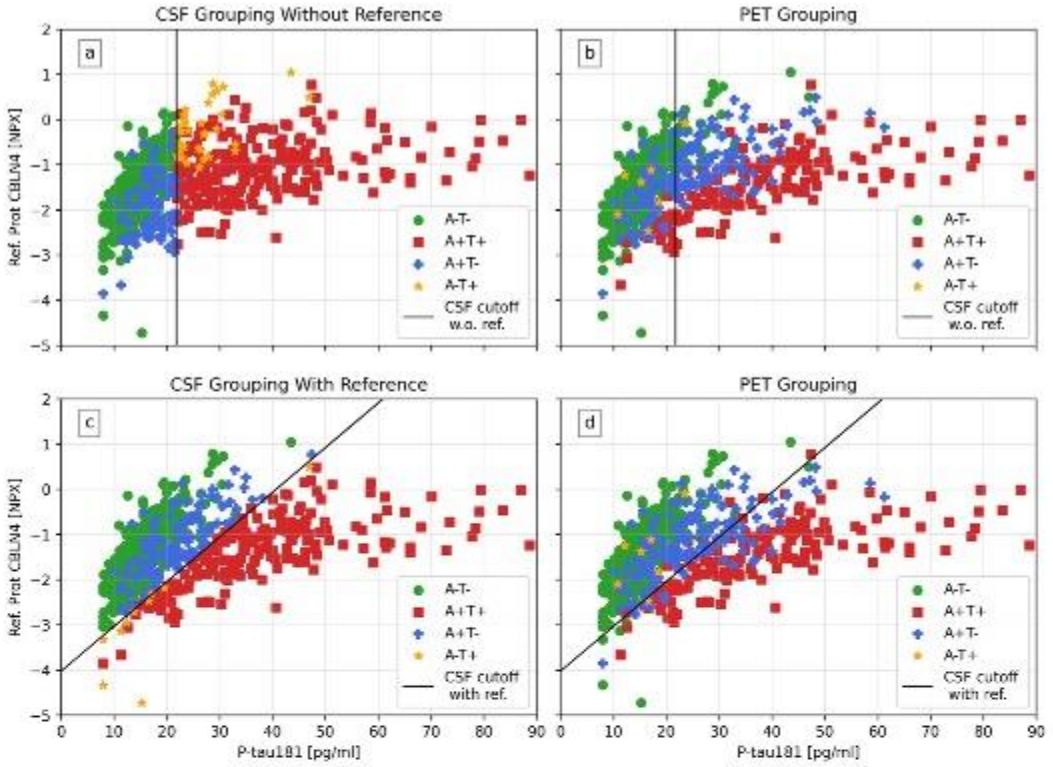
$^{*}P < 0.05$, $^{**}P < 0.01$ compared to the bar of same color as asterisk.



e

Without Reference Tau cutoff: CSF P-tau181 > 21.8					With Reference Tau cutoff: CSF P-tau181 > 39.0 + 10.1$_{CBLN4}$				
PET / CSF	A-T-	A+T+	A+T-	A-T+	PET / CSF	A-T-	A+T+	A+T-	A-T+
A-T-	285	-	-	6	A-T-	312	-	-	6
A+T+	-	137	86	-	A+T+	-	153	44	-
A+T-	-	26	63	-	A+T-	-	10	105	-
A-T+	36	-	-	1	A-T+	9	-	-	1
Accuracy: 486/640 (76%)					Accuracy: 571/640 (89%)				

FIGURE 3: Adjusting for an individual reference protein results in a better AT(N) grouping concordance between CSF P-tau181 and tau-PET. In a)-d), the x-axis is a participant's CSF P-tau181 concentrations, and the y-axis the suggested reference protein CBLN4. In a) and c), CSF P-tau181 and CSF Aβ42/Aβ40 (cutoff 0.08) has been used to group participants. In b) and d), a tau-PET composite corresponding to Braak I-IV with ROIs > 1.36 and CSF Aβ42/Aβ40 was used to group participants. The concordance between CSF P-tau181 and tau-PET grouping increased when not requiring a vertical cutoff line (no reference, a) and b)) but allowing for it to have a slope (with reference, c) and d)). In e) corresponding concordance matrices of PET and CSF with and without using a reference for CSF P-tau181 can be seen. The concordance increased from 76% to 89% when adjusting for the reference protein. Particularly notable is that the A-T− group was reduced from n=37 to n=10 when using a reference protein, again in higher concordance with PET grouping.

Conclusions: Our novel reference protein method improves the accuracy of CSF biomarkers, and reduces the risk for false positive findings, with broad implications for both research and clinical practice.

ASSOCIATION OF BIN1 RISK VARIANT WITH CSF BIOMARKERS IN THE LONGITUDINAL EARLY ONSET ALZHEIMER'S DISEASE STUDY

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Naazneen Khan[1], Kelly Nudelman[2], Trever Jackson[2], Suzanne Schindler[3], Elizabeth Herries[3], Rachel Henson[3], Ani Eloyan[4], Maria Carrillo[5], Bradford Dickerson[6], Gil Rabinovici[7], Liana Apostolova[1,2,8], Jeffrey Dage[1,2]
[1]Indiana University School of Medicine, Department Of Neurology, Indianapolis, United States of America, [2]Indiana University School of Medicine, Department Of Medical And Molecular Genetics, Indianapolis, United States of America, [3]Wasington University, Neurology, St. Louis, United States of America, [4]Brown university, Statistics, Providence, United States of America, [5]Medical & Scientific Relations Division, Alzheimer's Association, Chicago, United States of America, [6]Massachusetts General Hospital and Harvard Medical School, Neurology, Boston, United States of America, [7]University of California San Francisco, Neurology, San Francisco, United States of America, [8]Indiana University School of Medicine, Radiology And Imaging Sciences, Indianapolis, United States of America

Aims: Objectives: The Bridging Integrator 1 (BIN1) has been shown to be associated with late-onset Alzheimer's disease (AD) and is thought to play a role in the development or propagation of tau pathology. Explore the association of CSF biomarkers with the BIN1 risk allele rs7561528 in the Longitudinal Early-Onset Alzheimer's Disease Study (LEADS).
Methods: Methods: In this study, biomarkers (Aß42/40, p-tau181, Neurofilament light chain (NfL), t-Tau, visinin-like protein-1 (VILIP-1), Chitinase 3-like 1 (YKL-40), Neurogranin (Ng), Synaptosomal-Associated Protein (SNAP-25) were measured in the CSF of 159 LEADS participants who were classified by diagnostic groups (cognitively normal (CN) [n=35], amyloid-positive early-onset Alzheimer's disease (EOAD)[n=96], and amyloid-negative early-onset non-Alzheimer's disease [EOnonAD; n=28]). The CSF biomarker levels in each diagnostic group were standardized and studied for their association with the BIN1 rs7561528 risk variant. Levels of significance were determined between the three diagnostic groups, CN, EOAD, and EOnonAD, using one-way ANOVA.
Results: Results: The levels of CSF biomarkers (p-tau181(Table1, Figure.1), NfL, t-Tau, VILIP-1, Ng, SNAP-25) were elevated in the BIN1 rs7561528 risk allele carrier group as compared to the non-carrier group in both CN and EOAD diagnostic groups but not in EOnonAD. The plot for p-tau181(Table 1, Figure 1) exemplifies the risk allele effect on CSF biomarkers. Table1. CSF p-tau181 biomarker level in BIN1 rs7561528 variant. Figure1. CSF p-tau181 association with BIN1 rs7561528 risk variant. The plot was constructed using standardized (z score) biomarker level and BIN1 carrier and non-carrier groups.
Conclusions: Conclusions: This study evaluates the association of CSF biomarkers with BIN1 variants within diagnostic groups. Our findings on genetic variants associated with biomarkers may help further elucidate the mechanism behind BIN1 risk variants and their contribution to the progression of Alzheimer's Disease.

Aims: To determine the predictive accuracy of plasma amyloid β (Aβ) biomarkers for identifying the individuals with amyloid-positivity on amyloid positron emission tomography (PET) imaging in the community-based mild cognitive impairment (MCI) cohort.
Methods: Data from our prospective cohort study of 118 community-dwelling adults, aged 65 years and older (66 women with a mean age of 75.7 years and a median educational level of 12 years). All participants underwent ^{11}C-PiB PET and measurement of plasma Aβ biomarkers, such as amyloid-β precursor protein (APP) 669-711/ Aβ1-42 and Aβ1-40/ Aβ1-42 ratios, using immunoprecipitation coupled with mass spectrometry (IP-MS). Amyloid positivity was defined as a standardized uptake value ratio of ≥1.2. Binary logistic regression with receiver operator characteristic analysis was conducted to determine the area under the curve (AUC) values in identifying individuals with amyloid positivity.
Results: Using a cutoff value for PiB-PET SUVR of 1.2 or greater, 37 of 118 subjects (31.4%) were classified into the amyloid-positive subgroup. The AUC value of composite biomarker generated by APP669-711/ Aβ1-42 and Aβ1-40/ Aβ1-42 was 0.95.
Conclusions: Plasma Aβ biomarkers measured using IP-MS showed high performance for predicting the individuals with brain amyloid burden in community-based MCI cohort in Japan. Moreover, we conduct a prospective cohort study of 100 adults with MCI to develop diagnostic workflow for Alzheimer's disease and evaluate the diagnostic performance of plasma Aβ biomarkers, stress reactions of participants by disclosure of results, diagnostic latency, or the overall diagnostic cost.

Aims: Cerebral amyloid angiopathy (CAA) is characterized by cerebrovascular deposition of amyloid-β (Aβ), and a cause of intracerebral hemorrhages and cognitive decline in the elderly. There is however a lack of reliable biomarkers for early diagnosis and monitoring of CAA. Such biomarkers may in addition help in the identification of Alzheimer's disease (AD) patients with a high burden of CAA, who are at risk of developing amyloid-related imaging abnormalities (ARIA) due to anti-Aβ immunotherapy. We aimed to identify novel biomarker candidates for CAA in cerebrospinal fluid (CSF) using a targeted proteomics approach.
Methods: We analyzed CSF samples of 34 CAA patients and 50 matched controls using the Olink Explore 384-Neurology panel proximity-extension assay. We used automated ELLA immunoassays to validate our results in CSF and serum of a second, partly overlapping cohort of CAA patients and controls.
Results: We identified 13 proteins with significantly different CSF levels between CAA patients and controls. The strongest difference (increase in CAA) was observed for neurofilament light chain (NFL). Other candidates included MFGE8 and uPA, which were respectively decreased and increased in CAA. ELLA analyses confirmed the increase of NFL in CSF and serum of CAA versus controls. ROC analyses of NFL levels showed good discrimination between CAA patients and controls (AUC 0.77-0.84).
Conclusions: We identified multiple CAA biomarker candidates and were able to validate NFL in CSF and serum as biomarker to differentiate between CAA patients and controls, while identification of MFGE8 and uPA confirmed our previous findings[1,2]. Our results show the validity and strength of the used approach for CAA biomarker identification, and highlights the robustness of NFL as potential biomarker for CAA. Aims: To isolate and characterize plasma neuron-derived small extracellular vesicles (NDE), using multi-omics approaches for the discovery of novel biomarkers of Alzheimer's disease (AD), and to better understand the possible association of AD with peripheral insulin resistance.
Methods: Plasma samples were obtained from Look AHEAD-MIND study with 28 cognitively normal (18 female and 10 male) and 28 individuals with probable dementia (11 female and 17 male) based on central adjudication by an expert panel. These individuals had established type 2 diabetes (T2D) and overweight/obesity when enrolled in a randomized controlled clinical trial of a 10-year behavioral intervention. NDE were enriched from plasma sequentially using CD171 and synaptophysin surface markers by immunoprecipitation and characterized for non-coding RNAs by small RNA-sequencing and proteomics by mass spectrometry.
Results: The small RNA-sequencing analysis identified the expression of over 100 miRNAs in NDE from both groups. The comparison of differentially expressed miRNAs revealed 42 miRNAs to be downregulated, while 23 miRNAs were upregulated in individuals with dementia. Importantly, all these miRNAs (both up- and –downregulated) were found to be over-represented in AD- and insulin signaling-related pathways. Also, the targets of these miRNAs were associated with pathways like protein phosphorylation, autophagy, cell cycle and nervous system development. Alongside, the mass spectrometry-based proteomics analysis identified 3 proteins (haptoglobin, complement component C6, and alpha-2-macroglobulin) to be significantly downregulated and 1 protein (desmocolin-1) to be upregulated in the NDE of individuals with dementia. Interestingly, NDE showed upregulated expression of miR-185-5p, and simultaneously showed a downregulation of one of its potential targets complement protein C6, both known to be associated with AD and insulin signaling.
Conclusions: The study demonstrated multi-omics approach to identify novel plasma NDE biomarkers for dementia pathogenesis in individuals with T2D.

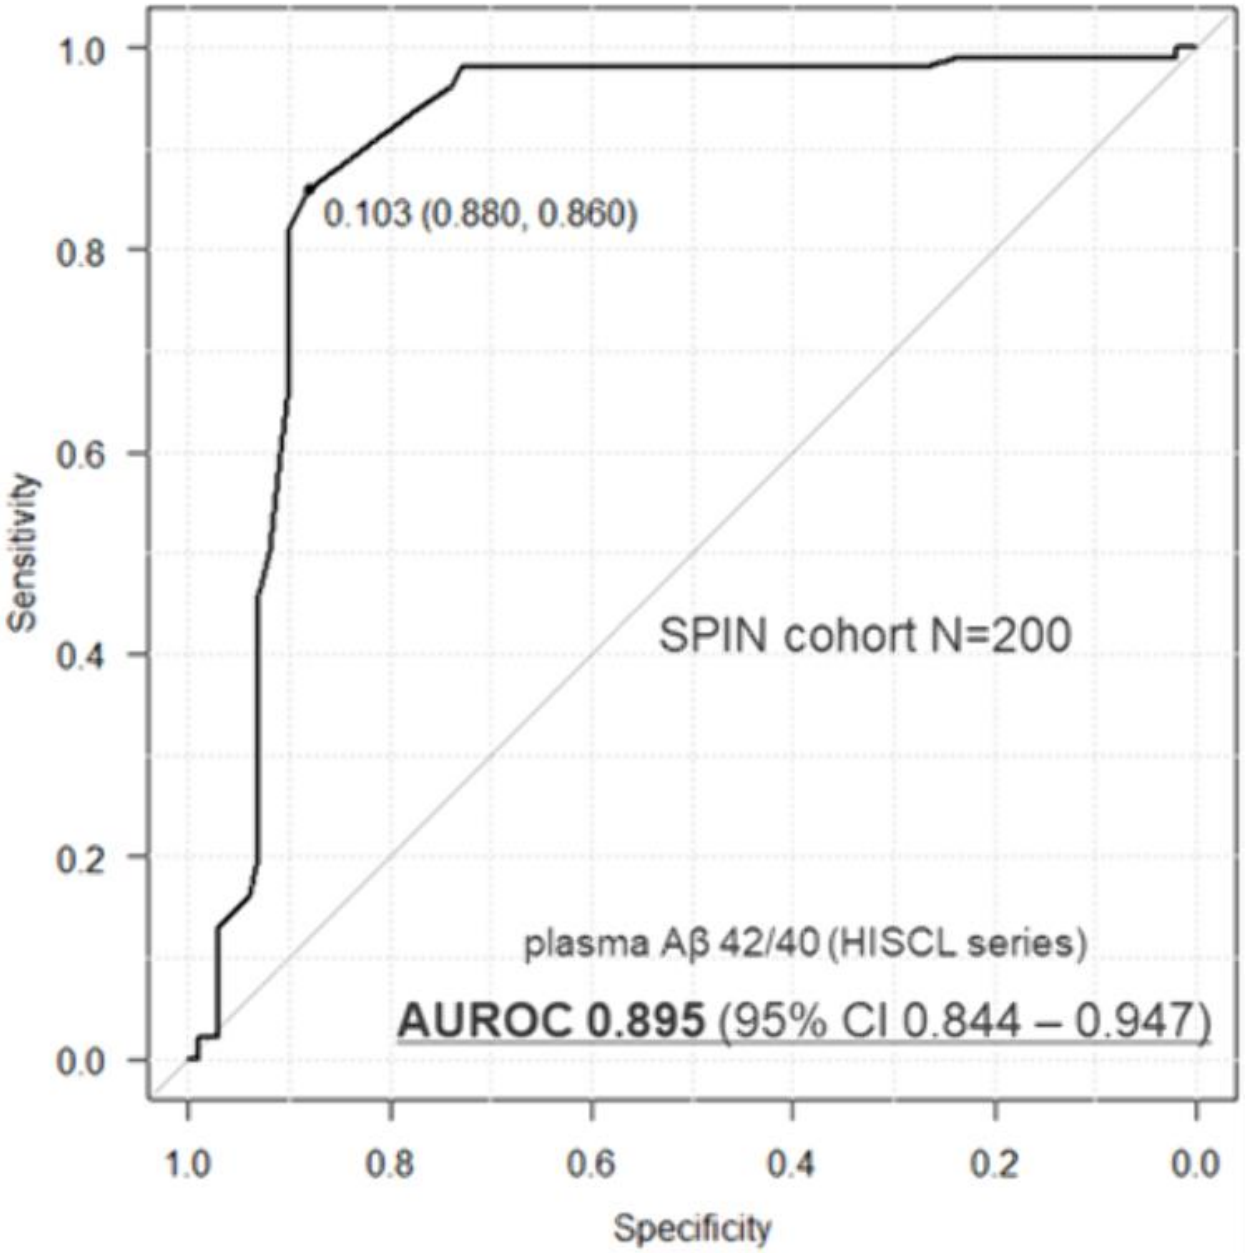
PERFORMANCE OF PLASMA AB42/40 RATIO TO PREDICT AB PATHOLOGY STATUS DEFINED BY CSF TESTING IN SPIN COHORT

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Yuko Sasaki[1], Roman Boeer[2], Yuko Saruta[3], Javier Arranz[4], Daniel Alcolea[4]
[1]Sysmex R&D Center Europe GmbH, Strategy & Planning Division, Hamburg, Germany, [2]Sysmex Europe SE, New Business Development, Norderstedt, Germany, [3]Sysmex R&D Center Europe GmbH, Clinical & Business Development Team, Hamburg, Germany, [4]Hospital de la Santa Creu i Sant Pau – IIB Sant Pau, Department Of Neurology, Sant Pau Memory Unit, Barcelona, Spain

Aims: Predicting the Amyloid status in brain by blood-based assays is useful for screening of Alzheimer's disease. The excellent performance of plasma Aβ42/40 ratio measured by an Automated Immunoassay System HISCL™-5000 / HISCL-800 to predict Aβ pathology status defined by Amyloid PET was previously reported. In this study, we aimed to evaluate the performance of plasma Aβ42/40 ratio to predict Aβ pathology defined by CSF testing in another cohort.
Methods: This study included 200 participants: 50 cognitively unimpaired (CU), 49 mild-cognitive impairment (MCI) due to Alzheimer's disease (AD), 50 MCI due to non-AD and 51 AD from The SPIN (Sant Pau Initiative on Neurodegeneration) cohort which was enrolled at Hospital de la Santa Creu i Sant Pau from 2013 to 2022. The Aβ pathology was defined by CSF Aβ42/40 ratio measured by Lumipulse (Fujirebio-Europe). The plasma Aβ42/40 ratio was measured by HISCL-5000.
Results: Plasma Aβ42/40 ratio could predict the Aβ pathology determined by CSF Aβ42/40 ratio at AUROC: 0.895 (95% CI 0.844 – 0.947) (Fig). The threshold determined by Youden Index was an Aβ ratio of 0.103 which is similar to the previously reported threshold 0.102. The sensitivity, specificity, PPV and NPV at the threshold 0.103 were 86.0%, 88.0%, 87.8% and 86.3%, while at 0.102 were 82.0%, 90.0%, 89.1% and 83.3%, respectively. The addition of ApoE4 allele possession status didn't improve the performance significantly. (AUROC 0.903 (de Long's test p=0.519, compared to Aβ ratio only)). When analyzed only within MCI patients (due to AD and not due to AD), AUROC was 0.902 (95% CI 0.828 – 0.975).



Conclusions: Plasma Aβ42/40 ratio achieved high accuracy in predicting Aβ pathology determined by CSF testing similarly to the previous report comparing with Amyloid PET in another cohort.

Aims: Alzheimer's Disease (AD) is characterized by Aβ pathology, followed by neurofibrillary tangles (NFTs) and neurodegeneration, referred to as the ATN framework. Neurofilament light (NfL) is increasingly found as an important biomarker for neurodegenerative disorders including AD, while its relative association and dynamics with different pathological phases of AD, reflected in the ATN continuum, remains to be studied in detail. These phases include normal healthy aging brain, amyloid pathology, and tau-pathology with tau-induced neurodegeneration.
Methods: Here, we studied the correlation of serum NfL concentrations in relation with respectively healthy aging, with amyloid pathology and tau pathology in the brain well characterized preclinical models, namely 5xFAD and TauP301S mice. We furthermore analysed pathological changes in neurofilament staining in the brain of these models. Immunohistochemical stainings of amyloid pathology, tau pathology and NfL are performed. Furthermore, measurements of NfL, in both serum and brain, at different disease stages in the different mouse models are performed.
Results: In the 5xFAD mouse model, immunohistochemical staining revealed a gradual increase of NfL in different brain regions in association with amyloid pathology. These changes correlated with the NfL concentrations in blood and brain homogenates of this mouse model. Super-resolution microscopy also showed irregularities of NfL organization in the area close to the amyloid plaques. Furthermore, in TauP301S mice, NfL signal increased in different regions of the brain after performing immunohistochemical stainings. The NfL concentrations in blood increased with age, correlating with NfL pathology in the brain.
Conclusions: No pathological staining of NfL was associated with normal aging. Our data indicate differences in Nfl biomarker dynamics and pathology, associated with different stages of the ATN continuum.

Aims: The diagnostic value of Blood-based biomarkers (BBBM) in differentiating Alzheimer´s disease (AD) from other non-AD dementias like corticobasal syndrome (CBS) was investigated.
Methods: From the prospective ActiGliA study we included 27 participants with probable AD (including participants with mild cognitive impairment [n=16] and AD-related dementia [n=11]), 17 age-matched controls with subjective cognitive impairment, 9 participants with corticobasal syndrome and underlying Ab pathology (Ab[+]CBS), and 26 participants with Ab[-]negative CBS. All participants underwent a thorough diagnostic work-up, including CSF and blood sampling, neuropsychological tests, amyloid-PET, and magnetic resonance imaging. Blood biomarkers (Ab1–40, Aβ1–42, apolipoprotein E4 [ApoE4], glial fibrillary acidic protein [GFAP], neurofilament light chain [NfL], and phosphorylated-tau 181 [pTau181]) were measured using Elecsys® plasma prototype immunoassays.
Results: Results: In amyloid-positive cases, plasma concentrations of Aβ1-42/1-40 ratio were decreased while ApoE, GFAP, and pTau181 levels were elevated. In the entire cohort, blood and CSF levels of both Ab1-42/1-40 ratio and pTau181 were significantly positively correlated. ApoE4, GFAP, and particularly pTau181 levels showed a strong negative association with neuropsychological performance. A positive association between NfL levels and hippocampal atrophy was demonstrated. pTau181 levels revealed an are under the curve (AUC) of 0.885 in the discrimination between amyloid-positive and -negative cases, plasma ApoE4 levels and Ab1-42/Ab1-40 ratio showed an AUC of 0.774 resp. 0.815. Regarding differentiation of AD from healthy aging and other dementias, elevated NfL levels were associated with a diagnosis of CBS and Ab[+]CBS, while elevated pTau181 and ApoE4 levels indicated a diagnosis of AD.
Conclusions: BBBMs may be useful in differentiating amyloid PET-positive from amyloid PET-negative cases and in differentiating AD from healthy aging and non-Alzheimer dementias. These results must be validated in a larger cohort.

ASSESSMENT OF CONCORDANCE AND DIAGNOSTIC ACCURACY OF ALZHEIMER'S DISEASE PLASMA BIOMARKERS: A COMPARISON BETWEEN THE LUMIPULSE AND SIMOA PLATFORMS

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Ricard Lopez-Ortega[1], Farida Dakterzada[2], Alfonso Arias[2], Iolanda Riba-Llena[2], Maria Ruiz-Julian[2], Raquel Huerto[2], Nuria Tahan[2], Gerard Piñol-Ripoll[2]
[1]Hospital Universitari Arnau de Vilanova, Clinical Laboratory, Lleida, Spain, [2]Hospital de Santa Maria - IRBLleida, Cognitive Disorders Unit. Cognition And Behaviour Study Group, Lleida, Spain

Aims: We compared plasma levels of Alzheimer's disease (AD) biomarkers measured by the Lumipulse and SiMoA platforms with their CSF levels to determine whether plasma can be a reliable CSF surrogate.
Methods: 149 patients with AD (n = 34), MCI (n = 94), and non-AD dementias (n = 21) were included. Aβ42, Aβ40, total tau, and phosphorylated tau (Ptau) were quantified in CSF using the Lumipulse platform and in plasma using the Lumipulse (Fujireibio) and SiMoA (Quanterix).
Results: We found some significant correlations between CSF and plasma measures of AD biomarkers for each platform (r_{rang}0.211-0.423). Plasma biomarkers measured by Lumipulse and SiMoA showed a good correlation between them (r = 0.794 for Aβ42; r = 0.891 for Ptau; r = 0.837 for Ptau/Aβ42; and r = 0.572 for Aβ42/40). Regarding diagnostic accuracy, the discriminatory power of plasma biomarkers measured by Lumipulse (AUC 0.735, 95% CI 0.589-0.882) and SiMoA (AUC 0.739, 95% CI 0.592-0.887) was significantly lower compared with the CSF biomarkers measured with Lumipulse (AUC 0.879, 95% CI 0.766-0.992). Finally, plasma Ptau/Aβ42 Lumipulse (AUC 0.870, 95% CI 0.806-0.934) and plasma Ptau SiMoA (AUC 0.801, 95% CI 0.712-0.890) showed the highest consistency with amyloid pathology (CSF Lumipulse Aβ42/40) at ≥ 0.084 and ≥2.127 cut-offs, respectively.
Conclusions: The Lumipulse and SiMoA platforms showed comparable clinical and analytical performances. However, their performance is lower compared with the CSF AD assays. With these data, these assays may be more useful for reducing the number of lumbar punctures in clinical settings than their use as a diagnostic tool.

Aims: Evaluate the potential utility of plasma p-tau217 as a surrogate biomarker in clinical trials across the AD spectrum.
Methods: We included 176 individuals with available plasma p-tau217 measurements at two time points across two cohorts:[MYHAT neuroimaging: 54 Cognitively Unimpaired(CU); BICWALZS: 122 Cognitively Impaired(CI) individuals]. All individuals had Aβ-PET available at baseline. Plasma p-tau217 was quantified using the ALZpath assay. Effect size was calculated as the mean change in biomarker divided by the standard deviation. We calculated the estimated sample size needed for a clinical trial testing a hypothesized 25% drug effect on longitudinal reduction in biomarkers with 80% power at a 0.05 level.
Results: The annual change in plasma p-tau217 presented a higher effect size in both groups: CU Aβ+(0.78) and CI Aβ+(0.77) compared to their respective whole population(**Figure 1**).In clinical trials targeting CU Aβ+ individuals, the sample size needed when using plasma p-tau217 as a surrogate would be 404, while trials targeting CI Aβ+ would require 458 individuals per study arm(**Figure 2A**).We compared the biomarker only and the total estimated trial cost for an Aβ+ population, using plasma p-tau217 and tau-PET for surrogacy(**Figure 2B**).Our results demonstrated that for CU Aβ+ the total cost of a clinical trial using plasma p-tau217 as a surrogate, was 4.5-fold lower than when using tau-PET. Similarly, the total cost for a clinical trial, including CI Aβ+ was 1.5-fold lower than when using plasma p-tau217 compared to using tau-PET as a
surrogate.

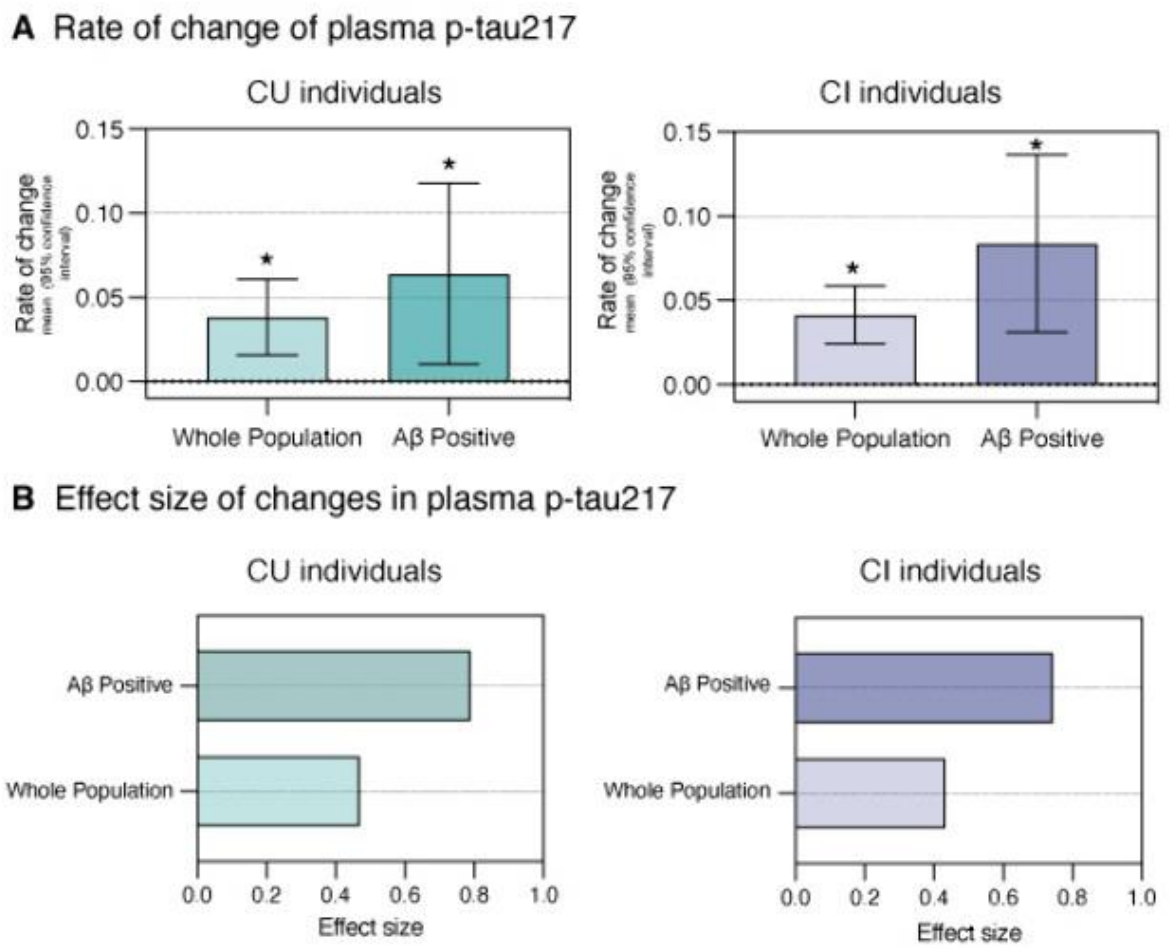

Figure 1. Annual change and effect size of plasma p-tau217 across the AD continuum. In panel **A** the bar plots show the annual change in plasma p-tau217 levels with their respective 95% confidence intervals for CU and CI individuals. Panel **B** shows that the effect size was larger in the Aβ positive group due to both a greater mean of progression and a relatively more stable change among participants (smaller standard deviation). The effect size was calculated as the ratio between the mean and standard deviation of the annual change. The higher the effect size, the smaller the measure's variability, which indicates a more precise populational estimate. * indicates that the 95% confidence interval did not cross the zero line, therefore, the longitudinal change was significantly different from zero.

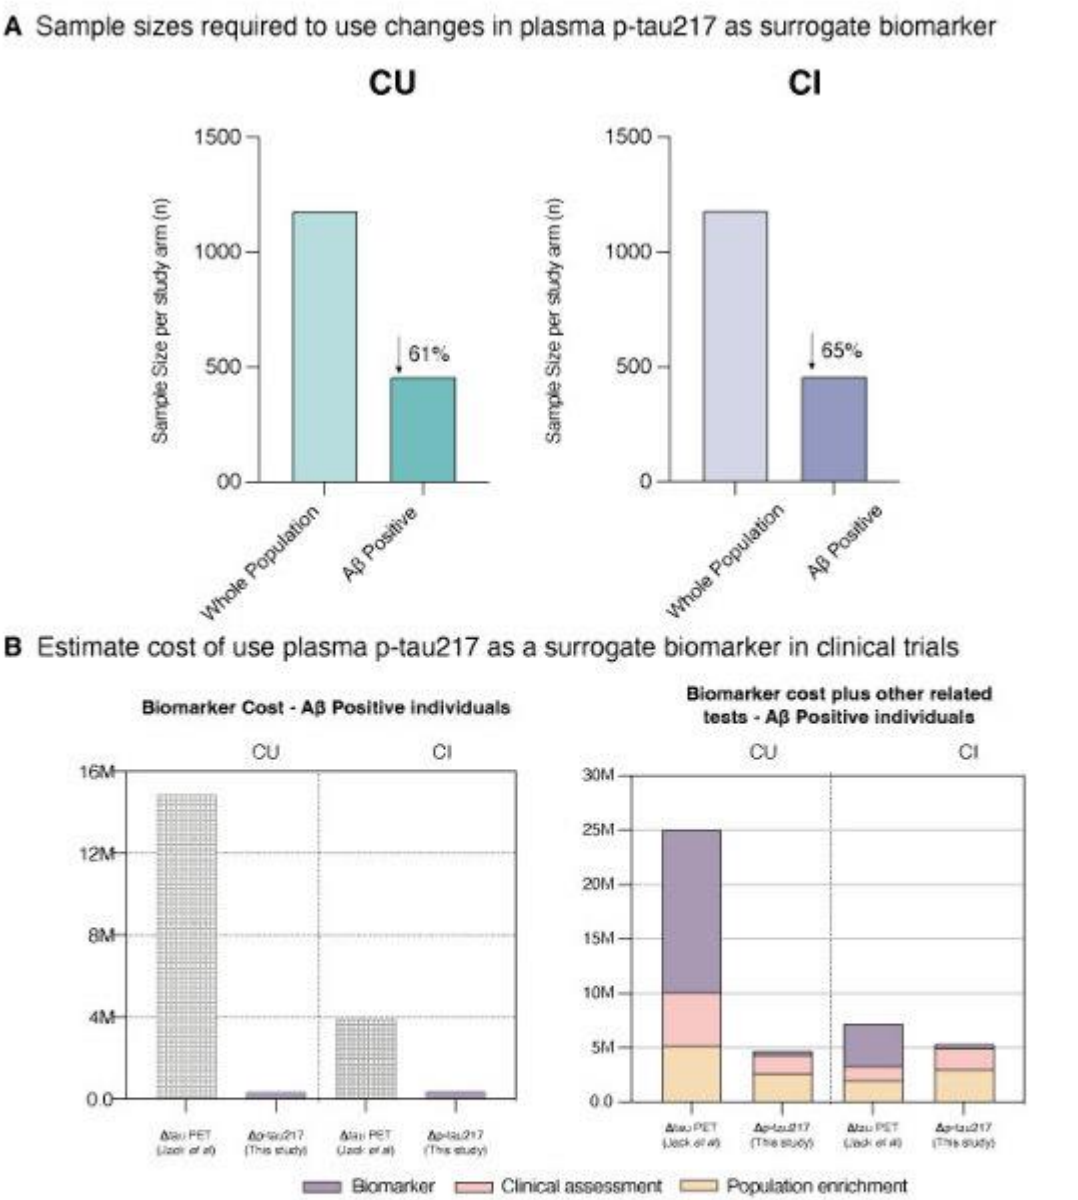

Figure 2. Cost-effectiveness of plasma p-tau217 as surrogate for preclinical and symptomatic AD clinical trials. (**A**) Sample sizes required for hypothetical clinical trials powered to use plasma biomarkers to monitor drug effects in CU and CI individuals. (**B**) The plot on the left shows the estimated cost with surrogate tau-PET (Jack et al. PMID: 29538647) and plasma p-tau217 for clinical trials powered to use changes in these biomarkers to monitor drug effects. The plot on the right shows the estimated cost of biomarkers plus the costs with some of the other necessary tests that are influenced by total sample size, such as costs of population enrichment, definition of Aβ-PET positivity, and clinical evaluation for each participant. The cost for Aβ-PET was set at $3,000; plasma p-tau217 at $200; and clinical assessments at $1,000. Δ = annual change. We estimated an attrition rate of 10% in the calculations. Δ = longitudinal change.

Conclusions: Our results suggest that plasma p-tau217 could potentially be used to monitor population interventions targeting CU and CI Aβ+ individuals. Additionally, we demonstrated that the cost of using plasma p-tau217 in clinical trials across the AD spectrum would be significantly lower than using tau-PET.

PERFORMANCE ASSESSMENT OF NOVEL CHEMILUMINESCENCE IMMUNOASSAYS FOR THE DETECTION OF SPECIFIC BIOMARKERS FOR ALZHEIMER'S DISEASE

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Philipp Arendt[1], Katharina Römpler[1], Britta Brix[1], Timo Lindemann[1], Viola Borchardt-Lohölter[1], Anette Schulz[1], Mandy Busse[2], Stefan Busse[3]
[1]EUROIMMUN Medizinische Labordiagnostika AG, Institute For Experimental Immunology, Lübeck, Germany, [2]University of Magdeburg, Department For Experimental Obstretics And Gynaecology, Magdeburg, Germany, [3]University of Magdeburg, Department Of Psychiatry, Magdeburg, Germany

Aims: To support diagnosis of Alzheimer's disease (AD), concentrations of $A\beta_{1-42}$, tTau and pTau(181) and the $A\beta_{1-42}/A\beta_{1-40}$ ratio are determined in cerebrospinal fluid (CSF). To increase standardization and comparability between diagnostic laboratories, certified reference material (CRM) is used to evaluate the trueness of novel assays. Due to lack of CRMs for tTau, pTau(181), and $A\beta_{1-40}$, comparability may be assessed by comparing assays from different manufacturers. This study compares the performance of novel chemiluminescence immunoassays (ChLIAs) developed by EUROIMMUN with established chemiluminescence assays.
Methods: Biomarker concentrations were determined in 110 CSF samples (patients without known diagnosis; mean age 57.2 years, range 11–94 years; 49 female, 60 male, 1 unknown) using the Beta-Amyloid (1-42), Beta-Amyloid (1-40), Total-Tau and pTau(181) ChLIAs (all EUROIMMUN) and the corresponding Lumipulse G assays (Fujirebio). The assays were performed according to the manufacturers' instructions on the fully automated random-access devices IDS-i10 (Immunodiagnostic Systems) and LUMIPULSE G 600II analyzer (Fujirebio), respectively. Agreement of results obtained with the two chemiluminescence systems was calculated.
Results: Overall agreement ranged from 89.0% to 97.3%. Agreement for the determination of normal biomarker concentrations was 93.4%–100% and 57.7%–94% for abnormal concentrations. The level of agreement was highest for $A\beta_{1-42}$ determination. Pearson's regression coefficient revealed high correlation of results (R=0.82 to R=0.99 for $A\beta_{1-42}$ determination). While concentrations determined using EUROIMMUN assays were generally higher, numerical differences had minor influence on the diagnostic evaluation.
Conclusions: Using the EUROIMMUN ChLIAs, AD-specific biomarkers can be measured with high precision and stability on fully automated random-access devices. The highest level of agreement and correlation was found for $A\beta_{1-42}$ determination as assays are aligned to the respective CRMs. This indicates the need to introduce CRMs for standardization of tTau, pTau(181), and $A\beta_{1-40}$ assays.

Aims: The correct interpretation of Alzheimer's disease (AD) fluid biomarkers depends on the recognition of factors interfering with their levels. Here, we assess whether body mass index (BMI) and waist circumference are associated with levels of AD biomarkers measured in the blood plasma and cerebrospinal fluid (CSF).
Methods: We assessed 151 cognitively unimpaired (CU) and 107 cognitively impaired (CI) older adults with clinical examination and biomarker testing including CSF and plasma glial fibrillar acidic protein (GFAP), neurofilament light (NfL), and phosphorylated tau (pTau) 181, 217, and 231. Linear regression models adjusted for age, sex, education, APOEε4 status, amyloid-beta status, and Mini Mental State Examination scores investigated the associations of BMI and waist circumference with fluid biomarkers. Subgroup analyses were conducted regarding cognitive status.
Results: In the whole sample, higher BMI was associated with lower plasma GFAP (beta=-5.74, $p<0.001$) and pTau 181 (beta=-0.27, $p=0.01$) (Figure 1). Among CU individuals, a negative association was observed between BMI and plasma GFAP (beta=-3.91, $p=0.01$). In CI participants, higher BMI was associated with reduced plasma NfL (beta=-0.60, $p<0.01$), GFAP (beta=-8.01, $p<0.01$) and pTau 181 (beta=-0.54, $p<0.01$). Moreover, an increased waist circumference was associated with lower plasma GFAP (beta=-38.68, $p=0.01$) in the whole sample (Figure 2). In the subgroup analysis, an increased waist circumference was associated with lower plasma NfL (beta=-6.46, $p<0.01$) and GFAP (beta=-33.74, $p=0.03$) respectively in CI and CU participants. No associations were observed with CSF biomarkers.

Figure 1. Association between BMI and fluid AD biomarkers

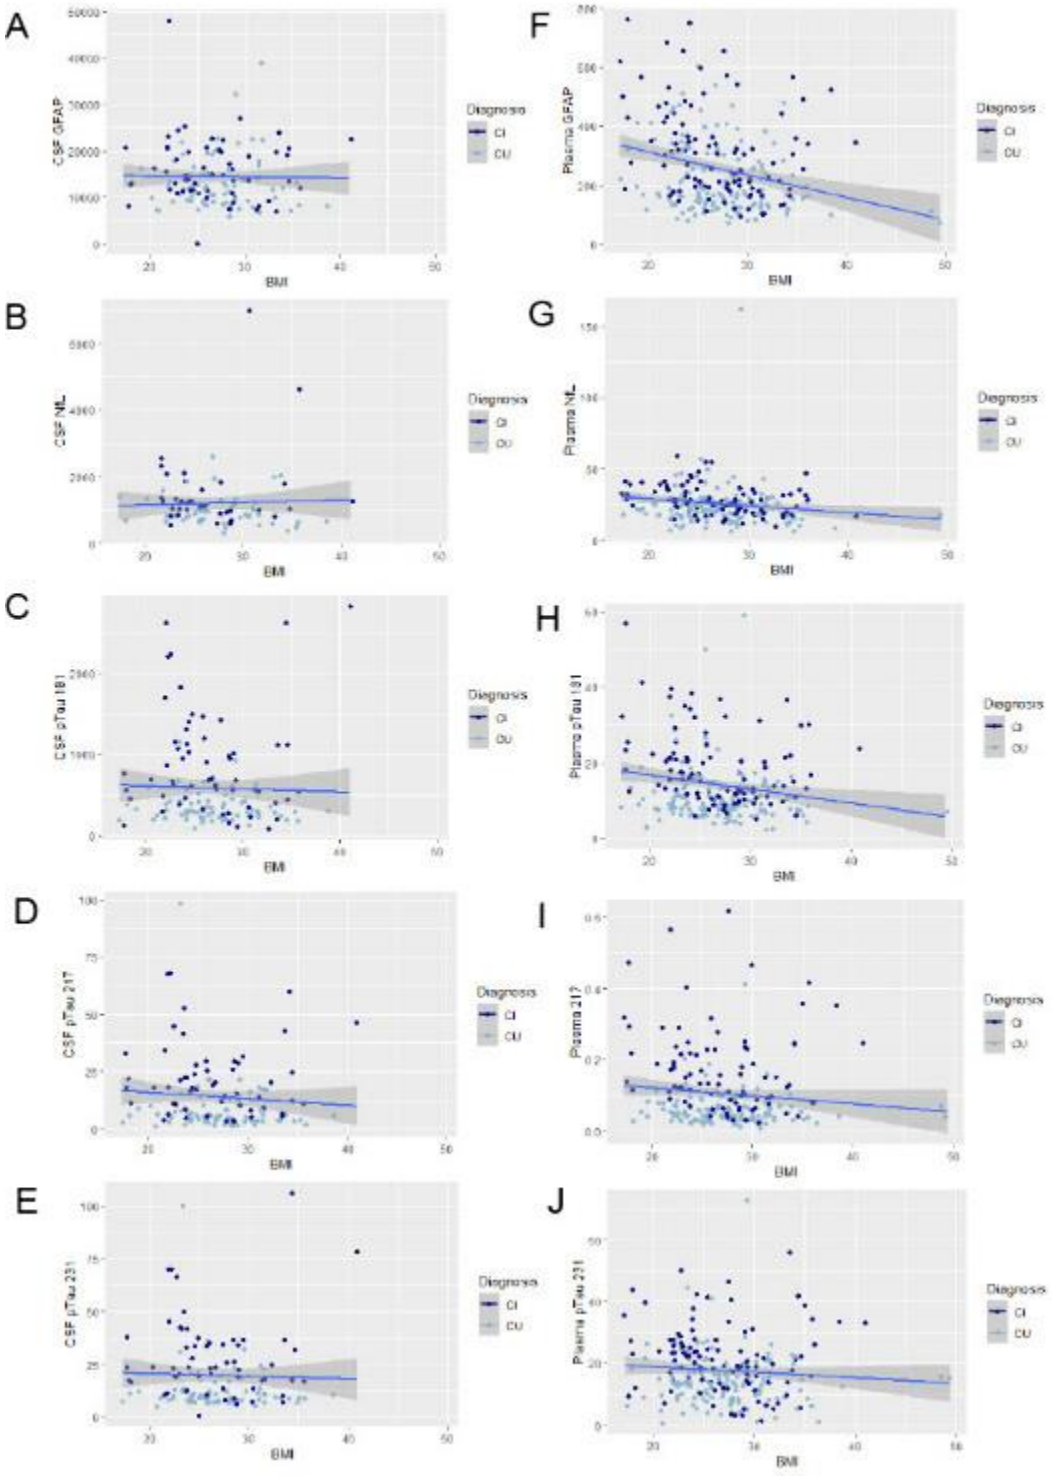

Figure 2. Levels of fluid AD biomarkers according to waist circumference

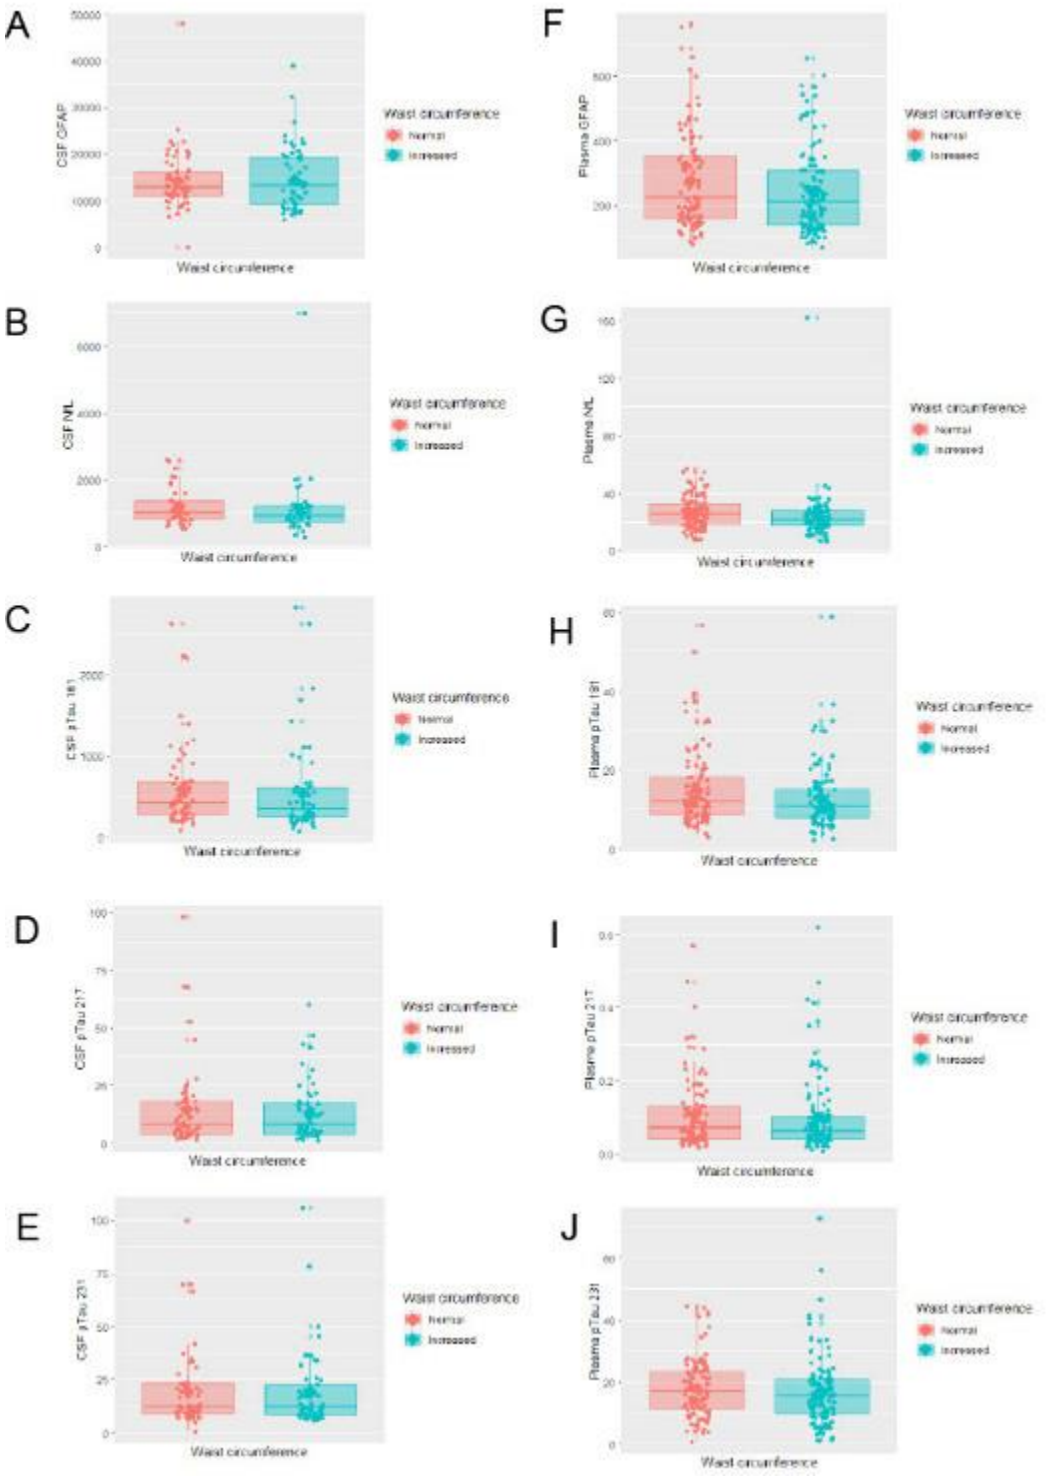

Conclusions: Our results suggest that BMI and waist circumference are factors to be considered when analyzing AD plasma biomarkers, in both preclinical and symptomatic stages. Further studies are needed to establish whether a causal relationship exists or whether those are relevant pre-analytical factors to consider.

Aims: Extracellular vesicles (EVs) can be found in distinct body fluids, including blood, being easily accessible and carrying a variated cargo that can be disease-specific. EVs can be particularly useful as a biomarker resource for Alzheimer´s disease (AD) allowing the identification of novel protein phosphorylation candidates, since the lipid bilayer can protect their content from degradation. This study employed a targeted phosphoproteomics approach to unravel blood-derived EVs phosphospecific candidates linked to AD.
Methods: Blood-derived EVs of Controls and AD cases were isolated and analyzed using an antibody microarray from Kinexus, which contains hundreds of pan- and phosphosite-specific antibodies. Significantly altered proteins and phosphoproteins were characterized by Gene Ontology and Reactome Pathways analyses, using ClueGo and CluePedia plugins from Cytoscape v3.9.1. An heatmap was constructed to assess the groups clustering. and the protein-to-protein interaction network was retrieved from STRING database, analyzed using the Cytoscape “Network Analyzer” using the betweenness centrality option to highlight central nodes.
Results: A total of 150 significantly altered proteins or phosphoproteins in AD were identified and both Gene Ontology and Reactome pathway analysis revealed relevant disease-related pathways. A clear segregation was obtained between Controls and AD cases in the heatmap analysis; and key targets were also unveiled in the protein-to-protein interaction network.
Conclusions: In sum, the proteome and phosphoproteome profiling approach used in this work unraveled a set of putative biomarker candidates in blood-derived EVs of AD cases which may hold value in AD diagnosis. To this end research was funded by Alzheimer’s Association under Grant 2019-AARG-644347, supported by iBiMED-UIDB/04501/2020, iBiMED-UIDB/04501/2020 and TSM individual PhD grant SFRH/BD/145979/2019.

Aims: Blood-based biomarkers (BBBMs) may enable scalable confirmation of amyloid pathology in the Alzheimer's disease (AD) care pathway, and some have shown test performance similar to cerebrospinal fluid (CSF) testing and positron emission tomography (PET). However, establishing effectiveness does not guarantee translation into the AD care pathway. The objective of this study is to demonstrate the clinical utility of a confirmatory BBBM in real-world settings by evaluating the feasibility of implementing amyloid confirmatory BBBM in clinical practice.
Methods: Based on the Consolidated Framework for Implementation Research (CFIR), we will conduct a US-based multicenter hybrid type II study. We will enroll a diverse population of individuals ≥55 years with mild cognitive impairment and mild AD but no prior dementia diagnosis. The diagnostic pathway (tests for reversible causes of cognitive impairment, cognitive and magnetic resonance imaging assessments, PET or CSF testing for amyloid pathology) will be compared between the standard-of-care arm and the confirmatory BBBM arm. Consistent with the CFIR, we will conduct qualitative semi-structured interviews at baseline and at the end of the study. When possible, we will use validated questionnaires to assess implementation science outcomes.
Results: The study will generate real-world data on clinical effectiveness of BBBMs (proportion of patients and time to biomarker-confirmed diagnosis [AD/non-AD] and proportion of eligible patients initiated on AD therapy within 6 months), implementation of BBBMs (feasibility, acceptability, appropriateness, sustainability, reach, adoption) and healthcare resource utilization.
Conclusions: This study will provide a blueprint for implementing BBBMs into healthcare systems by identifying facilitators and barriers, and will provide recommendations for implementation of BBBMs into routine practice. The study outcomes may lead to programs for accelerated uptake of BBBMs, simplifying the AD diagnostic pathway.

Aims: Due to the heterogeneous nature of Alzheimer's disease (AD), stratification of patients into biological subtypes employing multiple biomarker data may prove to be crucial for finding the most suitable prevention and treatment options. Despite advancements in subtype identification, a better understanding of how clinical characteristics are distributed between subgroups across the dementia spectrum is needed.
Methods: Cerebrospinal fluid (CSF) samples from 288 patients examined at the Karolinska University Hospital memory clinic in Solna, Sweden, were analyzed. The cohort containing subjective cognitive impairment (SCI), mild cognitive impairment (MCI), AD, and other dementias is deeply phenotyped with thorough neuropsychological tests, brain imaging, physical examinations, routine blood tests, and AD biomarker data from CSF and plasma. Using an antibody-based suspension bead array, a panel of 73 proteins was measured. Principal component analysis (PCA) was used to characterize the markers that contribute to variability. Furthermore, unsupervised clustering algorithm was used to identify subtypes of patients.
Results: The assessed panel revealed differences in protein levels between and within each diagnostic group. Neither PC1 nor PC2 was related to clinical diagnosis. PC1 was still associated with Aβ42, p-tau and t-tau, but not PC2. PC3 was associated with diagnostic groups, AD biomarkers in blood and CSF and results from cognitive tests. In ongoing analyses we further explore the data using unsupervised clustering algorithms. Identified protein signatures may reflect dementia related (patho)physiological states.
Conclusions: To conclude, AD, which falls under the umbrella term dementia, could in fact also be considered an umbrella itself with subgroups. In the current study, we demonstrate that measuring only tens of proteins in the CSF is adequate to stratify patients into subgroups with distinct pathological markers.

Aims: Phosphorylated tau (p-tau) 217 has recently received attention because it is more precise than other p-tau variants for identifying Alzheimer's disease (AD) pathology. Thus, we aimed to assess the diagnostic accuracy of p-tau217 in the blood and CSF, in comparison with p-tau181 and p-tau231 isoforms in a memory clinic cohort.
Methods: The study included 114 participants (CU=33; MCI=67; dementia=14) with measured plasma p-tau217. In 36 of them, p-tau217 was also quantified in the CSF. The association of p-tau isoforms was computed against a-PET Centiloid, tau-PET global-SUVR, hippocampal atrophy, and cognition. The diagnostic validity was evaluated by (i) effect sizes (δ) between diagnostic and A(+/-)T(+/-) groups; and (ii) receiver operating characteristic (ROC) analyses versus a- and tau-PET.
Results: The correlations between both plasma and CSF p-tau217 and a- and tau-PET (r from 0.64 to 0.83) were stronger than those of p-tau181 (r from 0.44 to 0.79) and p-tau231 (r from 0.46 to 0.76). Plasma p-tau217 showed significantly higher diagnostic accuracy in comparison with p-tau181 and p-tau231: (i) between diagnostic and biomarkers groups (δ ranges: p-tau217=0.55-0.96; p-tau181=0.51-0.67; p-tau231=0.53-0.71); and (ii) ROC curves to identify a- and tau-PET positivity (averageAUC: p-tau217=0.96; p-tau181=0.76; p-tau231=0.79). In contrast to this, CSF p-tau217 (averageAUC=0.95) did not show significantly superior accuracy to detect A and T positivity than p-tau181 (averageAUC=0.88) and p-tau231 (averageAUC=0.89).
Conclusions: Plasma p-tau217 demonstrated better performance in identifying AD pathology and clinical phenotypes in comparison with other p-tau isoforms in a memory clinic cohort. Furthermore, p-tau217 had comparable diagnostic performances in plasma and CSF. Our findings underline the potential of plasma p-tau217 in the diagnosis and screening for AD, which could decrease the need for more invasive biomarkers in the future.

Aims: Matrisome-associated heparin binding proteins are strongly correlated to β-amyloid (Aβ) and Tau pathology in Alzheimer's disease (AD) brain and cerebrospinal fluid (CSF). However, it remains challenging to detect these proteins in plasma using standard mass spectrometry-based proteomic approaches. Here we developed a heparin affinity approach for the capture and enrichment of heparin-binding protiens in plasma from healthy control and individuals with AD.
Methods: Plasma samples were collected from well-characterized participants in the Emory Goizueta Alzheimer's Disease research center and consensus clinical diagnoses were established. The diagnoses of control and AD were further supported by CSF Aβ levels and total Tau and phosphorylated Tau (pTau) levels detected by immunoassays. Plasma proteins were captured by heparin affinity chromatography and proteomic quantification was conducted in a discovery (n=36; 18 control, 18 AD) and replication dataset (n=85; 36 control, 49 AD) using tandem-mass tag mass spectrometry (TMT-MS). Differential expression and regression analyses were performed to assess the relationship of plasma proteins to CSF AD biomarkers and pTau in plasma.
Results: Collectively, 2865 heparin-enriched proteins were identified across 121 plasma samples. This included a significant increase in AD plasma of members of the matrisome-associated module in brain, SMOC1 and SPON1. Heparin-enriched proteins also exhibited strong correlations CSF Aβ, total tau, and pTau as well as plasma pTau. Utilizing a consensus AD brain protein co-expression network, we assessed relationship between the plasma and brain proteomes and observed that specific plasma proteins exhibited consistent direction of change in both brain and plasma, whereas others displayed divergent changes.
Conclusions: These findings provide support for coupled heparin-enrichment with TMT-MS based proteomics for identifying a wide spectrum of plasma biomarkers that mirror pathological changes in the AD brain.

Aims: Tau phosphorylated at threonine 217 (pTau217) is a promising plasma biomarker for monitoring Alzheimer's disease (AD) pathology. Commercial release of the ALZpath pTau217 Single molecule array (Simoa) immunoassay has expanded the availability of this biomarker, enabling studies across multiple laboratories and cohorts. The objective of this work was to understand the analytical performance of this assay in our local laboratory and to examine concordance with gold standard amyloid PET imaging in our mostly preclinical AD cohort.
Methods: The ALZpath pTau217 assay was validated on our Quanterix HD-X analyzer using pooled EDTA plasma. A pilot study was then performed with cross-sectional samples from 295 participants of Wisconsin Registry for Alzheimer's Prevention and the Wisconsin Alzheimer's Disease Research Cente. Some samples (N=90) were previously analyzed at the University of Gothenburg (UGOT, reported in PMID: 37502842). Amyloid positivity was determined by [^{11}C]-PiB PET and was based on a global PiB DVR threshold of 1.19 (21.6 centiloids).
Results: The ALZpath pTau217 assay demonstrated acceptable precision (<10 %CV), linearity, and recovery (102-111%) for endogenous protein. In the pilot study, the Pearson correlation coefficient (r) between samples analyzed locally and at UGOT was 0.95 ($p < 0.001$). Plasma pTau217 concentrations were significantly correlated with global PiB DVR ($r = 0.78$, $p < 0.001$), and the ROC AUC predicting PiB positivity was 0.92 (95% CI: 0.88-0.96). The optimal Youden-based threshold corresponding to PiB positivity was 0.60 pg/mL for pTau217.
Conclusions: These data suggest that the ALZpath pTau217 assay is fit-for-use to detect AD pathology in our late-middle aged preclinical cohort. The accessibility of blood-based biomarkers combined with a commercially available assay will enhance our ability to obtain longitudinal data across the preclinical phase, especially in difficult to reach communities.

Aims: Plasma biomarkers hold great potential in the management of Alzheimer's disease patients due to their high accessibility, affordability, and low invasiveness. Recently, baseline plasma levels were shown to predict cognitive decline in cognitively unimpaired (CU) subjects and patients with mild cognitive impairment (MCI). If neuroimaging biomarkers are also strong predictors of cognitive deterioration, it is still unclear how well they perform when compared to plasma biomarkers.
Methods: A total of 140 CU and 78 MCI subjects from the memory clinic of Geneva University Hospitals were included. Plasma and neuroimaging biomarkers were assessed at baseline, whereas global cognition was evaluated for up to 5.7 years. Linear mixed-effects (LME) models were built to test the prognostic value of plasma and neuroimaging biomarkers. Moreover, based on these analyses, sample size calculations for future AD clinical trials were also performed.
Results: Cognitive decline in MCI was significantly predicted by baseline NfL (β=-0.55, p<0.001), and GFAP (β=-0.36, p=0.016). All neuroimaging biomarkers significantly predicted cognitive decline in MCI, namely hippocampal volume (β=0.44, p = 0.01), Centiloid (β=-0.38, p=0.04), and tau-SUVR (β=-0.66, p<0.001). The multivariate LME model revealed that only NfL (β=-0.81, p=0.009) and tau-SUVR (β=-0.69, p=0.02) significantly predicted cognitive decline in MCI, whereas no significant effect was detected in CU subjects. Lastly, it was demonstrated that identifying at-risk subjects by adding NfL in inclusion criteria, it would be possible to reduce the sample sizes of future AD clinical trials by up to one-fourth, in subjects with amyloid-PET positivity.
Conclusions: Plasma NfL, and GFAP are equally good predictors of cognitive deterioration as neuroimaging biomarkers in MCI patients. Future clinical trials could employ plasma biomarkers in screening, as this would allow for smaller sample sizes and lower research expenses.

Aims: In fluid biomarker testing, sample storage conditions are one of the pre-analytical variables potentially impacting assay performance. To better understand the impact of sample storage conditions on AD CSF biomarker levels, fresh cerebrospinal fluid (CSF) samples from subjects being evaluated for Alzheimer's disease were stored at different temperature and time ranges (8 days at 25°C, 15 days at 2 to 8°C and 12 weeks at -15 to -25°C). Abeta42, pTau and tTau were measured after storage and compared to baseline levels.
Methods: Three experiments evaluating sample stability at 25°C, 2 to 8°C and -15 to -25°C were performed. Per subject, four to five aliquots were collected following the routine-use procedure recommended in the respective method sheet for the Elecsys® CSF assays. Storage at -80°C was not investigated.
Results: pTau and tTau remained stable in all experiments. Abeta42 was stable for up to 8 days at 25°C and up to 15 days at 2 to 8°C. Freezing and storage over 8 weeks at -15 to -25°C had a small but significant effect on Abeta42 concentrations shown in an Abeta42 value reduction; the storage effect was slightly greater after 12 weeks.
Conclusions: For all three biomarkers, the observed concentration bias was below 10% over the entire tested period. Abeta42 was less stable than pTau and tTau at 25°C for storage periods over 8 days, and overall at -15 to -25°C, probably due to the physical characteristics of the analyte. As a conservative approach, it is recommended to store fresh CSF samples for ≤ 5 days at room temperature and for ≤ 14 days at 2 to 8°C. The frozen samples can be stored for ≤ 8 weeks at -15 to -25°C.

Aims: Phosphorylated pTau 217 in plasma has emerged as a promising biomarker for the early detection of Alzheimer's disease (AD). We previously developed a pre-analytical sample workup based on semi-automated immunoprecipitation on FeliX platform followed by biomarker quantification using immunoassays (IP-IA). This study aims to compare the clinical performance of the novel pTau217 prototype immunoassay on the fully automated LUMIPULSE platform with and without the respective pre-analytical sample workup by Tau-immunoprecipitation in a preselected cohort.
Methods: A pre-selected cohort was studied comprising of 84 subjects dichotomized according to AT(N) classification. The IP-IA approach consists of semi-automated magnetic bead Aβ-IP followed by total Tau-IP and subsequent measurements of plasma Aβ1-42/1-40 ratio and pTau217 levels on Lumipulse.
Results: The levels of pTau217 after pre-analytical immunoprecipitation of Aβ and Tau correlated with the corresponding concentrations from direct measurements in plasma ($r=0.93$, $p<0.0001$). The Tau-IP prior to Lumipulse measurement resulted in a numerical increase in the area under the ROC curve (AUC) for identifying individuals A+ from 0.955 to 0.973 ($p=0.149$) for plasma pTau217. Although pTau217 performed generally better than Aβ1-42/1-40 ratio, the latter became superior when used to identify the early stages of AD defined as A+T-. We additionally assessed a novel term (AT-term) combining Aβ and pTau biomarkers, here defined as Aβ1-40/1-42*pTau217, which showed a further improvement in performance relative to the individual biomarkers.
Conclusions: Our preliminary findings in this preselected cohort indicate that reducing matrix effects potentially interfering in immunoassay performance by implementing pre-analytical Aβ and Tau immunoprecipitation can improve the performance of plasma biomarker assays for detecting brain amyloid pathology in a research context. Our observations also support the importance of the Aβ1-42/1-40 ratio as a biomarker for predicting early stages of AD.

BLOOD CD34+ CELL LEVEL IS A BIOMARKER OF PRECLINICAL ALZHEIMER'S DISEASE

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Daniel Nation[1], Arunima Kapoor[2], Amy Nguyen[1], Aimée Gaubert[1], Kathleen Rodgers[3], David Robert Bradford[3], Elizabeth Head[4], Trevor Lohman[1]
[1]University of Southern California, Leonard Davis School Of Gerontology, Los Angeles, United States of America, [2]University of California Irvine, Psychological Science, Irvine, United States of America, [3]University of Arizona, Center For Innovations In Brain Science, Department Of Pharmacology, Tucson, United States of America, [4]University of California Irvine, Pathology & Laboratory Medicine, Irvine, United States of America

Aims: Prior studies examining blood CD34+ cell levels in Alzheimer's dementia have been mixed, with increased, decreased and no differences being reported relative to controls. The present study aimed to evaluate blood CD34+ cell levels in older adults with and without preclinical Alzheimer's disease biomarker abnormality.
Methods: One-hundred participants age 55-to-89 years were recruited from the community to undergo clinical examination and venipuncture. Participants were screened for history of stroke, dementia or other major illness. Blood CD34+ cell levels were determined by flow cytometry. Plasma Aβ42, Aβ40, ptau181, total tau, GFAP and NfL levels were obtained by SIMOA (Quanterix) assay. Longitudinal follow-up was obtained on a subset. T-tests and regression analyses evaluated the relationship between CD34+ cell levels and plasma biomarkers.
Results: Blood CD34+ cell levels were not associated with age or sex, p's>.60. CD34+ cell levels were significantly elevated in individuals who met the cutoff for amyloid positivity compared to those who did not based of either plasma Aβ42/40 ratio, $t(91) = -6.8$, $p<0.001$, or p-tau181, $t(90) = -3.9$, $p<0.001$. CD34+ cell levels were linearly associated with Aβ42/40 ratio ($B = -2.1$, $p <. 001$) and p-tau181 levels ($B = 1730.7$, $p<0.001$). There was no association between CD34+ cell counts and either GFAP or NfL. Longitudinal analysis indicated greater increases in CD34+ cell levels in amyloid positive versus negative individuals.
Conclusions: Older adults with preclinical Alzheimer's disease biomarker abnormality on plasma Aβ42/40 ratio and/or ptau181 levels exhibit substantially elevated blood CD34+ cell levels. Amyloid positive older adults exhibit increasing blood CD34+ cell levels over time. Further study of CD34+ cell counts as a preclinical biomarker of Alzheimer's disease is warranted.

Aims: Alzheimer's disease (AD) is a devastating neurodegenerative disease with delayed diagnosis until the manifestation of symptoms. Although the emergence of blood-based biomarkers offers hope for easy detection of AD, existing AD-associated blood biomarkers, known as the "blood ATN biomarkers", mainly capture the pathological hallmarks of AD, overlooking other AD-associated biological processes such as inflammation and vascular dysfunctions. Therefore, developing a blood-based biomarker assay that captures dysregulation beyond the ATN biomarkers may help advance early detection and staging of AD, enabling a comprehensive examination of the disease status.
Methods: We leveraged ultrasensitive proteomic technology to develop a blood-based, multiplex biomarker assay for AD. This assay simultaneously measures the levels of 21 blood proteins associated with different biological pathways, including neurodegeneration, inflammation, innate immunity, vascular functions, and metabolic activities. Moreover, we developed an AD risk scoring system by integrating the level changes of these 21 proteins in a machine learning-based model. The performance of this 21-protein biomarker assay in AD classification and indication of AD-related endophenotypes was evaluated in three independent cohorts.
Results: We showed that this 21-protein biomarker assay accurately classifies AD (AUC = 0.9407–0.9867) and mild cognitive impairment (MCI) (AUC = 0.8434–0.8945). It also indicates amyloid pathology in Chinese and European populations. Moreover, this assay simultaneously evaluates changes in five biological processes, providing comprehensive assessment of disease status and revealing heterogeneity of AD among individuals. Notably, dysregulations of biological processes upon AD progression are different between Chinese and European populations, particularly in biological pathways related to inflammation and vascular functions.

Conclusions: Our findings demonstrate the utility of a blood-based multi-pathway biomarker assay for early screening and staging of AD in clinical settings and provide insights for patient stratification and the development of precision medicine.

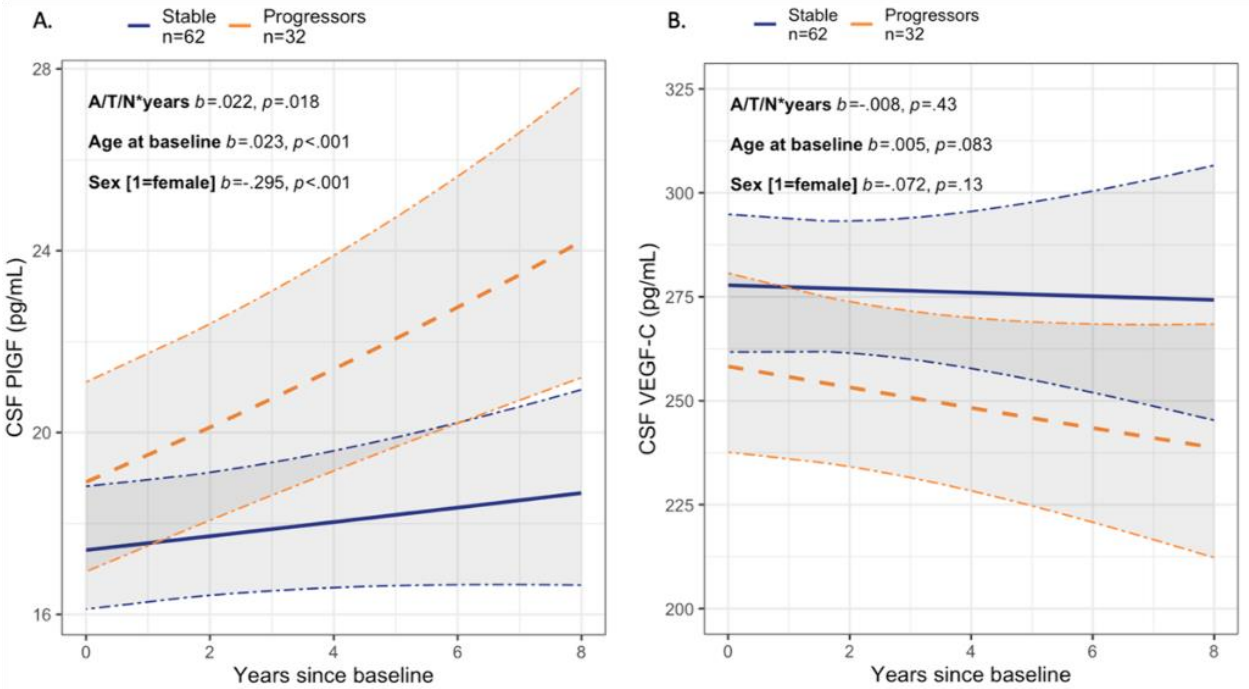
PROGRESSION OF ALZHEIMER'S DISEASE IS ASSOCIATED WITH INCREASING PLACENTAL GROWTH FACTOR IN CEREBROSPINAL FLUID

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Lene Pålhaugen[1,2], Julia Gundersen[1,3], Bjørn-Eivind Kirsebom[2,4,5], Berglind Gísladóttir[1], Jonas Jarholm[1,2], Per Selnes[1,2], Tormod Fladby[1,2]
[1]Akerhus University Hospital, Department Of Neurology, Lørenskog, Norway, [2]University of Oslo, Institute Of Clinical Medicine, Oslo, Norway, [3]University of Oslo, Institute Of Basic Medical Sciences, Oslo, Norway, [4]UiT The Arctic University of Norway, Department Of Psychology, Faculty Of Health Sciences, Tromsø, Norway, [5]University Hospital of North Norway, Department Of Neurology, Tromsø, Norway

Aims: Angiogenic mediators like placental growth factor (PlGF) and vascular endothelial growth factor-C (VEFG-C) are suggested as promising markers of cerebral small vessel disease. We aimed to compare these vascular markers in cerebrospinal fluid (CSF) between subjects with stable versus progressive A/T/N classification to explore a possible role of angiopathy in Alzheimer´s disease (AD) progression.
Methods: We analysed subjects (n=94) from the Norwegian multi-centre Dementia Disease Initiation (DDI) study. Participants were classified at baseline with either normal cognition (NC), subjective cognitive decline (SCD) or mild cognitive impairment (MCI). A/T/N staging based on CSF biomarkers was assessed in all participants at baseline, with biennial follow-up. Based on follow-up data, subjects were classified as stable A-/T-/N- (n=62) or progressing from A-/T-/N- to A+/T-/N- (n=23) or A+/T+ or N+ (n=9). Quantification of VEGF-C and PlGF in CSF was obtained at each follow-up. Linear mixed-effects models were used to estimate the longitudinal difference in biomarkers between stable A-/T-/N- and progressors, adjusted for age and sex.
Results: Degree of cognitive impairment at baseline differed between stable A-/T-/N- (25.8% NC, 74.2% SCD, none with MCI) and progressors (34.7% NC, 26.1% SCD and 39.1% MCI). We also observed a sex difference between stable A-/T-/N- (53.2% female) and progressors (39.1% female). Interestingly, PlGF showed a linear increase over time in progressors as compared to subjects with stable A-/T-/N- (*fig. 1*). Conversely, VEGF-C did not differ significantly between the groups.



Conclusions: Our longitudinal analysis shows that progression from A-/T-/N- to A+/T-/N- or A+/T+ or N+ is associated with increasing levels of PlGF, whereas VEGF-C levels remain stable. These findings suggest that PlGF-mediated angiopathy may play a role in AD pathogenesis.

Aims: Plasma biomarkers whoed high performance at group level but their as markers of Alzheimer's disease (AD) is debated as single-ubject level. Aim of the study was to evaluate the performance at single subject level of plasma biomarkers to diagnose CSF AD-related pattern
Methods: each patient underwent standard clinical and cognitive assessment and CSF analyses for biomarker-based AD diagnosis. Plasma p-tau181, p-tau231, NfL, GFAP, T-tau abeta 1-42, Abeta 1-40 Tau, P-tau and Abeta amyloid, NfL, using SIMOA analyses. The ability of different biomarkers to distinguish AD from other neurodegenerative diseases was evaluated using ROC analyses and binary logistic regression analyses
Results: 125 AD and 55 other neurodegenerative disorders (NDD) with CSF analyses and 115 matched controls entered included in the analyses. The combined cut-off based on P-tau181 and NfL assessment was able to correctly classified 85% of AD and 78% controls at individual level. A two.-step plasma process Amyloid42 and P-tau truly identified 83% of AD and 65% NDD at individual level
Conclusions: this study confirmed the relevance of p-tau and NfL to distinguish AD from controls, whereas amyloid markers were important to distinguish in a fair way AD from NDD at individual level. Further larger studies including other markers and different subtypes of disease are needed to implement plasma biomarkers in clinical routine.

Aims: Cerebrospinal fluid (CSF) biomarkers have proved to be highly informative, sensitive, and specific in detecting the preclinical as well as symptomatic stages of clinical Alzheimer's diseases (AD). The aim of this study is to access the robustness of LUMIPULSE G600II (Fujirebio®) compared to SR-X Ultra-Sensitive Biomarker Detection System (Simoa®, Quanterix), in detecting CSF and plasma biomarkers AD and no-AD subjects.
Methods: AD diagnosis was based on CSF biomarkers evaluation. Plasma p-tau181, amyloid β protein (A*β)* 42, A*β*-40, were performed on both platforms. AD neurodegenerative conditions and fluid biomarkers correlation were evaluated by ROC analyses and Spearman's rank correlation. Forty-nine A+T+N+ AD and 34 other neurodegenerative disorders (NDD) A-T-N+/- were included in the analyses. A group of cognitively normal subjects (CN) (n = 50) were also tested on plasma.
Results: The analytical values showed higher stability for plasma p-tau181 compared with AB42 and AB40 in Lumipulse testing . Plasma p-tau181 analysed on LUMIPULSE and SIMOA showed high correlation eachother and fair correlation with CSF values The ratio of p-tau181/AB42 and AB42/AB40 resulted to be robust in both system, presenting AUCs of 0.89 and 0.74 for Lumipulse and SIMOA for CSF AD-pattern, respectively.
Conclusions: Plasma markers showed high correlation between both Lumipulse and SIMOA techniques with a comparable discriminative value for the detection of CSF Alzheimer-related pattern in clinical setting.

Aims: Although plasma biomarkers for amyloid-β showed high predictability of amyloid positron emission tomography (PET) positivity, the characteristics of discordance between PET and plasma amyloid positivity is poorly understood.
Methods: We compared tau burden measured by PET, brain volume assessed by magnetic resonance imaging, cross-sectional cognitive function, longitudinal cognitive decline and polygenic risk score (PRS) between PET/plasma groups (PET-/plasma-, PET-/plasma+, PET+/plasma-, PET+/plasma+) using Alzheimer's Disease Neuroimaging Initiative database. Additionally, we investigated inter-assays variability between immunoprecipitation followed by mass spectrometry method and Elecsys immunoassay.
Results: The PET-/plasma+ showed intermediate changes between PET-/plasma- and PET+/plasma+ in terms of tau burden, hippocampal and precuneus volume, cross-sectional and longitudinal cognition, and PRS. PET+/plasma- represented heterogeneous characteristics with variability depending on plasma assays.
Conclusions: Characteristics of PET-/plasma+ support plasma biomarkers as early biomarker of amyloidopathy prior to amyloid PET. Various plasma biomarker assays might be applied distinctively to detect different target subjects or disease stages.

Aims: Glial fibrillary acidic protein (GFAP) is a cytoskeletal protein expressed in astrocytes. Reactive astrogliosis, hallmarked by increased GFAP expression, is part of the pathogenesis of Alzheimer's disease (AD). A set of N- and C-terminal monoclonal antibodies (mAbs) allowed us to build GFAP fragment-specific immunoassays that can help to understand the potential value of GFAP N- and C-terminal fragments in biomarker testing in AD and beyond. Here we report the preliminary clinical performance of a previously developed in-house N-terminal GFAP ELISA, and the development of a novel immunoassay allowing preliminary detection of C-terminal GFAP fragments.
Methods: Plasma samples from 50 AD patients (defined by CSF biomarker profile) and 50 healthy donors (HD) were tested in duplicate with our N-terminal research prototype ELISA. To develop the C-terminal GFAP immunoassay, mAb combinations including at least one mAb targeting the C-terminal tail were explored in ELISA. Detection of GFAP in brain lysate was evaluated.
Results: Using the N-terminal ELISA, GFAP concentrations in the AD group (median 623, IQR 420-889 pg/mL) were found to be significantly higher than in the HD group (median 385, IQR 275-478 pg/mL) (Mann-Whitney, $p<0.0001$) which is in line with published data. An ELISA set-up using C-terminal mAbs detected GFAP in AD and HD brain lysates (n=3).
Conclusions: Our N-terminal ELISA shows clinical value in this exploratory cohort and is therefore suitable for further clinical evaluation of GFAP levels in plasma from patients with different pathologies. Our C-terminal immunoassay demonstrated successful detection of GFAP in brain lysates and is under further development. Finally, analyzing clinical samples in both the N- and C-terminal assay would help to gain novel insights into the role of N- and C-terminal GFAP fragments as biomarker.

INTEGRATION OF AMYLOID-B OLIGOMERIZATION TENDENCY AS A PLASMA BIOMARKER IN ALZHEIMER'S DISEASE DIAGNOSIS

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Jung-Min Pyun[1], Young Chul Youn[2], Young Ho Park[3], Sangyun Kim[4]
[1]Soonchunhyang University Seoul Hospital, Neurology, Seoul, Korea, Republic of, [2]Chung-Ang University Hospital, Neurology, Seoul, Korea, Republic of, [3]Seoul National University Bundang Hospital, Neurology, Seongnam, Korea, Republic of, [4]Seoul National University Bundang Hospital, Neurology, Seongnam-si, Korea, Republic of

Aims: There has been significant development in blood-based biomarkers targeting amyloidopathy of Alzheimer's disease (AD). However, guidelines for integrating such biomarkers into AD diagnosis are still inadequate. Multimer Detection System-Oligomeric Amyloid-β (MDS-OAβ) as a plasma biomarker detecting oligomerization tendency is available in clinical practice.
Methods: We suggest how to interpret results of plasma biomarker for amyloidopathy using MDS-OAβ with neuropsychological test, brain MRI, and amyloid PET for AD diagnosis. Combination of each test result differentiates various stages of AD, other neurodegenerative diseases, or cognitive impairment due to causes other than neurodegeneration.
Results:

MDS-OAβ	Neuropsychological test	Brain MRI	The most probable diagnosis	Remarks
Positive	Cognitive impairment	AD-compatible atrophy	AD	Rarely, other ND LATE etc.) + am
		Normal	Early stage of AD	Rarely, cognitive (depression, vita electrolyte imbal condition etc.) +
	Normal	AD-compatible atrophy	Preclinical AD	Other preclinical VD, LATE etc.) +
		Normal	Preclinical amyloidopathy	
Negative	Cognitive impairment	AD-compatible atrophy	Other NDDs (DLB, FTD, NPH, PDD, VD, LATE etc.)	
		Normal	Cognitive impairment due to other causes (depression, vitamin B12/folate deficiency, electrolyte imbalance, poor general medical condition etc.)	
	Normal	Abnormal	Other preclinical NDDs (DLB, FTD, NPH, PDD, VD, LATE etc.)	
		Normal	Normal	

Conclusions: A systematic interpretation strategy could support accurate diagnosis and staging of AD. Moreover, comprehensive use of biomarkers which target

amyloidopathy such as amyloid PET on brain amyloid plaque and MDS-OAβ on amyloid-β oligomerization tendency can complement to gain advanced insights of amyloid-β dynamics in AD.

Aims: Plasma biomarkers related to amyloid, tau, neurodegeneration (ATN) and glial activation hold promise for both research and clinical applications. We sought to examine their relationship with cognitive performance in a diverse population of community-dwelling Hispanic/Latino adults.
Methods: Plasma samples from middle-aged and older adults (50 to 86 years) in the *Study of Latinos-Investigation of Neurocognitive Aging* (SOL-INCA; 2016–2018) were analyzed to quantify amyloid-beta ($A\beta_{42/40}$), phosphorylated tau-181 (p-tau), neurofilament light chain (NfL; neurodegeneration), and glial fibrillary acidic protein (GFAP) using the Simoa digital immunoassay platform. We used regression models to examine associations between plasma biomarkers and cognitive performance on the Brief-Spanish English Verbal Learning Test (verbal episodic learning and memory), Word Fluency (verbal fluency), Digit Symbol Subtest (processing speed/executive functioning), and a cognitive composite (global cognition). Adjusted models included demographic (age, sex, education, Hispanic/Latino background, field center), medical (body mass index, Framingham risk score, chronic kidney disease), and genetic factors (APOE genotype). Sampling weights and survey techniques were used to account for the complex design.
Results: The target subpopulation (unweighted n=6,071) was 54% female with mean age of 63.39 ± 8.16 years. In adjusted models, plasma NfL was associated with all cognitive measures (global cognition: β=-0.06; 95% CI=[-0.10;-0.02]; p<0.01). Plasma p-tau and GFAP were significantly associated with learning, memory, and global cognition (global cognition: β=-0.04; 95% CI=[-0.06;-0.01]; p<0.01, and global cognition: β=-0.04; 95% CI=[-0.07;-0.00]; p<0.05, respectively).
Conclusions: Our findings suggest p-tau, neurodegeneration, and glial activation, but not amyloid-beta, are negatively linked to cognitive performance in community dwelling diverse middle-aged and older Hispanic/Latino adults. Further research is needed to specify the mechanisms by which plasma ATN and glial activation biomarkers are associated with cognition.

ALZHEIMER'S DISEASE PLASMA BIOMARKERS IN AFRICAN AND AFRICAN AMERICAN POPULATIONS: CROSS-SECTIONAL ANALYSIS OF THE INDIANAPOLIS-IBADAN DEMENTIA PROJECT COHORT

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Kristen A. Russ[1], Kathleen Lane[2], Sujuan Gao[3], Fred Unverzagt[4], Hugh Hendrie[4], Tatiana Foroud[1], Jeffrey Dage[5]
[1]Indiana University School of Medicine, Medical And Molecular Genetics, Indianapolis, United States of America, [2]Indiana University School of Medicine, Biostatistics And Health Data Science, Indianapolis, United States of America, [3]Indiana University School of Medicine, Department Of Biostatistics, Indianapolis, United States of America, [4]Indiana University School of Medicine, Psychiatry, Indianapolis, United States of America, [5]Indiana University School of Medicine, Stark Neurosciences Research Institute, Indianapolis, United States of America

Aims: Study the use of plasma biomarkers in The Indianapolis-Ibadan Dementia Project (IIDP) to assess the effect of population differences between geographies on biomarker associations.
Methods: IIDP is a longitudinal study that evaluated subjects in Indianapolis, Indiana and Ibadan, Nigeria. Plasma collected from study participants in the 2001 evaluation wave (N= 1028 African Americans; N=1091 Yoruba) was analyzed for Alzheimer's Disease and neurodegenerative biomarkers using the Quanterix Simoa HD-X Neurology 4-Plex and pTau181 v2.1 Advantage kits. The concentrations of neurofilament light chain (NfL), glial fibrillary acidic protein (GFAP), beta amyloid 42/40 ratio (Abeta 42/40), and phosphorylated Tau 181 (pTau181) were determined for each subject with available plasma samples. Biomarker data were log transformed and standardized prior to analysis. Multivariate and other association analysis was performed in JMP Pro v16 software.
Results: The demographics of study subjects can be seen in Table 1. Biomarkers were standardized and assessed by site for correlation in subjects with and without dementia. NfL, GFAP, and pTau181 associations were the same when comparing subjects with dementia between sites; however, higher NfL, GFAP, and pTau181 correlations were observed in cognitively normal (CN) subjects in Indiana compared to Ibadan (Figure 1). Additional analysis is still ongoing and will be included in the presentation.

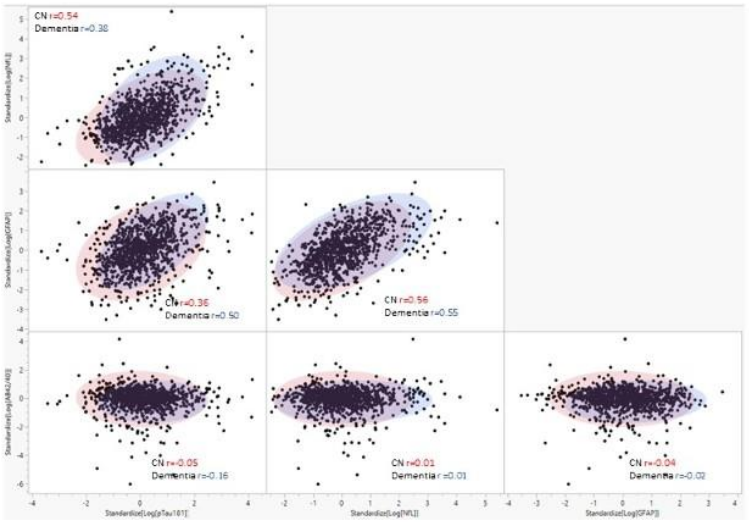
Table 1) Sample Demographics by Site

	Indiana, USA (N=1028)	Ibadan, Nigeria (N=1091)	Site differences P-value
Gender (n)	M: 334; F:686	M: 360; F:730	0.8902
Age at baseline visit Mean (SD)	75.6 (5.88)	73.4 (5.69)	<0.0001
Age at plasma collection Mean (SD)	78.5 (5.64)	77.8 (5.64)	0.0051
Age at diagnosis Mean (SD)	83.4 (5.70)	82.3 (5.79)	<0.001

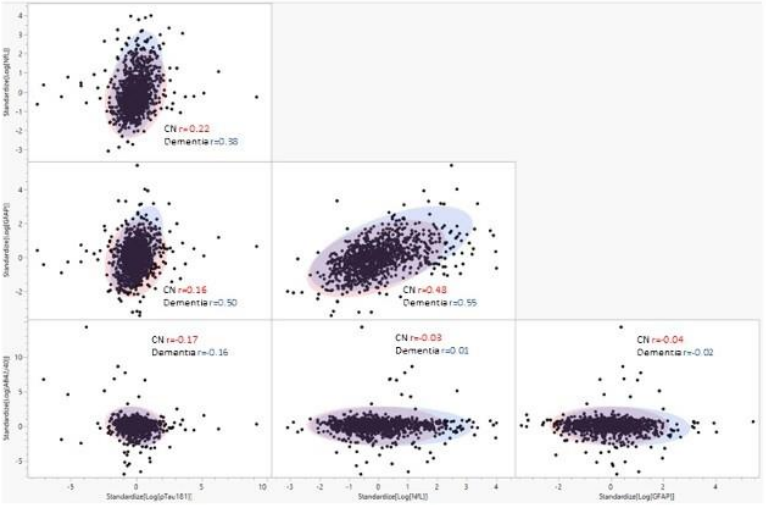
Table 1: Demographic info of samples with plasma collected as part of the 2001 cohort of IIDP. Mean age at plasma collection was calculated based on the collection date in associated with the sample. Mean age at diagnosis is the age at diagnosis of dementia or AD or the age at which they were non-demented at the last study visit. Group comparisons were tested for significance using t-test for continuous variables or Chi-square test for categorical variables.

Figure 1) Biomarker multivariate analysis by demented and non-demented (CN) groups

A) Site: Indiana, USA



B) Site: Ibadan, Nigeria



Conclusions: While biomarker associations for NFL, GFAP and pTau181 are consistent across sites for subjects with dementia, there are observed differences in biomarker associations for CN subjects between Indianapolis, Indiana, and Ibadan Nigeria. Previously published analyses (Deeg et al., 2008) regarding differences in potential comorbidities for these populations may be driving these differences. More analyses must be completed to determine the cause of these differences.

SERUM NEUROFILAMENT AS A TREATMENT-RESPONSE BIOMARKER IN THE EMERGE AND ENGAGE PHASE 3 TRIALS OF ADUCANUMAB IN ALZHEIMER'S DISEASE

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Carrie Rubel[1], Kyle Fraser[1], Laura Nisenbaum[2], Tianle Chen[1], Kyle Ferber[1], Tao Sun[1], John O'Gorman[1], Gersham Dent[1], Kate Dawson[1], Danielle Graham[1]
[1]Biogen Inc., Medical Affairs, Cambridge, United States of America, [2]Alzheimer's Drug Discovery Foundation, Drug Development, New York, United States of America

Aims: Neurofilament light chain (NfL) is a disease biomarker supporting clinical efficacy in several neurodegenerative diseases. We investigated the utility of serum NfL as a treatment-response biomarker in Alzheimer's disease (AD) using data from Phase 3 clinical trials of aducanumab, EMERGE (NCT02484547) and ENGAGE (NCT02477800).
Methods: Serum NfL levels were analyzed in 8303 samples from 4773 participants from EMERGE and ENGAGE, including screening samples from unenrolled amyloid-negative participants. Correlations between baseline serum NfL and *APOE* ε4 carrier status, age, baseline amyloid-PET, structural MRI, clinical progression, and plasma p-tau^{181} levels were evaluated. Change from baseline (CFB) in NfL at Weeks 56 and 78 were assessed and correlated with CFB in biomarker and clinical endpoints.
Results: Baseline serum NfL levels were modestly elevated in amyloid PET-positive vs. negative participants and increased with age, with no significant differences between *APOE* ε4 carriers and non-carriers. Baseline NfL correlated with baseline plasma p-tau^{181}, structural MRI, baseline and CFB in clinical endpoints. CFB in NfL correlated with CFB in plasma p-tau^{181}. Longitudinal changes in NfL were small and highly variable with no clear treatment effect from aducanumab on NfL; a small number of outliers significantly impacted the analysis despite strong assay analytical performance. A consistent biological cause for observed extreme values was unclear; however, cardiovascular disease, type 2 diabetes, and chronic kidney disease have been associated with higher NfL.
Conclusions: While NfL is a highly informative treatment-response biomarker in other therapeutic areas, in AD the small-magnitude, slow rate of change, and high biological variability limit its ability to reflect clinical efficacy. Future work will examine the utility of NfL as a biomarker for AD therapies targeting different aspects of disease pathophysiology and in predicting/monitoring amyloid-related imaging abnormalities.

EFFECTS OF APOE RISK ALLELE AND SEX ON THREE CORE CEREBROSPINAL FLUID BIOMARKERS ACROSS ANCESTRIES

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Ruiqi Yan[1], Xiaoyi Xu[1], Qijun Yang[1], Catherine Apio[1], Jigyasha Timsina[1], Lihua Wang[1], Taesung Park[2], Carlos Cruchaga[1], Yun Ju Sung[1]
[1]Washington University School of Medicine in Saint Louis, Psychiatry, Saint Louis, MO, USA, United States of America, [2]Seoul National University, Statistics, Seoul, Korea, Democratic People's Republic of

Aims: Women are at a higher risk of developing AD and present faster progression. APOE-e4 risk allele is the strongest genetic risk factor for late-onset AD. The three core CSF biomarkers are amyloid β 42 (Aβ42) for cortical amyloid deposition, total tau for neurodegeneration intensity, and phosphorylated tau 181 (p-tau) for neurofibrillary pathological changes. The study aims to investigate the effect of sex and APOE4 on these three CSF biomarkers across ancestries.
Methods: We obtained three core CSF biomarkers from 20 cohorts. Based on genetic principal components anchored with the 1000 Genomes Project data, participants were grouped into Europeans (N=5,699), Africans (N=149), and Asians (N=65). For each biomarker, we considered the main effect (sex and APOE4) model, the interaction model (additionally including the interaction between sex and APOE4), and the sex-stratified model. The heterogeneity test was used to determine fixed or random effect model for European meta-analysis. African and Asian samples were jointly analyzed.
Results: Tau and pTau were significantly associated with sex and APOE4 in Europeans and Africans. Asians had consistent effects. Aβ42 had significant APOE4 effects consistently in three ancestries. Females had higher APOE4 effects for Tau than males across all three ancestries. Tau had significant interaction between sex and APOE4 in Europeans ($\beta=0.11$; $P < 0.01$). We found some heterogeneity within European cohorts. Results from Africans and Asians were consistent.
Conclusions: This study found that the effect of the APOE risk allele on CSF tau biomarker is sex-specific and higher in females than males. This effect is consistent across ancestries. With the increase in sample size and number of studies, the precision and power of the meta-analyses were improved. Validations in Asians may require additional follow-up.

MINIMALLY INVASIVE DETECTION OF AD BIOMARKERS FOR DIFFERENTIATION OF AD IN COGNITIVELY IMPAIRED PATIENTS

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Marion San Nicolo[1], Oliver Peters[2], Hilary Wunderlich[1], Lutz Froelich[3], Jens Wiltfang[4], Timo Grimmer[5], Arno Schaepe[1], Richard Metzler[1], Sabine Mertzig[1], Klaus Hallermayer[1], Harald Waltenberger[1], Peter Kaspar[1], Thomas Heydler[1], Mareike Haack[1]
[1]Noselab, Na, Munich, Germany, [2]Department of Psychiatry, Charité-universitätsmedizin Berlin, Campus Benjamin Franklin, Berlin, Germany, [3]Heidelberg University, Department Of Geriatric Psychiatry, Central Institute Of Mental Health,medical Faculty Mannheim, Mannheim, Germany, [4]Universitätsmedizin Göttingen, Klinik Für Psychiatrie Und Psychotherapie, Goettingen, Germany, [5]Technical University Munich, Center For Cognitive Disorders, Munich, Germany

Aims: Evaluation of our proprietary diagnostic platform for minimally invasive, detailed quantification of the key Alzheimer's disease (AD) biomarkers in size and relative amount: pTau181 (pTau), total Tau (tTau), Amyloid-β1-40 (Aβ40), Amyloid-β1-42 (Aβ42) and total Amyloid β (Aβ).
Methods: Multicenter, prospective cohort study including patients with cognitive impairment. The presence (A+) or absence (A-) of amyloid pathology was determined by the Aβ42/Aβ40 ratio in CSF as reference test and compared to nasal secretion-based classification of AD biomarkers. Nasal secretion was collected from the vicinity of the olfactory cleft using a proprietary collection device (nosecollect®) and the relative protein amount as well as protein specific quaternary substructures (monomeric and oligomeric species) were quantified for the AD biomarkers using an automated protein separation and immunodetection system.
Results: Sampling procedure using nosecollect® is well tolerated, painless and yields a high sample volume. Different monomeric, oligomeric, and higher n-meric protein species of AD biomarkers were quantified. Patients with CSF-confirmed amyloid pathology (A+) show a significantly different protein-specific biomarker signature in nasal secretion as compared to patients without amyloid pathology (A-). Our protein-specific biomarker signature allows for a highly significant discrimination (p-value <0.001) of A+ vs. A- with an AUC of >0.90.
Conclusions: Simultaneous detection of multiple AD relevant biomarkers along the olfactory route constitutes a safe, minimally invasive, easy to obtain diagnostic procedure. Among patients with cognitive impairment, A+ patients and A- patients can be discriminated with high accuracy. Thus, our diagnostic platform has the potential for screening, diagnostics, patient stratification, intraindividual disease and treatment monitoring in AD as well as other neurodegenerative diseases.

PROTEIN FIBRIL AGGREGATION ON RED BLOOD CELLS: A POTENTIAL BIOMARKER TO DISTINGUISH NEURODEGENERATIVE DISEASES FROM HEALTHY AGING

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Thomas Schneider[1], Luisa Stöckli[1], Ansgar Felbecker[1], Peter Nirmalraj[2]
[1]Cantonal Hospital of St. Gallen, Neurology, St. Gallen, Switzerland, [2]Swiss Federal Laboratories for Materials Science and Technology, Transport At Nanoscale Interfaces Laboratory, Dübendorf, Switzerland

Aims: To investigate the prevalence and significance of fibril aggregation on red blood cells (RBCs) in both cognitively healthy adults and patients with cognitive complaints, and to assess its potential as a biomarker for neurodegenerative diseases, especially Alzheimer's disease (AD).
Methods: Study Population: Data from 50 cognitively healthy adults (aged 18-88 years), 8 patients with no evidence of a neurodegenerative disease, 11 patients with MCI or dementia who were amyloid negative and 18 patients with MCI or dementia who were amyloid positive were analyzed. **RBC Analysis:** Atomic Force Microscopy (AFM) was employed to study the nanoscale morphology of fibril aggregates on RBCs in blood smear samples. Approximately 1000 RBCs on 30-50 scanned areas were analyzed for each participant. **Statistical Analyses:** Descriptive statistics, grouo comparisons, and ROC analyses were conducted to differentiate between diagnosis groups based on the prevalence of fibrils on RBCs.
Results: Only a minority of healthy participants but all patients displayed fibril aggregates on RBCs. Patients with AD pathology, confirmed by a positive cerebrospinal fluid (CSF) Aβ 1-42/1-40 ratio, showed the highest levels of fibrils on RBCs. Healthy subjects had a mean fibril coverage of RBCs of 2.96 ± 6.1%, which was significantly lower than all patient groups. The 'MCI/D A+' group showed the highest fibril prevalence at 68.0 ± 14.1%. Different cutoffs of fibril prevalence accurately differentiated the healthy group from the patient groups with an accuracy ranging from 0.95 - 1.0 and AUC from 0.98 - 1.
Conclusions: Fibril aggregation on RBCs may serve as a potential biomarker for neurodegenerative diseases, though its specificity for AD remains uncertain. Combining AFM with chemical spectroscopy could enhance diagnostic precision, but further research is essential.

VALIDATION OF A NOVEL, LYSOSOME-FOCUSED, MULTIPARAMETRIC BIOMARKER PLATFORM FOR ALZHEIMER'S DISEASE

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Adam Shellard, Owen Connolly, Hernando M. Vergara, Florence Young, Souvik Modi
Esya Labs, R&d, London, United Kingdom

Aims: Biomarker development in Alzheimer's Disease (AD) has relied on techniques such as neuroimaging and proteomics to investigate tauopathy and amyloidosis. However, multiple studies show that lysosomal dysfunction is associated with AD by regulating both the formation and degradation of Aβ. To leverage this paradigm shift in our understanding of AD pathology, Esya's aim is to use a multiparametric approach that combines lysosomal two ion-mapping technology, an RNA panel and plasma biomarkers for early detection of AD.
Methods: Esya's multiparametric platform incoporates 1) 2-ion probes that ratiometrically measure concentrations of ions such as H^+ and Ca^{2+} with single lysosome resolution 2) ApoE genotyping 3) a panel comprising 12 RNA targets identified through RNA-Seq and 4) plasma biomarkers. The diagnostic utility of our platform was assessed through application to blood plasma analytes, and fibroblasts from a clinically diagnosed cohort comprising controls and patients diagnosed with AD, frontotemporal dementia, Parkinson's, and Huntington's disease. A model probability score of predicting AD was calculated using a logistic binary regression.
Results: The diagnostic power of Esya's platform is improved by addition of a custom RNA panel, ApoE genotyping and blood plasma analytes to our pre-existing 2-ion model. Logistic regression demonstrates that the assay is accurate in differentiating AD from controls. This was further validated using an independent sample set comprising AD and non-AD samples. The platform's accuracy of differentiating between AD and non-AD samples is >90%.
Conclusions: The multiparametric approach described here that incorporates four independent features accurately differentiates AD from non-AD dementias. This technology can be further optimised and applied to other neurological disorders and will allow Esya to develop a more accurate platform for diagnostics, drug discovery for organellar dysfunction and personalized medicine in neurology.

BLOOD-BASED BIOMARKERS AND COGNITIVE PROFILING AS EARLY INDICATORS OF ALZHEIMER'S DISEASE PATHOLOGY IN INDIVIDUALS WITH MEMORY COMPLAINTS

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Anuschka Silva-Spínola[1], Diogo Damas[2], Diana Duro[2], Marisa Lima[2], Maria João Leitão[3], Miguel Tábuas-Pereira[2], João Durães[2], Isabel Santana[2], Inês Baldeiras[1]
[1]University of Coimbra, Faculty Of Medicine, Coimbra, Portugal, [2]Coimbra University Hospital, Neurology, Coimbra, Portugal, [3]Center for Innovative Biomedicine and Biotechnology, Neurochemistry Lab, Coimbra, Portugal

Aims: In this work, we explored the associations between blood Alzheimer's disease (AD) biomarkers and comprehensive neuropsychological data in a cohort of individuals with memory complaints, characterized by their cerebrospinal fluid (CSF)-AD biomarkers profile.
Methods: We studied a prospective group of 73 non-demented individuals (67 years of median age, 67% female) with memory complaints followed at Coimbra University Hospital, with available CSF-AD biomarkers. Our measures consisted of baseline neuropsychological scores (encompassing orientation, episodic and working memory, language, abstract reasoning, executive and visuospatial function, learning, and verbal fluency) and plasma/serum AD biomarkers (Aβ42, Aβ40, t-tau, p-tau181, NfL and GFAP), determined by Single Molecule Array (SiMoA). As a measure of AD pathology, individuals were classified by their amyloid status (A) using the CSF Aβ42/Aβ40 ratio.
Results: When comparing A+ (n=30) and A- individuals (n=43), we observed significant differences in normative z-scores for confrontation naming and cube copy tests (p=0.019; p=0.043). A+ individuals had significantly higher levels of serum GFAP and plasma p-Tau181, as well as lower levels of plasma Aβ42, Aβ40 and Aβ42/40 ratio. They showed significant ($p<0.01$) moderate negative associations between serum GFAP levels and the previously mentioned tests (ρ=-0.53; ρ=-0.45), as well as with token (ρ=-0.47) and trail making section B (ρ=-0.52) tests. In contrast, these associations were very weak in A- individuals. Furthermore, our multinomial logistic regression model identified plasma p-Tau181 (β=1.72, p=0.007), serum GFAP (β=0.02, p=0.01) and confrontation naming (β=1.18, p=0.05), as independent significant predictors of amyloid status.
Conclusions: Our cohort displays a distinct pattern of deficits encompassing attention, working memory, and visuospatial function, which, in combination with blood GFAP and p-Tau181, emerged as early indicators of AD pathology.

LARGE-SCALE PLASMA PROTEOMIC PROFILING OF AMYLOID BETA POSITIVITY IDENTIFIES A ROBUST SET OF BIOMARKERS FOR EARLY DETECTION OF CLINICAL ALZHEIMER'S DISEASE

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Gyujin Heo, Muhammad Ali, Jigyasha Timsina, Menghan Liu, Lihua Wang, Carlos Cruchaga, Yun Ju Sung
Washington University School of Medicine, Department Of Psychiatry, St. Louis, United States of America

Aims: Several non-invasive plasma biomarkers for Alzheimer's disease (AD) show promise for routine clinical uses for early detection of amyloid beta (Aβ) positivity and for guiding AD treatment decisions. This study aimed to examine plasma proteins for their relevance in predicting Aβ positivity and clinical AD and monitoring disease progression.
Methods: We obtained approximately 7,000 proteins (SomaScan) from 2,916 plasma samples and performed differential abundance analysis. We examined Aβ positivity (638 Aβ+ vs. 908 Aβ-) and clinical AD status (685 AD vs. 685 cognitively normal) in separate data. We then developed a prediction model for clinical AD diagnosis. Protein-protein interaction network analysis using STRING and enrichment analysis with gene ontology were performed to understand the biological significance of the identified proteins.
Results: We identified 109 differentially abundant proteins with Aβ positivity and 148 with clinical AD status at FDR < 0.05. 20 proteins (including NEFL, SPC25, ACHE, CPLX1, and CPLX2) were associated with both outcomes in the same direction. The predictive model based on these 20 proteins achieved area under the curve (AUC) values of 0.714 in clinical AD status dataset and 0.759 in Aβ positivity dataset. With the use of 20 proteins, prediction model provided an AUC of 0.882 in cerebrospinal fluid data. Protein network analysis revealed interactions among multiple proteins (ACHE, CRP, PLA2G7, and STX1A) and key AD proteins (APP, APOE, and MAPT). Pathway analysis emphasized biological processes related to synaptic function (synaptic vesicle membrane organization, FDR=2.54E-03; regulation of neurotransmitter transport, FDR=2.18E-02).
Conclusions: We identified 20 plasma proteins as potential biomarkers for clinical AD diagnosis, highlighting the role of synaptic dysfunction in AD pathogenesis. The validation of our findings in additional samples and their relevance for tau pathology is underway.

EXPLORING AGE-RELATED ALTERATIONS IN LOCUS COERULEUS ANATOMICAL AND FUNCTIONAL CONNECTIVITY WITH DEEP LEARNING

POSTERS: A04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Blanca Zufiria Gerboles[1], Dániel Veréb[1], Jiawei Sun[1], Giovanni Volpe[2], Joana Pereira[1]
[1]Karolinska Institutet, Department Of Clinical Neuroscience, Stockholm, Sweden, [2]University of Gothenburg, Department Of Physics, Soft Matter Lab, Gothenburg, Sweden

Aims: The locus coeruleus (LC) is a structure in the brainstem responsible for producing and releasing noradrenaline in the brain. Although the LC sends widespread axonal projections to many brain regions, how these connections change across aging remains unclear. To address this question, we studied the anatomical and functional connections of the LC on diffusion-weighted and functional magnetic resonance imaging in 640 cognitively normal individuals between 18 and 88 years old.
Methods: We generated individual anatomical and functional connectivity vectors with probabilistic tractography and seed based analysis, respectively, using the regions of the Brainnectome atlas. To investigate the effects of aging on the LC connections we used a well-established deep learning architecture (multilayer perceptron).
Results: Two models were successfully trained to predict age using the anatomical (r2=0.331±0.113) and functional (r2=0.211±0.096) connectivity independently. Additionally, we developed a joint model combining anatomical and functional connectivity that outperformed the previous models in the prediction of age (r2=0.382±0.085). By employing a feature importance approach, we identified the most predictive connections and we calculated their Spearman's rank correlation (rs) with age. Anatomical connections significantly decreased with age and were located in the frontal lobe (rs = - 0.46,p- value=2.98e-34), bilateral thalami (left rs = -028,p-value=2.32e-13;right rs = -0.27,p-value=5.82e-12), left caudate (rs = -0.3,p-value=9.92e-15), left amygdala (rs = -0.3,p-value=6.77e-15) and right hippocampus (rs = -0.24, p-value=2.81e-10). Functional connections significantly increased with age in the temporal lobe (rs = 0.18,p-value=1.94e-06) and significantly decreased in frontal (rs = -0.16,p-value=3.05e-05), limbic (rs = -0.14, p-value= 0.0003) regions and right thalamus (rs = -0.18,p-value=2.27e-06).
Conclusions: Our study provides new insights into the anatomical and functional neural mechanisms underlying aging in LC and demonstrates the potential of deep learning to investigate brain connectivity patterns.

Aims: Emerging evidence suggests that impaired microcirculation contributes to Alzheimer's disease (AD) pathology exaggerating neurodegeneration due to a limited supply of nutrients and oxygen to affected brain areas. This may require the adaptation of red blood cells (RBC) to squeeze through narrowed capillaries in the microcirculatory bed. Here, we hypothesized that, in AD patients, RBCs are undergoing modifications in the expression and function of calcium-permeable mechanosensitive Piezo1 channels which control the flexibility of these cells.
Methods: To assess the function of Piezo channels, we either measured using a flow cytometry assay, Yoda1-induced Piezo1-mediated calcium responses in RBCs of healthy individuals, patients with mild cognitive impairment, and AD patients or tested the physical properties of the RBCs with a novel micropipette aspiration technique.
Results: RBCs obtained from patients with MCI and AD patients showed significantly higher calcium responses to the Piezo agonist Yoda1, compared to RBCs from age-matched healthy individuals suggesting enhanced function of Piezo1 channels in AD pathology. RBC membrane incubated with Aβ showed significantly higher activated pressure during aspiration and a decrease in the ability to withstand changes in the length during deformation implying that the blood level of this AD-associated peptide can control the function of Piezo1 channels in RBC.
Conclusions: Together, our data suggest a significantly altered function of Piezo1 channels in peripheral circulation which might be an adaptive reaction to the impaired microcirculation, and therefore, Yoda1 elicited activation of Piezo1 in RBCs may be used as a functional biomarker for early AD.

YOUNG-ONSET ALZHEIMER'S DISEASE (AD) DIFFERS IN INFLAMMATORY PROFILE FROM LATE-ONSET AD: A PROTEOMICS APPROACH

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Simrika Thapa[1], Chloe Anastassiadis[2], Anna Vasilevskaya[2], Mohsen Hadian[1], Patrick Salwierz[2], Faiza Robbani[2], Foad Taghdiri[2], Pia Kivisäkk[3], Bradley Hyman[3], Steven Arnold[3], Martin Ingelsson[1], Andres Lozano[1], David Tang-Wai[1], Maria Tartaglia[1]

Aims: Neuroinflammation is involved in Alzheimer's disease (AD) pathophysiology, including young-onset AD (YOAD) and late-onset AD (LOAD) subtypes. Limited post-mortem studies show a hyper-reactive immune response in YOAD compared to LOAD. Our aim was to investigate whether distinct neuroinflammatory profiles exist in YOAD and LOAD and their relationship to neurodegeneration markers.
Methods: We measured 737 inflammatory proteins in cerebrospinal fluid (CSF) from 90 AD [57 YOAD: mean age 60.84, %female 70; 33 LOAD: mean age 76.55, %female 55], and 26 healthy controls (HC: mean age 63.92, %female 46) using Olink's proximity extension assay. ANCOVAs, adjusted for age and sex, were used to compare inflammatory protein levels among the groups (FDR-corrected). To assess the link between inflammatory markers and neurodegeneration, we ran multiple linear regression analyses with an interaction of inflammatory markers by disease group as independent variable, and neurofilament light chain (NfL) as dependent variable.
Results: Comparing biomarkers of AD (Aβ42, p181-tau, total-tau), neuroaxonal injury (NfL), and astrogliosis (GFAP) across groups, only Aβ42 level differed significantly between YOAD and LOAD (mean=361.92 vs 456.21pg/mL, $q<0.05$). YOAD exhibited a significant elevation in twenty-six inflammatory proteins involved in extracellular matrix regulation, neuroprotection, signal transduction, synapse maintenance, and immune regulation compared to HC CSF ($q<0.05$). In LOAD, only two proteins (SCRN1 and MMP10) were significantly elevated compared to HC ($q<0.05$). Interestingly, among 72 proteins that showed a significant interaction of protein levels by AD-subtype on NfL, for 40 proteins LOAD displayed a positive linear relationship with NfL, while YOAD showed a negative linear relationship.
Conclusions: YOAD and LOAD patients display distinct inflammatory profiles with diverging relationships between markers of inflammation and neurodegeneration. Future analysis will investigate the effect of markers in clinical phenotype.

Aims: Blood biomarker analyses have become a valuable method to identify Alzheimer's disease (AD) related pathology. Identification of the pre-analytical factors that may alter blood biomarker concentration is critical for their implementation in clinical practice. This study aimed to evaluate the impact of fasting condition on the concentration of common plasma biomarkers used to detect AD pathology and neurodegeneration.
Methods: Plasma samples were obtained from 16 participants of the ALFA cohort under fasting (F) and non-fasting (NF) conditions. We measured plasma concentrations of Aβ40, Aβ42, NfL, GFAP and pTau181 in a Simoa HD-X analyser using the N4PE and the pTau181 v2.1 advantage kits (Quanterix). Aβ positivity was established using a previously defined CSF Aβ42/40 ratio cut-off.
Results: Plasma concentrations of Aβ40 and Aβ42 were lower in samples obtained under F conditions than NF ones independently of their amyloid status, but such effect was not observed in plasma Aβ42/40 ratio. No differences in the plasma concentration of GFAP, NfL or pTau181 were detected between F and NF conditions. The performance of the different markers to discriminate amyloid positivity was similar across fasting conditions. Concordance analysis (Bland-Altman test) between fasting status showed biases of less than 10% in all markers except for GFAP (16%).
Conclusions: These results indicate that the quantification of the canonical blood biomarkers for AD are not affected by the fasting condition except for the Aβ quantification, which can be overcome when considering the Aβ42/40 ratio. Importantly, pTau181, the marker that could best predict amyloid pathology, was not influenced by fasting conditions. Further studies in larger data sets will be needed to assess the impact of fasting conditions and on novel blood biomarkers developed for AD.

DEVELOPMENT AND OPTIMIZATION OF A HOMEBREW ASSAY FOR THE QUANTIFICATION OF DYRK1A LEVELS IN BODY FLUIDS FROM HUMAN AND RODENTS

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Idil Yuksekel[1], Daniella Victorino[1], Jean Delabar[1], Nicolas Villain[1,2], Kaj Blennow[1,3,4], Marie-Claude Potier[1]
[1]Sorbonne Université, INSERM U1127, CNRS 7225, Paris Brain Institute - Icm, Paris, France, [2]Hôpital Pitié-Salpêtrière, Département De Neurologie, Paris, France, [3]University of Gothenburg, Department Of Psychiatry And Neurochemistry, Institute Of Neuroscience And Physiology, The Sahlgrenska Academy At The University Of Gothenburg, Mölndal, Sweden, Molndal, Sweden, [4]Sahlgrenska University Hospital, Clinical Neurochemistry Laboratory, Mölndal, Sweden

Aims: Dual Specificity Tyrosine Phosphorylation Regulated Kinase 1A (*DYRK1A*) plays a role in Alzheimer's disease (AD) pathology. DYRK1A level increases with age in humans, whereas we have previously shown that individuals with AD, dementia, Down Syndrome or tauopathies have decreased plasma DYRK1A levels compared to controls. So far, we have been using Meso Scale Discovery (MSD) technology for assessing DYRK1A levels in different matrices. We now aim to implement our DYRK1A immunoassay in ultrasensitive single-molecule array (SIMOA HD-X platform), especially considering recent advances in the AD field regarding assessment of low concentrations of biomarkers in brain-derived exosomes isolated from blood.
Methods: In this study, antibody pairs and calibrators were evaluated, efficiency of the prepared beads and detectors were measured. Using the SIMOA technology; 2 step vs 3 step assay, detector antibody concentrations, buffers, diluents, sample volume effect and several dilution factors were tested.
Results: Currently, our DYRK1A homebrew assay is a 2-step digital immunoassay for the quantification of DYRK1A levels in plasma isolated from humans and rodents. Using the B diluent in our assay yielded higher percentage of recovery after spiking with 4 and 40pg/ml of DYRK1A (compared to Homebrew and A-E Sample Diluents, Quanterix).
Conclusions: At this point, our findings show a lack of dilution linearity and a low % of spike recovery in mice samples, which suggest a potential matrix effect. We expect to address this issue by optimizing assay conditions, such as adjusting the concentration of the agents and testing additional dilution factors. Once met the required acceptance criteria specified in our validation plan, our homebrew assay will be used for the quantification of DYRK1A levels in plasma longitudinally collected from newly generated mouse models of AD in our research team.

Aims: To assess blood-based levels of a circulating prefibrillar amyloid population to differentiate brain amyloid positivity in subjects across the Alzheimer's disease (AD) spectrum and to evaluate the APEX platform as a tool to facilitate AD disease diagnosis and monitoring.
Methods: Leveraging our discovery that prefibrillar beta-amyloid(Aβ) protein preferentially associates with extra-cellular vesicles (EVs), we have developed a dedicated detection platform, Amplified Plasmonic EXosome (APEX) that is size-matched for the enhanced detection of EV-associated prefibrillar Aβ directly from blood plasma, without a need for pre-enrichment, preserving the native association of the protein. Not achievable with conventional technologies, APEX uses Transmission Surface Plasmon Resonance to enhance the signal of an immunoassay and enables the direct detection of low circulating levels of intact EV-associated prefibrillar Aβ. We prospectively collected blood plasma from 18 subjects across the AD spectrum who were amyloid-PET positive by PET imaging of amyloid deposition in the brain and 15 age-matched healthy subjects who were amyloid-PET negative. Using the APEX technology, we measured the EV-associated Aβ levels in all samples and correlated them to brain Aβ PET status.
Results: Direct APEX measurements of an EV-associated prefibrillar Aβ biomarker showed high correlation (AUC >0.85) with amyloid brain deposition as determined by PET imaging. The biomarker measurements also showed a PPV of 80% and an NPV of >80%. One limitation of this study was a small sample size. Future work will include evaluation of an expanded clinical cohort.
Conclusions: We have developed APEX platform that is capable of detecting low levels of circulating EV-associated prefibrillar Aβ biomarker in blood. With this, we have demonstrated that measurements of blood-based prefibrillar Aβ biomarker can accurately differentiate brain amyloid positivity determined by PET imaging in a second cohort.

Aims: Traumatic brain injury (TBI) is associated with increased risk of dementia, suggested of the Alzheimer's disease (AD) type. It remains unknown if AD pathophysiology is influenced by TBI history. Here, we investigate whether history of TBI modifies the biological characteristics or cognitive trajectories in AD.
Methods: We included 1:1 matched AD patients with TBI history (ADTBI+, n=110), or without (ADTBI-, n=110), with mild cognitive impairment (MCI) or dementia. Baseline CSF was measured for amyloid beta-42 (Aβ42), total-tau (Tau), phosphorylated tau-181 (PTau181), neurofilament light (NfL), synaptosomal associated protein-25 (SNAP25), neurogranin (Ng), neuronal pentraxin-2 (NPTX2) and glutamate receptor-4 (GluR4). Group differences in biomarkers were calculated. Longitudinal cognition was assessed with neuropsychological test batteries. Baseline cognitive performance and cognitive changes over time were assessed with linear mixed models for MMSE and four cognitive domains, measuring the effect of TBI history and the interaction with biomarker concentrations. Exploratory, ADTBI+ was stratified by number of years since latest TBI; ≤5 years (TBI≤5yrs) or >5 years (TBI>5yrs) and analyses were repeated.
Results: No differences in baseline CSF biomarker levels or cognitive performance were detected between ADTBI+ and ADTBI- patients (Table 1). There were also no differences in cognitive trajectories (Table 2). Combinations of TBI history and high levels of Ptau181 (B=-0.117, p=0.021) or Ng (B=-0.154, p=0.002) were associated with greater attention decline over time (Figure 1, Table 2). TBI≤5yrs had lower NPTX2 concentrations compared to TBI>5yrs (p=0.027), but not compared to ADTBI- patients (Figure

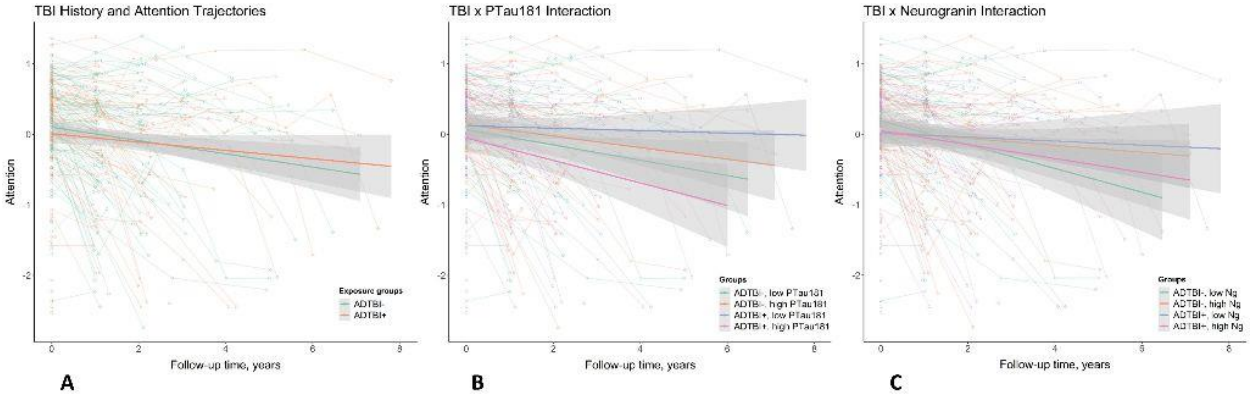
TBI x NPTX2 x Time	0.028 (0.038)	0.018 (0.043)	-0.092 (0.050)	-0.050 (0.043)	-0.022 (0.051)
TBI x GluR4 x Time	0.049 (0.045)	0.040 (0.064)	-0.095 (0.071)	-0.020 (0.062)	0.034 (0.073)

Note. Changes in MMSE and cognitive composite scores between AD patients with TBI history compared to AD patients without TBI history (Model: TBI x Time), as well as the interaction between TBI history and biomarker concentration (Model: TBI x biomarker x Time). Models included years of education as covariate. Data is presented with standardized beta (B) and standard errors (SE). * **p<0.05**, ** **p<0.01**

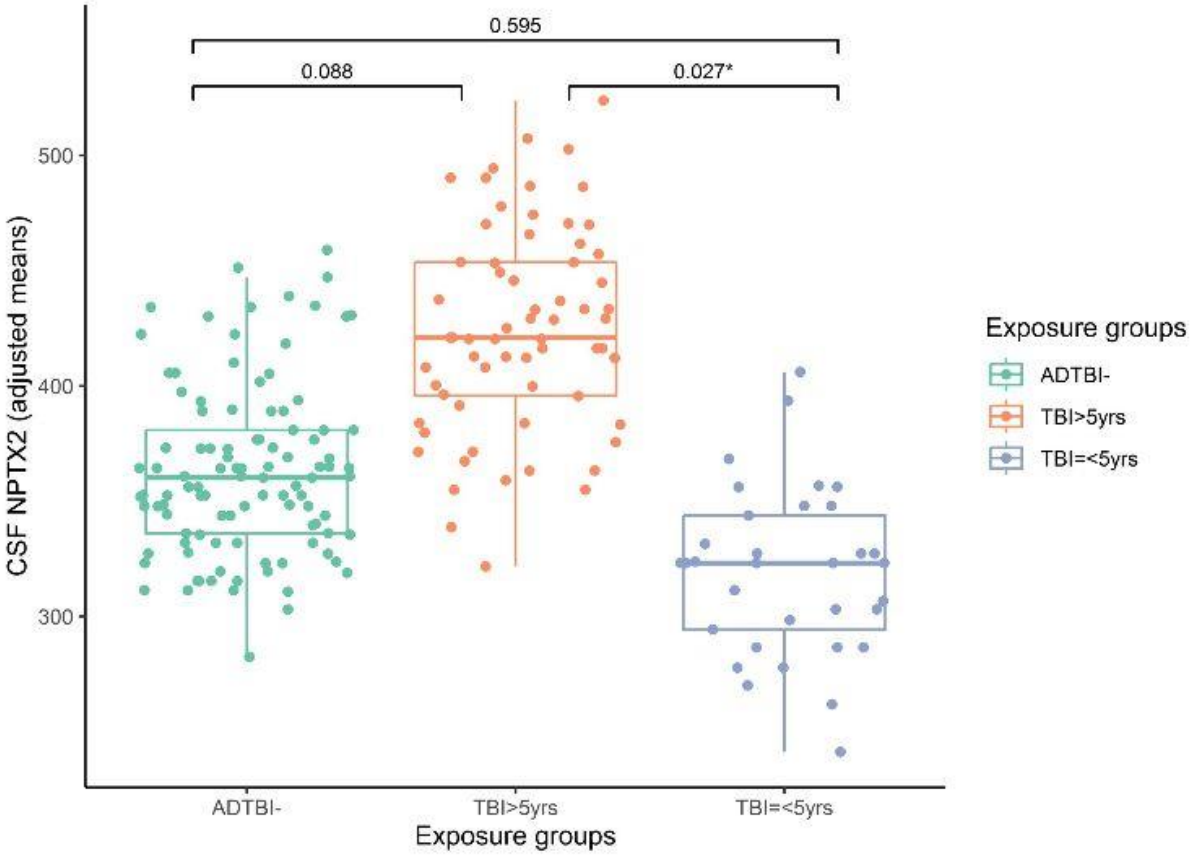
Conclusions: The link between TBI history and stronger attention decline in AD appeared to be dependent on more severe p-tau pathology and synaptic dysfunction. A recent TBI in AD patients was associated with different biological characteristics but not cognitive characteristics than a remote TBI.

Figure 1. Trajectories of Attention



Note. Attention decline over time visualized with spaghetti plots. Four groups were created by median splits of biomarkers concentrations. No differences in decline were seen between ADTBI- and ADTBI+ groups (Figure 1A), but the interaction between TBI and PTau181 (Figure 1B) or Neurogranin (Figure 1C) was significant..

Figure 2. Group differences in NPTX2 concentrations



Note. Differences in baseline NPTX2 concentrations in CSF among ADTBI-, TBI>5yrs, TBI≤5yrs groups. Group differences were assessed using analysis of covariance (ANCOVA), including covariates age, sex, and disease stage, and presented with adjusted means.

Aims: Mitophagy impairment has been identified as an important pathophysiological hallmark of Alzheimer's disease (AD) in animal models, cell models, and brain biopsies of AD. However, whether these changes are reflected in the biofluids of individuals with AD and non-AD pathologies and whether these changes are associated with AD-related phenotypes remains unknown.
Methods: We evaluated levels of mitophagy markers (ULK1, PINK1, BNIP3L, TFEB) in cerebrospinal fluid and serum samples from 300 biomarker-defined individuals with AD, with frontotemporal lobar degeneration (FTLD) and cognitively unimpaired individuals (CU) from the Czech Brain Aging Study. Levels of mitophagy markers were correlated with biomarker, cognitive, and brain atrophy profiles.
Results: We identified increased levels of CSF PINK1 in AD dementia compared to MCI-AD (p<.001) and CU individuals (p<.001). Also, the levels of serum BNIP3L were higher in AD dementia compared to other groups (p=0.020). In contrast, serum TFEB levels were decreased compared to MCI-AD (p=0.033) and CU (p=0.040). In FTLD, there was a significant increase in CSF ULK1 and serum TFEB levels compared to AD (p**<.**05). Additionally, the CSF PINK1 levels correlated with AD biomarkers and cognition.
Conclusions: Our study highlights compromised mitophagy in the AD continuum reflected by increased levels of PINK1 and BNIP3L (mitophagy activators) and reduced levels of TFEB (a master regulator of lysosomal biogenesis) in biofluids of AD individuals, suggesting an impairment in the final stage of autophagy. We also found a significant increase in ULK1 and TFEB in FTLD compared to AD, suggesting a different role of mitophagy in the sub-type of neurocognitive disorders. Moreover, our data indicate that mitophagy impairment is associated with advanced AD pathology demonstrated by increased positivity of AD biomarkers, severity of ATN profile, and cognitive impairment.

UNDERSTANDING THE IMPLICATIONS OF DYRK1A OVEREXPRESSION FOR ALZHEIMER'S DISEASE PATHOGENESIS IN PRECLINICAL MOUSE MODELS: A CROSS-SECTIONAL AND LONGITUDINAL STUDY

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Daniella Victorino, Idil Yuksekel, Domitille Des Robert, Jean Delabar, Marie-Claude Potier
Paris Brain Institute - ICM, Alzheimer And Prion's Diseases Team, Paris, France

Aims: Individuals with Down syndrome (DS) have an increased risk of early-onset Alzheimer's disease (AD) and dementia. The overexpression of the Dual Specificity Tyrosine Phosphorylation Regulated Kinase 1A (DYRK1A) gene, which is located on chromosome 21, has been hypothesized to play a role in this process. We showed that individuals with AD have decreased plasma levels of DYRK1A compared to controls, as well as DS individuals with dementia compared to those without dementia. However, it is not clear yet whether peripheral levels of DYRK1A are modulated by the progression of AD-related processes in the brain.
Methods: To address gaps in knowledge, we crossed AD mouse models with mice overexpressing DYRK1A, wherein wild-type mice, mice expressing either APP23 or P301S mutation only, mice overexpressing DYRK1A only, and mice that express either APP23 or P301S mutation and overexpression of DYRK1A have been studied.
Results: Starting at 5 months of age, mice carrying both APP23 and DYRK1A transgene show decreased body weight compared to those carrying only APP23 transgene. Similar findings were observed for mice carrying both P301S and DYRK1A transgene compared to those carrying only P301S transgene at 6 months of age. From 2 to 10 months of age, mice have been subjected to monthly plasma sampling for the longitudinal characterization of AD biomarkers by using SIMOA (undergoing analysis). Cross-sectional mouse cohorts at different ages will also be used to assess the association between plasma levels of AD biomarkers and AD-related neuropathology, as well as behavioral deficits by using several tasks (undergoing experiments).
Conclusions: A better understanding of AD pathogenesis is of paramount importance to accelerate biomarker discovery for early detection of AD in at-risk individuals and potential identification of pharmacological targets.

Aims: The identification of biomarkers for Alzheimer's disease (AD) remains a significant challenge, particularly for the clinical severity of the disease. Recent studies have shown that plasma brain-derived-tau (BD-Tau) could be a promising biomarker for the identification of AD-type neurodegeneration. This study aimed to investigate the potential of BD-Tau in differentiating various clinical stages of AD, ranging from cognitively unimpaired AD to severe dementia AD. Additionally, the study intended to examine the association of BD-Tau with clinical severity and elucidate its dynamic behavior throughout the natural course of AD.
Methods: Cross-sectional and longitudinal EDTA plasma data, along with clinical information, were utilized from the Pitié-Salpêtrière hospital INSIGHT (cognitively unimpaired individuals with amyloid PET) and SOCRATES cohorts (AD and non-AD symptomatic neurodegenerative disease according to up-to-date international criteria). Plasma BD-Tau was analyzed using the Gothenburg University homebrew Quanterix Simoa immunoassay.
Results: The results revealed that BD-Tau is only elevated in individuals with symptomatic AD, whether the primary or secondary neurodegenerative disease, and not in other neurodegenerative conditions. Additionally, BD-Tau follows the clinical dynamics of AD, as it is only elevated in symptomatic AD patients, while individuals with AD biological changes but no symptoms have normal levels of BD-Tau. BD-Tau levels were also found to be significantly correlated with episodic memory scores and global cognitive performance across a wide range of AD severity. Longitudinal analyses further support BD-Tau's potential as an AD-type neurodegeneration biomarker, as it was found to increase over time only in the symptomatic AD group and not in other groups.
Conclusions: These results support the notion that plasma BD-Tau could be a promising specific biomarker for AD staging, as it follows the AD clinical severity spectrum and is not elevated in asymptomatic amyloidosis.

CSF ERBB4: A CANDIDATE FOR THE SYNAPTIC BIOMARKERS TOOLBOX IN ALZHEIMER'S DISEASE

POSTERS: A04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Agathe Vrillon[1], François Mouton-Liger[1], Elodie Bouaziz-Amar[1], Nicholas Ashton[2], Kaj Blennow[2], Henrik Zetterberg[2], Jacques Hugon[1], Claire Paquet[1]
[1]Inserm U1144, Therapeutical Optimization In Neuropsychopharmacology, Paris, France, [2]University of Gothenburg, Department Of Psychiatry And Neurochemistry, Molndal, Sweden

Aims: The expression of the post-synaptic tyrosin kinase receptor ErbB4 has been shown to be modified in the AD brain. The objective of our study was to explore CSF ErbB4 levels as a synaptic biomarker for AD.
Methods: This retrospective study included 206 patients with AD dementia (n=67), MCI related to AD (AD-MCI) (n=41), non-AD MCI (n=40), non-AD dementia (n=32), and neurological controls (n=26). CSF ErbB4 levels were measured using a commercial ELISA kit. We explored correlations with CSF core AD biomarkers, synaptic markers GAP-43 and neurogranin, and cognitive status evaluated with MMSE, as well as MMSE change over time for a subgroup of cases (n=139).
Results: CSF levels of ErbB4 were significantly increased in AD (mean: 1130 pg/mL, P=0.001) and AD-MCI (mean: 1122 pg/mL, P=0.002) versus neurological controls (mean: 843.7 pg/mL), after adjustment on age and sex. Amyloid positive patients displayed higher CSF ErbB4 levels than amyloid-negative patients (952.4 pg/mL versus 1127 pg/mL, P=0.004). CSF ErbB4 correlated with core AD biomarkers in the whole cohort (Aβ ratio: r=-0.297, p-tau: r=0.491, t-tau: r=0.520) and in the amyloid-positive patients (Aβ ratio: r=-0.241, p-tau: r=0.397, t-tau: r=0.432). CSF ErbB4 levels were associated with CSF GAP-43 and neurogranin levels (r=0.531 and r=0.340 respectively, P<0.001). In a subgroup of n=139 patients, higher CSF ErbB4 concentration at baseline associated with higher MMSE decline over time (P=0.082).
Conclusions: CSF ErbB4 levels were increased in AD and AD-MCI, and were associated with core AD biomarkers, CSF synaptic markers and cognitive decline. Thus, CSF ErbB4 could have potential for monitoring synaptic demise and cognitive status in AD.

Hussman Institute For Human Genomics, Miami, United States of America, [4]University of Miami Miller School of Medicine, The Dr. John T. Macdonald Foundation Department Of Human Genetics, Miami, United States of America, [5]Case Western Reserve University, Department Of Nutrition, Cleveland, United States of America, [6]Case Western Reserve University, Genetics And Genome Sciences, Cleveland, United States of America, [7]University Hospitals Cleveland Medical Center, Neurology, Cleveland, United States of America, [8]Case Western Reserve University, Neurology, Cleveland, United States of America

Aims: This study aims to examine the heritability of core AD plasma biomarkers in the Old Order Amish, including the 42- and 40-residue forms of amyloid beta (Aβ40, Aβ42), Aβ42/Aβ40, total tau (tTau), and phosphorylated tau 181 (pTau181), and the association of these plasma biomarkers with AD in the Old Order Amish.
Methods: Plasma biomarker concentrations were measured for 1,169 Old Order Amish individuals from Ohio and Indiana using Simoa™ Neuro-3Plex, 4Plex, and pTau181 Advantage V2 assays. Logistic regression was applied to model each plasma biomarker's effect on AD phenotype, adjusting for study center, age, sex, and APOE4 allele count. Controlling for the same covariates and diagnosis, a variance component model was used to calculate pedigree-based heritability. SNP-based heritability was estimated by QuantHer using individual-level genotype data with covariates as above.
Results: Compared to unimpaired individuals, individuals with AD had lower plasma Aβ42 (6.5 ± 3.8 pg/mL, $p = 0.014$) and higher plasma pTau181 levels (2.3 ± 1.3 pg/mL, $p = 0.01$). In multivariate regression models, decreasing plasma Aβ42 (OR = 0.52, $p < 0.001$) and increasing pTau181 (OR = 1.86, $p = 0.001$) were associated with AD risk. Pedigree-based heritability estimates were: Aβ40 = 23.2%, Aβ42 = 26.2%, Aβ42/40 = 20.8%, tTau = 5.7%, pTau181 = 29.3%. The SNP-based approach yielded lower heritability for all biomarkers (Aβ40 = 16.4%, Aβ42 = 12.5%, Aβ42/40 = 7.4%, tTau = 2.4%, pTau181 = 19.4%).
Conclusions: Plasma Aβ42 and pTau181 are associated with the risk of AD in the Old Order Amish. We found plasma biomarkers are highly heritable and may serve as surrogate markers of AD pathology to study the genetics of AD.

Aims: To demonstrate the utility of selected reaction monitoring mass spectrometry (SRM-MS) for clinical assessment of cerebrospinal fluid (CSF) proteins reflective of Alzheimer's disease (AD).
Methods: We developed an SRM-MS method with isotopically labeled standards for relative protein quantification in CSF to find protein biomarkers that are robustly measured and related to AD. Two pools of CSF were generated based on Amyloid-Beta and Tau immunoassay levels to create AD-positive and AD-negative quality control (QC) standards. The QC pools were processed and analyzed identically to the CSF clinical samples reported. CSF samples from two separate cohorts, Emory Goizueta ADRC and affiliated Emory Healthy Brain Study (EHBS; 133 controls, 127 asymptomatic AD, 130 symptomatic AD) and Alzheimer's Disease Neuroimaging Initiative (ADNI; N=706), were analyzed using SRM-MS to examine the clinical utility of targeting a novel CSF protein panel.
Results: We found approximately 50 proteins in each cohort that were precisely measured (coefficient of variation <20%). The EHBS cohort was used to determine which proteins could distinguish CSF biomarker positivity (SMOC1, GDA, 14-3-3 proteins, glycolysis-involved proteins) and cognitive impairment (neuronal proteins; VGF, NPTX2, NPTXR, SCG2). Utilizing the power of ADNI as a longitudinal study, we found that the SRM biomarker proteins could independently predict Amyloid-Beta and Tau status, and disease state with 97% and 94% accuracy, respectively. Furthermore, by combining Amyloid-Beta, Tau, and SRM biomarkers, we improve the prediction accuracy for cognition, disease severity, and neurodegeneration compared to either measure alone.
Conclusions: We demonstrate the ability to use high-throughput, targeted MS to quantify CSF proteins as different stages of AD and show the targeted CSF protein panel complements existing AD CSF biomarkers to significantly improve diagnosis and predict future cognitive decline and dementia severity.

Aims: Short amyloid beta (Aβ) peptides such as Aβ(1-38) appear to be less neurotoxic in Alzheimer's disease (AD), and may counteract AD neuropathology. However, their effect on AD pathophysiology and disease progression in humans in vivo remains unclear. We investigated whether higher baseline concentrations of CSF Aβ(1-38) compared to Aβ(1-40), Aβ(1-42) and pTau181 are associated with slower cognitive decline and lower risk of conversion to AD dementia within six years.
Methods: 177 participants from the longitudinal, multicenter German DELCODE study with a pathological CSF Aβ42/pTau181 ratio (> 9.68) at baseline were included. Conversion to AD dementia was assessed with the CDR and NINCDS-ARDA criteria and analysed using Cox regression. Cognitive performance was assessed annually for six years with the MMSE and the PACC5. Data on cognitive performance were analysed using model fitting procedures for mixed linear regression (MLR) models, i.e., Likelihood Ratio (LR) testing.
Results: MLR analyses yielded that higher Aβ(1-38) baseline levels were associated with higher PACC scores after three years ($p = .009$) and higher MMSE scores after five years ($p = .003$). Cox regression showed a reduced AD dementia conversion risk ($HR = 0.12$, $p = .037$) for those with higher Aβ(1-38) baseline levels within six years.
Conclusions: Across the AD spectrum, higher Aβ(1-38) levels are associated with slower cognitive decline. This could inform individual risk prediction in memory clinic patients.

Aims: A large body of research has elucidated the potential utility of blood-based biomarkers in Alzheimer's disease (AD). Some studies have investigated the performance of various plasma pTau isoforms utilizing different assays on the Simoa or mass spectrometry (MS) platforms, but only few studies evaluated the performance of both techniques across various tau species. Our aim was to compare the performance of different tau species, measured by both MS and Simoa, in predicting Aβ and tau-PET pathologies
Methods: We included 44 older participants from the TRIAD cohort who underwent Aβ- and tau-PET imaging as well as plasma measurements. We performed receiver operating characteristic curve analyses followed by DeLong test to compare the performance of various p-tau species, including the accuracy of the ratio phosphorylated/non-phosphorylated peptides for p-tau217 and p-tau205, in distinguishing Aβ -and tau-PET positivity
Results: Pearson correlation analyses revealed strong correlations across plasma p-tau231(r = 0.679), p-tau181 (r = 0.637), and p-tau217 (r = 0.587) between Simoa and MS platforms. Plasma p-tau217/non-p-tau (with non-p-tau refers to non-phosphorylated form of the same tau peptide; tau212-221) exhibited the highest AUC, surpassing plasma p-tau217 alone measured through either assay. This marker demonstrated superior performance in predicting Aβ (AUC = 0.955), and tau-PET (AUC = 0.945). Among markers measured using both immunoassays (p-tau181, p-tau231, and p-tau217), there were no significant differences in AUC values, indicating comparable performance between both assays. We also assessed plasma p-tau205, a marker believed to increase along the AD continuum, and found no such differences when using Aβ or tau-PET as outcomes.
Conclusions: Plasma p-tau217/non-p-tau ratio showed a slightly superior performance in predicting AD-related pathologies, as compared with p-tau217 alone, followed by plasma p-tau217 that exhibited comparable accuracy on both Simoa and MS.

Tina Loeffler, Magdalena Daurer, Livia Breznik, Roland Rabl, Stefanie Flunkert, Manuela Prokesch
QPS Austria GmbH, Neuropharmacology, Grambach, Austria

Aims: As an amyotrophic lateral sclerosis (ALS) biomarker, NF-L levels can forecast the conversion from presymptomatic to symptomatic stage and time of survival by analyzing patients CSF or plasma. Recently, first drugs were approved relying on changes in peripheral NF-L levels as primary read-out. Additionally, NF-L can act as translational marker, being a valuable tool in preclinical mouse models of ALS, Alzheimer's (AD), and Parkinson's disease (PD) as well as lysosomal storage diseases. However, a detailed time course analyses of NF-L progression in these mouse models in relation to other disease-relevant markers are still missing.
Methods: We first focused on the analysis of NF-L levels in the plasma and CSF of the ALS mouse model SOD1-G93A low expressor as well as SOD1-G93A high expressor mice bred on a C57BL/6 background at various time points and correlated data with other disease-relevant read-outs such as motor deficits or oxidative stress. Furthermore, also plasma and CSF of the 5xFAD AD model, the Line 61 PD model and the Gaucher disease model 4L/PS-NA was assessed for NF-L at various ages using commercially available ELISA kits, including those from UmanDiagnostics.
Results: NF-L levels are highly increased in the plasma of ALS, AD and Gaucher disease mouse models, while NF-L plasma levels barely changed in the analyzed PD model. Most of the analyzed models show a progressive increase of NF-L levels with age.
Conclusions: NF-L measurements in mouse models of ALS and AD are thus a good tool to evaluate disease progression. Compared to results in human tissues our results suggest that murine NF-L levels and their progression have a high translation value. Furthermore, our data indicate that NF-L might be a good biomarker for diseases with a neuronal component.

Aims: The preclinical phase of AD is characterized by a non-linear evolution of brain connectivity. Our study aimed to investigate alterations in connectivity measures within EEG activity during the process of healthy aging and to understand the connectivity alterations linked to Alzheimer's disease (AD).
Methods: We conducted this exploratory analysis using two different data sets, where we applied Phase-locking value and Magnitude-Square Coherence analysis to resting-state EEG data. The first data set denoted as LEMON dataset (N=162) included participants aged between 20 and 80 years with no disease diagnosis. Furthermore, we applied the same analysis on resting-state EEG recordings (N=220) from individuals aged 60 years and older, categorized into healthy, subjective cognitive decline, mild cognitive impairment, and those diagnosed with AD.
Results: It was observed that healthy aging was linked to heightened connectivity in the Delta and Theta bands, along with diminished connectivity in the Alpha band. On the contrary, individuals with AD exhibited more substantial increases in connectivity across all three bands—Delta, Theta, and Alpha—compared to their cognitively healthy counterparts. Individuals with Mild Cognitive Impairment (MCI) displayed more pronounced increases in connectivity within the Delta and Theta bands than healthy controls, whereas those with subjective cognitive decline shew heightened connectivity only in the Theta band.
Conclusions: These findings collectively suggest the potential of the analyzed connectivity metrics for differentiating among various stages of the disease. Its non-linear nature presents a challenging but exciting opportunity for a more comprehensive characterization of disease progression.

EEG BASED CLASSIFICATIONS OF ALZHEIMER'S DISEASE BY USING MACHINE LEARNING TECHNIQUES

POSTERS: A04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: EEG, BRAIN MAPPING, MEG

Nagarathna C R[1], Kusuma M[2]
[1]BNM Institute of technology, Ai And Ml, Bangalore, India, [2]Dsatm, Ise, Bangalore, India

Aims: Using EEG analysis is contemporary even today to identify the characteristics of brain functioning illnesses, although it is unclear how these characteristics relate to AD. EEG provides non-invasive, cost-effective data with great temporal precision on electrical activity in the brain during neurotransmission as compared to other imaging modalities. Using a DWT to decompose the EEG signal into its frequency sub-bands and by extracting a set of statistical features to represent the distribution of wavelet coefficients, the proposed framework undertook the processing and analysis of EEG. Data dimension reduction techniques comprises of PCA and independent components analysis (ICA). Following this, these attributes were sent into MLP and a SVM that could only produce one of the two outcomes: AD or NC. To demonstrate the superiority of the classification process, there was a need to demonstrate and compare the performance of the process based on various approaches. These results serve as an illustration of how to train and test an AD prediction system using data from specific petit mal epileptic patients. Given the diversity of epilepsy, it is likely that these kinds of technologies are crucial to tailor intelligent devices for treating epilepsy to each person's neurophysiology before practically adopting them
Methods: First pre-process the input EEG signals and use the PCA, ICA and DWT approaches to extract the latent components from the pre-processed signals. Next, the model is trained using more extracted features. Last of all, evaluate the model using the test dataset.
Results:

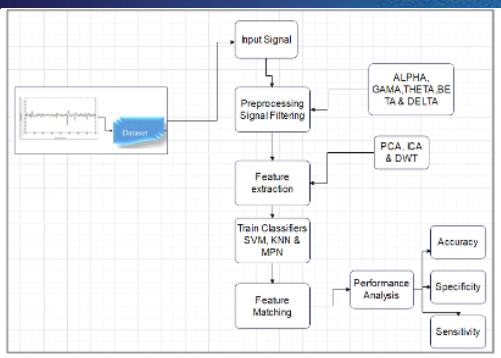

Fig 1 Proposed Model for AD prediction

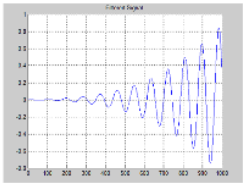

Fig 5 Filtered Signal

The suggested EEG-based AD detection model is depicted in Fig 1.

Conclusions: The proposed model is experimented with SVM, KNN and MLP, among these KNN shows good performance by giving an accuracy of 95%.

RELEVANCE OF SUBCLINICAL EPILEPTIFORM ACTIVITY IN CLINICALLY HEALTHY ELDERLY POPULATION

POSTERS: A04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: EEG, BRAIN MAPPING, MEG

Emoke Anna Csernus[1], Gergő Bolla[2], Viktória Rosenfeld[3], Anita Kamondi[3], Andras Horvath[3]
[1]National Institute of Mental Health, Neurology, Neurosurgery, Neurocognitive Research Center, Budapest, Hungary, [2]Semmelweis University, School Of Phd Studies, Budapest, Hungary, [3]National Institute of Mental Health, Neurology and Neurosurgery, Neurocognitive Research Center, Budapest, Hungary

Aims: Subclinical epileptiform activity (SEA) has been considered of benign etiology and an EEG variant in elderly population. However, epileptiform activity has been associated with decreased cognitive performance, and is a proven marker of progression in Alzheimer's disease. We investigated the relevance of SEA in clinically healthy elderly population with regard to neuropsychological performance and structural neuroimaging.
Methods: We studied 62 elderly subjects determined as healthy based on physical, neuropsychology, neuroimaging(MRI), and serological workup. All subjects underwent 24-h Holter electroencephalography (EEG), visual analysis was conducted by two independent raters. Subjects were classified into EEG positive (EEG+) and negative (EEG-) groups based on detecting epileptiform activity on their EEG. Neuropsychology battery and structural MRI results were compared between the groups.
Results: EEG analysis showed epileptiform activity in 26% of cases. 87% of subjects in the EEG+ group were women (p 0,03). EEG positivity was associated with significantly lower verbal and category fluency subscores on Addenbrook Cognitive Examination (p 0,03 and 0,01). This group also performed worse on both Trail Making A and B Test (p 0,02 and 0,003 respectively). Age and education had a significant effect on neuropsychological performance in both groups. Structural MR analysis showed significant group differences in various areas, particularly in the parietotemporal regions (p 0,001). Interestingly, EEG+ patients had larger temporal brain volume bilaterally (<0,001).
Conclusions: Presence of subclinical epileptiform activity among healthy elderly shows a discrete but significant association with decreased cognitive performance in certain subdomains, as well as bilateral increased brain volume in several temporal areas. Our results underscore the relevance of data suggesting presence of a hippocampal sparing phenotype in Alzheimer's disease and its potential connection to epileptiform activity.

DETECTING COGNITIVE DECLINE IN ELDERLY: AN EEG COMPLEXITY MARKER EVALUATION ON HIGH-DENSITY EEG

POSTERS: A04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: EEG, BRAIN MAPPING, MEG

Víctor Fernández[1], Eleni Kroupi[1], Claire Braboszcz[1], Ioannis Kompatsiaris[2], Spiros Nikolopoulos[2], Ioulietta Lazarou[2], Kostas Georgiadis[2], Vangelis Oikonomou[2], Anthoula Tsolaki[3], Magdalini Tsolaki[4], Aureli Soria-Frisch[1]
[1]Starlab Barcelona S.L., Neuroscience, Barcelona, Spain, [2]ITI, Center For Research And Technology Hellas, Thessaloniki, Greece, [3]Greek Association of Alzheimer's Disease and Related Disorders, Gaadr, Thessaloniki, Greece, [4]Aristotle University of Thessaloniki (AUTh), Greek Association Of Alzheimer's Disease And Related Disorders (gaadrd), Thessaloniki, Makedonia, Hellas. 1st Department Of Neurology, School Of Medicine, Macedonia, Greece

Aims: To evaluate the efficacy of electroencephalographic (EEG) complexity markers, namely Higuchi Fractal Dimension (HFD), Waveform Complexity (Cw), Permutation Entropy (PE), Lempel Ziv Welch (LZW) and Weighted Symbolic Mutual Information (wSMI), for cognitive decline detection in the CERTH-GAADRD High-Density EEG Database, which include subjects at different neurodegenerative stages (N=220).
Methods: The validation dataset includes distinct groups of individuals: healthy controls (HC), subjective cognitive decline (SCD), mild cognitive impairment (MCI), and Alzheimer's disease (AD) patients. First, EEG signals were averaged over various cerebral areas. Complexity markers were then computed on this averaged data and the outliers were eliminated using the Tukey method. Lastly, the discrimination capability of the complexity markers among the groups was statistically analyzed.
Results: revealed consistent patterns across several complexity markers. HFD, Cw, and PE markers showed potential to differentiate between various stages of cognitive decline. These markers excelled statistically in the middle-posterior brain region, unlike LZW and wSMI which did not provide statistical significance.
Conclusions: EEG complexity markers, specifically HFD, Cw, and PE, provide discriminatory power in cognitive decline progression. These markers present a nonlinear evolution with respect to the pathological stage. This behavior is analogous to that observed in other EEG markers, such as connectivity ones.

MEG MEASURED CENTRALITY ALTERATIONS ASSOCIATED WITH ALZHEIMER'S DISEASE PATHOLOGY IN HEALTHY INDIVIDUALS

POSTERS: A04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: EEG, BRAIN MAPPING, MEG

Alejandra García Colomo[1], David López Sanz[1], Ignacio Taguas[1], Martín Carrasco[2], Alberto Nebreda[1], Fernando Maestú[1]
[1]Universidad Complutense de Madrid, Psicología Experimental, Procesos Cognitivos Y Logopedia, Pozuelo de Alarcón, Spain, [2]Universidad Politécnica de Madrid, Department Of Electronic Engineering, Madrid, Spain

Aims: The preclinical stage of Alzheimer's disease (AD) has gained attention for the window of opportunity it opens for early detection and intervention. However, classically used techniques to measure alterations, such as PET and CSF punctures are too invasive to be good candidates for early detection and disease tracking. In this line, electrophysiology and plasma biomarkers show great promise. The aim of this study is twofold. First, to address the relationship between a compound centrality score (CS; i.e., a measure of the relevance of a region within the network) and plasma pathology markers of AD in unimpaired individuals with elevated neurofilament-light chain (NfL) and phosphorylated tau 231 (p-tau231). Lastly, to evaluate whether this association is greater in hubs.
Methods: 33 individuals with available MEG recordings and over-the-median plasma NfL and p-tau231 levels were included. A compound CS for each 1210 brain sources of every subject was calculated combining node strength, betweenness centrality and eigenvector centrality. Spearman correlations were carried out to address the association between each node's CS and plasma biomarkers. Next, to test whether greater associations were found in hubs (i.e., highly central sources) a correlation between the obtained rho and the grand-average of the CS was carried out.
Results: Increasing concentrations of p-tau231 were associated with greater relevance of posterior areas through their theta oscillations and lower relevance of left areas through their gamma oscillations. The most relevant areas are also the ones that present the greatest association between their CS and p-tau231.
Conclusions: The results of this pioneering study are consistent with previous literature and demonstrate early alterations in network communication associated to elevated plasma biomarkers in cognitively unimpaired individuals, particularly in vulnerable areas to AD pathology.

AN APPLE A DAY KEEPS ALZHEIMER'S DISEASE AWAY

POSTERS: A04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: EEG, BRAIN MAPPING, MEG

Alejandra García Colomo[1], Alfredo Trabado-Fernández[2], María Dolores Salas-González[2], Ana Lorenzo-Mora[2], África Peral-Suárez[2], Ester Cuadrado-Soto[2], Aranzazu Aparicio[2], Ana López Sobaler[2], Fernando Maestú[1]
[1]Universidad Complutense de Madrid, Psicología Experimental, Procesos Cognitivos Y Logopedia, Pozuelo de Alarcón, Spain, [2]Universidad Complutense de Madrid, Departamento De Nutrición Y Ciencia De Los Alimentos, Madrid, Spain

Aims: Cognitively unimpaired relatives of Alzheimer's disease (AD) patients are a key population to study the early changes associated with the disease due to the compound risk factors they present. On a related note, lifestyle factors such as nutritional patterns, are being addressed for their interventional potential to change the course of the disease. Despite the broad knowledge of the cardiovascular and brain benefits from adhering to a Mediterranean diet (MeD), no studies have addressed the relationship between this dietary pattern and electrophysiological activity. The aim of this study is to evaluate this relationship within regions of the default mode network (DMN), classically affected in AD, in unimpaired relatives of AD patients and controls.
Methods: 147 individuals with a family history of AD (FH+) and 80 controls (FH-) completed a thorough nutritional questionnaire and a magnetoencephalography recording. The odds ratio of having high or low alpha relative power in relation to the adherence to a MeD was calculated.
Results: High adherence to MeD was associated with high relative power of alpha in the precuneus, inferior parietal lobe and hippocampus in the whole sample. FH- presented an additional benefit from adhering to this diet, while FH+ only showed this association when considering other risk factors such as hypertension or smoking.
Conclusions: The DMN and activity in the alpha frequency range have been extensively studied and are known to be altered from the earliest stages of the AD continuum. The positive relationship observed between the activity of this regions with a good adherence to a MeD could indicate a protective effect of this dietary pattern. Future studies should evaluate further which components of this diet contribute the most to this positive association.

Aims: Diabetes mellitus (DM-T2) and Alzheimer's disease (AD) are highly prevalent diseases in elderly and although they have apparently different pathological characteristics.Fluid biomarkers have become potential diagnostic and prognostic tools for neurodegenerative diseases.The aim of this study is to investigate the longitudinal trajectory of 6 blood biomarkers of neurodegenerative disease in patients with AD and DM-T2.
Methods: Cognitive-behavioral variables and blood biomarkers were obtained from 147 dementia patients (80.3% women, 23.6% DM-T2 group, mean age 83.6 ±6.4),residents of the Queen Sofia Foundation Alzheimer Centre and brain donors to the CIEN Foundation Tissue Bank.Patients were followed up during an average of 4.3±3.1 years, and 78% had a main pathological diagnosis of AD.The serum concentrations of GFAP, Nfl, AB40, AB42, tauTotal,and ptau181 were measured using SIMOA technology (Quanterix SR-X) in three timepoints (baseline, intermediate, and last visit before death). The rate of change of each biomarker over time was analysed using linear mixed-effects models (LMM).
Results: The mean survival time of the disease was higher for diabetic patients compared with non-diabetics (DM-T2=9.79; non-DM =12.63; p<0.001). Basal GFAP serum levels were similar in both groups (B=0.002; p=0.985) and the rate of change was significantly higher in subjects with DM-T2 compared to the non-DM (B=0.255; p= 0.048).Serum Nfl levels were similar in both groups (B=0.04; p=0.539), but the rate of change differs from the non-DM to the DM group (B=0.14; p=0.045).
Conclusions: Diabetic patients with dementia show a more aggressive course, with a shorter disease duration and a higher rate of increase in the neurodegenerative marker NfL.Additionally, astrocytic activation, measured by serum GFAP, seems to increase more steeply in diabetic dementia patients during the follow-up period,suggesting a higher inflammatory component in them.

BRAIN-AGE PREDICTION AS A TRANSDIAGNOSTIC MARKER FOR NEURODEGENERATION

POSTERS: A04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: EEG, BRAIN MAPPING, MEG

Gabriel Gonzalez-Escamilla
University Medical Centre, Johannes Gutenberg University Mainz, Department Of Neurology, Mainz, Germany

Aims: N**euroimaging-derived brain-age prediction is increasingly used for the evaluation of brain diseases. We aim to evaluate the set of MRI-derived morphometric variables that maximizes the differences in age prediction accuracy across various neurodegenerative disorders.**
Methods: Brain T1-weighted 3T MRI of participants aged 40-90 years were collected from various databases and preprocessed using FreeSurfer v6 to derive cortical thickness (CT), surface area, cortical volume, and subcortical volume (SubVol). Brains' age was predicted for each morphometric measure by training a support vector regression on healthy participants (HC; n = 816), randomly divided into "training set" (80%) and "test set" (20%). The validation cohorts comprised neurodegenerative patient cohorts within the same age range, particularly patients with advanced Parkinson's disease (aPD; n=66), frontotemporal degeneration (FLD; n=218), Alzheimer's disease (AD; n=85), and late-onset multiple sclerosis (loMS; n=145). Age predictions were evaluated using the coefficient of determination (R^2) computed after cross-validation. Additionally, associations between individual deviations in predicted age (delta-age) and relevant clinical test scores (e.g., disability status and cognition) were evaluated.
Results: Age-prediction accuracy in HC was best using a combination of CT and SubVol (R^2=0.74). In these settings, validation accuracy was lowest in AD, followed by FTD, loMS, and aPD. The delta-age was similar between aPD and AD, while marked differences arose with FTD and loMS. Higher predicted ages associated with worse cognitive functioning in all groups.
Conclusions: Overall, morbidity was associated with elderly appearing brains regardless of the disorder, indicating great utility of MRI-derived morphometric patterns to identify premature brain aging. Comparison of age prediction across diseases may enhance our ability to recognize increased vulnerability and early disease stages, as well as shed light on the disease-specific patterns of neuropathology.

THE RATIONALE FOR USING EEG WITH ASSOCIATIVE MEMORY TASKS FOR THE EARLY DETECTION OF ALZHEIMER'S DISEASE.

POSTERS: A04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: EEG, BRAIN MAPPING, MEG

Richard Jagger
University of Bolton, Psychology, Bolton, United Kingdom

Aims: Objectives In the asymptomatic stages of Alzheimer's disease there is a progressive pathology within areas of the larger 'episodic memory network'. The lack of symptoms has been postulated to be due to compensatory activity within the prefrontal cortex. EEG can measure prefrontal cortical activity precisely and is non-invasive. As associative memory tasks can be easily manipulated in terms of task difficulty, hypothetically greater input (compensatory) from prefrontal cortical areas due to decreases in the entorhinal cortex signal strength, should be observed.
Methods: Task based approaches have been less forthcoming than so called 'resting state' investigations. Event related potentials and source localisation are powerful tools in the EEG analysis suite. As memory is the primary neurocognitive component affected, due the changes in the episodic memory network, it would seem worthwhile to test and load the network and if compensatory activity is present. A series of associative memory tasks that have increasing task difficulty are currently being developed that can be used in event related potential experiments.
Results: Preliminary data will be available in March 2024 Scores on tests of memory should be equal (compensatory) however the neural response to the tasks i.e. the event related potentials should be quantitatively different, reflecting increasing compensatory activity in the prefrontal cortex.
Conclusions: Recently increasing attention has been given to measurements of non-task activity so called resting states or default mode activity using quantitative EEG methods to detect general changes in the level of activity in a resting state. It is proposed that Associative memory tasks will contribute to the early detection of early Alzheimer's detection using EEG methods. An EEG test battery is proposed.

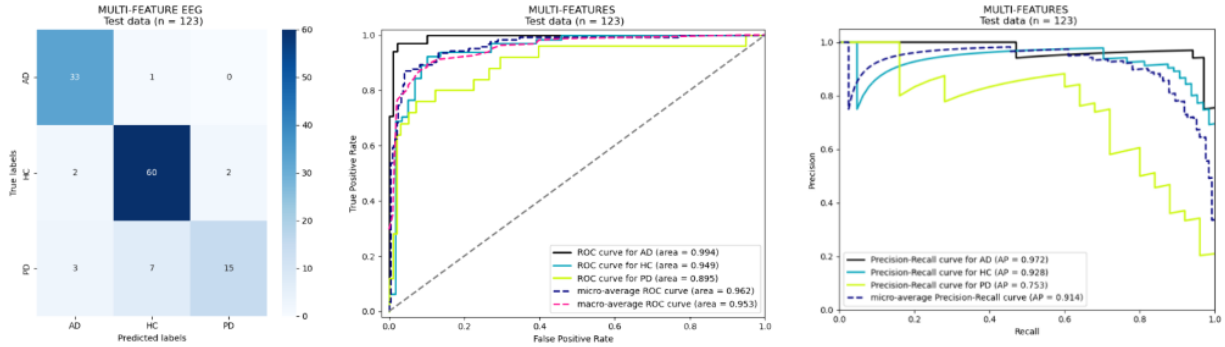
BEYOND POWER: HARMONIZING MULTI-CENTRIC MULTI-FEATURE EEG DATA FOR NEURODEGENERATIVE DISEASES CLASSIFICATION WITH AUTOMATED MACHINE LEARNING

POSTERS: A04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: EEG, BRAIN MAPPING, MEG

Alberto Jaramillo-Jimenez[1,2,3,4], Yorguin Mantilla-Ramos[2], Diego Tovar-Rios[1,4,5], John Ochoa[2], Kolbjørn Brønnick[1,4], Dag Aarsland[1,4,6], Laura Bonanni[7]
[1]Stavanger University Hospital, Centre For Age-related Medicine (sesam), Stavanger, Norway, [2]Universidad de Antioquia, Grupo Neuropsicología Y Conducta, School Of Medicine, Medellín, Colombia, [3]Universidad de Antioquia, Grupo De Neurociencias De Antioquia, Medellin, Colombia, [4]University of Stavanger, Faculty Of Health Sciences, Stavanger, Norway, [5]Universidad Del Valle, Grupo De Investigación En Estadística Aplicada - Inferir, Cali, Colombia, [6]Institute of Psychology, Psychiatry & Neuroscience (IoPPN), King's College London, Department Of Old Age Psychiatry, London, United Kingdom, [7]G. d'Annunzio University, Department Of Medicine And Aging Sciences, Chieti, Italy

Aims: Despite the multi-feature richness of resting-state electroencephalogram (rsEEG), power spectrum analysis remains the state-of-the-art approach. Automated machine learning (autoML) performs equal to or better than handcrafted models, even in small samples (n < 1000), but has not been tested on rsEEG for the classification of neurodegenerative diseases (NDD). Also, site-specific "batch" effects are reported in multisite rsEEG studies. The Combining Batches (ComBat) method controls batch effects, preserving biological covariates' variability, but its use in rsEEG data has not been examined. We aimed to evaluate the performance of autoML for classifying NDD from rsEEG features (oscillatory, aperiodic, complexity, connectivity) harmonized using a ComBat variant.
Methods: Signals (n = 410) from Alzheimer's Disease (AD, n = 113), Parkinson's Disease (PD, n = 83), and healthy controls (HC, n = 214) were preprocessed. Oscillatory and aperiodic spectrum, entropy metrics (complexity), and weighted Phase Lag Index connectivity (wPLI) were extracted in sensor space. Datasets (n = 8) harmonization was performed using reComBat, and feature selection using the minimum redundancy – Maximum relevance (mrMR) algorithm. AutoGluon was used to fit models on the training set (n = 287), evaluating the best model on the test set (n = 123).
Results: reComBat mitigated batch effects. Selected features included oscillatory theta-alpha descriptors, aperiodic parameters in anterior-central leads, complexity in posterior derivations, and whole-brain alpha wPLI. Multilayer stacked ensemble achieved a Balanced accuracy (Bacc) of 81.7 % in validation. In the test set **(Figure 1)**, we obtained a Bacc of 83.6 % and a classification of AD (ROC = 0.994), PD (ROC = 0.895), and HC (ROC = 0.949).

Figure 1. Results on the hold-out test set.



Conclusions: Batch harmonization, feature exploitation, and autoML are standardized tools for data integration and improved NDD classification from rsEEG.

NEGATIVE CONNECTIVITY IN ALZHEIMER'S DISEASE: INSIGHTS INTO NETWORK TOPOLOGY AND POTENTIAL IMPLICATIONS

POSTERS: A04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: EEG, BRAIN MAPPING, MEG

Ignacio Taguas, David López-Sanz, Fernando Maestú
Complutense University of Madrid, Experimental Psychology, Cognitive Psychology And Speech & Language Therapy, Madrid, Spain

Aims: In recent years, a large body of evidence has underscored the significant impact of Alzheimer's Disease (AD) on the Default Mode Network areas. These areas deactivate during cognitive tasks, which has led numerous authors to speculate that negative functional connectivity might be crucial in AD. However, other studies analyzing BOLD signals suggest that negative correlations can be explained by the patterns of positive connectivity –i.e., there is not an inhibitory force driving negative connectivity– and should therefore be discarded. In this work, we will study if the networks formed by anticorrelations are organized, or if the present a random structure, both in healthy participants and patients.
Methods: The sample consists of 172 cognitively unimpaired participants and 105 patients with amnestic mild cognitive impairment. Using resting-state closed eyes MEG recordings acquired in previous years, we will construct the brain networks of each subject using only the negative functional connectivity values, measured using corrected amplitude envelope correlation. Afterwards, these brain networks will be analyzed and compared between groups in terms of their topological structure –metrics including smallworldness, clustering, and modularity– to test the organization of the structure.
Results: Based on previous literature using fMRI, we expect negative brain graphs to show a random structure, or at least significantly less organized than that of positive networks. However, if we do find an organized structure, we will study the correlation between this organization and the punctuation on neuropsychological tests assessing different cognitive domains.
Conclusions: Functional connectivity is a widespread methodology to assess brain functioning in AD. However, existing results exhibit significant inconsistency, partially attributed to a lack of knowledge of how to handle negative values. Thus, clarifying whether they should be considered will be highly valuable.

FULLY AUTOMATED SCORING OF AUDIO-VERBAL COGNITIVE ASSESSMENTS DIRECTLY FROM AUDIO RECORDINGS: RESULTS FROM THE AMYPRED STUDIES

POSTERS: A04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC & BEHAVIORAL TESTS, DIGITAL ENDPOINTS, REMOTE TESTING

Jack Weston[1], Caroline Skirrow[1], Udeepa Meepegama[1], Michael Ropacki[2], Emil Fristed[1]
[1]Novoic Ltd, R&d, London, United Kingdom, [2]Strategic Global Research & Development, Neuroscience, Temecula, United States of America

Aims: Scoring of cognitive assessments is burdensome, subjective and varies across raters, introducing measurement noise. This study evaluates a fully automated system for scoring audio-verbal cognitive tests.
Methods: Semantic ("animals") and phonemic ("F") fluency tests and Wechsler Logical Memory Test (LMT) from 100 participants (N=48 MCI or mild AD, N=52 cognitively unimpaired) in the AMYPRED studies (NCT04828122, NCT04928976) were administered during supervised assessments. Tests were manually scored by site staff across four sites, and manually re-scored from audio-recordings by one researcher (CS; fluency tests) or consensus scored by two researchers (CS and JW; LMT) to provide a consistent ground truth. Automatic scores were derived from audio files, using a custom transcription model and a fully automated natural language processing system. Reliability of the automated system was evaluated using correlational analyses.
Results: Automated ratings correlated highly with all manual ratings (all $r>0.91$, $p<0.001$). Compared to ground truth scores, correlation coefficients were higher for automated scores than those from site staff, significant for "animals" ($r=0.99$, 95% CI 0.99-0.99; $t=3.59$, $p<0.001$) and LMT consensus scores ($r=0.98$, 95% CI=0.97-0.99, $t=4.28$, $p<0.001$), but not for "F" ($r=0.96$, 95% CI=0.94-0.97, $t=0.39$, $p>0.05$).
Conclusions: The automated rating system demonstrated high convergence with ground truth scores, and equal or better to manual scores by trained raters. Automated scoring could reduce measurement error in outcome assessment, refine detection of group differences and change over time, and/or reduce sample sizes required to detect clinical change in clinical trials.

COGNITIVE AGING TRAJECTORIES AMONG ENGLISH AND SPANISH TAKERS

POSTERS: A04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC & BEHAVIORAL TESTS, DIGITAL ENDPOINTS, REMOTE TESTING

Carlos Araujo Menendez[1], Rubi Carpio[2], Rachel Membreno[2], Armando Lemus[2], Shaun Goycoochea[2], Ursula Saelzler[3], Ariana Stickel[2]
[1]SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, Psychology, San Diego, United States of America, [2]San Diego State University, Psychology, San Diego, United States of America, [3]UC San Diego, Psychiatry, San Diego, United States of America

Aims: Cognitive assessments are typically designed for English speakers, creating a potential disadvantage and misrepresentation of cognitive functioning for non-English testing speakers. We aimed to determine whether English and Spanish test takers have similar or different cognitive trajectories.

Methods: This study included 2,266, Hispanic/Latino adults without dementia, ages 46-104 years (mean = 69.9 years, SD = 8.6), from the National Alzheimer's Coordinating Center (NACC). Mixed-effects regression analyses were used to examine baseline differences and longitudinal changes in immediate and delayed episodic memory, verbal fluency, processing speed and language (confrontation naming) between Spanish- and English-test takers (n=1097 and n=1169, respectively). All models were adjusted for age at baseline, years of education, sex and clinical status [cognitive normal (CN) or mild cognitive impairment (MCI)].

Results: English speakers performed significantly better than Spanish speakers across all cognitive tests at baseline (βs=0.32-0.47, $p < 0.05$). No differences in cognitive trajectories were detected on any tests.
Conclusions: Although both the English and Spanish testing groups began at different levels of cognition, the rates of decline remained similar across all cognitive domains, which may suggest similar cognitive aging trajectories. Differences in cognitive performance cross-sectionally, but not longitudinally, may be due to measurement bias, resulting in underestimation of cognitive abilities of Spanish-speakers, especially those with lower education. Further studies are needed to better understand the mechanisms of how language differentially affects cognitive performance cross-sectionally and longitudinally.

Aims: Behavioral readouts are essential for preclinical research on neurodegenerative disorders. The pathological changes are typically manifested with gradual changes in animal movement and/or in social behavior. Traditionally, the observation and recording of behavioral assays has relied on a human observer, subjecting the collected data to variability and possibly bias. Additionally, the required human resource needed to analyze large data sets can be overwhelming.
Methods: Novel machine learning approaches to image and video analysis open up new possibilities to behavioral data analysis with its speed, more objective detection of behavior and improved quality of data. DeepLabCut (DLC) is a software package for markerless 2D and 3D pose estimation based on transfer learning with deep neural networks (Lauer *et al*. 2022, Nat Methods 19, 496-504). In this study DLC was used to analyze video recordings of typical behavioral assays utilized in Parkinson's disease and Alzheimer's disease animal model research.
Results: We implemented automated analysis pipelines for the tapered beam balance test and Barnes maze, enabling reliable and objective assessment of the readouts of these tests.
Conclusions: As summary, machine learning does not just streamline and enhance the repeatability of scientific studies, it also allows us to scale up the amount of data that we can process in an efficient manner. Machine learning can be utilized in all behavioral analysis where there is a need to track the animals' movement.

ALTERATION OF VISUOSPATIAL SYSTEM IN MCI – UNDERLYING STRUCTURAL AND FUNCTIONAL CHANGES

POSTERS: A04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC & BEHAVIORAL TESTS, DIGITAL ENDPOINTS, REMOTE TESTING

Dalida Berente[1,2], Andras Horvath[2,3], Gergő Bolla[1], Mate Kiss[4], Anita Andrassy[2], Anita Kamondi[2,5]
[1]Semmelweis University, School Of Phd Studies, Budapest, Hungary, [2]National Institute of Mental Health, Neurology and Neurosurgery, Neurocognitive Research Center, Budapest, Hungary, [3]Semmelweis University, Department Of Anatomy Histology And Embryology, Budapest, Hungary, [4]Siemens Healthcare, Siemens Healthcare, Budapest, Hungary, [5]Semmelweis University, Department Of Neurology, Budapest, Hungary

Aims: Alzheimer's Disease (AD) is the most common cause of major neurocognitive disorders in the elderly, preceded by a prodromal phase called Mild Cognitive Impairment (MCI). Despite the urgent need for early diagnosis, optimal screening methods for considerable patient groups are yet to be developed. Recent literature highlights that assessing visuospatial function might be an ideal candidate. In our study, we detected a significant association between our participants' cognitive performance and hand movement characteristics measured by a computer mouse with the Precognize paradigm. Our objective was to identify the underlying structural and functional changes in the brain.
Methods: 44 individuals participated in this study, 28 healthy controls and 16 MCI patients. They underwent comprehensive neurological and neuropsychological evaluation, structural- and functional MRI acquisition (sMR, fMR) and executed tasks with the Precognize paradigm. MRI images were analyzed using Freesurfer 6.0 software and the CONN Toolbox. Meticulous statistical analysis was completed for all data.
Results: Significant correlations were found between the computer mouse movement parameters derived from the Precognize parading and the sMRI and fMRI data. For sMRI, the most significant correlations were detected between the speed of movements by the right hand and cortical thickness of the right fusiform ($r=0.54$, $p<0.001$) and lingual ($r=0.37$, $p=0,01$) gyri. For the fMRI BOLD signal, the most significant correlation was found between the intrinsic connectivity of the right middle temporal gyrus and the speed of the right hand's movements ($r=0.53$, $p<0,001$).
Conclusions: Based on the Precognize paradigm's association with neuropsychological test results and cortical areas relevant for the Trail Making Test and AD, hand movement analysis by the Precognize paradigm seems a promising candidate for an automatic, digital screening method for MCI.

CLINICAL MEANINGFUL CHANGES IN ALZHEIMER'S DISEASE: CDR PROGRESSION AND EFFECT ON MMSE, ADAS-COG, RBANS AND ADC ADLI

POSTERS: A04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC & BEHAVIORAL TESTS, DIGITAL ENDPOINTS, REMOTE TESTING

Catarina Cunha[1], Raymond Blattner[2], Selam Negash[2], Silvia Gamazo Navarro[1], Barbara Echevarria[1], Christopher Randolph[3]
[1]WCG Clinical Research Solutions, Clinical Science, Munich, Germany, [2]WCG Clinical Research Solutions, Clinical Data Analytics, Princeton, United States of America, [3]WCG Clinical Research Solutions, Chief Scientific Officer, Princeton, United States of America

Aims: The Clinical Dementia Rating (CDR) is commonly used to characterize Alzheimer's disease (AD) and disease progression. CDR Global score (GS) determines cognitive impairment/dementia and quantifies disease severity from very mild to mild, moderate, and severe. Identifying clinically meaningful changes in cognitive/functional tests is essential when cognition is an outcome in clinical trials. We aimed to establish clinically important differences for commonly cognitive/functional tests when subjects progress from very mild to mild AD stage (CDR0.5 to 1) and from mild to moderate AD stage (CDR1 to 2)
Methods: Effect sizes (ES) were calculated to estimate clinically important changes on the MMSE, ADAS-Cog, RBANS and ADCS ADLI when subjects progressed from very mild AD to mild AD and from mild AD to moderated AD. Clinically important changes were defined as mean change of MMSE, ADAS-Cog, RBANS and ADC ADLI in subjects rated for the first time CDR GS1 and CDR GS2 at 6 and 12 months since baseline. Data from these scales was analyzed for baseline, 6/12 months for 466 subjects with AD enrolled in four multinational double-blind, placebo controlled clinical trials.
Results: The mean changes for CDR rated first time mild (CDR0.5 to 1) in the MMSE, ADAS-Cog, RBANS and ADCS ADLI were respectively: -2.34±3.77 (d=-0.72), 2.83±7.35 (d= 0.43), -4.23±11.58 (d=-0.38) and -3.90±6.78 (d=-0.65). The mean changes for CDR rated first time moderate (CDR1 to 2) in the MMSE, ADAS-Cog, RBANS and ADCS ADLI were respectively: -5.07±3.99 (d=-1.45), 5.61±8.77 (d= 0.68), -4.23±6.96 (d=-0.55) and -14.22±12.00 (d=-1.29).
Conclusions: All scales captured worsening effectively when AD progressed from mild to moderate stage but the MMSE and the ADCS ADLI demonstrated being more sensitive to capturing worsening when AD progressed from very mild to mild stage.

PREDICTION OF ALZHEIMER'S DISEASE USING VOCAL BIOMARKERS: AN AI APPROACH

POSTERS: A04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC & BEHAVIORAL TESTS, DIGITAL ENDPOINTS, REMOTE TESTING

Young Chul Youn[1], Sangyun Kim[2], Hotae Jeong[1], Hyunjoo Choi[3], Nayoung Ryoo[4], Minsu Kim[5]

Aims: Alzheimer's disease (AD) is a progressive neurodegenerative disorder that significantly impacts memory and cognitive abilities. Early and accurate diagnosis of AD is crucial for effective therapeutic interventions. In this study, we propose an innovative approach that utilizes Artificial Intelligence (AI) to predict AD using vocal biomarkers.
Methods: We recruited participants with varying degrees of cognitive impairment and collected voice recordings during specific tasks designed to elicit speech patterns affected by AD-related cognitive decline. Several AI models were trained on the collected voice data, including spectrograms, 1D & 2D Convolutional Neural Networks (CNNs), Audio Spectrogram Transformer (AST), and Wav2vec 2.0. These models underwent various transformations and augmentations to enhance their robustness and generalization capabilities.
Results: Our study demonstrated the effectiveness of the Wav2vec2 model as the most accurate across all categorizations, closely followed by the AST model. These models exhibited high efficiency in both binary and multi-class audio classifications related to cognitive impairments associated with AD.
Conclusions: The findings suggest that leveraging vocal biomarkers in combination with AI algorithms holds promise for early detection of AD. The non-invasive nature of vocal biomarker analysis makes it a potentially accessible tool for widespread screening and monitoring within communities.

EYE-TRACKER ASSESSMENT OF THE IMPACT OF DONEPEZIL ON VISUOSPATIAL ABILITIES IN MILD COGNITIVE IMPAIRMENT: PRELIMINARY FINDINGS

POSTERS: A04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC & BEHAVIORAL TESTS, DIGITAL ENDPOINTS, REMOTE TESTING

Ko Woon Kim, Qi Wang, Eunsu Lee, Byoung-Soo Shin
Jeonbuk National University, Neurology, Jeonju, Korea, Republic of

Aims: Cholinesterase inhibitors (ChEIs) have been shown to reduce cognitive decline over the long term in patients with Alzheimer's disease (AD). However, there is limited evidence to suggest that ChEIs influence cognitive test results in patients experiencing mild cognitive impairment (MCI) due to AD. Traditional evaluation criteria, including cognitive tests may not be sufficiently responsive to detect subtle therapeutic effects in MCI patients. We propose a randomized controlled trial to assess the effect of donepezil with MCI due to AD.
Methods: Our study enrolled 16 participants with MCI (8 in each arm, donepezil vs. control), who had amyloid positron emission tomography (PET)-positive results. We employed eye-tracking metrics and digital pen data during the execution of the simplified Rey Complex Figure (RCFT). Eye-tracking was recorded during the copying of the simplified RCFT. After standard gaze mapping, we quantified eye-tracking metrics such as the number and duration of fixations in the perception and working areas. The primary outcome measure involves evaluating alterations in the ratio of the number of fixations (working space/perceptual space) using the simplified RCFT, from baseline to the 12-week mark, as evaluated through eye-tracking metrics. Statistical analyses for primary outcome was applied on the donepezil and control groups between the baseline session and follow-up session using paired-Wilcoxon test.
Results: Eye-tracking metrics showed that the ratio (working space/perceptual space) of the visit count (P=0.036), total visit duration (P=0.025), total fixation duration (P=0.036), and first fixation duration (P=0.025) were significantly increased in the follow-up visit compared to the baseline visit in the donepezil group. And the metrics in the control group showed no significant changes.
Conclusions: This research suggests the potential utility of eye-tracking metrics as valuable digital biomarker for detecting subtle alteration.

Aims: The Mini-Cog© assessment was developed to aid in the early detection of dementia; however, its adoption in Japan remains limited. The aim of this study was to assess the effectiveness of Mini-Cog© in the context of cognitive screening.
Methods: The study included 170 older participants (76 men and 94 women) attending the Memory clinic, ranging in age from 66 to 94 years, with an average of 11.4 ± 2.7 years of education. Among the participants, 100 were diagnosed with dementia, 53 with mild cognitive impairment (MCI), and 17 exhibited normal cognitive function. Mini-Cog© scores were evaluated to determine sensitivity and specificity for dementia and mild cognitive impairment.
Results: Among the 36 patients with total scores in the normal range (≥4 points) on the initial Mini-Cog© assessment, 5 (13.9%) had dementia, 17 had MCI (47.2%), and 14 were cognitively normal (38.9%). In contrast, of the 134 patients with abnormal total scores (3 or less), 95 (70.9%) had dementia, 36 (26.9%) had MCI, and only 3 (2.2%) were cognitively normal. The sensitivity and specificity for dementia were 0.95 and 0.44, respectively, while those for cognitive decline (dementia and MCI) were 0.86 and 0.82, respectively. The agreement between the Mini-Cog© scores obtained at the first and second visits was 44.4%.
Conclusions: These findings suggest that Mini-Cog© represents a convenient and efficient tool for screening cognitive decline in primary care and health checkup settings.

TECHNICAL AND CLINICAL VALIDATION OF NOVEL COGNITIVE TESTS FOR REMOTE SAMPLING OF MEMORY AND EXECUTIVE FUNCTION

POSTERS: A04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC & BEHAVIORAL TESTS, DIGITAL ENDPOINTS, REMOTE TESTING

John Dyer[1], Alison Buick[1], Laura Rueda-Delgado[2], Md. Nurul Islam[2], Judith Jaeger[3], Niamh Kennedy[4], James Rowe[5], Brian Murphy[2]
[1]Cumulus Neuroscience, Science, Belfast, United Kingdom, [2]Cumulus Neuroscience, Science, Dublin, Ireland, [3]CognitionMetrics LLC, Science, Stamford, United States of America, [4]University of Ulster, Psychology, Coleraine, United Kingdom, [5]University of Cambridge, Clinical Neurosciences, John Van Geest Centre For Brain Repair, Cambridge, United Kingdom

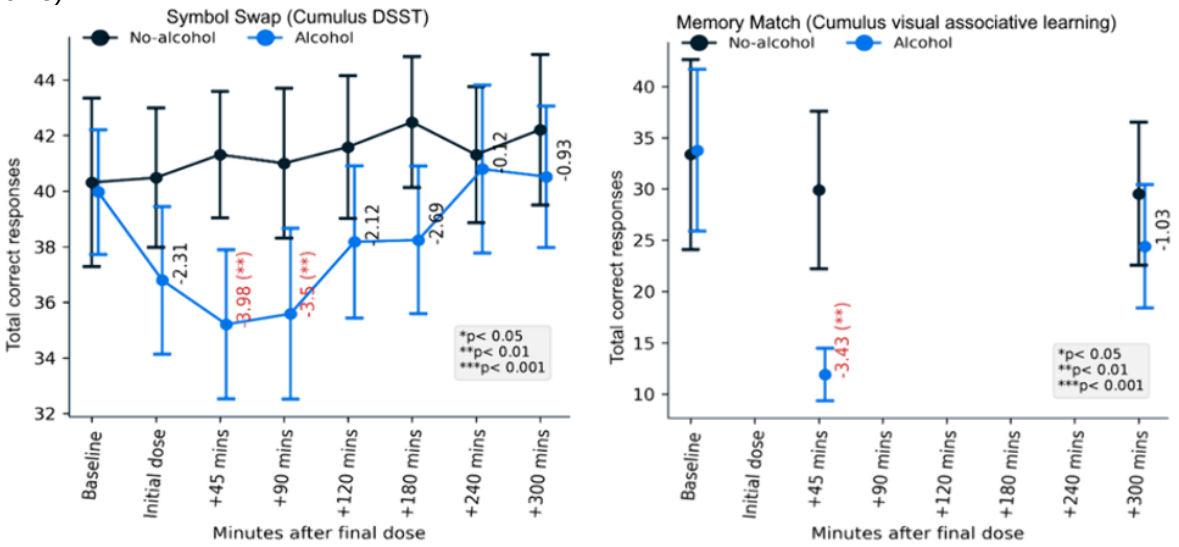
Aims: Frequently repeatable and valid measures of disease-relevant cognitive functions can be used in aggregate to increase the precision of measurement in dementia. This could enable earlier detection of the disease, and also the streamlining of clinical trial designs. We here present data from the validation of two novel assessments in the Cumulus Neuroscience platform, suitable for at-home use by patients, in terms of sensitivity to change in cognitive impairment.
Methods: Tablet-based assessments covering episodic memory and executive function were developed in collaboration with a panel of dementia stakeholders (N = 10), representing patients, carers and practitioners in the field. “Symbol Swap” is a symbol-coding task, related to the classic DSST. “Memory Match” is a visual associative learning paradigm, designed to test recollection memory. These underwent technical validation in a small (N=30) alcohol challenge lab study to evaluate sensitivity to subtle cognitive impairment. The tasks were also deployed in a longitudinal field study involving 59 participants living with mild AD dementia and 60 matched healthy control participants, for which we report cross-sectional

Task screenshots from Cumulus tasks Symbol Swap (top) and Memory Match (bottom). In Symbol Swap, tiles must be dragged (using a stylus or finger) to the next open slot in the row. In Memory Match, the position of abstract patterns must be recalled, with the number of patterns to be remembered growing at an ever-increasing rate.

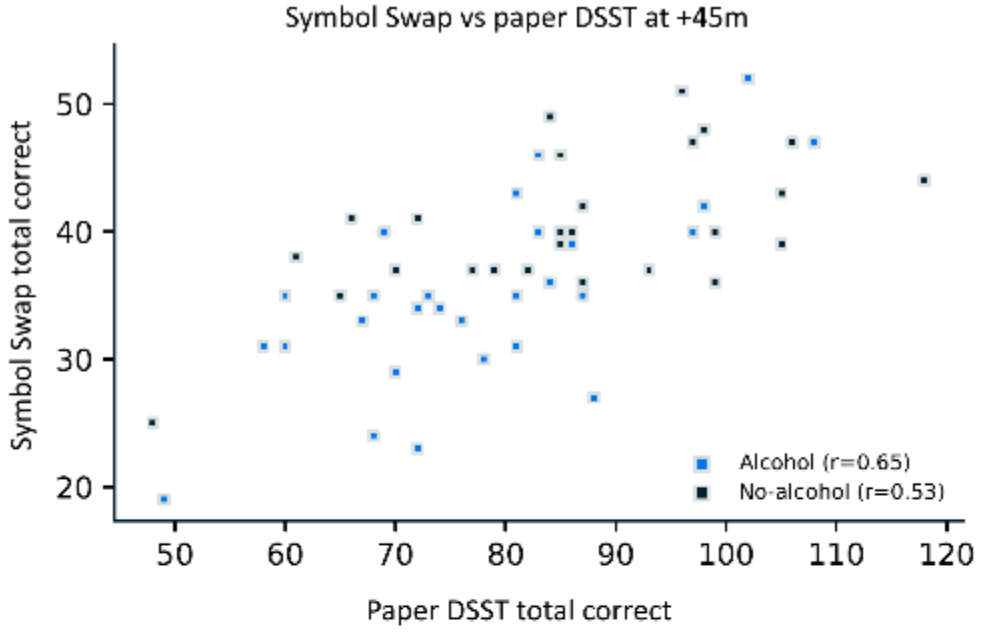
analyses.

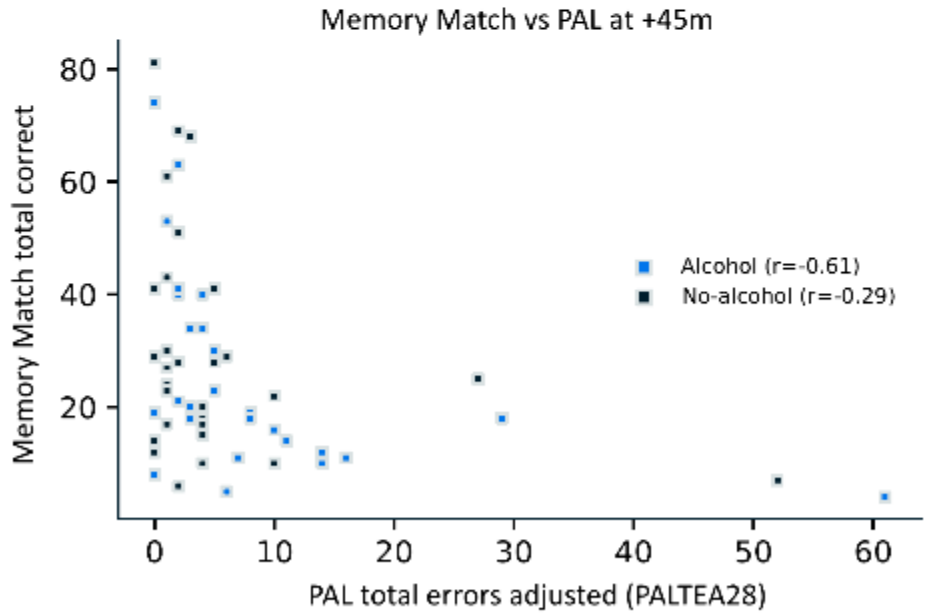
Results: In the alcohol study practice effects were small, and performance demonstrated a curve of impairment and return to baseline with intoxication. Correlations with benchmark measures were high (r > 0.61). In the patient study both tasks strongly differentiated AD status with equivalent or greater sensitivity

than ADAS-Cog (Symbol Swap: t(98) = 10.32, p=4.8e-17; and Memory Match: t(98) = 8.11, p= 2.4e-11). Furthermore, strong correlations with benchmark measures were found (r > 0.75).

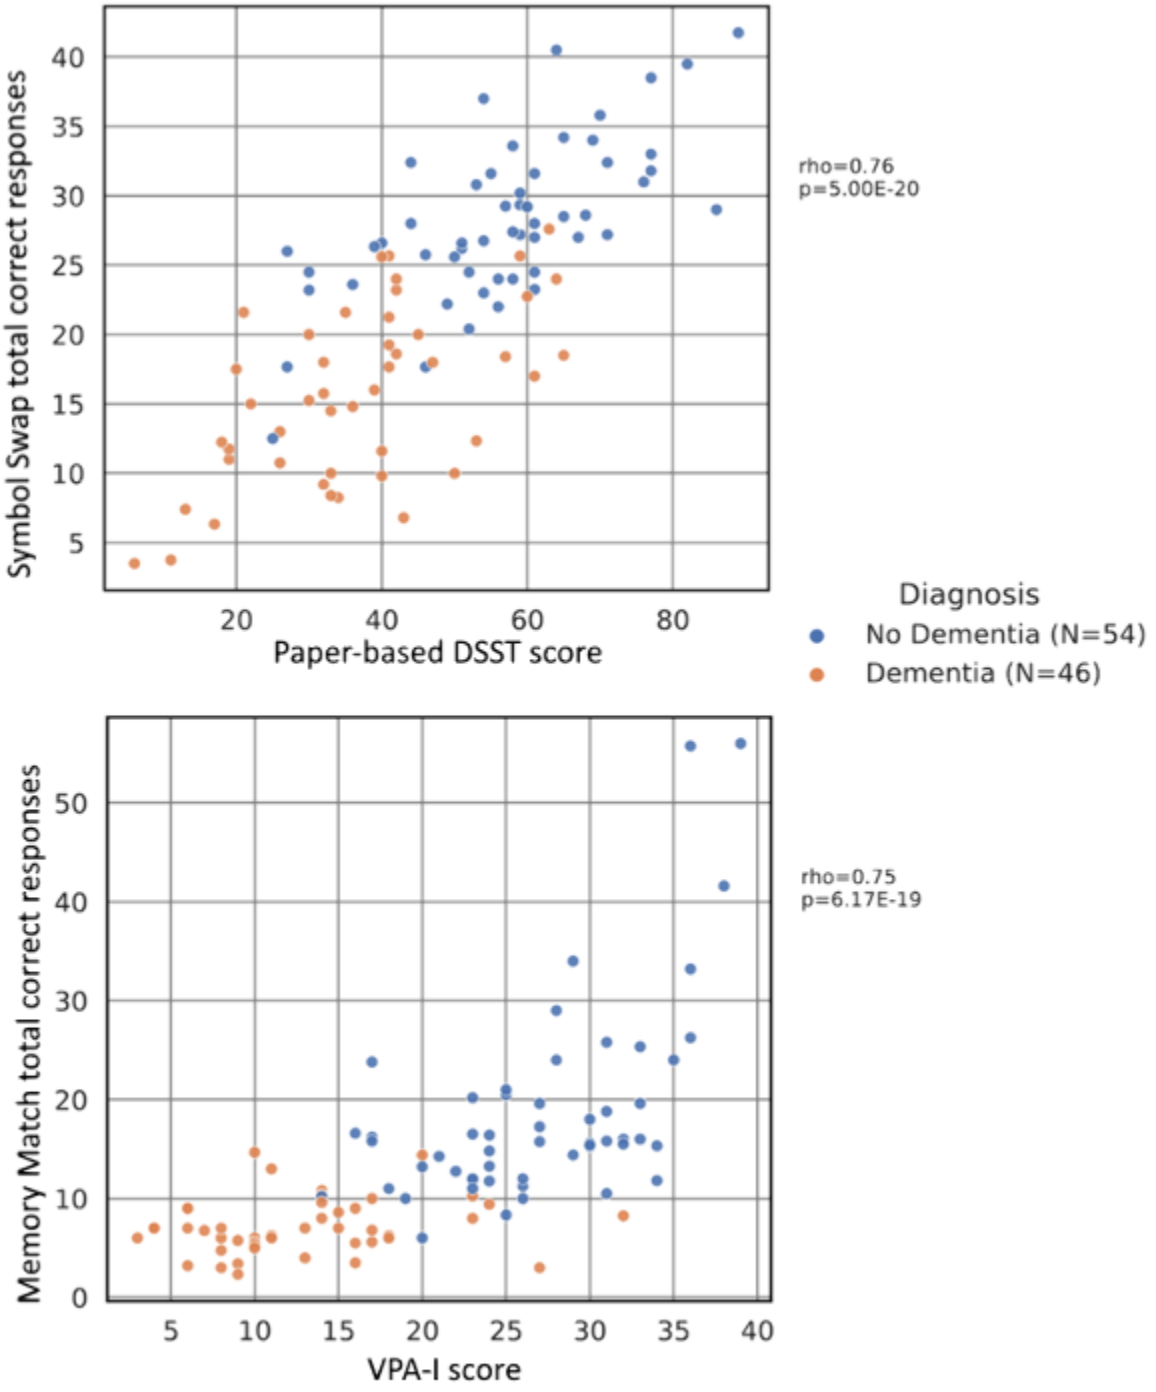


Timecourse of alcohol-induced impairment over the experiment, for the alcohol and placebo arms. Error bars are 95% confidence intervals. t values are shown for the interaction of session type (alcohol/placebo) and session timepoint, with significant interactions highlighted (Holm-Bonferroni corrected). Left: Alcohol vs placebo performance data over time for Symbol Swap. Right: Alcohol vs placebo performance data over time for Memory Match (note that Memory Match was administered at baseline, peak intoxication and finish only, due to time constraints).

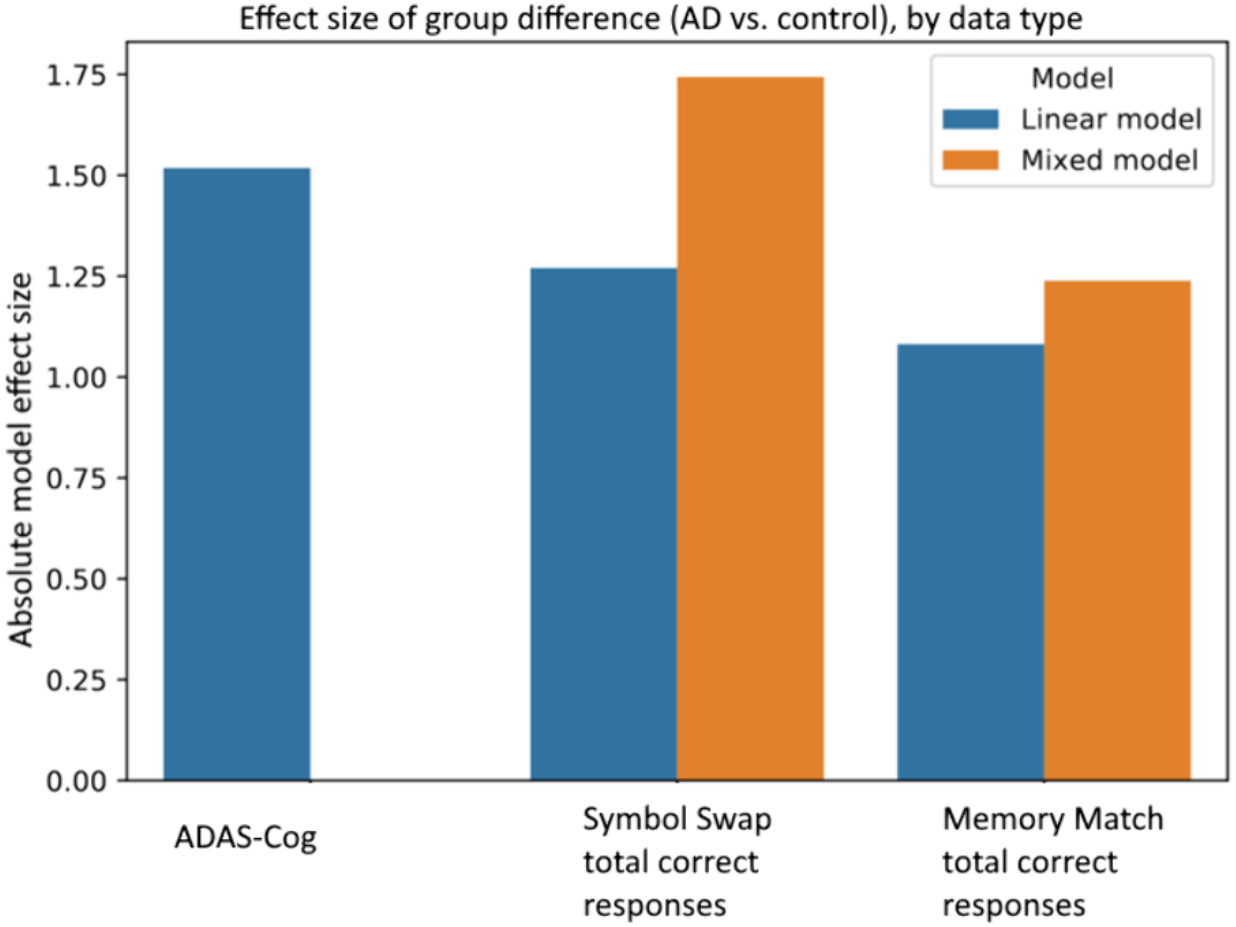




Scatterplots showing scores for Cumulus tasks against benchmark comparators with Spearman rank correlation. Top: Cumulus Symbol Swap vs paper DSST. Bottom: Cumulus Memory Match vs PALTEA28 (one of two primary metrics from PAL). Data here are taken from 45 minutes after final dose of alcohol or placebo (peak intoxication where applicable).



Scatterplots of Cumulus variables against paper-based benchmarks. Top: Symbol Swap showed a correlation with the paper-based DSST 0.76 (p=5e-20). Bottom: Memory Match task showed a correlation with the Verbal paired associates (VPA-I)of 0.75 (p=6.2e-19).



Group effect size of selected Cumulus variables and the ADAS Cog 13. Using the average of Cumulus sessions results in a lower effect size than the one obtained from the ADAS Cog. With mixed models, we exploit the within-user variability and obtain an effect size higher than the ADAS Cog.

Conclusions: These studies demonstrate that the novel tasks are usable by patients, and sensitive to impairment – making them suitable for use in modern clinical trials where individual-level precision measurement is required.

A DETECTION MODEL OF COGNITIVE IMPAIRMENT VIA THE INTEGRATED GAIT AND EYE MOVEMENT ANALYSIS FROM A LARGE CHINESE COMMUNITY COHORT

POSTERS: A04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC & BEHAVIORAL TESTS, DIGITAL ENDPOINTS, REMOTE TESTING

Bin Jiao[1], Jingyi Lin[2], Tianyan Xu[1], Lu Shen[1]
[1]87 Xiangya Road Xiangya Hospital, Central South University, Department Of Neurology, Changsha, China, [2]Xiangya Hospital Central South University, Hunan International Scientific And Technological Cooperation Base Of Neurodegenerative And Neurogenetic Diseases, Changsha, China

Aims: Whether the integration of eye-tracking, gait, and dual-task analysis can distinguish cognitive impairment (CI) patients from controls has been elusive.
Methods: 1481 participants, including 724 CI and 757 controls, were enrolled in this study. Eye movement and gait, combined with dual-task patterns were measured. The LightGBM machine learning models were constructed.
Results: A total of 105 features of gait and eye-tracking were extracted. 46 parameters, including 32 gait and 14 eye-tracking features, showed significant differences between two groups ($p<0.05$). Among them, the Gait_3Back-TurnTime and Dual-task cost-TurnTime patterns were correlated to plasma p-tau 181. The model based on dual-task gait, dual-task smooth pursuit, prosaccade and antisaccade achieved the best AUC of 0.987 for CI detection, while combined with p-tau181, the model could discriminate mild cognitive impairment (MCI) from CN with an AUC of 0.824.
Conclusions: Combining dual-task gait and dual-task eye-tracking analysis has the feasibility in non-invasive detection of CI.

CORRELATION ANALYSIS OF APOB, APOA1, AND APOB/APOA1 WITH CORTICAL MORPHOLOGY IN PATIENTS WITH MEMORY COMPLAINTS

POSTERS: A04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC & BEHAVIORAL TESTS, DIGITAL ENDPOINTS, REMOTE TESTING

Wang Jiayu[1], Wang Ziqi[2], Duan Mingjun[2]
[1]Zunyi Medical University, Nursing, Zunyi, China, [2]the Fourth People's Hospital of Chengdu, Geriatrics, Chengdu, China

Aims: To examine whether apolipoprotein B (ApoB), apolipoprotein A-1 (ApoA1), and their ratio (ApoB/ApoA1) are associated with early changes in cortical morphology in patients with memory complaints.
Methods: A total of 100 patients from two centers were grouped based on recruitment location, and underwent neuropsychological tests, plasma Alzheimer's biomarker assessments, apolipoprotein E (ApoE) genotyping, and 3T magnetic resonance imaging. The CAT12 toolbox (SPM12) was used to measure cortical morphology.
Results: Significant positive correlations were found between ApoB and sulcal depth in the occipital cortex for both individual groups (p=0.001 and p=0.002) and the total combined group (p=0.000). Sulcal depth showed negative correlations with time measurements from the Shape Trails Test Part A and B in the total combined group (β=-0.336, p=0.001 and β=-0.228, p=0.023), the first group (β=-0.49, p=0.002 and β=-0.251, p=0.031), and the second group (β=-2.79, p=0.007 and β=-0.452, p=0.001). In the second group, positive associations were identified between sulcal depth and scores on the Montreal Cognitive Assessment Basic (β=0.407, p=0.002), Animal Fluency Test (β=0.392, p=0.007), and Boston Naming Test (β=0.407, p=0.006). No correlations were found between other cortical shapes and ApoB, ApoA1, or ApoB/ApoA1.
Conclusions: ApoB influences the sulcal depth in the lateral occipital cortex, potentially impacting executive function in individuals with memory complaints.

Aims: Prediction of the dementia progression is important for patient's management. We aimed to investigate the cognitive trajectories of Alzheimer's disease dementia (ADD) and dementia with Lewy bodies (DLB) according to the initial structural change measured by comprehensive visual rating scales (CVRS).
Methods: We retrospectively included the patients who initially visited the Dementia Clinic of Chonnam National University Hospital between 2010 and 2012. All patients underwent dementia work up including neuropsychological battery (Seoul Neuropsychological Screening Battery, SNSB). We recruited the participant who underwent SNSB annually for three years successively. Total 136 patients of ADD and 63 patients of DLB were included for analyze. We analyzed the decline pattern of cognitive profile according to the initial brain structural changes.
Results: The general cognitive trajectories between ADD and DLB patients were not different. However, DLB patients showed more rapid decline of cognitive function in language and related function, visual memory function, and frontal executive function. The scores were lower in participants with DLB without atrophic group in attention, visuospatial function, and frontal executive function. In analysis of the cognitive trajectories, the visual memory domain declined rapidly in DLB without atrophy group compared with the ADD without atrophy group.
Conclusions: We founded that the differences in visual cognitive profile in ADD and DLB patients in serial follow up of neuropsychological tests. It is prominent in the mild structural change group of ADD and DLB.

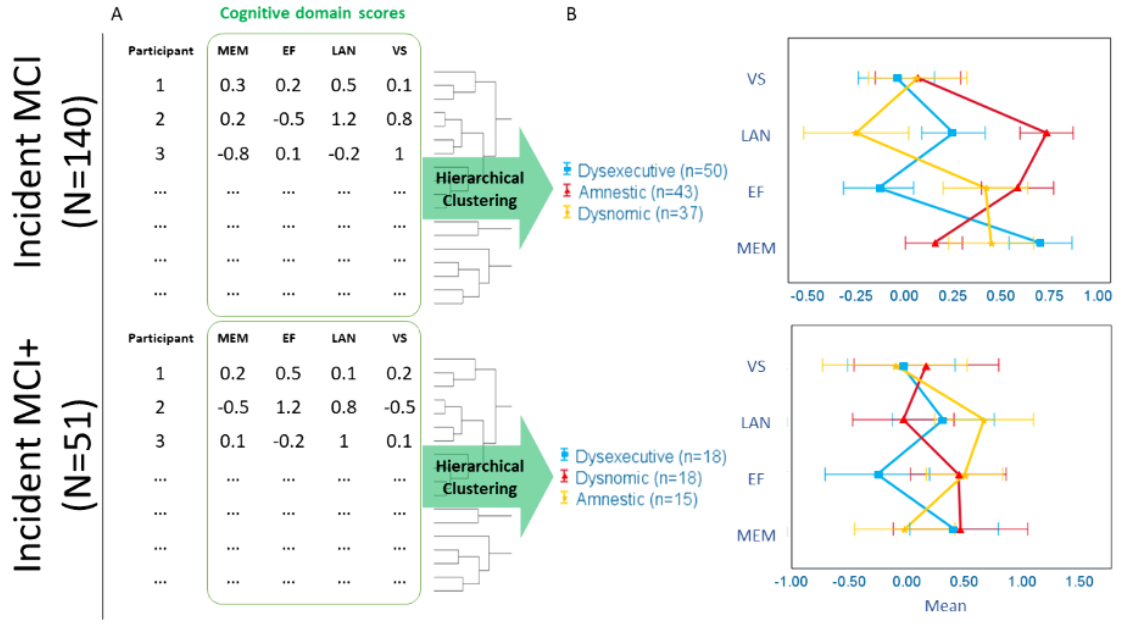
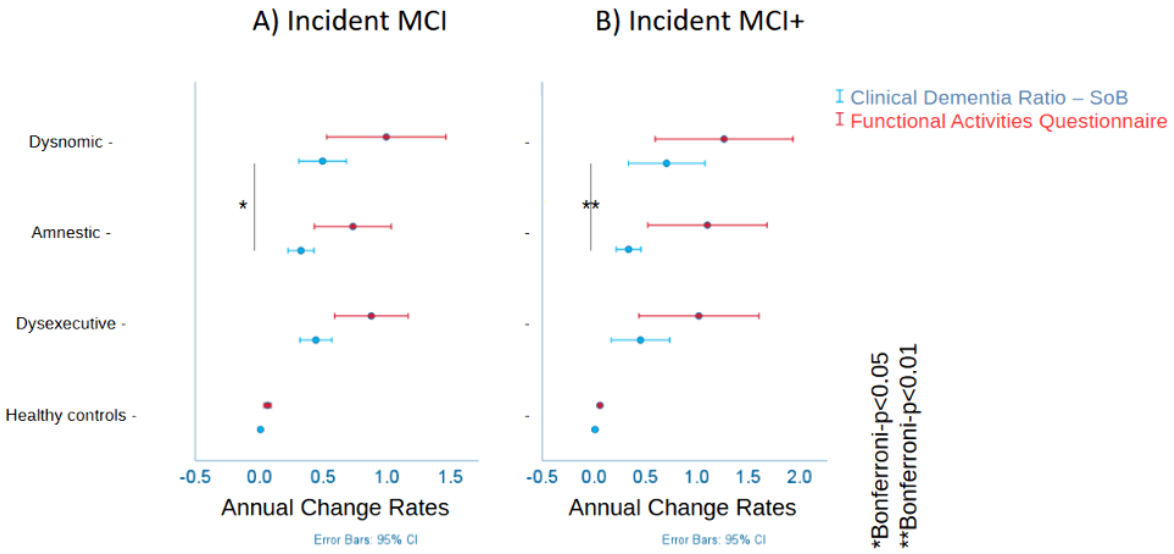
COGNITIVE SUBTYPES DIFFER IN CLINICAL PROGRESSION IN BETA-AMYLOID POSITIVE INDIVIDUALS WITH INCIDENT MILD COGNITIVE IMPAIRMENT

POSTERS: A04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC & BEHAVIORAL TESTS, DIGITAL ENDPOINTS, REMOTE TESTING

Ersin Ersözlü[1], Alzheimer'S Disease Neuroimaging Initiative (Adni)[2]
[1]Charité, Campus Benjamin Franklin, Department Of Psychiatry And Psychotherapy, Berlin, Germany, [2]University of Southern California, Neurology, Los Angeles, United States of America

Aims: Alzheimer's disease (AD) is proven to cause heterogeneous clinical manifestations. The recent studies identified clinical phenotypes, including the amnestic, dysexecutive and dysnomic, using neuropsychological test batteries in mild cognitive impairment (MCI). However, the studies did not consider the biological definition, i.e., abnormal β-amyloid (Aβ), while defining disease groups. We aim to explore possible clusters of neuropsychological domain scores in Aβ+ patients with MCI and their relations to cognitive trajectories.
Methods: We included n=180 cognitively normal participants without abnormal Aβ, phosphorylated-tau or total-tau and n=130 patients with an incident MCI (iMCI) and n=51 patients with abnormal Aβ and iMCI (iMCI+). iMCI was defined as the first diagnosis of MCI after at least one prior visit without a diagnosis of MCI. A hierarchical clustering approach was used on the cognitive composite scores of memory, executive functions and language domains to determine three clusters in iMCI and iMCI+ groups. We defined a priori the three-cluster solution and compared the clusters' baseline characteristics and cognitive trajectories.
Results: The clustering method classified the disease group into three clusters and showed similar phenotypes in iMCI and iMCI+, presenting amnestic, dysexecutive and dysnomic clusters (**Fig. 1**). The baseline demographics and global cognition did not differ among clusters, while amnestic and dysnomic clusters were more likely Apolipoprotein E ε4-allele-carriers. The dysnomic cluster revealed a higher annual change rate of the Clinical Dementia Ratio - Sum of Boxes than the amnestic cluster, adjusted for confounders (**Fig. 2**).





Conclusions: Our results demonstrate that identifying MCI subtypes might enhance the accuracy of prognostic predictions for clinical progression. Moreover, the consistency of iMCI subtypes within the iMCI+ group indicates that the observed clusters may be a part of the biologically defined AD continuum.

AUDITORY COGNITION IS RELATED TO NEUROIMAGING MARKERS OF ALZHEIMER'S DISEASE

POSTERS: A04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC & BEHAVIORAL TESTS, DIGITAL ENDPOINTS, REMOTE TESTING

Meher Lad, Tim Griffiths
Newcastle University, Auditory Laboratory, Newcastle upon Tyne, United Kingdom

Aims: Hearing loss is related to an increased risk of dementia but the reasons for this are unclear. Poor central hearing has previously been shown to increase risk of Alzheimer's disease dementia. Poor performance on these tests have also shown associations with greater rates of temporal lobe atrophy. This study tested whether two types of central hearing: speech-in-noise perception ability and auditory memory could differentiate groups with or without Alzheimer's disease dementia and whether performance on these tests was associated with morphometric measures in regions that are specifically associated with risk of the condition. These included region thickness and volume in Alzheimer's disease signature regions, medial temporal lobe and auditory processing areas.
Methods: 50 participants (25 Cognitively normal, 10 Mild Cognitive Impairment and 15 Alzheimer's disease dementia) underwent a battery of auditory tests including speech-in-noise perception (digits-in-noise and sentence-in-babble perception) ability and auditory memory. 3T structural MR imaging for T1-weighted and T2-weighted imaging was conducted on a Philips Acheiva scanner. All scans were preprocessed using sMRIprep and underwent a full recon-all surface reconstruction using Freesurfer 7.0. Normalised volumetric measures and mean cortical thickness values for Alzheimer's disease signature regions, medial temporal lobe structures and auditory processing regions were used for group-level analysis.
Results: All regions of interest showed group-level differences in volume and cortical thickness with lower values progressing from cognitively normal, mild cognitive impairment due to Alzheimer's disease to Alzheimer's disease dementia. Effect sizes were stronger for auditory memory rather than speech-in-noise perception measures.
Conclusions: This study presents cross-sectional evidence linking auditory behavioural performance to neuroimaging markers related to neurodegeneration in AD, suggesting a direct link between central hearing and neurodegeneration.

CAN COGNITIVE CHARACTERISTICS AND AGE OF HEALTHY PEOPLE BE PREDICATED BY WHOLE BRAIN STRUCTURAL CONNECTOME?

POSTERS: A04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC & BEHAVIORAL TESTS, DIGITAL ENDPOINTS, REMOTE TESTING

Yong Li[1], Sebastian Kopetzky Kopetzky[1], Markus Butz-Ostendorf[1], Marcus Kaiser[2]

Aims: The ability to predict cognitive states and age of healthy people via whole brain structural connectome alone is highly challenging but extremely meaningful in identifying individuals at high-risk in presympotomatic neurodegenerative diseases stage within healthy people. This study provides a plausible option, which employs a simple machine learning model, an automated imaging processing pipeline and whole brain structural connectome features extracted by the pipeline, to predict changes in crystallized intelligence, fluid intelligence and age based on limited brain image modality alone.
Methods: Our in-house automated brain imaging processing pipeline was applied for the healthy subjects from the Human Connectome Project Young Adult (HCP, N=1048) and ANDI-3 study (N=94) to extract whole brain probabilistic tractography-based connectome features. To predict crystallized and fluid intelligence as well as age, we used the correlation-based regression algorithm (Han et al. 2014) with a 10-fold cross-validation for each data set.
Results: For the HCP subjects, predictability of crystallized intelligence was better than that of fluid intelligence in all investigated conditions (Wilcoxon signed-rank test, P_{Total}=1.38e-10, P_{Male}=3.26e-06, P_{Female}=2.18e-06, Benjamini-Hochberg multiple testing correction FDR=0.05). Our results well predicted age for ADNI-3 subjects (r=0.57, NMAE=0.14), whereas it was less profound for the HCP subjects (r=0.21, NMAE=0.20) under all conditions.
Conclusions: Our study provides a realistic attempt to explore different predictabilities of cognitive assessments as well as age in healthy people by using a simple machine learning approach constructed based on limited brain imaging data features.

Aims: Effective treatment of Alzheimer's disease and related dementias (ADRD) relies on the availability of scalable biomarkers that enable early detection, prognosis, and monitoring of AD. Biomarkers generated from speech have high potential to meet this need, but their development has been restricted by the size of speech and language datasets with requisite clinical data. SpeechDx aims to enable AD speech biomarker development and validation through (1) generation of a large volume of speech and language data samples across partner clinical sites, (2) pairing of each individual's speech and language data with their clinical data gathered at each site, and (3) harmonization of paired speech-clinical data across all sites.
Methods: SpeechDx is a 3-year observational study enrolling 2,650 participants spanning the full AD spectrum. Quarterly, each participant will remotely complete a brief battery of speech- and language-eliciting tasks via a custom-built SpeechDx app installed onto a study-provided tablet. Tasks included have been selected to elicit semi-constrained and unconstrained speech. SpeechDx clinical sites were selected to ensure reliable longitudinal clinical data collection, which may include blood and CSF ADRD biomarkers, MRI and PET imaging, and neuropsychological testing data. Clinical data across participating sites will be paired with individuals' speech and language data to serve as ground truth for machine learning training and validation. These data will be de-identified and harmonized across clinical sites to form the unified SpeechDx Dataset, accessible via the ADDI AD Curation Studio.
Results: SpeechDx is currently enrolling across 7 clinical sites in the US, Australia, and Spain, with full dataset completion anticipated by the 2028.
Conclusions: SpeechDx enables ADRD speech biomarker development via the creation of a new, gold-standard database of paired, harmonized speech and clinical data.

MINIMUM MMSE INCLUSION CRITERIA AND RELATION TO SUBSEQUENT COGNITIVE CHANGE

POSTERS: A04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC & BEHAVIORAL TESTS, DIGITAL ENDPOINTS, REMOTE TESTING

Cai Gillis[1], Jin Wang[1], John O'Gorman[1], Wenting Cheng[1], Shardae Showell[1], Philip Montenigro[1], Nancy Maserejian[1], Sharon Cohen[2], Paul Aisen[3], Jennifer Murphy[1]
[1]Biogen Inc., Medical Affairs, Cambridge, United States of America, [2]Toronto Memory Program, Neurology, Toronto, Canada, [3]Keck School of Medicine, University of Southern California, Department Of Neurology, San Diego, United States of America

Aims: Better understanding of the impact of MMSE inclusion criteria on disease progression rates would help inform clinical trial design. In this work we explore differences in progression on clinical and cognitive measures comparing those with a baseline MMSE=22 to those with MMSE=21 or with MMSE=20, the minimum MMSE criteria often used in modern early AD trials.
Methods: NACC participants with AD dementia and evidence of amyloid-positivity were eligible for inclusion. Included participants were required to have a clinical dementia diagnosis, a CDR global score of 0.5 or 1.0, and a minimum MMSE score of 20, 21, or 22 all at the same visit. Additionally, at the time of MMSE index baseline, participants were required to be 60-85 years, have ≥6 years of education, and at least one additional follow-up visit with cognitive scores available. Linear mixed effect models adjusted for age, sex, years of education, and APOE ε4 status were examined to estimate mean annualized change in cognitive score (MMSE or CDR-SB) by baseline MMSE score for up to 5 years post-baseline.
Results: In adjusted-models, those with baseline MMSE=20 (n=116) had marginally greater annual progression compared to those with baseline MMSE=22 (n=159) on CDR-SB (0.03 points/year, p=0.13) and MMSE (-0.05 points/year, p=0.13) over follow-up. However, there were no differences in progression rates comparing those with index MMSE=22 (n=159) to those with baseline MMSE=21 (n=116) on CDR-SB (0.01 points/year, p=0.52) or MMSE (-0.02 points/year, p=0.39).
Conclusions: While there was suggestion of marginal differences in progression among baseline MMSE=20 compared to MMSE=22, differences were small and may be potentially relevant statistically but not clinically. Successful measurement of treatment effect in neurologically progressive disease requires a granular understanding of population differences in disease progression rate.

ASSESSING FINGER IMITATION TESTS FOR DEMENTIA AND MCI SCREENING IN CLINICAL PRACTICE

POSTERS: A04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC & BEHAVIORAL TESTS, DIGITAL ENDPOINTS, REMOTE TESTING

Shintaro Nakarai[1], Shinichiro Maeshima[2], Aiko Osawa[1], Hitoshi Kagaya[1]
[1]National Center for Geriatrics and Gerontology, Rehabilitation Medicine, Obu, Japan, [2]National Center for Geriatrics and Gerontology, Education And Innovation Center, Obu, Japan

Aims: In the context of an increasingly elderly population, the prevalence of dementia and mild cognitive impairment (MCI) is on the rise, underscoring the importance of early detection and intervention. The aim of this study is to elucidate the utility of the finger construction imitation test (Fox and Reverse Fox) conducted in routine clinical settings.
Methods: We studied 170 patients attending a memory clinic. They consisted of 100 dementia patients, 53 MCI patients, and 17 cognitively normal individuals. During their initial consultation, patients were asked to imitate the shapes created with their fingers, such as the Fox and the combination of left and right fingers. The study also evaluated the sensitivity and specificity of this test for screening dementia and MCI.
Results: Concerning the imitation of the Fox shape, 121 patients (67 dementia, 44 MCI, 17 cognitively normal) were able to successfully imitate it, while 49 patients (40 dementia, 9 MCI) were not. The imitation of left and right finger combinations was achieved by 27 individuals (10 healthy, 9 MCI, 8 dementia). Significant differences were observed in the success rates of both Fox shape imitation and combination imitation. The sensitivity of Fox shape imitation for dementia and MCI was 0.4 and 0.32, which is relatively low, but the specificity was 1, indicating a high likelihood of success when cognitive function is normal. In contrast, finger combination (Reverse Fox) imitation showed good sensitivity for dementia and MCI, with values of 0.92 and 0.89, but the specificity was somewhat lower at 0.27 and 0.58.
Conclusions: The finger imitation task used in this study is simple and can be performed in a short time, even by non-specialists, suggesting its potential to identify cognitive decline.

IMPAIRED DYNAMICS OF GLOBAL BRAIN COUPLING AND INHIBITORY SIGNALS PREDICT NEURAL OSCILLATIONS IN ALZHEIMER'S DISEASE

POSTERS: A04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: EEG, BRAIN MAPPING, MEG

Parul Verma[1], Benjamin Sipes[1], Kamalini Ranasinghe[2], Faatimah Syed[2], Bruce Miller[2], Katherine Rankin[2], Srikantan Nagarajan[1], Ashish Raj[1]
[1]University of California San Francisco, Radiology And Biomedical Imaging, San Francisco, United States of America, [2]University of California San Francisco, Memory And Aging Center, Department Of Neurology, San Francisco, United States of America

Aims: Recent neuroimaging findings indicate that the brain's functional activity does not remain static even while resting. Instead, it constantly switches between "micro-states", which are dynamic fluctuations of functional activity. We quantify micro-state dynamics in Alzheimer's disease (AD) using a biophysical model that predicts brain function from its structural network.
Methods: The model is characterized by global parameters that describe the coupled excitatory and inhibitory mesoscopic activity and the long-range excitatory macroscopic activity. We aimed to use the dynamic profiles of these parameters to classify AD patients versus a cohort of age-matched controls. Accordingly, we generated time-frequency spectrograms from a 1 min MEG recording with ~0.5s intervals. We then fit the model to each interval across subjects to obtain estimates of the biophysical model parameters, and we used sample entropy as a measure of model parameter temporal dynamics (Fig.1A). We hypothesized that the global coupling parameter, which can reflect microstates of whole-brain integration from those of segregated activity, would be less dynamic in AD.
Results: We indeed found that the global coupling parameter has significantly less dynamics, measured by the lower sample entropy, in AD ($p < 0.001$). We also found that another parameter reflecting inhibitory neural gain had significantly higher entropy in AD ($p < 0.05$; Fig.1B). Further, we found that the sample entropy of these model parameters was useful in classifying AD from controls (AUC = 0.86, Fig.1C), with the most important dynamic feature being global coupling (Fig.1D).

Conclusions: These results indicate that, in addition to biophysical parameters associated with static spectral changes observed previously, we can identify biophysical parameters associated with abnormal micro-state behavior in AD. Lower global coupling entropy indicates less dynamic switching between

integrative and segregated states in

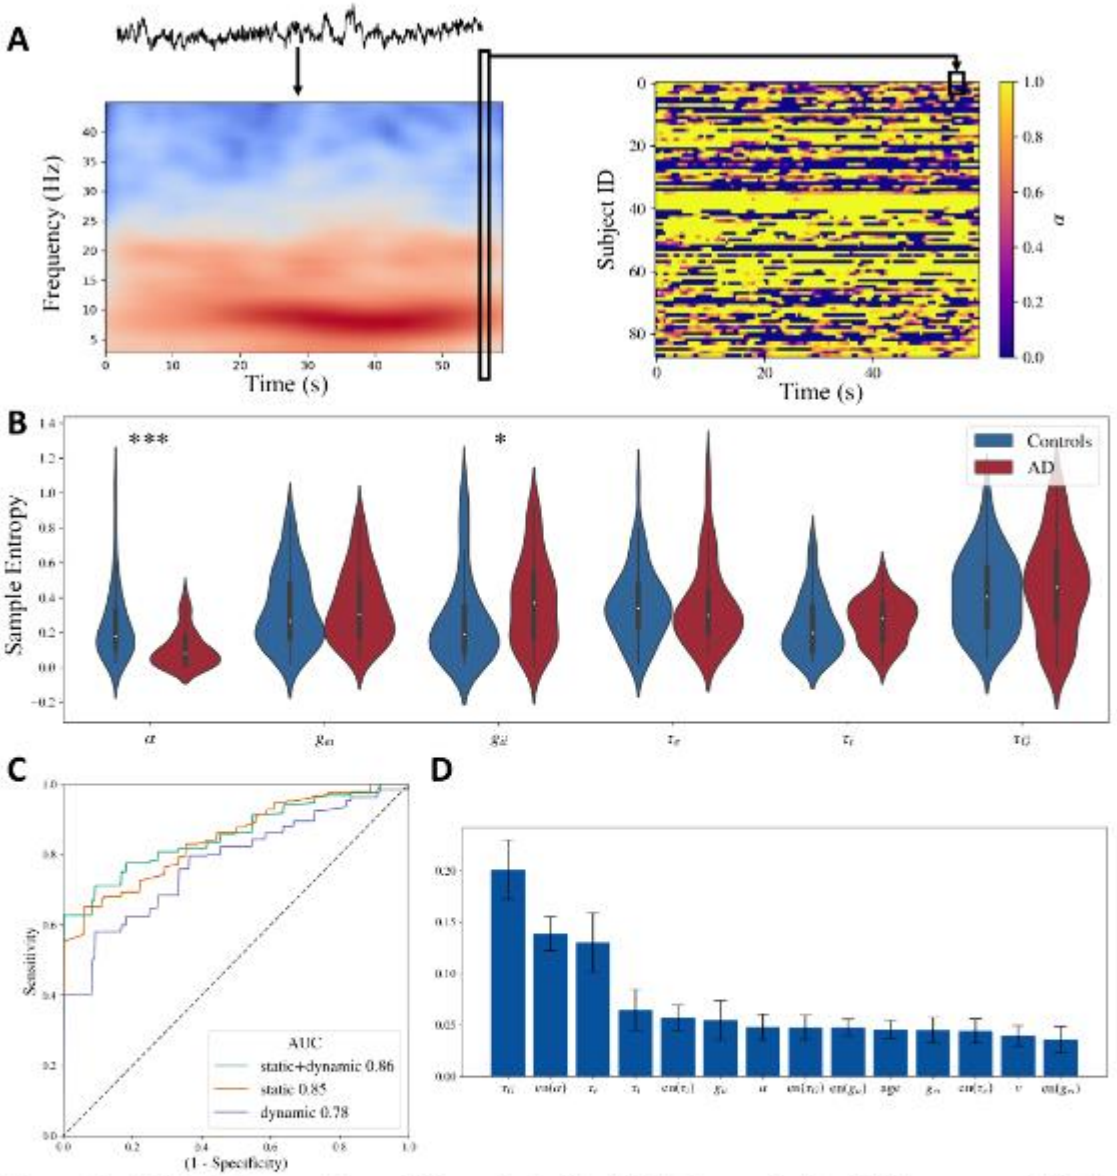

Figure 1: **A**) Illustrative workflow of the method. The MEG time series (top left) are converted into spectrogram (bottom left). We extract frequency spectra every 0.5s and then infer model parameters for each frequency spectra (right). The parameter plot shown on right is for the coupling parameter α. **B**) Sample entropy of parameters α: coupling among brain regions, g_{ei}: mesoscopic neural gain of signals coupled between excitatory and inhibitory populations, g_{ii}: mesoscopic neural gain of inhibitory population signals, τ_e: mesoscopic excitatory signal time constant, τ_i: mesoscopic inhibitory signal time constant, τ_G: macroscopic long-range excitatory time constant (***:p<0.001, *:p<0.05). **C**) Receiver operating characteristics curve obtained with entropy of parameters (purple), model parameters obtained by fitting to static frequency spectra (orange), and both entropy and static parameters (green) as features of a random forest classifier. **D**) Feature importance plot with both static parameters and entropy of dynamic parameters as features of the classifier. en() stands for entropy; v stands for speed parameter.

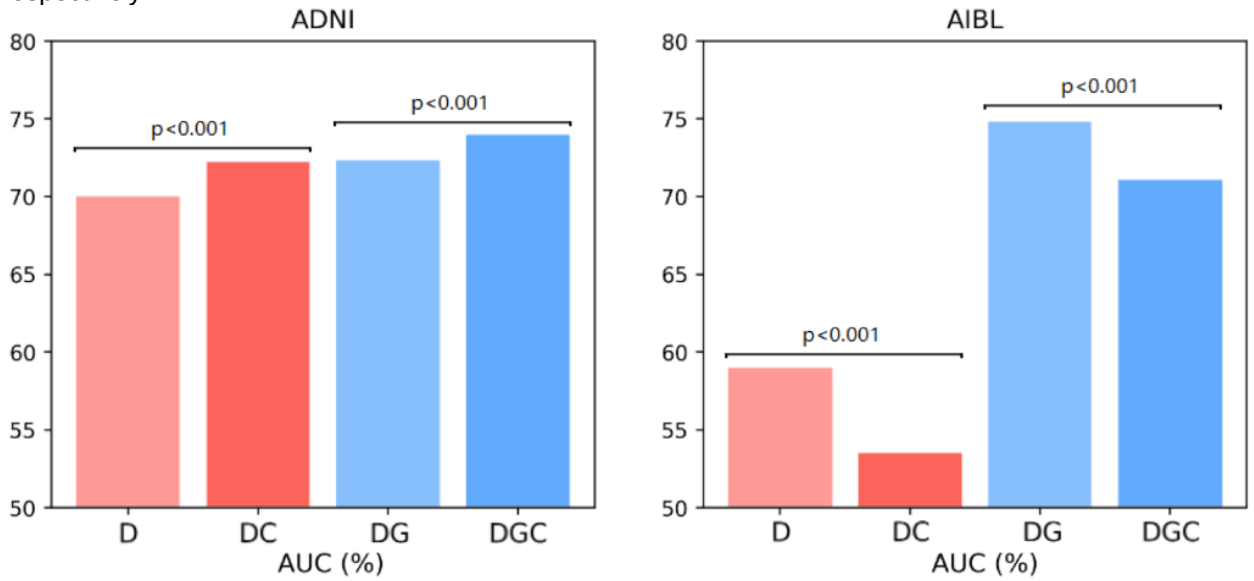
CLASSIFYING BETA-AMYLOID POSITIVITY USING COGNITIVE ASSESSMENTS IN COGNITIVELY UNIMPAIRED COHORTS

POSTERS: A04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC & BEHAVIORAL TESTS, DIGITAL ENDPOINTS, REMOTE TESTING

Shu Liu[1], Benjamin Goudey[1], Victor Fedyashov[1], Paul Maruff[1,2]
[1]University of Melbourne, Florey Institute Of Neuroscience & Mental Health, Carlton, Australia, [2]Cogstate, Cogstate, Melbourne, Australia

Aims: For preclinical Alzheimer's disease (Pre-AD), individuals with Beta-amyloid (Aβ) deposition do not meet criteria for cognitive impairment, there is evidence of subtle cognitive impairment. Therefore, cognitive tests may improve the prediction of Aβ status based on established demographic and genetic risk factors. This study aimed to quantify the benefit of cognitive measures when predicting Aβ status among cognitively unimpaired individuals beyond established risk factors.
Methods: Data came from 65-85 years old cognitively unimpaired individuals of the anti-amyloid treatment in asymptomatic Alzheimer's disease (A4) (n=4,036), the Alzheimer's Disease Neuroimaging Initiative (ADNI) (n=400), and the Australian Imaging, Biomarker & Lifestyle Flagship Study of Ageing (AIBL) cohorts (n=141). Aβ-PET+ status was defined as a Centiloid score>30 based on florbetapir or florbetaben PET imaging. A Ridge regression was trained in the A4 using variables including demographics (D: age, sex, education), genetics (G: APOEe4 status), and cognition (C: CogState Brief Battery, PACC). The performance was evaluated in the AIBL and the ADNI using Area under ROC (AUC).
Results: In AIBL, cognitive measures significantly improved AUC by 2.22% and 1.65% beyond models with D and DG models. In the ADNI, cognitive measures significantly reduced sensitivity by 5.66% and 3.66% vs. age with and without APOE4
respectively.



Conclusions: Cognitive measures designed to be sensitive to AD showed limited or even reduced

sensitivity to Aβ+ compared to age with and without APOE4, motivating the development of Pre-AD specific cognitive tests.

[1]Novartis, Institutes For Biomedical Research, Basel, Switzerland, [2]Cambridge Cognition, Clinical Science, Toronto, Canada

Aims: Sensitive, easy to use, and meaningful markers of early cognitive decline are essential to AD drug development. We examined how audio recordings of the Clinical Dementia Rating (CDR) Scale interview could be used as objective measures of early cognitive decline.
Methods: We analyzed audio recordings of the CDR from 75 English-speaking participants at risk of developing AD enrolled in the Alzheimer's Prevention Initiative Generation Program. All participants were cognitively healthy at baseline. Recordings were processed using the Winterlight speech analysis platform; producing an array of objective speech features. We applied different machine learning strategies to examine which groups of features were predictive of the emergence of clinically significant cognitive decline.
Results: 52% of the participants showed cognitive decline over the course of the study (assigned via expert clinicians at each visit). Examination of classifier learning curves highlighted the recent experience task, and the memory repetition task as showing the strongest association with cognitive decline. Complexity of speech (represented by timing and syntactic features) within the recent experience task showed the strongest effect, predicting a transition to cognitive impairment with 70% accuracy. Other informative categories included acoustic (spectral properties of the sound wave, 69%), morphological (inflection, case and tense changes, 69%) and discourse (organization and repetitiveness, 68%). Sentiment (emotional content) and lexical (types of words used) features performed above chance but were less informative.
Conclusions: These results further support the growing literature linking measurable changes in speech to cognitive decline. New measures are needed to stage and monitor patient cohorts in the earliest phases of disease. These results highlight the utility of speech in these cases and support future validation and use of these tools in clinical trials.

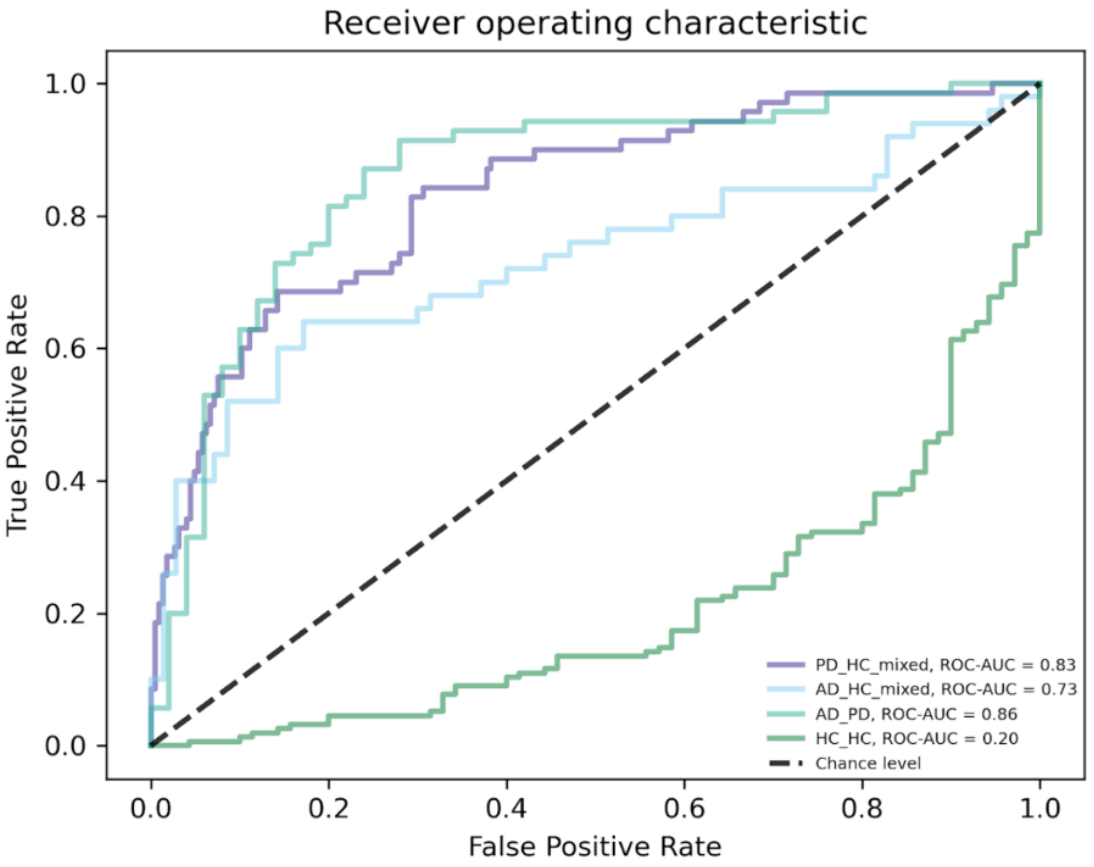
DISTINCT ACOUSTIC SPEECH PROFILES DIFFERENTIATING AD AND PD FROM A READING PASSAGE IN SPANISH

POSTERS: A04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC & BEHAVIORAL TESTS, DIGITAL ENDPOINTS, REMOTE TESTING

Johannes Tröger[1], Elisa Mallick[1], Felix Dörr[1], Alexandra König[2,3], Ebru Baykara[2], Nicklas Linz[1], Juan Rafael Orozco-Arroyave[4]
[1]ki:elements, Research, Saarbrücken, Germany, [2]ki:elements, Clinical, Saarbrücken, Germany, [3]inria, Cobtek, Sophia Antipolis, France, [4]Universidad de Antioquia, Gita Lab, Medellín, Colombia

Aims: The aim of this work is to investigate whether acoustic speech biomarker profiles from a standardized reading passage speech task can differentiate Alzehimer's from Parkinson's disease and associated behavioral clinical symptoms.
Methods: This feasibility research is based on two different Spanish reading speech data sets—the Dementia Bank IVANOVA (Ivanova et al., 2022) and the PC-GITA (Orozco-Arroyave et al., 2014). Both data sets recorded patients and matched healthy controls: IVANOVA (AD_dementia 54/ HC 155) and PC-GITA (PD 70 / HC 70). From the recordings, we extracted acoustic features using the ki:elements speech extraction library SIGMA. We normalized acoustic features for potential cohort effects (loudness normalization) and subsequently preselected acoustic features that do not show significant differences on their distributions when comparing the respective HC groups using p = 0.20 as cutoff on the Two Sample Smirnov Test. We then combined those features in logistic regression models using 10-fold x-validation for better generalisability to simulate downstream clinical utility.
Results: After preprocessing set of acoustic features remained significant measuring temporary aspects of speech, voice quality as well as prosodic aspects. Those features have been traditionally associated with symptoms in PD such as aprosodia or dysphonia as well as apathy in AD dementia. The logistic regression models were able to differentiate between PD and AD with a balanced accuracy of .81. The Receiver Operating Characteristics of all models evaluated can be seen in Figure
1.



Conclusions: The results show that acoustic speech biomarker profiles can indeed differentiate AD and PD. A limitation of these results is that patient groups stem from different cohorts. However, both are Spanish and we conducted a series of preparatory steps ensuring that speech features are not significantly different between the cohorts per se.

Aims: To identify actigraphy and sleep differences between Alzheimer's disease (AD) and dementia with Lewy bodies (DLB).
Methods: Participants with probable AD (n=8) and DLB (n=12) wore triaxial wGT3X-BTs actigraphy devices on their non-dominant wrists for 2 weeks and Sleep Profiler X8 EEG devices on their foreheads for 2 consecutive nights. Raw actigraphy data were converted into daily activity counts (ACs) using activityCounts R with fragmentation calculated using ActFrag R.
Results: AD participants were ~10 years older than DLB participants, but other demographics and cognitive scores were similar. AD participants had shorter sedentary bouts (mean minutes [SD]=4.30 [0.85] vs 5.44 [1.34]) and slightly higher ACs (mean [SD]=$1.45x10^6$ [$5.82x10^5$] vs $1.38x10^6$ [$6.99x10^5$]) than DLB participants (Fig. 1a/1b). A threshold of 200 counts/minute showed the most separation between groups, with AD participants spending more time above the threshold (mean minutes [SD]=657 [89] vs 550 [161]; Fig. 1c). AD participants spent more time in REM sleep (mean [SD]=17.8% [4.51] vs 6.89% [7.19]) and less in NRH (mean [SD]=5.03% [4.95] vs 12.8% [11.3]) than DLB participants (Fig. 2).

Figure 1a: Sedentary bout duration

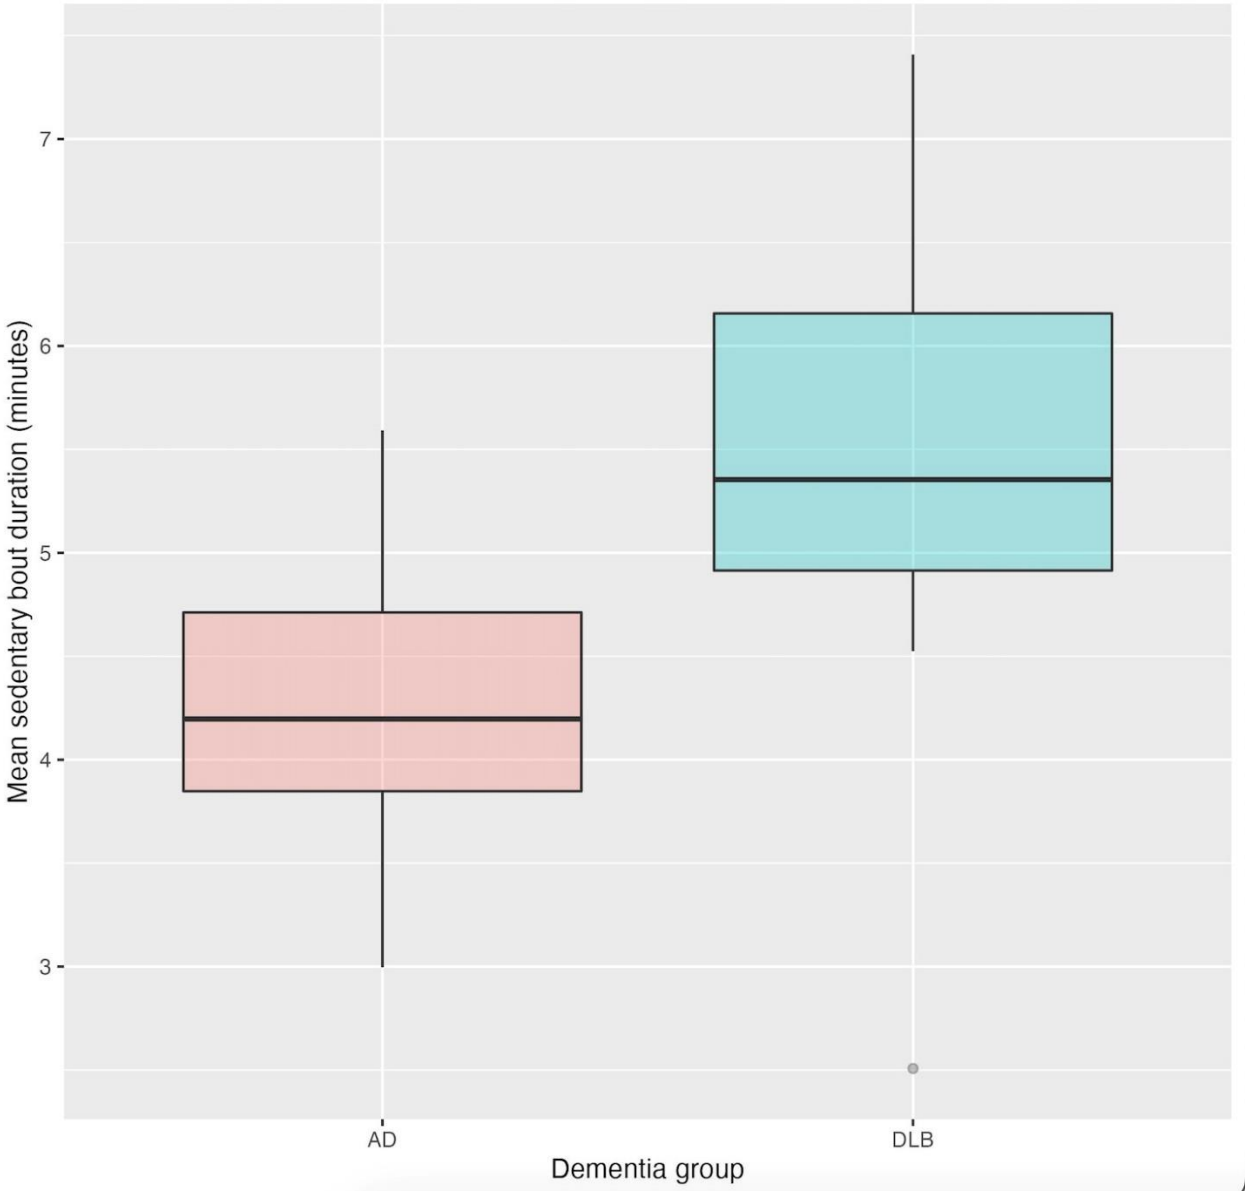

Figure 1b: Total activity

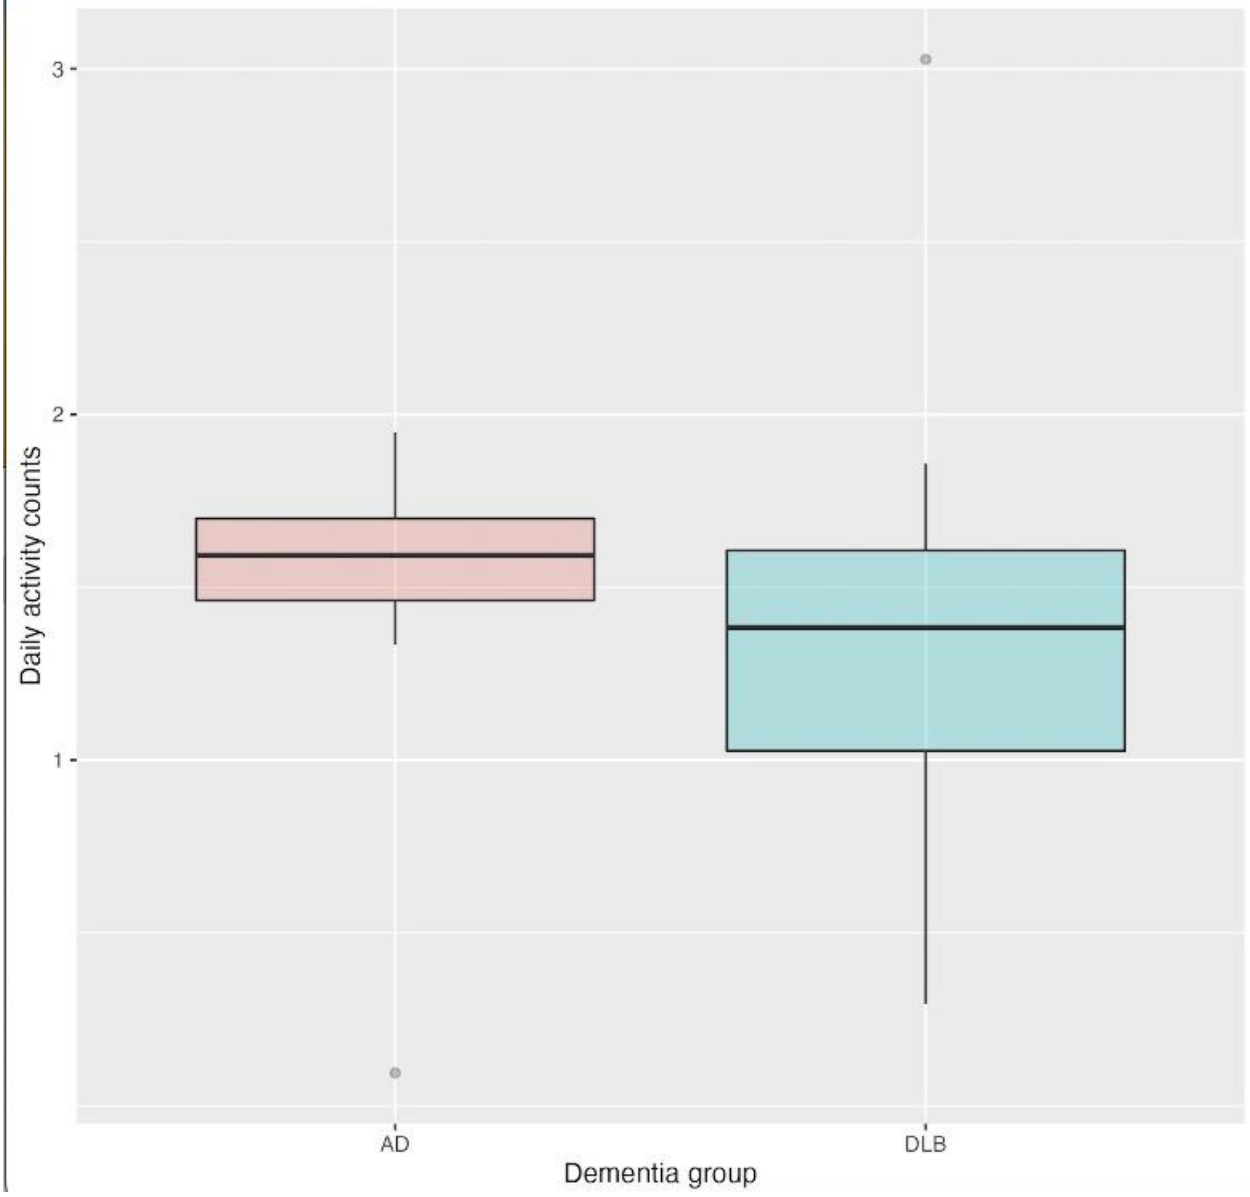

Figure 1c: Activity count cutpoint thresholds

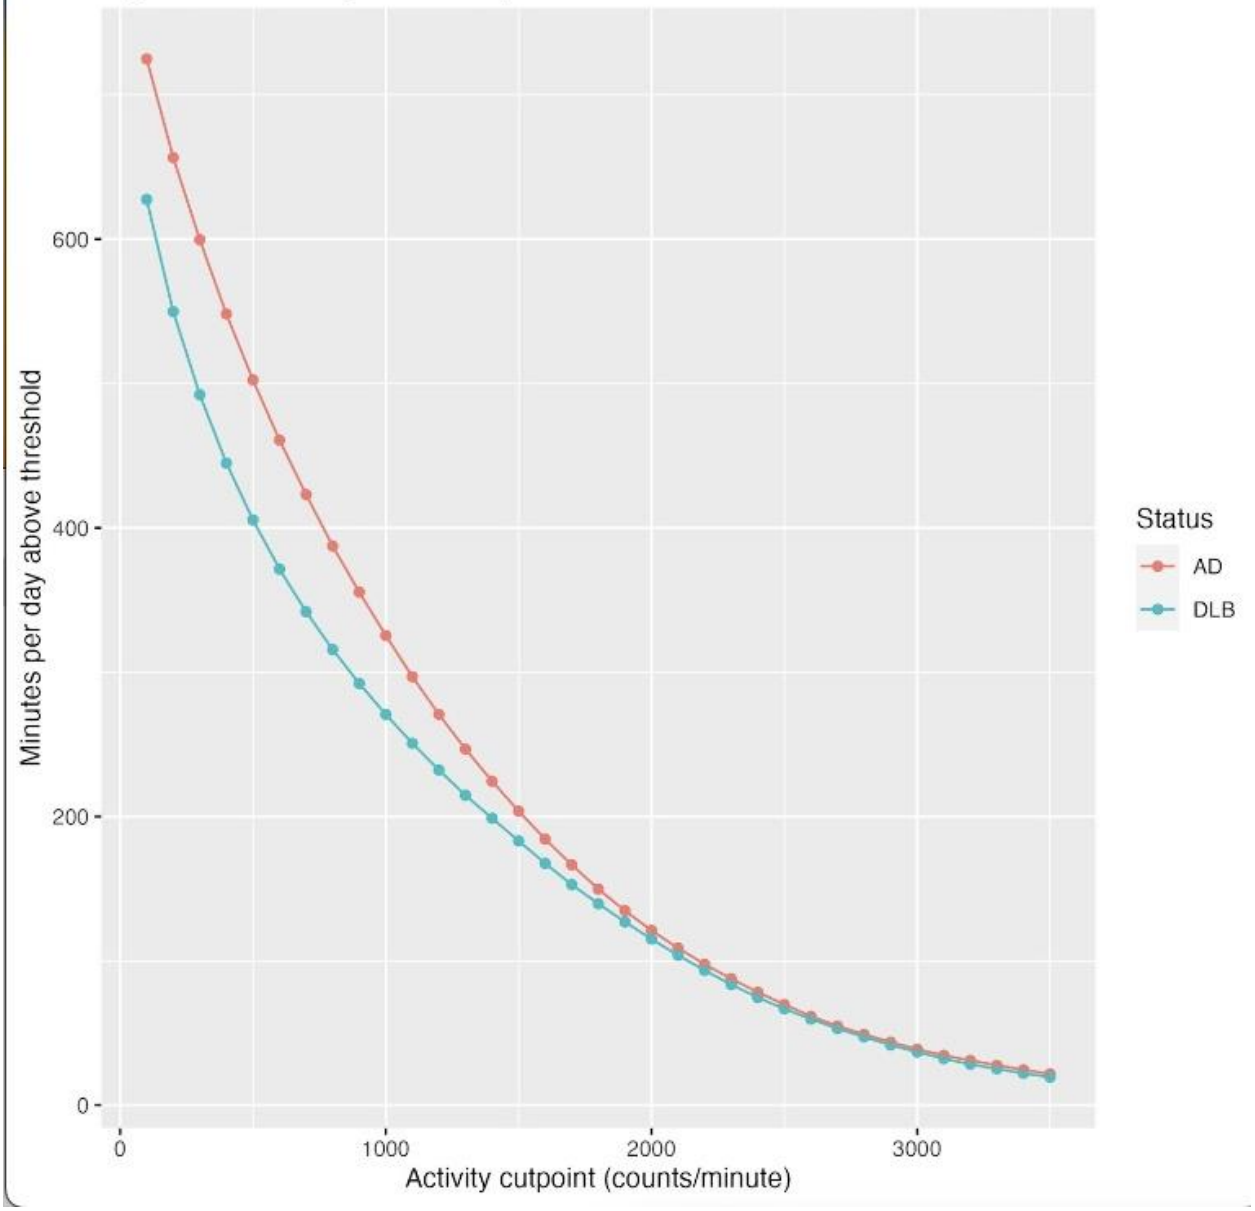

Figure 2: Sleep metrics

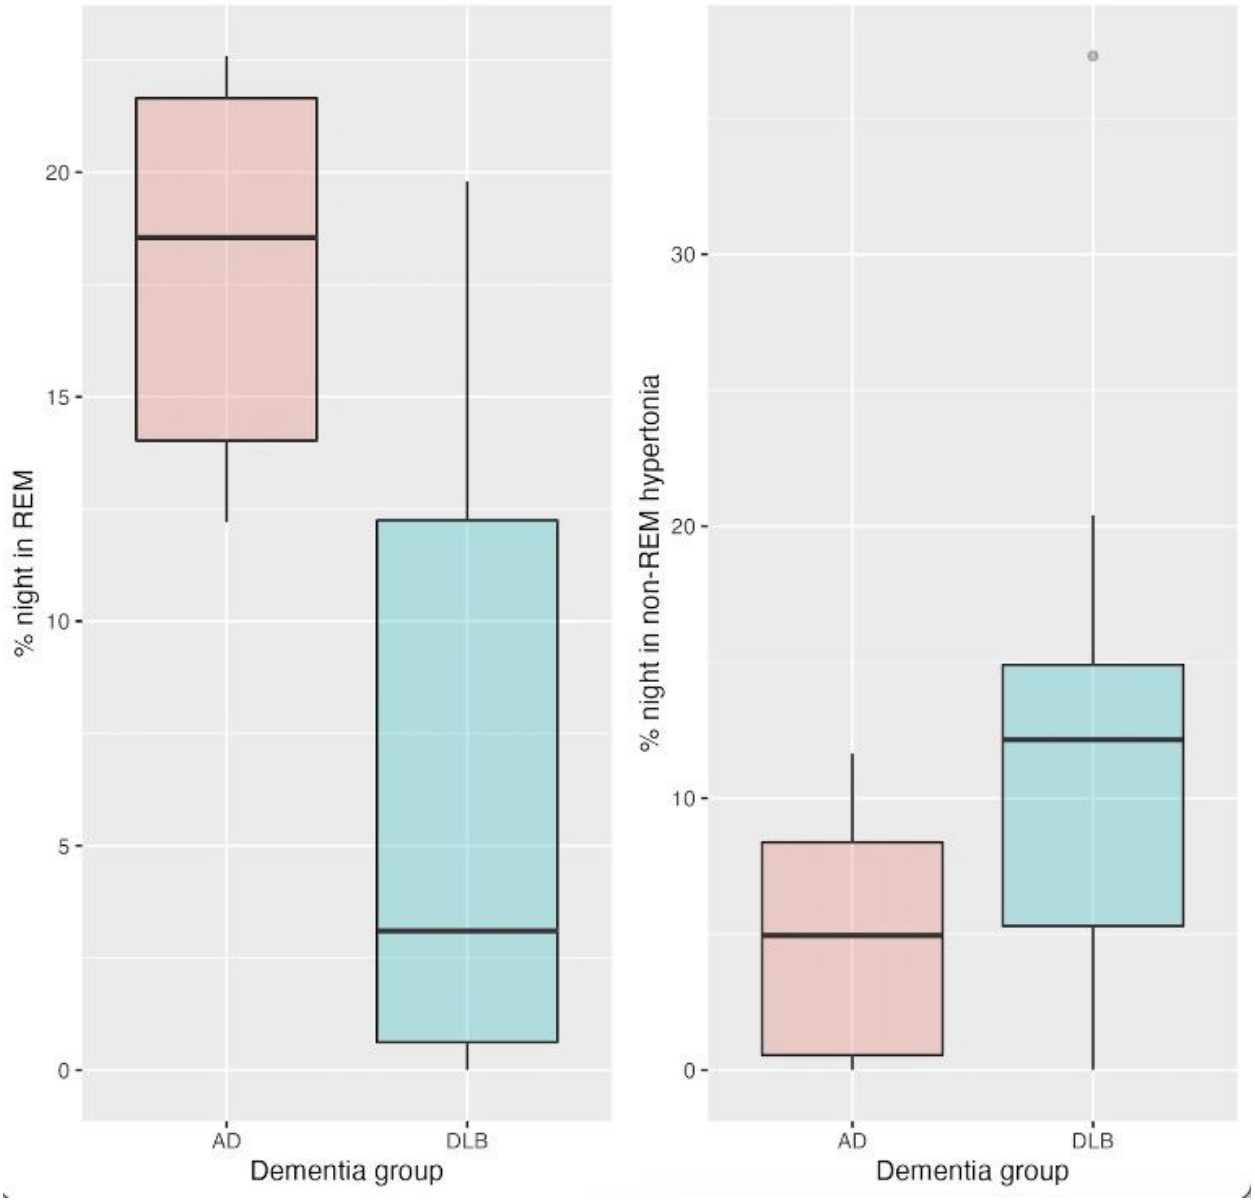

Conclusions: Actigraphy and sleep-monitoring devices can elucidate potential differences between AD and DLB in REM and NRH time, sedentary bout duration, and activity at low-activity thresholds.

Aims: Previous studies suggest that in prodromal Alzheimer's disease (AD) stages, AD pathology (i.e., deposition of Aβ(1-42) and p-tau181) may be differentially associated with different cognitive function domains. Precisely, one study showed that abnormal CSF Aβ(1-42) status predicts executive function decline, and abnormal CSF p-tau181 status predicts memory decline in cognitively unimpaired (CU) individuals with AD neuropathology. Here, we aimed to validate and extend these previous findings.
Methods: CU participants from the German DELCODE cohort with available CSF biomarker data (p-tau181, Aβ(1-42) and total tau) and neuropsychological test data on executive functions, memory, visuospatial functions and verbal fluency (i.e., TMT, Delayed Recall, Clock Copying, Animal Fluency Task) were included. Additionally, analyses were conducted not only for single test scores but also for cognitive domain composite scores. Analyses were performed using Multiple linear regression models.
Results: 287 participants were included. Aβ(1-42) was associated with executive functions as measured by the TMT (β=0.12, p=0.043). However, no association was found between Aβ(1-42) and the executive functions composite score. P-tau181 was associated with memory (i.e., ADAS Delayed Recall test; β=0.16, p=0.005), but not with the memory composite score. None of the predictors were associated with verbal fluency or visuospatial function. In a second step to investigate the prodromal AD stages, participants were classified in A+/A- and T-/ N- biomarker profiles. Again, Aβ(1-42) was associated with executive function (β=0.12, p=0.047) but not with memory. No association was found for the executive functions composite score.
Conclusions: In line with previous findings, Aβ(1-42) was associated with worse executive function performance, while p-tau181 was associated with worse memory performance. However, no effect of Aβ(1-42) on executive functions was found using composite scores, which ultimately warrants additional research into this topic.

LONGITUDINAL IN VIVO MICROSCOPIC IMAGING OF AB PATHOLOGY IN A NOVEL HUMANIZED APP KNOCK-IN MOUSE MODEL (APPSAA)

POSTERS: A04.J. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Evgeny Pryazhnikov[1], Ulrika Julku[1], Tamas Kopcsanyi[1], Tom Cornelissen[2], Wannes Dejonckheere[2], Sofie Carmans[2]
[1]Neurotar LtD, Neurotar Ltd, Helsinki, Finland, [2]reMYND, Cro, Leuven, Belgium

Aims: *In vivo* two-photon imaging of cerebral Aβ deposits is an invaluable tool for studying these hallmarks of Alzheimer's disease (AD) and evaluating the efficacy of disease-modifying treatments. We present the results of the first-time *in vivo* assessment of the growth patterns of parenchymal and perivascular Aβ plaques in a new humanized APP knock-in mouse model (APPSAA) which endogenously expresses APP with three clinical mutations.
Methods: We used longitudinal *in vivo* two-photon imaging to follow the growth of Aβ plaques in the somatosensory cortex of 6.5 months old humanized APPSAA knock-in mice. The plaques were labeled using a Methoxy-XO4 tracer 24 hours before the start of imaging.
Results: Initial observations revealed a moderate density of Methoxy-XO4-labeled plaques with a small dense core surrounded by fibrillar Aβ. This is in line with previously observed Aβ staining by immunohistochemistry. Follow-up imaging sessions revealed an increase in density of cortical plaques primarily due to the emergence of new small Aβ cores, rather than the expansion of pre-existing plaques. Notably, perivascular amyloid deposition escalated after 7 months of age. In 80% of the mice, the cranial windows remained clear, permitting the longitudinal tracking of individual deposits over multiple sessions. No behavioral abnormalities linked to anesthesia were observed in these subjects.
Conclusions: This first *in vivo* pathological characterization of the APPSAA model underscores its potential for *in vivo* testing of compounds aimed at slowing AD progression.

THE GAIT PATTERN OF ALZHEIMER'S DISEASE IS ASSOCIATED WITH THE REGIONAL BETA-AMYLOID DEPOSITION AND CORTICAL ATROPHY

POSTERS: A04.J. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Min Seok Baek[1], Dong Ho Kim[2]
[1]Wonju Severance Christian Hospital Yonsei University Wonju College of Medicine, Department Of Neurology, Wonju, Korea, Republic of, [2]Korea University, 1department Of Artificial Intelligence, Seoul, Korea, Republic of

Aims: To investigate the association between gait patterns and neuroimaging biomarkers in Alzheimer's disease.
Methods: We prospectively included 33 cognitively unimpaired (CU) individuals, 20 patients with MCI due to AD, and 43 patients with AD dementia at the Memory Disorder Clinic of Wonju Severance Christian Hospital between January 2022 and May 2023. Participants underwent brain magnetic resonance imaging (MRI), ^{18}F-florbetaben PET, neuropsychiatric tests, and APOE genotyping. Gait was evaluated using a 5.79-m long walkway. We conducted a comparative analysis using Pearson correlation to examine the relationships between gait parameters and several variables, including cortical thickness and regional Standardized Uptake Value Ratios (rSUVR).
Results: After controlling for age, sex, and duration of education, the MCI group exhibited distinct gait patterns compared to the CU group. Specifically, the MCI group displayed lower velocity, reduced step length, and decreased swing %. The gait patterns of the Dementia (DEM) group were characterized by even more pronounced decreases in velocity, step length, and swing percentage in comparison to the CU group. Decreased gait velocity and step length was associated with greater Aβ burden in prefrontal, sensorimotor, parietal, lateral temporal, occipital, and anterior cigulate cortices and precuneus. Decreased step length was associated with greater Aβ burden in the prefrontal, inferior parietal, lateral temporal, occipital, anterior cingulate cortices and precunes after multiple region-wise correction. Gait velocity and step length was associated with cortical thickness in the lateral temporal, inferior parietal, entorhinal, parahippocampus, insular cortices and
precuneus.

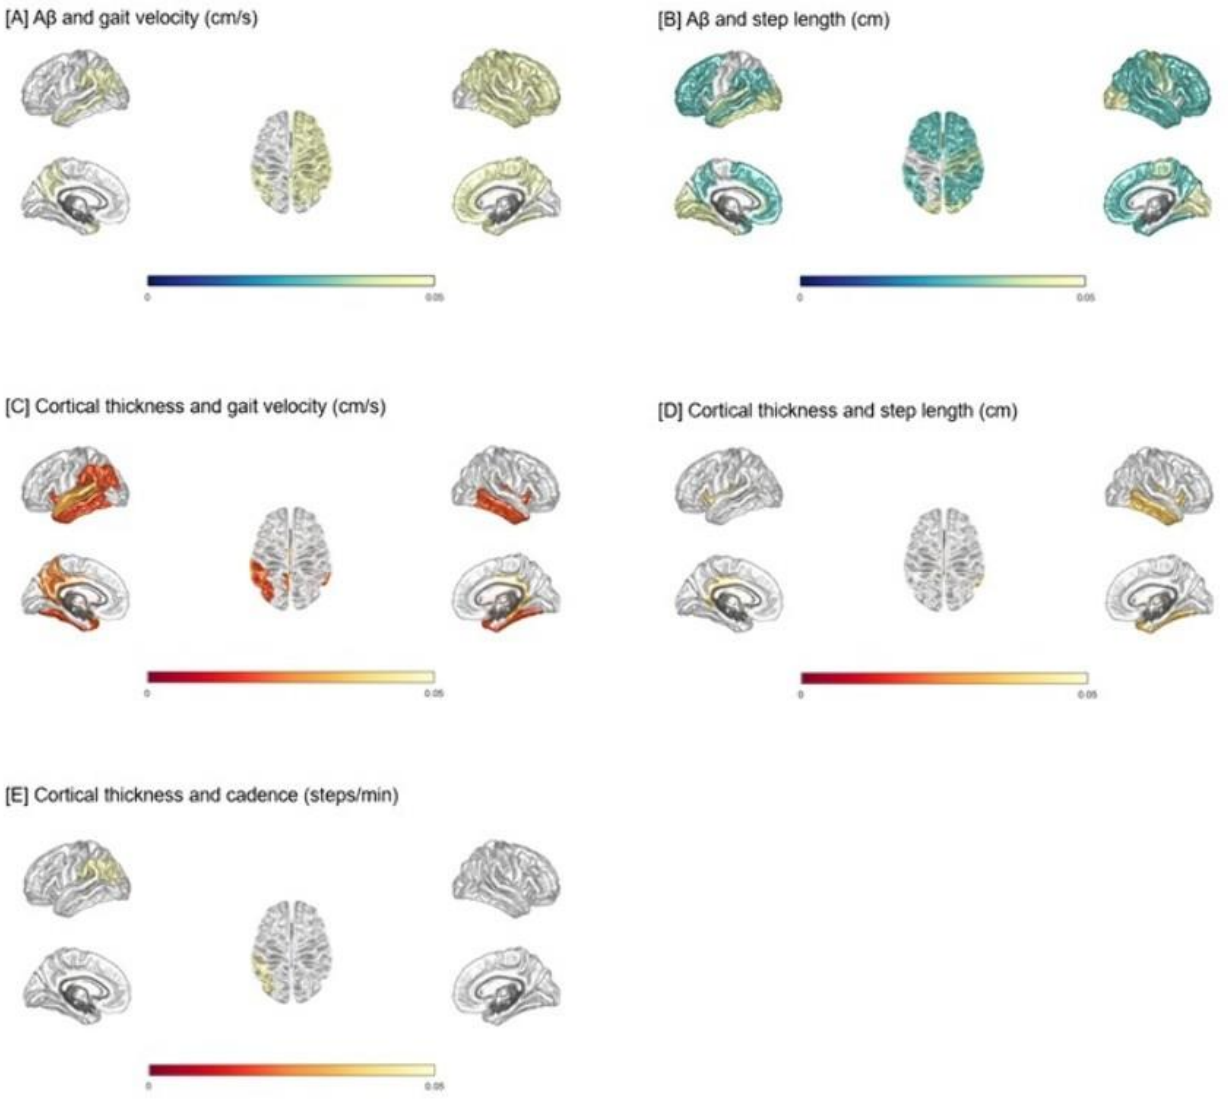

Figure 1. Association of gait parameters with ^{18}F-florbetaben SUVR (A, B), and cortical thickness (C, D, E) after adjustment for age, sex, and duration of education.

Conclusions: Our study has revealed significant correlations between gait parameters and Aβ, and cortical thickness in AD. T

Aims: Proteomic subtyping is a valuable tool for understanding the biological differences between individuals, regardless of clinical presentation. Our recent proteomic studies of human brain tissues have identified disease subtypes in cognitively impaired individuals linked to distinct biological mechanisms and clinicopathological phenotypes in the aging brain. Here, we extend these analyses by including over 300 new individual samples, which include over 100 African Americans.
Methods: Over 9000 proteins were quantified from more than 900 postmortem brain samples obtained from the Religious Orders Study and Rush Memory and Aging Project using tandem mass tagged mass spectrometry (TMT-MS). Module hub proteins from a recent consensus network analysis of the human brain were utilized to classify samples into subtypes based on patterns in shared biology, using the MONET M1 modularity clustering algorithm. Furthermore, to preserve the effects of demographic factors on proteomic subtyping, age and sex were not regressed. Supervised machine learning approaches were utilized to identify proteins driving subtype distinction.
Results: Unbiased classification of control, mild cognitively impaired (MCI) and Alzheimer's Disease (AD) brain proteomes resolved multiple subtypes with expression differences across numerous cell-types and biological ontologies. Each subtype differs in their clinical and pathological presentation and demographics (e.g., age, sex, race). One subtype enriched with MCI and AD presented with atypical proteomic features associated with clinical and pathological hallmarks of cognitive resilience.
Conclusions: Unbiased clustering can resolve pathological and cellular phenotypes linked to cognitive impairment. Further investigation of these distinct subtypes promises to meaningfully impact diagnostic, prognostic, and therapeutic precision.

A NOVEL APPROACH TO DETECT ABERRENT TRIGLYCERIDES IN AD TRANSGENIC MOUSE BRAIN USING MALDI-2 MASS-SPECTROMETRY IMAGING

POSTERS: A04.J. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Bandana Bera[1], Daniela D'Amico[1], Prem Shankar[1], Eliseo Eugenin[1], Giulio Taglialatela[2], Brendan Prideaux[1]
[1]University of Texas Medical Branch, Department Of Neurobiology, Galveston, United States of America, [2]University of Texas Medical Branch, Neurology, Galveston, United States of America

Aims: Neutral storage lipids, such as triacylglycerides (TAGs) and cholesteryl esters (CEs), accumulate as lipid droplets (LDs) within tissues and cells in multiple neurodegenerative disorders including Alzheimer's disease (AD), Parkinson's disease (PD), Huntington's disease, and amyotrophic lateral sclerosis. Due to their poorer ionization efficiencies than other abundant lipids visualization of TAGs and CEs in brain is challenging using traditional MALDI-1 MSI techniques. A modified MALDI-2 MSI imaging approach has been developed with improved sensitivity to detect and visualize the distribution of neutral lipids in brain tissues to elucidate their role in AD pathogenesis.
Methods: MALDI-2 MSI was applied to examine neutral lipid distribution such as triglycerides accumulation within the subventricular zone (SVZ) in brain tissue obtained from 5 and 17 months old 3xTGAD mice and wild type controls. A combination of lipidomic MALDI-2 MSI assessment, immunofluorescence (IF) analysis, and histological staining for morphological evaluation were used for a direct co-localization of lipid/metabolite with protein signals at a single cell spatial resolution.
Results: We have found that MALDI-2 increases the sensitivity of TAG analysis when spiked onto brain tissue sections. MALDI-2 ionization also enhances TAG imaging in 3xTG mouse brain tissues, more interestingly we found that TAG accumulate within the SVZ early period of disease pathogenesis in the 3xTg mouse model (~ 5 months) and the accumulation increased with disease progression. Moreover, we also found that our MALDI-2 methods produce IF equivalent image quality.
Conclusions: Our optimized MALDI-2 MSI approach enables imaging of TAGs in 3xTG mice brain tissues at the single cell spatial resolution. This characterization can be translated to other neurodegenerative diseases to elucidate potential targets for new pharmacological therapies.

NEW INSIGHTS INTO ETIOLOGY OF ALZHEIMER'S DISEASE: THE ROLE OF DIACYLGLYCEROL KINASE Θ (DGKΘ)

POSTERS: A04.J. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Giovanna Casili, Marika Lanza, Laura Cucinotta, Rossella Basilotta, Irene Paterniti, Salvatore Cuzzocrea, Salvatore Oddo, Emanuela Esposito
University of Messina, Chemical, Biological, Pharmaceutical And Environmental Sciences, Messina, Italy

Aims: Objectives. Diacylglycerol kinase (DGK) is a key enzyme in regulating diacylglycerol turnover and is involved in various physiological functions. The isoform DGKθ has a unique domain structure, and it is predominantly expressed in excitatory neurons throughout all parts of the mammalian brain. This study aimed to reveal the involvement of DGKθ in neurodegenerative diseases, highlighting its role in Alzheimer's disease (AD).
Methods: Methods. The evaluation of DGKθ was verified in brains of APP/PS1 and control mice (4-5 and 12-18 months of age) through western blot analysis. Immunohistochemistry analysis was used to reveal b-amyloid depots and glial fibrillary acid protein (GFAP) immunostaining. Statistical correlations between DGKθ expression, inflammatory markers and autophagy activation were also performed.
Results: Results. In older APP/PS1 mice (12-18 months of age), DGKθ levels were significantly higher compared to control mice and positively correlated with b-amyloid deposit. In addition, GFAP immunoreactivity and mTOR activation positively correlated with DGKθ levels. Interestingly, the absence of DGKθ modulation in control APP/PSN1 mice at 4-5 months of age, supports the idea that the AD disease triggers the increase in DGKθ.
Conclusions: Conclusions. These results suggest that DGKθ may play a significant role in AD, potentially serving as a crucial diagnostic biomarker and offering valuable insights into its use as a pharmacological therapeutic target.

ASSOCIATION BETWEEN CSF AB42/40 RATIO AND AMYLOID DISCRIMINABILITY OF ATN CLASSIFICATION IN ODOR IDENTIFICATION IN ALZHEIMER'S DISEASE

POSTERS: A04.J. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Yukifusa Igeta[1], Isao Hemmi[2], Kohei Yuyama[3], Yasuyoshi Ouchi[1]
[1]Toranomon Hospital, Department Of Dementia, Minato-ku, Tokyo, Japan, [2]Japanese Red Cross college of Nursing, Faculty Of Nursing, Shibuya-ku, Tokyo, Japan, [3]Hokkaido University, Faculty Of Advanced Life Dcience, Kitaku,Sapporo, Japan

Aims: Screening tests are necessary to identify patients who are suitable for Alzheimer's disease (AD) disease-modifying therapies. We studied whether odor identification scores can identify patients at each stage of the ATN classification system.
Methods: This study included 132 Japanese participants, with 49 having AD, 23 having mild cognitive impairment (MCI), and 60 normal controls. Participants underwent comprehensive medical evaluations, including neuropsychological tests, imaging studies, and CSF biomarker assessments. ELISA was used to measure Aβ42, p-Tau181, and t-Tau in CSF. ROC analysis was performed to determine cutoff values for each biomarker for diagnosing AD. Based on this index, ATN classification was performed. The discriminative ability of odor identification scores was evaluated among four ATN subgroups, which included the normal biomarker group and the AD continuum, after removing the SNAP group. The correlation between odor identification scores and various CSF biomarkers and neuropsychological tests were also examined.
Results: The odor identification scores correlated significantly with major neuropsychological scores, regardless of apolipoprotein E(APOE)4 status. They also correlated with effective cerebrospinal fluid (CSF) biomarkers (amyloid β(Aβ)42 ($p=0.0005$) and the Aβ42/40 ratio($p=0.0001$) and phosphorylated Tau (p-Tau)/Aβ42 ratio ($p<0.0001$) but not ineffective biomarkers (Aβ40($p=0.813$) and the p-Tau/total Tau (t-Tau) ratio($p=0.262$). Covariate analysis showed a slight positive correlation between the odor identification scores, and CSF Aβ42 ($\rho=0.230$; $p=0.043$) and the Aβ42/40 ratio ($\rho=0.292$; $p=0.010$). Conclusively, according to the ATN classification, the odor identification scores demonstrate excellent discriminative power for amyloid deposition but are unsuitable for differentiating between the p-Tau accumulation and neurodegeneration stages.
Conclusions: The odor identification scores show a mild association with CSF Aβ42 and the Aβ42/40 ratio and is a potential screening parameter for preclinical AD.

EXPLORATORY ANALYSIS OF 3000 PROTEINS IN POSTMORTEM HUMAN BRAIN TISSUE LYSATES USING PROXIMITY EXTENSION ASSAY

POSTERS: A04.J. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Anne-Li Lind[1], Christoffer Cambronero[2], Ryan Lamers[1], Mariana Fontes[1], Tarif Awad[1]
[1]Olink Proteomics, Scientific Affairs, Uppsala, Sweden, [2]Olink Proteomics, Data Science, Uppsala, Sweden

Aims: The development of effective management strategies of neurological disorders is challenging, in part because of the complexity and inaccessibility of the affected systems and tissues. Omic, and multi-omic analyses of bio-banked postmortem donor brain tissues offer a unique opportunity to map complex mechanisms in the actual tissue affected by neurological disease. In this study we aimed to evaluate the matrix compatibility and technical performance of a new Olink® Proximity Extension Assay (PEA) technology measuring 3000 proteins in human brain tissue lysates.
Methods: In this exploratory technical study, we examined, for the first time, the detectability of 3,000 human proteins in 15 postmortem human brain tissue lysate samples using PEA technology. The study protocol and platform performance were evaluated for data quality and technical reproducibility.
Results: The results showed robust detectability for the neat dilution of this complex sample matrix for the majority of assays, including hundreds of proteins relevant for neurological conditions.
Conclusions: We conclude that the PEA proteomic platform can serve as a valuable tool for neurological studies involving brain tissues. Leveraging recent technological advances in sample-sparing scalable proteomic methods, such as the PEA, can accelerate insights into pathophysiological mechanisms and the identification of novel drug targets.

NON-DESTRUCTIVE SYNCHROTRON X-RAY IMAGING OF METAL LEVELS IN HUMAN HIPPOCAMPUS FOR CONTROL, MCI AND ALZHEIMER'S

POSTERS: A04.J. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Yunxing Ma[1], Joanna Collingwood[2], Natalie Arigundiya[2], Kalotina Geraki[3]
[1]University of Warwick, Engineering, Coventry, United Kingdom, [2]University of Warwick, School Of Engineering, Coventry, United Kingdom, [3]Diamond Light Source, I18 Beamline, Didcot, United Kingdom

Aims: Synchrotron X-ray fluorescence (SXRF) imaging is non-destructive and provides excellent sensitivity and specificity for trace metals. The objective is to understand the evolution of metal element levels and distributions through the development from healthy control to advanced Alzheimer's, as this has implications for pathogenesis and therapeutic interventions.
Methods: SXRF imaging and subsequent elemental quantification was performed at 30μm resolution for human hippocampus sections from 6 cases with clinical diagnoses of control, mild cognitive impairment (MCI), and AD (healthy or Braak stage I&II, III&IV, V&VI respectively). Corresponding adjacent H&E stained sections informed segmentation of hippocampal subfields.
Results: Detailed evaluation by hippocampal subfield revealed some metal elements unchanged as a function of disease status, whereas others differed. For example, iron clusters were prominent in the region between the cornu Ammonis (CA) pyramidal cell layer and dentate gyrus (DG) granule layer. AD cases had lower average iron levels (35 ppm, n=2) in this region compared to MCI (39 ppm, n=1) and healthy control (46 ppm, n=3). CA4 had the highest level of zinc among the hippocampal subfields evaluated, regardless of disease status. The average and standard deviation for zinc in CA4 was 35 ppm +/- 6 ppm. Zinc contrast clearly highlighted the boundary between CA4 and DG.
Conclusions: Metal-ion distributions in human hippocampus subfields were quantified at high resolution with excellent sensitivity and specificity. Correlation with optical microscopy and adjacent stained sections permitted unprecedented non-destructive investigation of the elemental properties, with scope for further evaluation of pathological hallmarks in the XRF-imaged human brain tissue sections.

Aims: We conducted a study to assess which acoustic variables related to prosody were most associated with intact neuropsychological test performance in a group of community dwelling research participants.
Methods: Community dwelling participants (n= 245) were assessed with a 10-minute digitally administered and scored neuropsychological protocol encompassing verbal memory (6-word Philadelphia [repeatable] Verbal Learning Test [P(r)VLT]), working memory (backward digit span), and lexical access (semantic fluency) abilities. Cluster analysis using standard test scores classified participants into cognitively normal (CN), dysexecutive (dMCI), and amnestic mild cognitive impairment (aMCI) groups. Linear regression analyses of standardized residuals created a single residual acoustic score (RAS) for each test. Acoustic analyses measuring decibel, speech duration/total syllables, and variations in signal frequency (jitter) and amplitude (shimmer) were obtained from the P(r)VLT-delay free recall and semantic ('animals') fluency tests.
Results: Nominal regression analysis (CN reference group) using the P(r)VLT-delay free recall and 'animal' fluency RAS were able to classify participants into their respective groups ($p < 0.016$, all analyses). Between-group analyses examining the P(r)VLT delay free recall test revealed that the aMCI group had greater attenuated voice volume range than other groups ($p < 0.016$, both analyses); shorter speech duration ($p < 0.005$) than CN participants; and greater jitter ($p < 0.010$, both analyses) than other groups. Between-group analyses examining the semantic fluency test revealed that dMCI participants had attenuated voice volume range ($p < 0.029$); shorter speech duration ($p < 0.001$); and greater jitter ($p < 0.003$) than CN participants.
Conclusions: Results revealed a double dissociation between clustered groups and acoustic variables. These data suggest that digitally obtained voice behavior can provide neurocognitive biomarkers that are sensitive and specific and are potentially scalable for widespread administration to persons at risk for Alzheimer's disease and related dementias syndromes.

PROCESS MINING: A POWERFUL TOOL TO STUDY COGNITIVE PATIENT JOURNEYS

POSTERS: A04.J. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Stefania Orini[1,2], Claudio Singh Solorzano[3], Simona Buscarnera[4], Francesco Rossato[5], Federica Ribaldi[6], Cristina Festari[3], Giovanni Frisoni[6,7], Roberto Gatta[2]
[1]IRCCS Istituto Centro San Giovanni di Dio Fatebenefratelli, Alzheimer's Unit, Memory Clinic,, brescia, Italy, [2]University of Brescia, Department Of Clinical And Experimental Sciences,, Brescia, Italy, [3]IRCCS Istituto Centro San Giovanni di Dio Fatebenefratelli, Laboratory Of Alzheimer's Neuroimaging And Epidemiology, Brescia, Italy, [4]Università la Sapienza di Roma, Dipartimento Di Neuroscienze Umane, Roma, Italy, [5]University of Padova, Italy, Department Of Neuroscience, Padova, Italy, [6]University of Geneve, Laboratory Of Neuroimaging Of Aging (lanvie), Geneve, Switzerland, [7]University Hospitals of Geneva, Memory Centre, Division Of Geriatrics And Rehabilitation, Geneva, Switzerland

Aims: Process mining is a data science technique that could be used to extract the most frequent diagnostic workup and describe the temporal evolution of patients' diagnostic pathways using an AI-based data-driven approach applied to real-world data. The study aims to explore the diagnostic workup of Mild Cognitive Impairment.
Methods: We analyzed 717 medical charts of consecutive patients who visited the Geneva Memory Clinic for a first visit between June 2021 and December 2022. We utilized a machine learning algoritm for process discovery using pMiner, a R library.
Results: Among the 664 participants meeting the inclusion criteria for this study (syndromic hypothesis of mild dementia or MCI), 32 were excluded because they only completed the first visit and did not continue with the assessments. Out of the remaining 632 selected patients, the most common pathway observed was as follows: an initial visit (330), followed by either neuropsychological assessment (306) or MRI (228), a second visit (290), CSF (123) and the majority of patients reached their diagnosis by the third visit
(fig1).

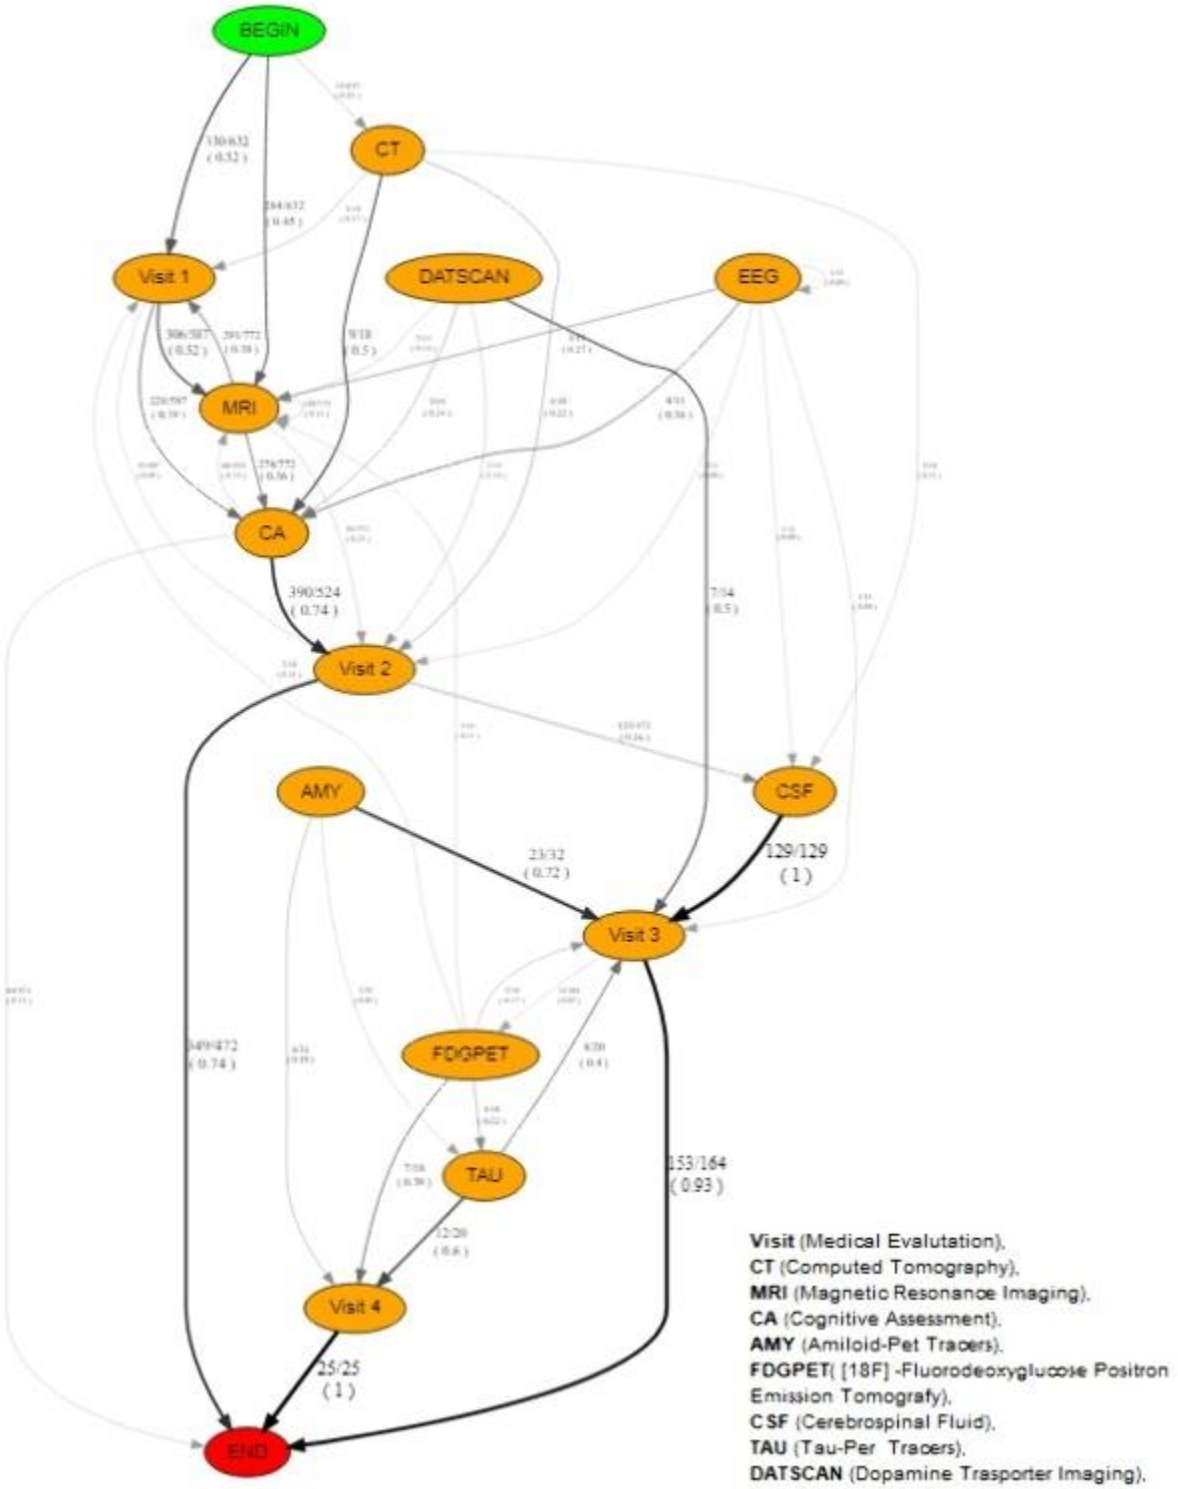

Fig 1. Graphical representation of the diagnostic pathways (without outlier) according a temporal evolution of the diagnostic pathways, the branches and their effects. The numerator of the archs represents the number of transitions to that connection, while the denominator represents the total transitions through

the node, the thickness of each arrow is proportional to the number of transitions.

Conclusions: This study has allowed us to analyse the actual patient's pathways at the Memory Clinic, which are not evident using traditional statistics. Based on this evaluation, it is possible to assess the efficiency of the clinic's diagnostic process, adherence to proposed diagnostic protocols, and potentially address bottlenecks to improve the process.

Aims: The limbic system comprises cortical and subcortical structures functionally integrated by short- and long-range white matter (WM) fibers, involved in memory, emotion and behavioral regulation. The degeneration of limbic structures and related WM connections have been described in Alzheimer's Disease (AD) patients since prodromal stages, but research in cognitively unimpaired at-risk individuals (i.e., APOE ε4 carriers) is currently limited.
Methods: Cognitively unimpaired APOE ε4 carriers (n=22, age=66±6 years, 59% females, MMSE=29±1) and non-carriers (n=35, age=69±6 years, 43% females, MMSE=30±1) underwent 3T MRI exams, including Diffusion-Weighted Imaging (DWI), and neuropsychological assessment. DWIs were pre-processed using the FMRIB's Software Library (FSL) toolbox (*topup, eddy,* and *DTIfit* from FDT toolbox for fractional anisotropy [FA], mean [MD], axial [AxD], and radial [RD] diffusivities measurement). TBSS was used to warp the individual native DWIs to MNI standard space and backward. Limbic tracts (cingulum bundle, fornix, uncinate fasciculus, anterior thalamic radiation) were extracted from JHU atlas, combined, and overlaid to DTI native maps for mean values' extraction. A multivariate GLM, adjusting for age, sex, and education, was used to compare FA, MD, RD, and AxD values between groups. Partial correlations between FA/diffusivities values and RBANS immediate and delayed memory index were explored.
Results: Significantly lower left FA (p=.014) and higher left RD (p=.037) were detected in carriers compared to non-carries. Specifically, carriers showed lower FA in parahippocampal cingulum (p=.033) and anterior thalamic radiation (p=.007), higher RD in fornix (p=.026) and anterior thalamic radiation (p=.022). No significant association emerged between limbic FA/RD and memory.
Conclusions: Our preliminary results suggested that microstructural WM changes of the limbic system are detectable in unimpaired at-risk subjects, suggesting their early involvement in AD pathophysiology.

Aims: Brain computed tomography (CT) is a widely accessible and affordable modality routinely used to assess neuroimaging signatures of idiopathic normal pressure hydrocephalus (iNPH), particularly ventricular enlargement. Previously, we developed deep learning U-Net-based models to segment various brain tissue classes in brain CTs. In this study, we aim to assess the association of CT-based volumetric measures (CTVMs) with radiological markers of iNPH.
Methods: We included 734 (52.6% female, 70.44 ± 2.6 years) CT scans which had paired T1-weighted magnetic resonance images scans from the Gothenburg H70 Birth Cohort collected on the same day. An experienced rater evaluated various iNPH related radiological markers in all T1-weighted images. Our trained U-Net models were used to predict brain volume (BV), intracranial volume (ICV), cerebrospinal fluid (CSF), and ventricular CSF (VCSF) segmentations from input CT scans. Then, we assessed the relationship between CTVMs such as VCSF/ICV, BV/ICV, and VCSF/CSF and standard radiological markers such as Evan's index, Z-Evan's index, and callosal angle using Spearman's rank correlation tests.
Results: CT-based volumetric measures showed good correlation with Evan's index (ρ= 0.64, $p<0.001$) and Z-Evan's index (ρ= 0.8, $p<0.001$). CTVMs had lower but significant correlation with callosal angle (ρ= -0.31, $p<0.001$). CT-VCSF/ICV showed higher correlation with radiological markers of iNPH in comparison to CT-BV/ICV and CT-VCSF/CSF. Higher levels of Evan's index and Z-index associated with higher levels of CT-VCSF/ICV and CT-VCSF/CSF and lower levels of CT-BV/ICV.

Correlation matrix of CT-based volumetric measures and radiological markers of idiopathic normal pressure hydrocephalus in the Gothenburg H70 Birth Cohort (n= 734). Spearman correlation coefficients are plotted. Cells were coloured according to the strength and trend of correlations (shades of blue = positive, shades of red = negative correlations). *Abbreviations: BV- Brain volume; CSF- cerebrospinal fluid; CT- computed tomography; ICV- intracranial volume; VCSF- ventricular CSF*

Conclusions: CT-based volumetric measures correlate with relevant radiological markers of iNPH. This supports the potential application of CTVMs in aiding diagnostics and monitoring the progression of iNPH. Association between CTVMs with diagnosis and other clinical iNPH markers will be further explored in future.

X-RAY BASED BRAIN TISSUE MATERIAL DECOMPOSITION AND QUANTIFICATION OF OLIGOMERIC AND FIBRILLAR AMYLOID-BETA AGGREGATES

POSTERS: A04.J. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Karthika Suresh, Eshan Dahal, Aldo Badano
U.S. Food and Drug Administration (FDA), Division Of Imaging, Diagnostics, And Software Reliability, Office Of Science And Engineering Laboratories, Center For Devices And Radiological Health, Silver SPring, United States of America

Aims: Label free spectral small angle X-ray scattering (sSAXS) is an emerging tool for detecting amyloid-β deposition in the brain in vivo based on the cross-β sheet structure of oligomeric and fibrillar aggregates. We aim at recovering and quantifying X-ray scattering signals of the pathogenic protein aggregates from the cumulative X-ray spectrum contributed by different brain tissue components.
Methods: Brain tissue material decomposition and quantification were performed by scatter specific peak deconvolution on sSAXS spectra followed by integration of deconvolved signal. The method was evaluated for clinically relevant quantities in the microgram (μg) range of amyloid oligomer and fibrillar models embedded in different regions of sheep brain tissues varying from stem to cortex.
Results: The X-ray scattering spectrum of the brain tissue within the wavevector (q) range of 4.5-22 nm^{-1} is primarily dominated by the lipid scattering with q centered between 13-14 nm^{-1} along with minor contribution from water near q=21 nm^{-1}. The X-ray intensities of μg range protein aggregates are significantly lower than lipids and the scattering signals arising from inter- (q=6.7 nm^{-1}) and intra- (q=13.3 nm^{-1}) β-sheet spacings of the amyloid cross-β motifs that are hidden within the broader lipid spectrum. By performing peak deconvolution with component specific peak center, we were able to decompose signals from mixtures of the brain tissue and recover the hidden amyloid signals. Integration of deconvolved peak accurately estimated the amyloid burden. Preliminary investigations show that the Aβ index quantified by q-spectrum normalization is a metric for amyloid burden.
Conclusions: Our findings suggest that the proposed approach would allow amyloid quantification at regional level using sSAXS. This method could also be extended to other neurodegenerative diseases including Parkinson's diseases due to the generalized cross-b structure of pathogens.

POPULATION-SCALE LONG-READ SEQUENCING TO BETTER UNDERSTAND THE GENETICS OF NEURODEGENERATIVE DISEASES

POSTERS: A05.A. GENETICS, EPIDEMIOLOGY: WHOLE GENOME SEQUENCING

Kimberley Billingsley[1], Kensuke Daida[2], Pilar Alvarez Jerez[3], Rylee Genner[3], Andrew Singleton[1], Cornelis Blauwendraat[1]
[1]CARD, NIH, Center Of Alzheimer's And Related Dementias, Card, Nih, Bethesda, United States of America, [2]NIH, Laboratory Of Neurogenetics, Bethesda, United States of America, [3]CARD, NIH, Center Of Alzheimer's And Related Dementias, Card, Nih, Bethesda, United States of America

Aims: We aim to generate a new genetic resource for Neurodegenerative diseases by discovering and genotyping structural variants. Structural variants drive gene expression in the brain and are causative of many neurological conditions. However, most existing genetic studies have been based on short-read sequencing methods which poorly capture these regions.
Methods: We leverage a new scalable wet-lab protocol and computational pipeline (Napu) for Oxford Nanopore Technologies (ONT) and apply it to neurologically normal control samples from the North American Brain Expression Consortium (NABEC) cohort and Parkinson's disease case and control samples from the Parkinson's Progression Markers initiative (PPMI).
Results: Through this work, we present a publicly available long-read resource from hundreds of human brain and blood samples (average N50 ~30kb and ~40X coverage). We discover over 100k structural variants, consisting mainly of insertions and deletions. Utilizing matched expression datasets for these samples including CAGE-seq and bulk and single-cell RNA-seq we apply quantitative trait locus (QTL) analyses and identify structural variants that impact gene expression in post-mortem frontal cortex brain tissue and whole blood. Further, we determine haplotype-specific methylation rates of millions of CpGs and with this data identify cis-acting structural variants.
Conclusions: In summary, these results highlight that long-read sequencing at population scale can identify disease-relevant regulatory loci that were inaccessible using previous technologies. We believe this new resource will provide a critical step toward understanding the biological effects of genetic variation in the human brain. Expanding on this, as part of the NIH's Center of Alzheimer's and Related Dementias (CARD) long-read sequencing initiative, we are currently applying this framework to sequence thousands of human case and control samples to build the first highly accurate catalog of structural variants in Neurodegenerative diseases.

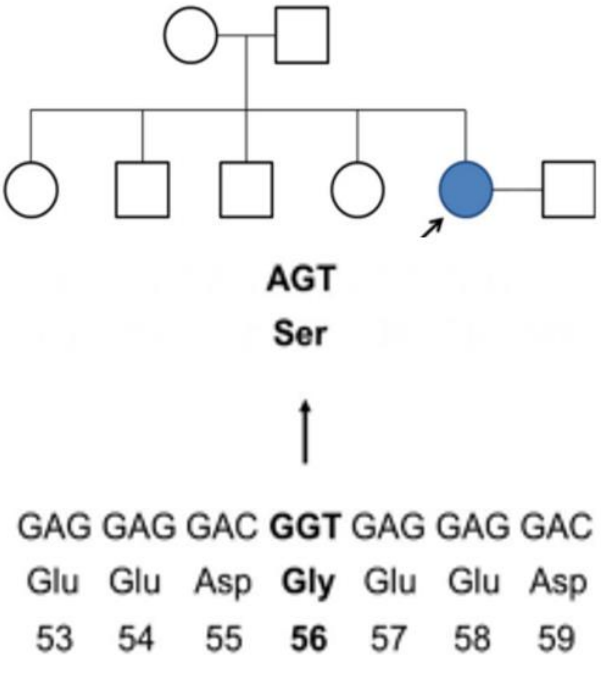
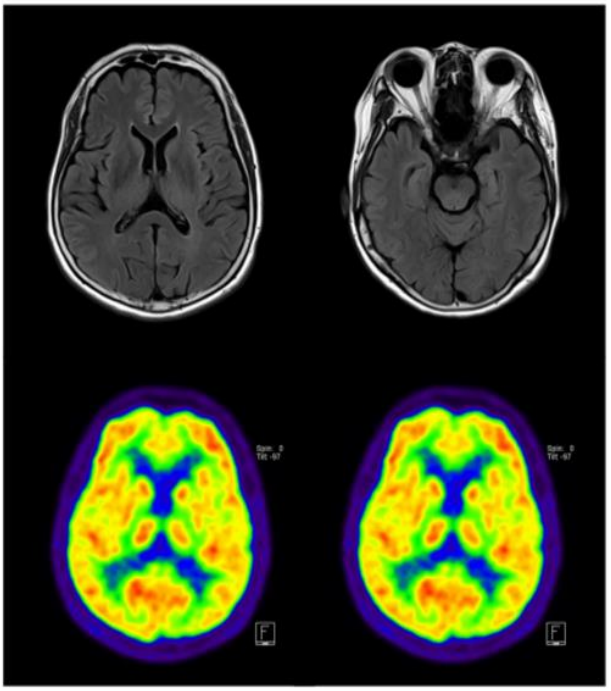
A POSSIBLE PATHOGENIC PSEN2 GLY56SER MUTATION IN A KOREAN PATIENT WITH EARLY-ONSET ALZMEIMER'S DISEASE

POSTERS: A05.A. GENETICS, EPIDEMIOLOGY: WHOLE GENOME SEQUENCING

Da Eun Jeong
Central Veterans Hospital, Neurology, Seou, Korea, Republic of

Aims: In this study, we described a clinical data of a Korean EOAD patient with Gly56Ser mutation in PSEN2. To address the pathogenicity of the mutation, in silico analysis and structural predictions were also conducted.
Methods: Patient information A 64-year-old right-handed woman with 12 years of education presented with a 4-year history of progressive cognitive impairment. Her symptoms occurred insidiously, with short-term memory loss and insomnia. The patient scored 24/30 in a Mini-Mental State Examination (MMSE). The subscores seven serial calculations were 3 out of 5 and the delayed word recall score was 0 out of 3, with a 0.5 Clinical Dementia Rating (CDR). Brain magnetic resonance imaging showed that the volume of the bilateral hippocampus was reduced. (Figure 1). 18F-Fluorodeoxyglucose positron emission tomography (FDG-PET) showed bilateral temporoparietal association cortices, precuneus, inferiorparietal lobule, and middle temporal gyrus
hypometabolism.





Results: From in silico analysis, the bulkiness score of mutant PS2 was higher than that of the wild-type protein (Figure 2). The hydrophobicity score of the mutant protein was markedly lower than that of the wild-type one. Based on the 3D structural modeling of the secondary structure, the positions of Gly56 and Ser56 of the wild-type and mutant proteins, respectively, were anticipated to be located within loop structures without definite structures. Based on a model of the mutant protein, Ser56 displayed the

potential interactions with Met1, Ala6, Asp8, and Glu54. Interestingly, in mutant model 2, a hydrogen bond formed between Ser56 and Leu396 that reduced the distance between the loop and the helix region in PS2

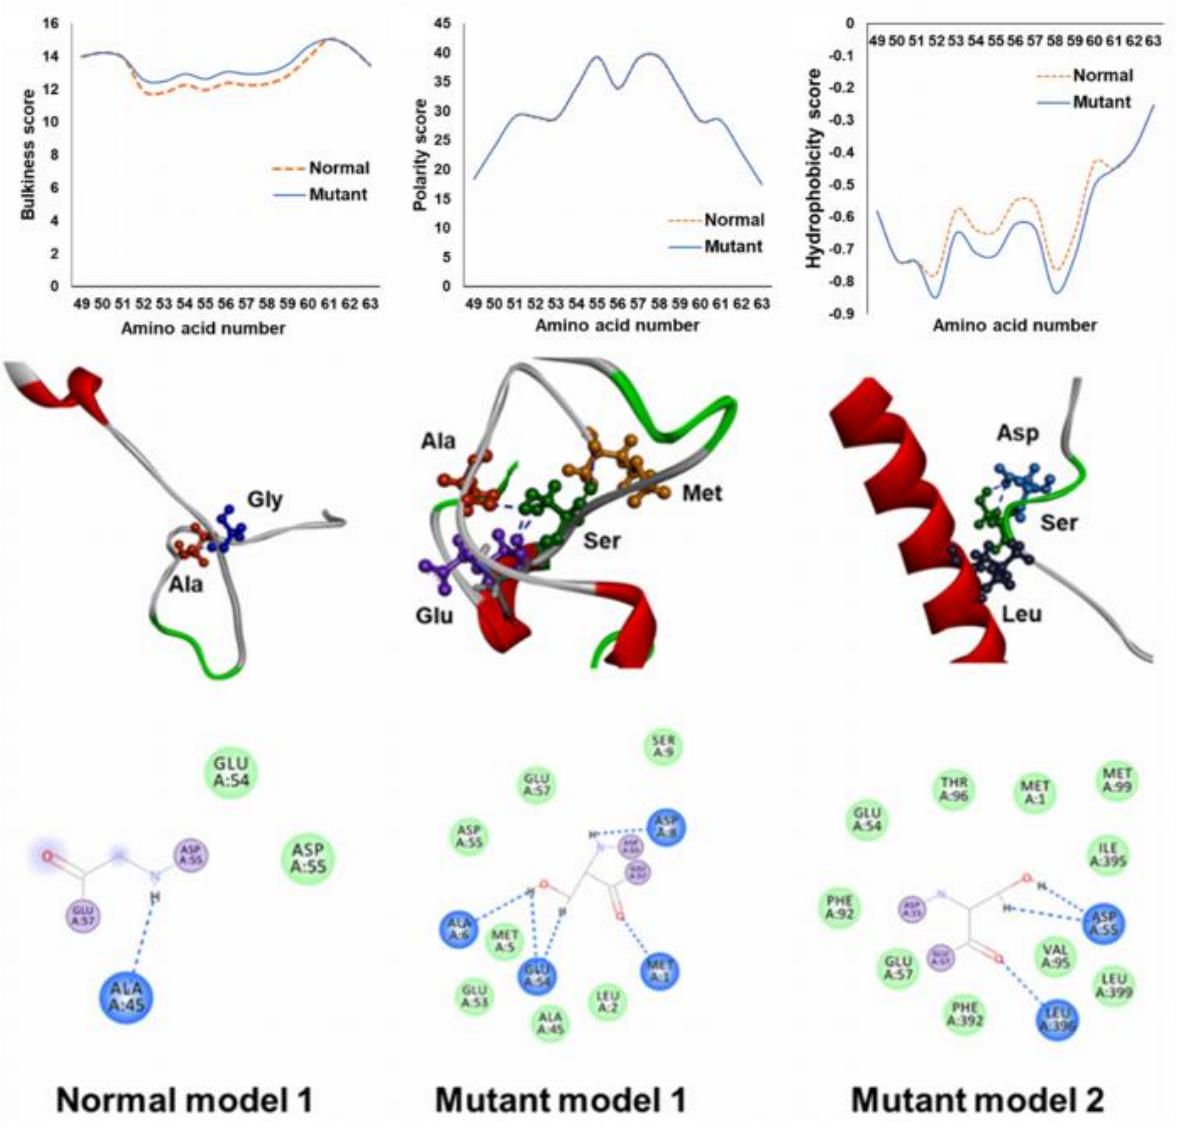


Figure 2. ExPASY scores, 3D predicted structure and possible intramolecular interactions of Gly56Ser PS2.

Conclusions: Substitution with serine may affect interactions with other residues and/or phosphorylation, promoting AD pathogenicity Future functional studies will be required to fully understand disease progression and mechanisms.

Hussman Institute For Human Genomics, Miami, United States of America, [5]Case Western Reserve University, Neurology, Cleveland, United States of America

Aims: A shift in focus from risk to resilience for Alzheimer's disease (AD) encourages efforts to uncover novel AD biological mechanisms. We examined whole genome sequencing data from a Midwestern Amish population in a genome-wide search for rare coding protective variants shared only among cognitively unimpaired (CU) individuals and performed a sequence-based genome-wide association study (seqGWAS) of cognitive status, CU vs. cognitively impaired (CI).
Methods: The cognitive status of each individual was assigned via a consensus review of medical history and neuropsychological testing. Allele frequencies were calculated across all samples for all variants. Allele frequencies of rare variants (MAF<0.05) within CU and within CI individuals were compared. Variants with a minor allele count (MAC)>10 in the CU group and 0 in the CI group were annotated to determine likely loss of function. Variants were further filtered to exclude those shared by younger (age < 75) CU individuals. A linear mixed model was used to test for association with common variants (MAF>=0.05).
Results: After extensive QC, 1141 individuals, 549 CU (mean age=80.33±5.71, 62% female) and 432 CI (mean age=83.07±5.60, 56% female) were available for analysis. 3459 rare variants with MAC >10 were found only in CU. There were 31 coding variants (25 *missense*, 1 *inframe_deletion*, 5 *splice donor*) and 11 synonymous variants. 9 missense, 2 splice, and 3 synonymous variants were shared by at least 10 CU with age > 75. No SNPs reached genome-wide significance($p=5\times10^{-8}$) among common variants but 272 variants had suggestive associations ($p=1\times10^{-5}$).
Conclusions: Numerous rare variants potentially impacting gene function were found only in CU individuals, providing a rich resource for further investigation of genes that may provide protection from cognitive impairment. We identified novel common variants in 32 gene regions.

CHARACTERISTICS OF TREM2 L15Q MUTATION ON AB-RELATED PATHOGENESIS

POSTERS: A05.B. GENETICS, EPIDEMIOLOGY: DISEASE-CAUSING MUTATIONS

Danyeong Kim[1,2], Kyuhwan Shim[1], Hyewon Yang[1], Heewon Bae[2], Seong Soo A. An[1], Min Ju Kang[2]
[1]Gachon University, Department Of Bionano Technology, Seongnam, Korea, Republic of, [2]Veterans Health Service Medical Center, Neurology, Seoul, Korea, Republic of

Aims: *TREM2* L15Q mutation was found in a 65-year-old AD patient. To assess its pathogenicity, we produced transfected cells and investigated the relationship between the *mutation* with Aβ-related pathology.
Methods: *TREM2* Wild type (WT) and L15Q were transfected onto the HEK 293 by using a plasmid transfection system and selected using geneticin. Gene expression and protein were measured for confirmation of modifying cells. The $A\beta_{42}$ and $A\beta_{40}$ performed commercial kits. In Aβ uptakes, the cells were incubated with $A\beta_{42}$ and then, measured $A\beta_{42}$. Aβ phagocytosis was obtained cell images and video by treating Aβ-labeling pHrodo.
Results: *TREM2* gene and protein were confirmed in *TREM2* WT and L15Q transfected cells. Although both were overexpressed in HEK 293(MOCK), *TREM2* L15Q was a lower protein than in WT. *TREM2* L15Q had a higher $A\beta_{42/40}$ ratio than WT. The $A\beta_{42}$ uptake was relatively lower than WT. In Aβ phagocytosis images and video, *TREM2* L15Q showed lower red fluorescence than WT, but similar to MOCK.
Conclusions: In this study, we investigated the pathogenicity of the *TREM2* L15Q mutation using the generation of mutant cells. Our results revealed that *TREM2* L15Q led to an increase in extracellular Aβ42 levels while reducing Aβ42 uptake. These findings suggest that the mutation impairs the Aβ uptake and elimination functions of *TREM2*, resulting in incomplete Aβ clearance and an increase in extracellular Aβ in mutant cells. Consistent with our confocal images and live cell video analyses, which showed a decreased red fluorescence signal in *TREM2* L15Q cells, we conclude that Aβ phagocytosis is hindered by the *TREM2* mutation. Taken together, *TREM2* L15Q interfered with Aβ phagocytosis and reduced Aβ uptake, which may allow Aβ to accumulate rather than be removed, thereby affecting the pathogenicity of AD.

EVALUATION OF A NEW STRATEGY TO IDENTIFY PATIENTS AT HIGH RISK FOR UNDERLYING GENETIC CAUSES

POSTERS: A05.B. GENETICS, EPIDEMIOLOGY: DISEASE-CAUSING MUTATIONS

Theresa König, Sara Silvaieh, Tandis Parvizi, Raphael Wurm, Evelyn Berger-Sieczkowski, Helena Untersteiner, Stella Göschl, Alexander Zimprich, Elisabeth Stögmann
Medical University of Vienna, Department Of Neurology, Vienna, Austria

Aims: Pathogenesis, clinical course and pathological processes differ significantly between dementias. However, diagnosis remains challenging and reliable *in vivo* biomarkers are needed for patient stratification and therapeutic intervention. Our objective was to i) assess the extent of putative high genetic risk in our dementia cohort and ii) enhance diagnostic efficacy in clinical whole exome sequencing (WES) routines.
Methods: We retrospectively applied a recently proposed classification scheme (Koriath et al. 2020, Mol. Psychiatry) considering dementia type, family history and age of disease onset (AAO) to evaluate the genetic risk in a well-characterized dementia patient cohort (AD, FTD, and other dementias, n=703). Patients were divided into groups with high, medium and low genetic risk in a blinded approach according to the adapted scheme. If available, WES, as well as *APOE* and *C9ORF72* genotyping data of high-risk patients was analyzed.
Results: 53 high-risk patients were identified. To date, full genetic data was available for 28 patients (53%). 11 individuals were carriers of established pathogenic variants and three were *APOE4* homozygous. Thus, overall, 14 of the 53 patients (26.4%) were carriers of diagnostic relevant, pathogenic variants (*APP, PSEN1, MAPT, PGRN, C9ORF72* and *APOE4/4*). Excluding the 25 patients that have yet to be fully resolved, the diagnostic yield reaches up to 50% (14 out of 28 patients).
Conclusions: Utilizing a classification scheme based on AAO and family history proved effective in increasing the probability of detecting pathogenic variants relevant for diagnosis and patient counseling. This approach significantly enhanced the diagnostic yield of WES in our cohort, demonstrating a marked improvement compared to the previously observed 20% in our clinical setting.

CHCHD2 AND DNAJC6 DOUBLE GENE MUTATION IN AN ITALIAN PATIENT WITH EARLY-ONSET ALZHEIMER'S DISEASE

POSTERS: A05.B. GENETICS, EPIDEMIOLOGY: DISEASE-CAUSING MUTATIONS

Federico Menegon[1], Francesca Vignaroli[1], Lucia Corrado[2], Fabiola De Marchi[1], Silvio Daffara[3], Fjorilda Caushi[2], Sandra D'Alfonso[2], Cristoforo Comi[4], Giacomo Tondo[4]
[1]University of Piemonte Orientale, Department Of Translational Medicine, Novara, Italy, [2]University of Piemonte Orientale, Department Of Health Sciences, Novara, Italy, [3]Sant'Andrea Hospital, Biology Unit, Vercelli, Italy, [4]Neurology Unit, Sant'Andrea Hospital, Vercelli, University Of Piemonte Orientale, Vercelli, Italy

Aims: Alzheimer's disease (AD), Parkinson's disease (PD), and other neurodegenerative diseases (NDDs) share pathological mechanisms, combining genetic and environmental factors.
Methods: Early-onset AD, appearing before age 65, accounts for roughly 10% of all AD cases, and is largely unexplained by known genetic mutations, resulting in a lack of understanding of its molecular etiology.
Results: A 51-year-old female reported a one-year history of progressively worsening memory, attentive and planning disturbances. She had no family history of neurological or psychiatric disorders. Neuropsychological assessment revealed memory, language, and executive function deficits. MRI showed diffuse atrophy and FDG-PET revealed hypometabolism in bilateral temporo-parietal regions and in the left frontal lobe. CSF T-tau and p-tau levels were normal, while amyloid β was markedly reduced. Based on the clinical phenotype, and the exam findings, early-onset AD was diagnosed. The patient has a rapidly progressive worsening of cognitive functions. A genetic analysis testing for the genes associated with AD and other neurodegenerative diseases was performed, and two rare different heterozygous mutations in CHCHD2 and DNAJC6 genes were revealed.
Conclusions: CHCHD2 encodes for protein involved in mitochondrial function. Mutations in this gene have been associated with familial and sporadic PD, but are also described in amyotrophic lateral sclerosis/frontotemporal dementia and AD. DNAJC6 encodes for protein involved in the endo-lysosomal pathway. Mutations of DNAJC6 have been associated with early-onset PD, and only in one study with AD. We present the first Caucasian patient carrying a double gene mutation in CHCHD2 and DNAJC6, manifesting with early-onset and rapidly progressive AD, giving new insight into the pathology and genetics of NDDs.

DISTINCT AMYLOID-B DEPOSITS IN PSEN1 P.G206A MUTATION CARRIERS ASSOCIATE WITH DISEASE DURATION

POSTERS: A05.B. GENETICS, EPIDEMIOLOGY: DISEASE-CAUSING MUTATIONS

Baayla Boon[1], Sarah Lincoln[1], Daniel Wickland[1], Erica Engelberg-Cook[1], Darren Rothberg[1], Michael Deture[2], Nilüfer Ertekin-Taner[2,3], Neill Graff-Radford[3], Dennis Dickson[1], Melissa Murray[1], Cyril Pottier[4]
[1]Mayo Clinic, Neuroscience, Jacksonville, United States of America, [2]Mayo Clinic, Department Of Neuroscience, Jacksonville, United States of America, [3]Mayo Clinic, Department Of Neurology, Jacksonville, United States of America, [4]Mayo Clinic Florida, Neuroscience, Jacksonville, United States of America

Aims: *PSEN1* mutations lead to an increased amyloid-β processing and production, however, even in individuals with the same mutation, there is a large phenotypical variability. We hypothesized that neuropathologic characteristics, cellular and transcriptomic alterations are associated with clinical phenotype. We investigate the association between types of amyloid-β deposits, brain cell type proportion, gene expression, and splicing isoforms with age at onset, disease duration and severity of Alzheimer's Disease (AD) neuropathologic change.
Methods: Histologic stains (hematoxylin-eosin and thioflavin S) as well as immunohistochemistry for phosphorylated-tau (AT8)and amyloid-β (6F/3D) were performed in eight Hispanic *PSEN1 p.G206A* AD cases in the inferior parietal gyrus and motor cortex. Single-nuclei long-read RNA sequencing is being performed on both brain regions. We will stratify our transcriptomic analyses on phenotype and neuropathology.
Results: We observed large variability in age at onset (median = 53 years; range: 42-59 years) and disease duration (median = 10 years; range: 8-17). Disease duration did not correlate with amyloid-β (correlation coefficient = 0.09) and phosphorylated-tau (correlation coefficient = 0.0003) burden. In cases with a shorter disease duration (8-10 years), we observed a high burden for coarse-grained plaques and cerebral amyloid angiopathy, whereas in cases with a longer disease duration (13-17 years) we observed a high burden of classic cored plaques (Fig.1, Table
1).

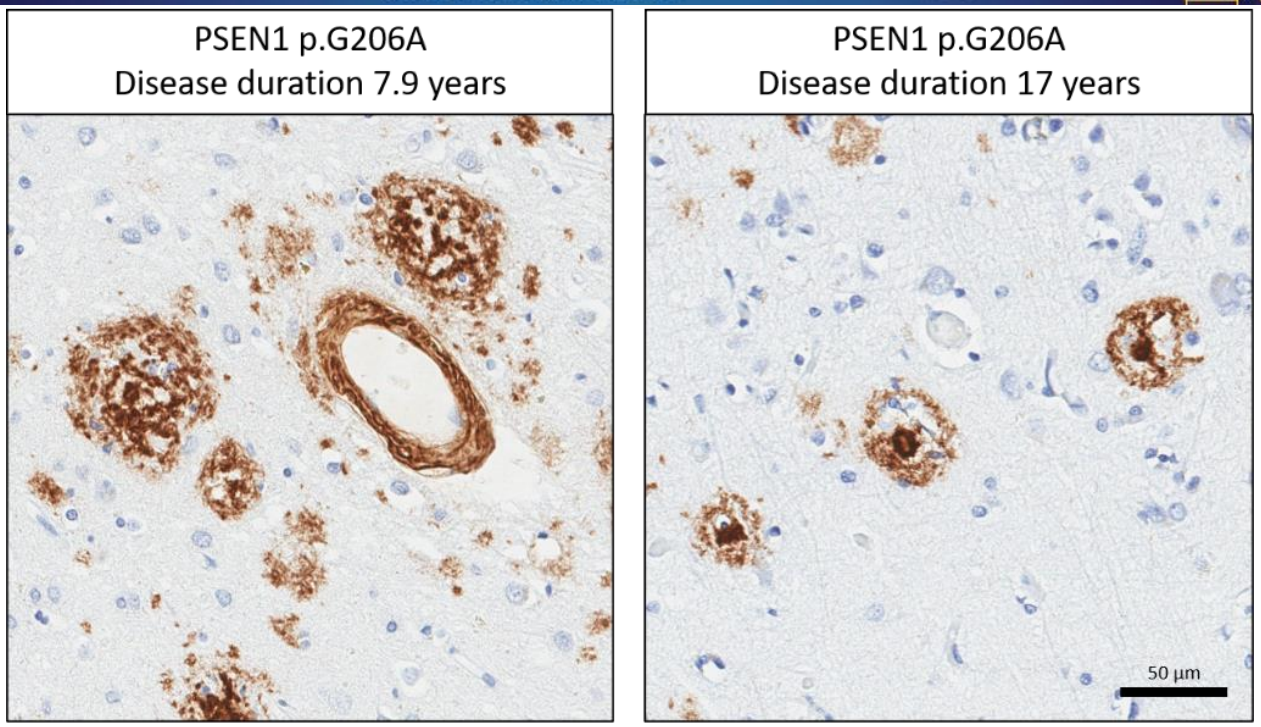

Fig. 1. Amyloid-β (clone 6F/3D) immunohistochemistry on the middle frontal gyrus of cases with a *PSEN1 p.G206A* mutation. We observed a higher burden for coarse-grained plaques and cerebral amyloid angiopathy in cases with a shorter disease duration, whereas we observed a higher burden for classic cored plaques in cases with a longer disease duration.

Table 1. Amyloid-β deposit scores for *PSEN1 p.G206A* mutation carriers

Case	Sex	APOE	Disease duration	CCP	CGP	CAA2	CAA1
1	M	33	17	3	0	0	0
2	F	34	13	3	1	0	0
3	M	33	10	3	1	0	0
4	M	33	11	3	1	1	0
5	F	33	8	2	1	1	0
6	M	34	10	2	3	3	0
7	M	44	14	2	3	2	1
8	F	34	7.9	2	3	3	1

CAA1 cerebral amyloid angiopathy type 1, CAA2 cerebral amyloid angiopathy type 2, CCP classic cored plaque, CGP coarse-grained plaque, F female, M male. Disease duration in years.

Conclusions: The observation that amyloid- β and phosphorylated-tau amount did not correlate with disease duration, but that distinct amyloid-β deposits were associated with disease duration in cases with the same Mendelian cause for AD, strongly suggests a relationship between plaque composition and

disease progression. Transcriptomic analyses will provide new insights into disease mechanisms regarding amyloid-β deposit formation and phenotypic variability.

Aims: Aim: There are limited genes known to increase the risk of Alzheimer's disease (AD), most well-known is *APOE* e4. It is estimated 25% of people carry one copy and 2-3% carry two copies. The gene encodes the ApoE protein which helps to carry cholesterol and fats in the blood stream and into cells including brain cells, and this may contribute to AD pathology. The Lumipulse ***G*** ApoE4 and Lumipulse ***G*** Pan-ApoE <RUO>, assays to detect the proteins encoded by the *APOE* variants, were used to retrospectively analyze plasma from a phase 2 study.
Methods: Method: Plasma was collected from 181, 133 and 90 subjects at Baseline, Week 26 and Week 52, respectively. Genotyping was not conducted, but plasma was tested retrospectively to determine proteotype status of these subjects. Three different ApoE protein isoforms (ApoE2, ApoE3, and ApoE4) were detected representing 6 phenotypes (3 homozygous types [E2/E2; E3/E3; E4/E4]) and 3 heterozygous types [E2/E3; E3/E4; E2/E4]). When Lumipulse ***G*** ApoE4 is used in conjunction with the Lumipulse ***G*** Pan-ApoE assay to determine the ApoE4/Pan-ApoE ratio meaning absence (null <5%) or presence of ApoE4 only (homozygous ≥75%) or the combination with ApoE2 or E3 (heterozygous ≤5% to <75%).
Results: At Baseline 77 (42.5%), 27 (14.9%), 77 (42.5%) had a ratio consistent with null, homozygous and heterozygous respectively. Subjects with protein levels/ratio consistent with these categories continued to express the same pattern at Week 26 (n=133) and Week 52 (n=90). No subjects expressed a different ratio through Week 52 of testing.
Conclusions: Conclusion: The Lumipulse ***G*** ApoE4 and Lumipulse ***G*** Pan-ApoE assays appear to be highly consistent across multiple timepoints for the detection of both ApoE4 heterozygous, homozygous and those without ApoE4 protein expression.

Aims: Genome-Wide Association Studies (GWAS) have identified >117 risk loci associated with various neurodegenerative diseases, including Alzheimer's disease and Parkinson's disease. However, GWAS-SNPs are generally not causative, implying that other nearby genetic variation in linkage disequilibrium (LD) may drive association signals. Here, we leveraged long-read sequencing data from 214 individuals to genotype large structural variants (SVs) genome-wide and investigated their interplay with GWAS-SNPs.
Methods: We performed long-read whole-genome sequencing of 214 individuals: N=93 AD patients (age 67.2∓8.5), and N=121 cognitively healthy centenarians (age 101.2∓1.8). We identified candidate SVs using sniffles2 genome-wide, and further characterised them through (local) de novo assembly. After quality control, we calculated LD between high quality SVs and imputed genotyped SNPs that were within 1Mb distance from each other. We primarily focused on known GWAS-SNPs associated with neurodegenerative diseases.
Results: In total, we found more than 112,000 unique SVs, of which ~52,000 (46%) were present in at least 5% of individuals. Of these 'common' SVs, 39% were transposable elements (TEs), predominantly from the SINE and LINE groups. Linkage disequilibrium (LD) analysis revealed several TE-related SVs, which were in moderate to strong LD to common SNPs that have been associated with neurodegenerative diseases (R2 = 0.2-1.0) by previous GWAS. These included intronic TEs in TMEM106B, TPCN1, GMNC, CRLS1 and ACE, that were previously associated with neurodegenerative diseases, validating the sensitivity of our approach. The remaining TE-SNP pairs are mostly intronic insertions of TEs that have not been previously reported, and may be candidate drivers of GWAS associations, potentially perturbing gene transcription and/or translation.
Conclusions: This study identifies novel SVs as potential genetic drivers of various previously identified GWAS of neurodegenerative diseases.

Aims: Mutations in the amyloid precursor protein (APP) gene can cause early onset familial Alzheimer's disease and/or cerebral amyloid angiopathy (CAA). We analysed pathological aspects of the novel *de novo* APP Y681H *Aros* mutation, identified in a Swedish subject who presented with a cerebral hemorrhage at the age of 55. The brain showed prominent amyloid-beta (Abeta) plaque deposition in the cortex and abundant CAA. Because this mutation is located next to the BACE1 beta'-cleavage site on APP and in proximity of neprilysin and insulin degrading enzyme (IDE) Abeta cleavage sites, we analyzed how it affects APP processing, Abeta degradation and aggregation propensities *in vitro*.
Methods: HEK293 cells were transfected with WT or *Aros APP*-containing vectors, and Abeta levels were measured in the supernatants though ELISA assays. Monomers of synthetic Abeta1-42 WT and *Aros* peptides, isolated by size exclusion chromatography, were incubated at 37°C with 20μM ThT to monitor their time-dependent aggregation. *In vitro* digestion of abeta monomers, incubated with recombinant neprilysin and IDE for 2 h at 37°C, was visualized with western blot and quantified with Image Lab software.
Results: Abeta1-40 levels and of Abeta1-40/Abetax-40 ratio was significantly increased in *APP Aros*-transfected cell supernatant compared to *APP* WT. No changes were observed in Abeta1-42 *Aros* aggregation kinetics compared to WT, while Abeta1-42 *Aros* was digested to a lesser extent by neprilysin and IDE *in vitro*.
Conclusions: The *APP Aros* mutation appears thus to influence APP processing and increase Abeta production. Although no changes in aggregation propensities were observed for Abeta1-42 *Aros*, the variants appear to be less degradable, which could also lead to increased Abeta brain levels. We are next assessing the deposit composition, structural features, and toxic properties of the *Aros* Abeta mutant.

THE ROLE OF AUTOSOMES IN ALZHEIMER'S DISEASE GENETICS ACROSS APOE*4 AND SEX

POSTERS: A05.C. GENETICS, EPIDEMIOLOGY: GWAS, GENETIC ASSOCIATIONS, SUSCEPTIBILITY & PROTECTIVE GENES

Michael Belloy[1], Pablo García-González2[2], Atahualpa C. Morales[3], Yann Le Guen[4], Ilaria Stewart[4], Christina Young[4], Elizabeth C Mormino[4], Valerio Napolioni[5], Zihuai He[4], Andre Altmann[6], Michael Greicius[4]
[1]Washington University in Saint Louis, Neurology, Saint Louis, United States of America, [2]Universidad Internacional de Catalunya, Research Center And Memory Clinic, Ace Alzheimer Center Barcelona, Barcelona, Spain, [3]Cardiff University, School Of Medicine, Cardiff, United Kingdom, [4]Stanford University, Department Of Neurology And Neurological Sciences, Stanford, United States of America, [5]University of Camerino, School Of Biosciences And Veterinary Medicine, Camerino, Italy, [6]University College London, Centre For Medical Image Computing (cmic), London, United Kingdom

Aims: We performed a large-scale, stratified genome-wide association study (GWAS) of Alzheimer's disease (AD) to chart the role of autosomal genetic variation in AD sexual dimorphism and heterogeneity of *APOE**4-related AD risk.
Methods: The study overview and GWAS models are shown in **Figure.1A**. SNP-array AD GWAS datasets primarily composing the ADGC, together with whole-genome sequencing (WGS) from ADSP (NG00067.v7), provided case-control diagnoses for phase-1. The UK Biobank provided subjects with ICD codes and family history of AD status for phase-2. Subjects were of European ancestry. Linear mixed model regressions were performed (LMM-BOLT v.2.3.4) on AD outcome measures, adjusting for sex, *APOE**4/*APOE**2 dosage, genetic principal components, and array/batch/center. GWAS hits (P<5e-*8) were evaluated for interactions effects (meta-regression for phase1+2 meta-analyses) and assessed in functional follow-up analyses.
Results: Stratified AD GWAS identified 28 loci/variants, including 5 known lead variants in known AD loci, 6 novel independent variants in known AD loci, and 17 novel loci (**Figure.1B**). 13 out of 17 novel loci showed varying degrees of functional support, with 4 also showing evidence for QTL colocalization (**Figure.2**). Many implicated genes showed prior support or effects relevant to AD (e.g. *MARCHF10* was recently implicated as a risk gene for all-cause dementia) Nonetheless, most novel hits were low/uncommon frequency variants and QTL colocalization evidence was limited. Further, there appeared to be no predictive benefit for stratified GRS analyses (**Figure.3**).

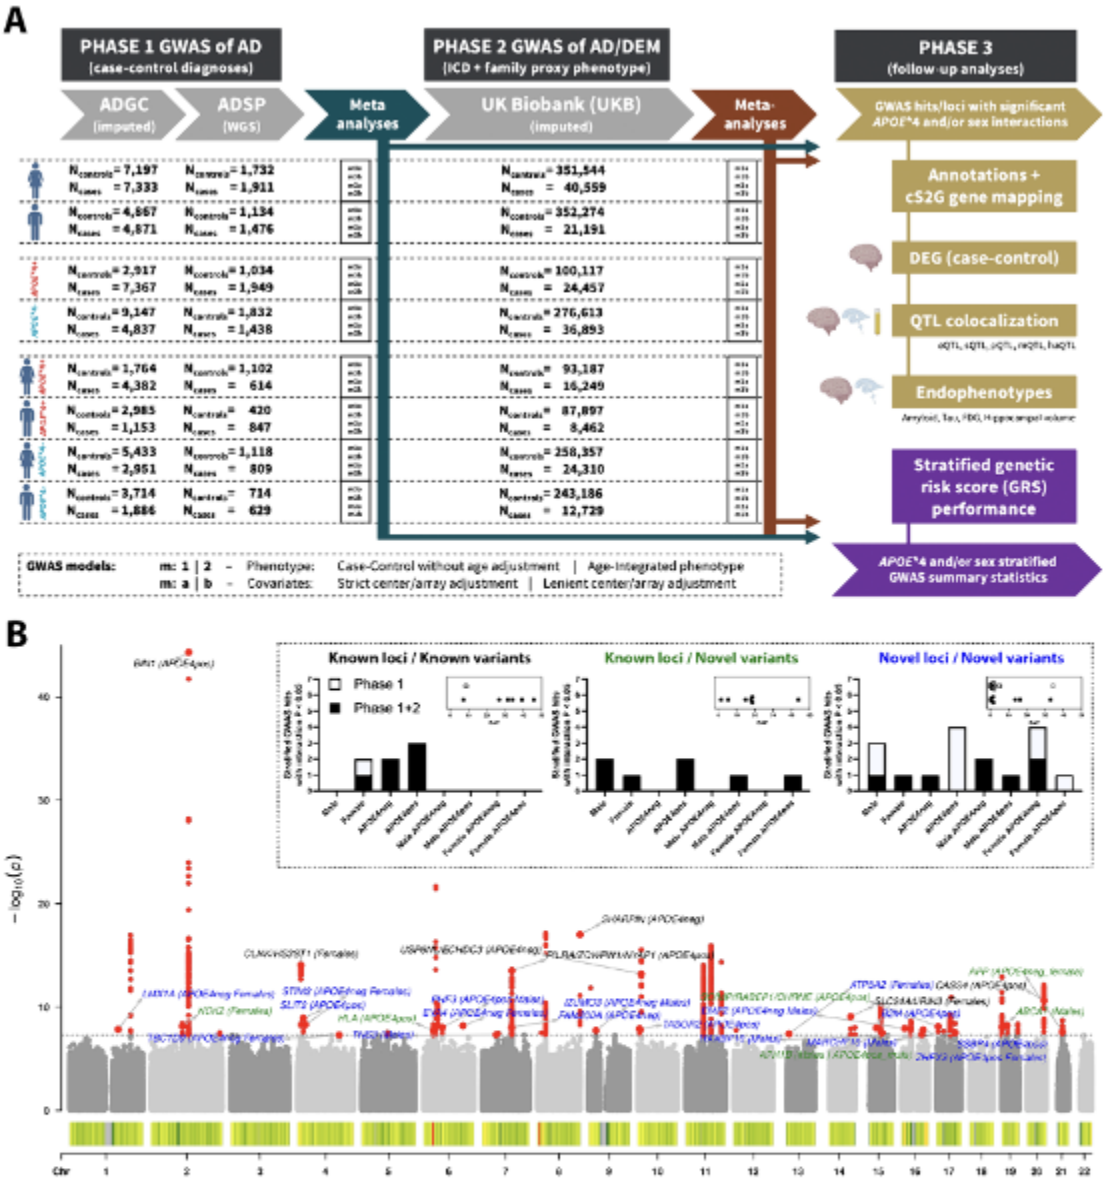

Figure 1. Comprehensive GWAS of AD across *APOE4- and sex strata. A)** Study design illustrating phase 1 and phase 1+2 GWAS meta-analyses with subsequent phase 3 functional mapping and genetic risk score (GRS) follow-up analyses. **B)** GWAS Manhattan plot showing minimum P-value per variant for all GWAS (8 strata * 4 models * 2 designs = 64 GWAS). Variants passing GWAS significance (P<5e-8) in a given stratum and having at least nominal significance for matching variant-by-stratum interaction tests are labelled: Black) known index variants from prior AD GWAS; Green) novel variants in known AD loci independent from known index variants (R2<0.1), and Blue) novel index variants in novel loci (labelled with nearest protein coding gene from GENCODE v42). Inset shows distribution across strata and GWAS designs, together with effect allele frequencies (EAF) for labelled variants.

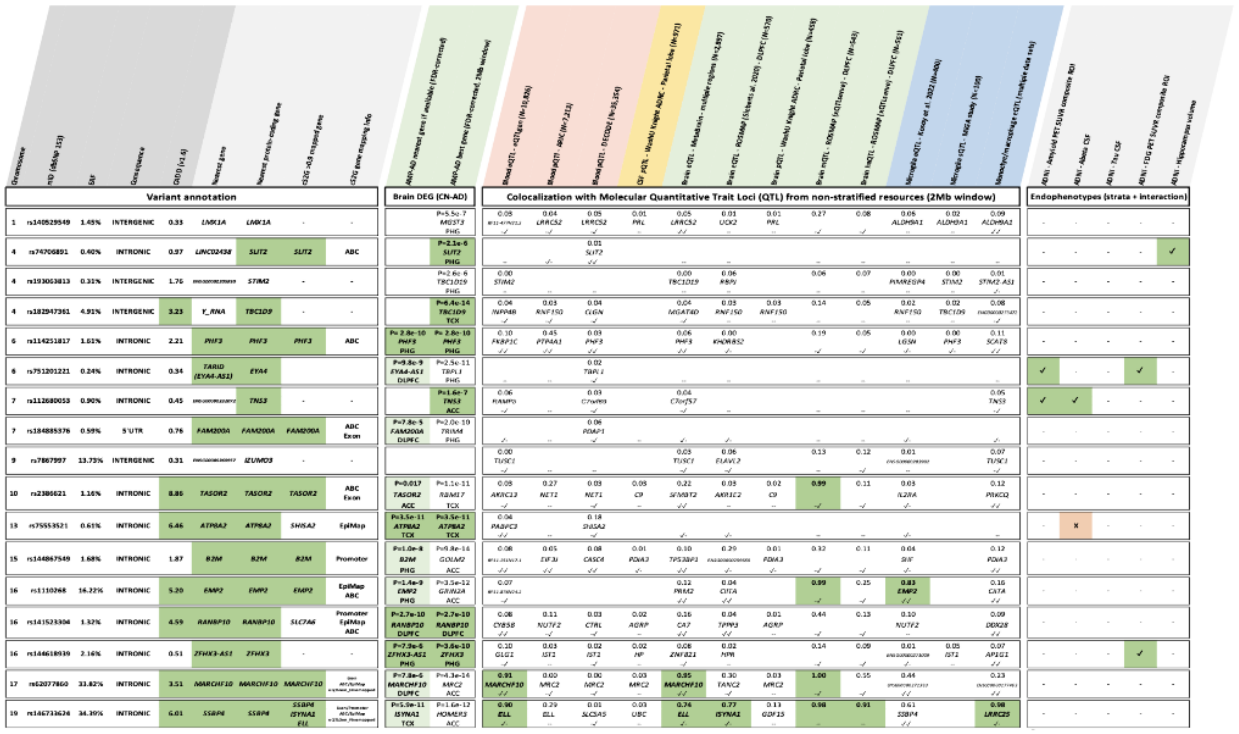

Figure 2. Stratified GWAS functional follow-up analyses of novel loci. Every row represents a novel locus with its index variant. Green shaded cells indicate positive follow-up results, which include: elevated CADD scores, nearest (protein coding) gene matching to cS2G mapped gene and/or differentially expressed gene (DEG) in brain tissues, closest by gene having the most significant DEG in brain tissues (or at least significant DEG = light green), colocalization probability >0.7, and endophenotype effects that match with the stratified GWAS effects.

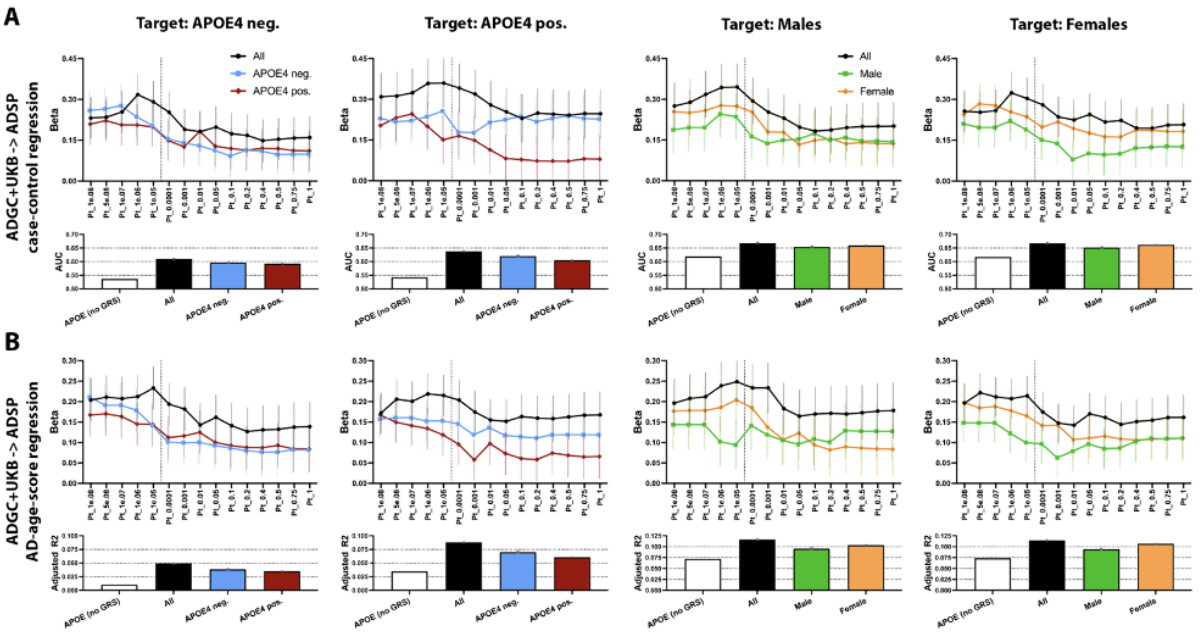

Figure 3. Stratified GWAS genetic risk score (GRS) follow-up analyses. Stratified GRS performance was evaluated using meta-analyzed GWAS summary statistics from ADGC+UKB (base) to construct GRS in independent samples from ADSP (target), using a case-control regression model without age adjustment **(A)** or an age-integrated phenotype model termed "AD-age-score" **(B)** as in Le Guen & Belloy et al., 2021 (similar to cox regression). Columns indicate the target strata in ADSP. Colored traces/bars indicate the base strata from ADGC/UKB. Top panels indicate betas with 95% confidence intervals for GRS derived at different P-value thresholds (Pt), where the vertical dotted lines distinguish oligogenic (left) from polygenic (right) signal. Lower panels show predictive performance. Note that stratified GRS never improved predictive performance and GRS derived from full sample GWAS provided the highest performance (results were consistent when only ADGC was used as the base for GRS).

Conclusions: We identified novel loci/variants differentially associated with AD risk across *APOE*4* and/or sex. Yet, we inferred relatively limited evidence for stratified effects (propensity for low frequency hits and no benefit for stratified GRS). Overall, our findings contribute to our understanding of the genetic etiology of AD, which in turn contributes to advance personalized genetic medicine.

CLUSTER BUSTER: A MACHINE LEARNING APPROACH TO GENOTYPING SNPS FROM RAW DATA

POSTERS: A05.C. GENETICS, EPIDEMIOLOGY: GWAS, GENETIC ASSOCIATIONS, SUSCEPTIBILITY & PROTECTIVE GENES

Jessica Martin, Nicole Kuznetsov, Mathew Koretsky, Daniel Vitale
National Institutes of Health, Center For Alzheimers And Related Dementia, Rockville, United States of America

Aims: The Global Parkinson's Genetics Program (GP2) collects information about single nucleotide polymorphisms (SNPs) from individuals with and without Alzheimer's or Parkinson's Disease. Here we develop ClusterBuster, a machine learning method for recovering previously uncalled genotypes from Illumina's GenCall algorithm to refine genotypes for GWAS studies.
Methods: We trained a Support Vector Classifier (SVC) of 3rd degree polynomial kernel on a subsection of 750 genotyped SNPs data from GP2 with an even distribution across minor allele frequency rarities, ancestries and phenotypes represented to ensure generalizability. Using R and Theta values from the Illumina SNP array machine as features, the SVC then predicts the genotype of the SNP.
Results: Our genotype predicting machine learning model reached an accuracy of 99% on a section of training data (80:20) held out for validation purposes. Comparing model genotype predictions with previous genotype calls produced by Illumina revealed a discrepancy in 0.39% of validation SNPS. Using this novel machine learning method, we have recovered 662 unique SNPs in the APOE locus, 421 unique SNPs in the LRKK2 locus, 614 unique SNPs in the GBA1 locus, and 354 SNPs in the SNCA locus.

Conclusions: Our novel algorithm allows for previously unusable SNP data to be included in future analyses in the GP2 data. This genotyping algorithm will be added to the GP2 cohort browser and allow for interested parties to view our reclustering efforts on the SNP metrics page for all SNPs on the NeuroBooster array. In the future, we will use this algorithm to validate genotypes for the full release of GP2 data and make this a deployable tool for researchers to apply to their own data.

APOE AND ALZHEIMER DISEASE RISK ACROSS AGE, SEX, RACE AND ETHNICITY, AND ANCESTRY

POSTERS: A05.C. GENETICS, EPIDEMIOLOGY: GWAS, GENETIC ASSOCIATIONS, SUSCEPTIBILITY & PROTECTIVE GENES

Michael Belloy[1], Shea J. Andrews[2], Yann Le Guen[3], Michael Cuccaro[4], Lindsay A Farrer[5], Valerio Napolioni[6], Michael Greicius[3]
[1]Washington University in Saint Louis, Neurology, Saint Louis, United States of America, [2]University of California San Francisco, Department Of Psychiatry And Behavioral Sciences, San Francisco, United States of America, [3]Stanford University, Department Of Neurology And Neurological Sciences, Stanford, United States of America, [4]University of Miami Miller School of Medicine, John P. Hussman Institute For Human Genomics, Miami, United States of America, [5]Boston University Schools of Medicine and Public Health, Department Of Medicine, Boston, United States of America, [6]University of Camerino, School Of Biosciences And Veterinary Medicine, Camerino, Italy

Aims: *APOE* status is highly relevant towards clinical trial design and AD research broadly. The associations of *APOE* genotypes with AD are modulated by age, sex, race, ethnicity, and ancestry, but these associations remain unclear, particularly in historically understudied non-white samples.
Methods: The study overview is shown in **Figure.1**. Various case-control, family-based, and longitudinal AD genetic cohorts were available through public repositories and underwent extensive genotype and phenotype quality control. These cohorts contributed data for Non-Hispanic Whites (NHW), Non-Hispanic Blacks (NHB), and Hispanics (HISP). Global ancestry was determined using SNPweights v2.1. Case-control logistic regression models evaluated the AD risk associations of *APOE**2 dosage, *APOE**4 dosage, and *APOE* genotype, with regard to *APOE**33 as the reference, while adjusting for sex, array/batch/center, and global European, African, and Amerindian ancestry. *APOE* associations in East-Asians (EAS) were obtained through meta-analyses of published AD genetic studies, given the relative paucity of EAS in publicly available genetic
cohorts.

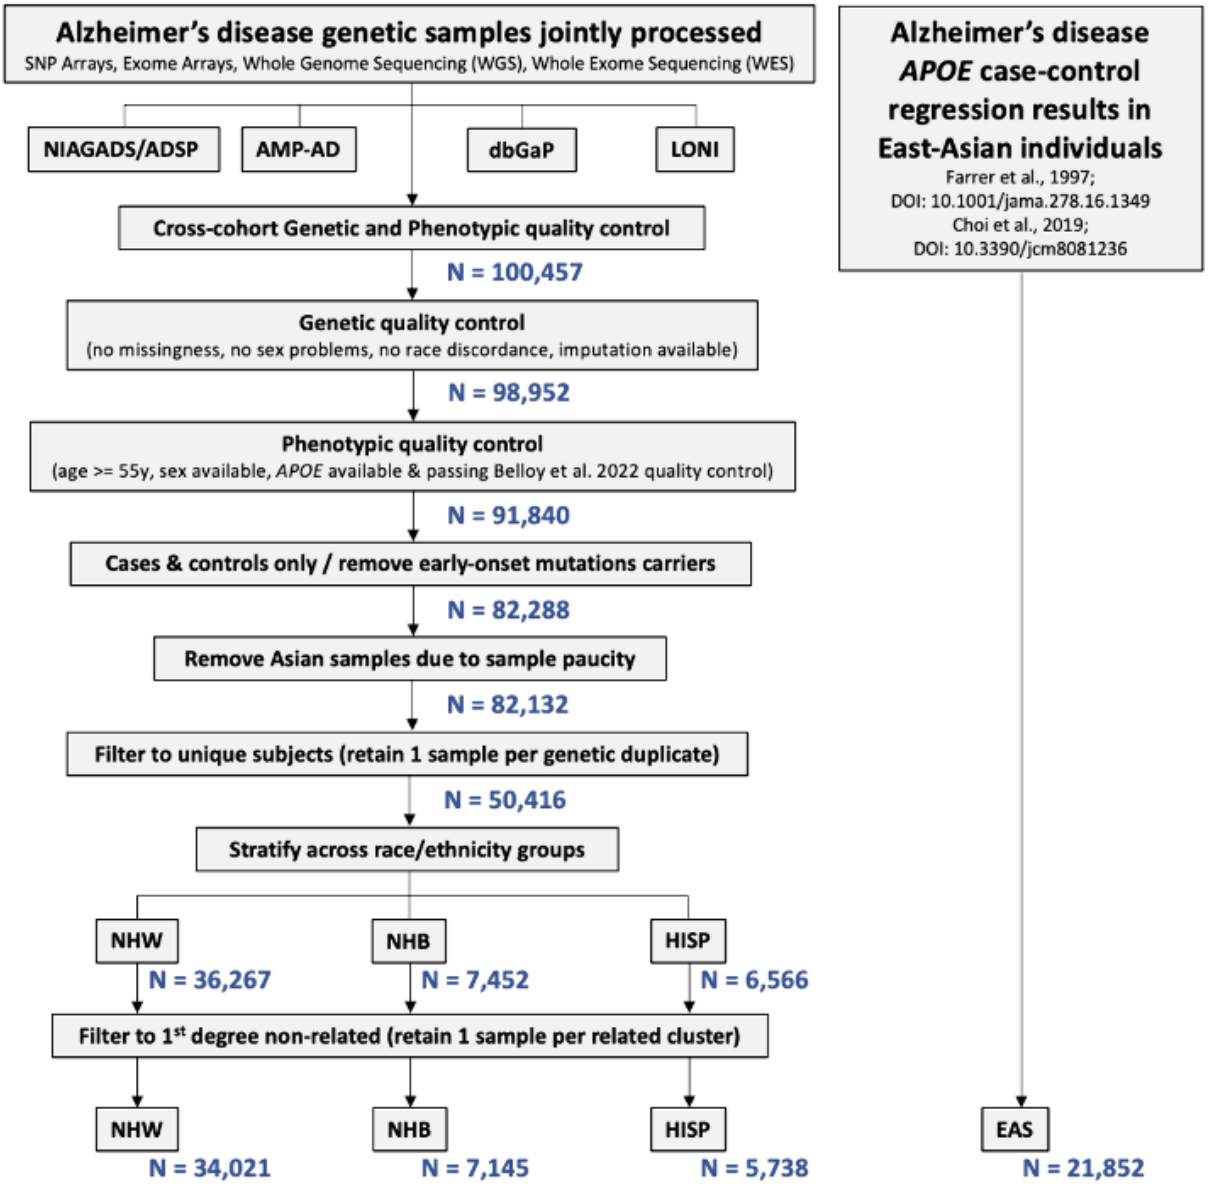

Figure 1. Flow chart of sample/participant filtering for *APOE* association analyses with Alzheimer's disease risk.

Results: We made several novel observations (**Figure.2**). Notably, the associations of *APOE* genotypes with AD risk were least pronounced in HISP, which was not explained by global ancestry. Further, not just *APOE**4, but also *APOE**2 followed a reduced association strength with AD risk according to the pattern of EAS > NHW > NHB > HISP (with the exception of *APOE**2 in EAS, which showed no significant association). The sex-by-age-specific association of *APOE**34 in NHW, which was shown to be stronger in women, was reproduced here at ages 60-70 years, and additionally replicated in NHB and HISP.

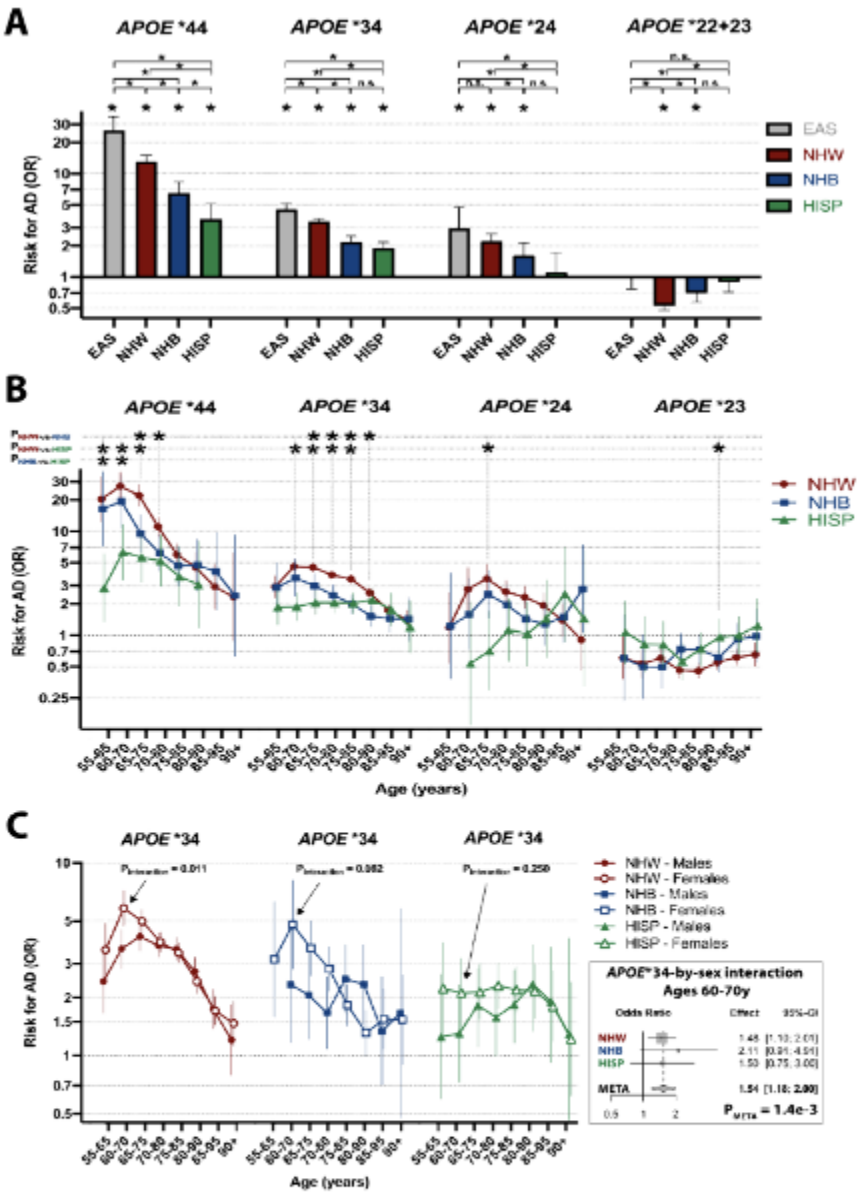

Figure 2. Associations of *APOE* genotypes with AD risk across race/ethnicity, age, and sex. A) Race/Ethnicity stratified and heterogeneity results. Note the stepwise pattern across groups and least pronounced associations of *APOE* genotypes with AD risk in Hispanics. Significance (*) was P<0.05. **B)** Race/Ethnicity stratified and heterogeneity results, further stratified across 10-year age bins using a sliding window approach (5-year overlap). In age-stratified analyses, significant discoveries (*) were considered for Bonferroni correction of the number of non-overlapping age windows (P<0.05/4=0.0125). **C)** *APOE**34-by-sex stratified and interaction results, across age strata. The age bin of 60-70 years indicated a significant *APOE**34-by-sex interaction effect in NHW, which was replicated with nominal significance upon meta-analysis of NHB and HISP (P=0.048). Right inset shows the overall meta-analysis.

Conclusions: We provide the largest-to-date overview of *APOE*'s associations with AD risk across important biological and demographic strata. We expect these insights to be critical to guide AD research and clinical trial design.

Aims: Increased oxidative stress and mitochondrial dysfunction are known features of Alzheimer's disease (AD) pathomechanism. The pathological protein amyloid-beta (Aß) drives oxidative stress in AD. These effects are largely counteracted by the glutathione (GSH) system within our cells. Glutathione peroxidase 4 (fly homologue PHGPx) is a critical brain antioxidant within the GSH system. Reduced expression is evident in AD patient brain regions affected by Ferroptosis; a cell death mechanism associated with increased lipid peroxidation and mitochondrial alterations. These observations point towards potential therapeutic value in overexpressing PHGPx to rescue oxidative stress and neurodegeneration. We aimed to discover how levels of PHGPx affect phenotypes within a *Drosophila* model of AD, including survival, Aß accumulation and neurodegenerative phenotypes.
Methods: Levels of PHGPx were altered specifically in fly neurons via the UAS-GAL4 system, using either RNAi for knockdown or cDNA for overexpression. To measure longevity the percentage survival state of flies was recorded over the lifespan compared to control. Locomotor function, used as a readout for overall CNS function, was assessed using a negative geotaxis assay. Analysis of mitochondrial morphology was then achieved using genetically encoded GFP and imaged by confocal microscopy. Mitochondrial dynamic changes that occur during oxidative stress were quantified using ImageJ.
Results: We found overexpression of PHGPx ameliorates Aß toxicity through extension of survival in *Drosophila* and protects against progressive climbing deficits observed in adult *Drosophila.* Conversely, knockdown of PHGPx was shown to cause significantly more round mitochondria and to enhance oxidised glutathione levels in mitochondria.
Conclusions: This suggests overexpression of PHGPx may act as a protective mechanism in context of neurodegenerative diseases involving the pathological hallmark amyloid including AD. Identifying the mechanisms underlying these phenotypes may lead to new therapeutic interventions for AD.

CONTRIBUTION OF GENETIC POLYMORPHISMS TO VARIABLE SLEEP DISTURBANCES IN ALZHEIMER'S DISEASE

POSTERS: A05.C. GENETICS, EPIDEMIOLOGY: GWAS, GENETIC ASSOCIATIONS, SUSCEPTIBILITY & PROTECTIVE GENES

Alesha Heath[1], M Windy Mcnerney[2], Jerome Yesavage[1]
[1]Stanford University, Psychiatry And Behavioral Sciences, Stanford, United States of America, [2]VA Palto Alto, Mirecc, Palo Alto, United States of America

Aims: Alzheimer's disease (AD) presents itself as a highly heterogeneous disorder. Many diagnosed express variable symptom base which may further contribute to cognitive decline or be protective against the neurodegeneration caused by this disorder. One such factor is sleep. Aspects of sleep architecture are known to be heritable and influenced by genetic polymorphisms. Therefore, we hypothesized that genetic differences which underlie sleep disturbances influence the progression of AD.
Methods: This study used existing data collected through the Alzheimer's Disease Sequencing Project and National Alzheimer's Coordinating Center's Uniform Data Set (NACC). In order to determine whether genetic differences underlie these sleep effects, we used VNTRseek to genotype over 200,000 tandem repeats of interest in sequencing data from non Hispanic White population (n=5116).
Results: Using a logistic regression model controlling for sex and AD status we did not find any association of VNTRs with sleep disturbances in this dataset after correction for multiple testing. As it is well known that having sleep disturbances increases the chance of developing AD, we wanted to see if any genetic polymorphisms mediated this effect. Using a cox regression model controlling for sex and APOE4 status we found one tandem repeat, upstream from the carbohydrate sulfotransferase 3 gene, was associated with faster time to diagnosis of AD in those with sleep disturbances.
Conclusions: We plan to extend these findings to include SNPs to evaluate multiple types of polymorphic contributions. As sleep remains one of the only modifiable factors that could easily influence the progression of AD, by identifying genetic associations which could allow us to predict factors which may accelerate the progression of this disorder we will open up avenues to apply early interventions and monitor the progression of this symptom closely.

Aims: Family-based Genome-Wide Association Studies (GWAS) serve as a powerful analysis for the identification and investigation of rare genes associated with heightened risk while avoiding issues with population stratification in population-based GWAS. To effectively conduct family-based GWAS, the familial relationships among the study participants must be validated. We present a tool that will be implemented within an automated quality-control tool for pre-GWAS workflows to do thorough relatedness profiling for whole-genome sequencing for RedLat, an initiative studying Alzheimer's disease and related dementias in Latin America.
Methods: We built a Python pipeline for family-based GWAS that leverages the RedLat genomic data, accurately determining and verifying familial relationships among individuals. The tool utilizes PLINK2 and KING to infer pairwise kinship coefficients, labeling the relationships as either full siblings, parent-offspring, 2nd-degree, or 3rd-degree relatives. We also compare the reported familial relations with the genomically determined relatedness using identity-by-descent (IBD) values.
Results: This method will label all of the samples within the RedLat dataset based on kinship clusters and the familial relationships that exist within the clusters. The kinship coefficients are used to flag and remove samples with cryptic relatedness (individuals found to be related to more than two families) and ignore background relatedness as noise. We also confirm that the disclosed relatedness matches the genomic relatedness using IBD cutoffs to differentiate the relationships. We have verified that the results generated from our automated pipeline align with results produced manually.
Conclusions: Our pipeline will confirm relatedness within RedLat so that family-based studies can be performed confidently on the data, increasing the accessibility and power of familial GWAS. In the future, this pipeline can be applied to any disease dataset once hereditary information is available.

Aims: Objectives: Efforts to establish valid blood-based diagnostic approaches for individual susceptibility to Alzheimer's Disease (AD) play a pivotal role in advancing strategies aimed at AD prevention and early therapeutic interventions. Two emerging indicators, Neurofilament light chain (NfL) and polygenetic risk scores (PRS) for AD, show promise in this context. The present study evaluated the correlation of both markers and their combined predictive value in cognitively healthy persons prior to clinical AD onset.
Methods: We conducted data analysis using a cohort of 144 75-year-old participants drawn from the Vienna Transdanube Aging (VITA) longitudinal study. Participants were categorized based on development of AD over a 90-month study period. Plasma NfL was assessed using single molecular array technology (Simoa) at baseline, 30-, 60-, and 90-months. For validity control, NfL z-scores were computed accounting for the influence of age and BMI. Furthermore, genotype data from participants were collected and used to calculate individual late-onset AD continuous shrinkage polygenetic risk scores (PRS) based on the largest available AD genome-wide association study (GWAS).
Results: 19 participants developed AD after a median time to diagnosis of 60 months (IQR 30). Plasma NfL levels increased significantly in both groups over 90 months (AD: $p=1.2x10^{-4}$, controls: $p=6.0x10^{-18}$). In the AD group baseline NfL plasma levels correlated with PRS (r=0.75, p<0.001). This relationship was not observable in the control group (r=-0.06, p=0.49; Fisher's r-to-z: z=3.89, p<0.001). PRS-CS combined with baseline plasma NfL predicted development of AD (p<0.01).
Conclusions: Our data suggest that polygenic risk for AD and plasma NfL closely interact years before onset of clinical symptoms. Our findings support the notion that peripheral NfL may serve as a diagnostic measure supporting early therapeutic intervention and secondary prevention in AD.

Aims: Alternative splicing as well as distinct cell types have been gaining in interest regarding their role in complex human diseases, as advances in technologies have made studying their respective impact on disease risk increasingly feasible. We attempt to combine both long-read and single-cell sequencing to investigate the effect of alternative splicing in a cell-type specific context in the etiology of Alzheimer's disease (AD).
Methods: We sequenced a cohort of n = 15 AD patients and n = 8 controls using 10X single-nuclei Oxford Nanopore Technologies (ONT) long-read sequencing. Nuclei isolation was performed using a density gradient protocol optimized for human fresh frozen brain. For comparison, we performed Illumina short-read sequencing on the same 10X libraries. We compared short-read-free classification of barcodes, gene calling and cell typing results to short-read Cell Ranger-based analysis, which is the current "gold standard".
Results: Using our ONT-single-nuclei-based generated data we obtain highly similar results to the standard short-read workflow. Identification of non-empty droplets and percentage of cell type distributions show very high overlap, and we find a strong correlation in per-cell UMI count, with correlation coefficients ranging between 0.92 and 0.85. Importantly, we also obtain isoform counts, which are unreliable when relying on short reads.
Conclusions: We show that short-read sequencing is not required for either barcode assignment, clustering, or cell-type characterization, which evidently comes with a great reduction in experiment cost. Furthermore, without significant loss of information we generate transcript isoform information, which is unreliable in short-read based experiments, which we will use next to investigate alternative splicing in human disease.

Aims: The Seoul Neuropsychological Screening battery (SNSB) is a widely used cognitive test battery for Korean speakers. However, the effects of genetic variation on the SNSB are not well understood, despite the fact that it is widely used in Korea. We conducted a genome-wide association study (GWAS) using genotype data to investigate associations with neuropsychological tests in order to address these research concerns.
Methods: Over 10,000 subjects enrolled in Gwangju Alzheimer's and Related Dementia cohort undergo cognitive assessment with SNSB with follow-up diagnosis. SNSB contains five cognitive domains; attention, language, visuospatial functions, memory, and executive functioning. We used the latest SNSB screening results from 2,055 subjects. Subject genotype data were acquired using Affymetrix® Axiom KORV1.0 and imputed with HRC panel V.1.1. SNPs with minor allele frequency<1%, call rates<95%, HWE p-value $<1\times10^{-6}$ were excluded from analysis. We performed linear regression with raw test scores and 10 million imputed genotype variants with PLINK software. Age, sex, education level, and the first four PCs were adjusted as covariates.
Results: The missense variant of the genome-wide significant (GWS) loci on chromosome 14 showed substantial associations in RCFT delayed recall (1.71×10^{-11}) and K-MMSE total score (4.14×10^{-9}).
Conclusions: The missense variant on chromosome 14 may effectively predict overall cognitive dysfunction and long-term visuospatial memory loss, which are the testing domains of MMSE and RCFT. Additional analyses on protein structure and in-vivo studies are required to thoroughly investigate the functional effects of the missense mutation. Since RCFT delayed recall also showed significant associations with CSF phospo-Tau level (Seo et al., 2021), the identified GWS variant may indicate neurodegeneration in Tauopathy and AD.

Imperial College London, Epidemiology And Biostatistics, London, United Kingdom

Aims: Inflammation is involved in a plethora of pathophysiological conditions including brain dementia. Several genes of Alzheimer's disease (AD) have also been associated with inflammation biomarkers including C-reactive protein (CRP). Here, we aim to investigate further the common genetic architecture between AD and inflammatory biomarkers and identify pleiotropic loci. We perform a large-scale multi-trait GWAS analysis on AD and CRP followed by genetic colocalization analysis to highlight candidate pleiotropic genes and their tissue sites of action.
Methods: We performed a multi-trait analysis on AD and CRP using MTAG followed by colocalisation analysis on the top signals indicated from MTAG. A trait-expression quantitative trait loci (eQTL) colocalisation using AD, CRP and eQTL from 48 tissues to detect possible shared genes between the traits and investigate the tissues they are expressed.
Results: We highlight 13 possibly shared genes between AD and CRP located in 4 loci and additionally, we prioritise 4 candidate causal variants. The variant rs11136254 colocalises via EEF1D in brain hypothalamus, while rs1582763 via RP11-1036E20.9 in whole blood and via TMEM132A in muscle skeletal. The variant rs34173062 colocalises in 6 different tissues via 4 distinct genes including CPSF1 in lung, artery coronary, muscle skeletal and adipose subcutaneous, PARP10 in artery tibial, ZNF251 in lung and SLC52A2 in adipose visceral omentum. Finally, rs62090056 colocalises via SERPINF2 in testis.
Conclusions: Our findings provide insights into shared mechanisms underlying inflammation and neurodegeneration, representing potential preventive and therapeutic targets.

Hussman Institute For Human Genomics, Miami, United States of America, [2]University of Miami, Human Genetics, Miami, United States of America, [3]University of Pennsylvania, Perelman School Of Medicine, Philadelphia, United States of America

Aims: Studies have shown non-Hispanic white (NHW) females carrying the *APOEε*2 or ε4 allele differ in risk of developing Alzheimer's disease (AD) compared to men, though this difference may be age-dependent. Here we comprehensively evaluate the association between sex, age, ancestry, and *APOE* with AD in cohorts from the Alzheimer's Disease Genetics Consortium (ADGC).
Methods: A case-control study was conducted in 50 datasets (n=42,295). Logistic, linear, and Cox regression models were used to evaluate associations between disease status and age, sex, race/ethnicity (as proxy of ancestry), and *APOE*.
Results: Men and women with *APOE*ε3/ε4 showed no significant difference in risk of AD after accounting for age. Ancestry-specific analyses showed when comparing subjects with *APOE*ε3/ε4 (vs. ε3/ε3), East-Asian (EA) females (*OR,* 5.00) and males (*OR,* 4.20) had strongest risk; whilst the weakest risk was for South-Asian (SA) men (*OR,* 1.23). Age and ancestry-specific analyses found NHW females (*OR,* 4.66 vs. males: *OR,* 3.99) and African American (AA) females (*OR,* 4.27 vs. AA men: *OR,* 1.98) with *APOE* ε3/ε4 presented higher risk between ages 66-75; whereas EA and SA exhibited this pattern at 55-64. In Hispanics, the relationship was reversed, with males aged 55-65 years carrying *APOE*ε3/ε4 (*OR,* 3.42 vs. females: *OR,* 2.30) having stronger risk than females. Nonetheless, these differences were not statistically significant. Case-only and survival analyses also established that NHW, AA, and EA female APOEε3/ε4 carriers had earlier age-at-onset than their male counterparts. When comparing *APOE*ε2 carriers vs. ε3/ε3 carriers, NHW women (*OR*, 0.64) and men (*OR*, 0.50) presented the lowest *OR*s among ancestries.
Conclusions: Our findings suggest ancestry and age-specific sex differences in AD risk in *APOE*ε2 and ε4 carriers. However, local ancestry analyses for *APOE* are warranted to confirm these findings.

Aims: *APOEε4* is the major genetic risk factor for sporadic Alzheimer's Disease (sAD). Despite its strong effect in disease development, there is a huge variability in the age of onset of *APOEε4* carriers. We aim to detect synergistic combinations of low-risk variants that dramatically modify *APOE* influence in sporadic Alzheimer's Disease (sAD).
Methods: We accessed the European AD Biobank (EADB) dataset with >42.000 individuals. We conducted multifactor dimensionality reduction and multiplicative logistic regression on 85 GWAS index variants over the EADB data stratified by the number of *APOEε4* alleles, to study the synergistic effect of all possible trios of variants. We combined the effect deviated from the additive weight of those combinations and compared the performance of both standard GRS and epistatic GRS models in >4.200 independent samples.
Results: We identified >400 novel combinations of genetic variants that significantly deviate from their predicted additive effect and drastically associate AD. The epistatic GRS model outperform significantly standard GRS, identifying >80% of the individuals' status correctly. When stratifying by the number of apoe4 alleles, epistatic GRS also significantly improves AD prediction when compared to standard GRS. The improvement is remarkable in *APOEε44* carriers, where standard GRS have an AUC of 78% and the epistatic GRS of >88%.
Conclusions: We described numerous *APOE* interactors that dramatically influence the disease development, many of them interacting synergistically to promote sAD.

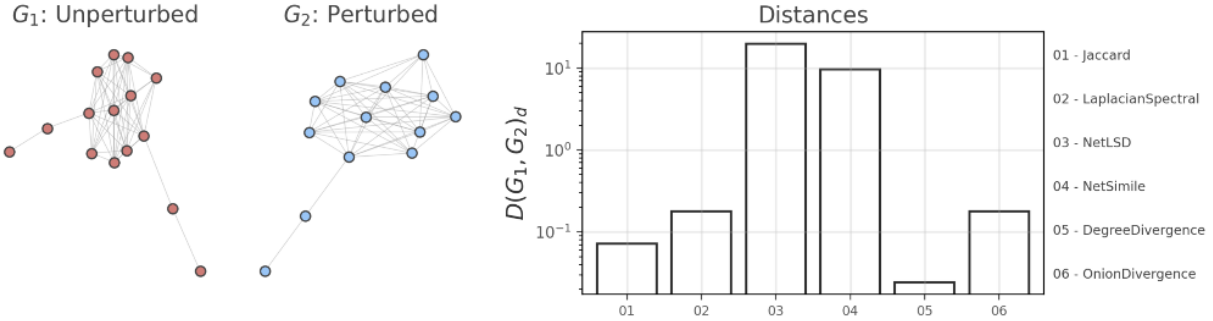
Aims: The rapid evolution of transcriptomics is highlighting the importance of understanding the complex gene networks within the human brain, especially across neurodegenerative diseases such as Alzheimer's. Here we provide a community resource, termed "Synthetic Perturbation INteractions in Networks (SPINN)", an in silico method that leverages machine learning to decipher, query, and visualize these networks and provide researchers with a method to prioritize gene knock-out experiments in vivo or in vitro.
Methods: Key genes in this pilot research include *APOE*, *GRN*, *KANSL1*, and *NOTCH4*. The OpenTargets API was queried to extract associated genes from databases like IntAct, Signor, and Reactome, to construct preliminary networks. A distinct matrix reflecting gene expression across multiple cell types in the adult human brain, focused on the profiles from blood, serum, and cerebrospinal fluid, by Linnarsson and colleagues was used. Employing community clustering and graph network analyses, gene networks were formed. Distance metrics to compare the similarities in the network dynamics pre- and post-synthetic perturbations are calculated.
Results: Our pilot research to assess *APOE* gene networks in microglia indicates that the overall structure of the network is maintained, while the way the genes connect and interact has changed considerably following perturbation (NetLSD distance metric = 1; **Supplementary Figure**). The analysis emphasizes understanding expression shifts based on their regulatory roles. To ensure robustness, the methodology will be applied to a mouse-derived expression matrix, where *APOE* was knocked out.
Conclusions: SPINN presents a framework for decoding the gene expression networks present in neurodegenerative diseases to aid in nominating knockout experiments, directly inform CRISPR studies, and provide an accessible platform to assess the impact of drugs on gene networks.



SPINN prototype: Assessing connectivity of *APOE* in microglia pre- and post-synthetic perturbation with distance metrics

Aims: Hippocampal sclerosis of aging (HS-aging) is a cause of dementia in older adults which is often misdiagnosed as Alzheimer's disease (AD). HS-aging hippocampal atrophy pattern might help differentiate it from AD. We aim to find risk SNPs previously associated with AD that might be more related to HS-aging.
Methods: We calculated a polygenic risk score (PRS) combining 83 SNPs associated with AD by the European Alzheimer and Dementia consortium (EADB; Bellenguez et al. 2022) and assessed their relation with an HS-by-proxy based on magnetic resonance imaging (MRI) data of hippocampal subfield volumes from 1,130 individuals without dementia syndrome from Fundacio ACE (FACE) and ADNI. We used data from 322 cases and 1,386 controls from EADB–FACE/BBB to associate the EADB AD-PRS (83 variants) with AD in the presence of concomitant brain pathologies, as previously done by de Rojas et al. (2021) using their AD-PRS (39 variants).
Results: From the 14 subfields analyzed, fimbria and hippocampal body and head (HBH) showed a significant association with AD-PRS. Association with these hippocampal subfields was also observed in *SHARPIN* rs34173062 (OR_{HBH}=0.85[0.77-0.93]; $p\text{-value}_{HBH}=2.63\times10^{-04}$;$OR_{fimbria}$=0.83[0.75-0.91]; $p\text{-value}_{fimbria}=2.09\times10^{-04}$) and *TNIP1* rs871269 ($OR_{HBH}$=0.90[0.85-0.95]; $p\text{-value}_{HBH}=1.71\times10^{-04}$). These loci remained consistently associated to HS-aging after analyzing an independent cohort of cognitively healthy individuals (N = 729) from Fundacion CIEN. We replicated the stronger association of AD-PRS with AD in the presence of HS-aging than with AD pathology alone.
Conclusions: The results presented in this study suggest that some SNPs that have recently been identified as AD risk variants might be more closely related to atrophy in hippocampal subfields instead of AD. Hence, these results could be instrumental to refine genuine AD and HS-aging pathways, their interrelationships, and to identify specific therapeutic targets for each condition.

Aims: The misfolding of amyloid β-peptide (Aβ) into β-sheets caused Alzheimer's disease (AD) but this knowledge has not yet led to treatments to prevent AD. To identify novel molecular players in Aβ toxicity, we carried out a genome-wide screen in *Saccharomyces cerevisiae*, using a library of gene knock-out strains expressing $A\beta_{1-42}$.
Methods: i) Cell viability assay of 5,154 knock-out strains of *Saccharomyces cerevisiae* that overexpress $A\beta_{1-42}$ and identification of the enhancer and protective genes regarding amyloid toxicity; ii) *In silico* analysis of genes to perform text-mining and interactome studies; iii) Molecular and cellular studies of the role of SURF4 in $A\beta_{1-42}$ toxicity in human neuroblastoma cells (SH-SY5Y cells).
Results: We identified 81 mammalian orthologue enhancers and 157 protectives genes regarding $A\beta_{1-42}$ toxicity. Text mining and interactome studies showed that the most relevant cellular functions implied in $A\beta_{1-42}$ toxicity/protection are calcium regulation, protein translation and mitochondrial activity. SURF4, a major regulator of store operated calcium entry (SOCE), arose as an enhancer of amyloid toxicity. We demonstrated that its overexpression in SH-SY5Y cells enhanced amyloid toxicity, while its silencing protects cells, by decreasing basal intracellular calcium.
Conclusions: Our data suggest that there are more genes involved in the regulation of amyloid toxicity than those proposed in human GWAS and SURF4 is one of them contributing to amyloid neurotoxicity by decreasing SOCE activity. Karolinska Institutet, Department Of Medical Epidemiology And Biostatistics, Stockholm, Sweden

Aims: To identify potential drug targets for Alzheimer's disease and related dementia (ADRD) by integrating multi-omics data.
Methods: Genetic and observational study approaches were combined to identify drug targets for ADRD (Figure 1). We integrated summary statistics of genetic associations from ADRD GWAS and *cis*-pQTL data, and then performed colocalization analysis to identify the candidate causal variant between two traits within the target gene region. Leveraging the candidate causal variant as the instrument, *cis*-Mendelian Randomization (MR) can estimate the effect of target proteins on ADRD risk. SATSA is a longitudinal study with genotypes and DNA methylation in 468 twins whose dementia status was followed through December 31, 2016. A HyPr-genetic risk score (GRS) was constructed using aforementioned candidate causal variants weighted by coefficients in ADRD GWAS. The HyPr-GRS effect on dementia risk in SATSA was estimated by Cox models. The association between the causal variant and dementia was estimated in subgroups with different CpG methylation levels to evaluate CpG island modulation of causal variants on
dementia.

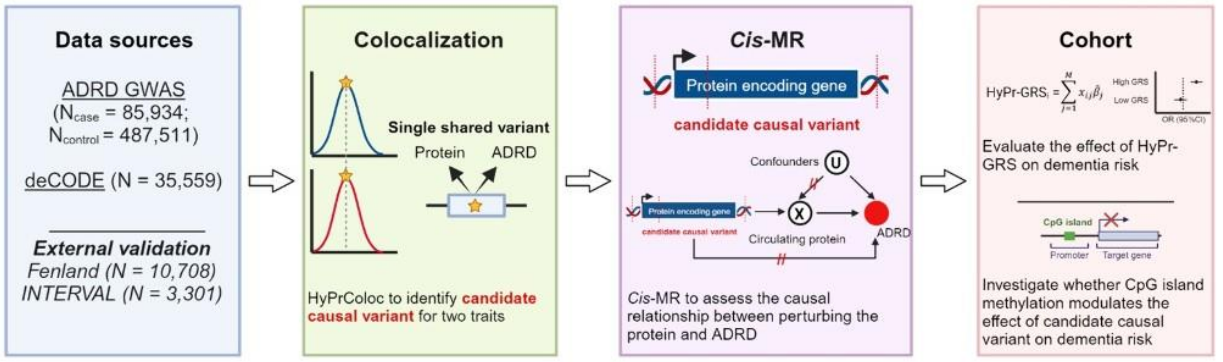

Figure 1. The study design flowchart

ADRD, Alzheimer's disease and related dementia; MR, Mendelian randomization; GRS, genetic risk score.

This study integrates summary statistics of genetic associations from ADRD GWAS and *cis*-pQTL data, and then performs colocalization analysis to identify the candidate causal variant between two traits within the target gene region. Leveraging the causal variant as the genetic instrument, *cis*-MR is used to estimate the causal effect of the target gene of interest on the risk of ADRD. Based on these candidate causal variants, a HyPr-genetic risk score (GRS) is calculated and its effect on dementia risk is evaluated in Swedish Adoption/Twin Study of Aging. And the candidate causal variant effect on dementia risk is further estimated in subgroups with different methylation levels in the CpG island of the target gene of interest.

Results: Seven loci were identified by colocalization. Genetic variation in CR1, SIGLEC9, *CTSH* and *C1S* exhibited an increased ADRD risk, while genetic variation in *PILRA*, *PLOD2* and *GRN* had a lower ADRD risk (Figure 2). The highest tertile of HyPr-GRS was associated with a higher all-cause dementia risk compared with the lowest tertile (HR 1.82, 95%CI 1.00-3.32) (Table 1). The causal variant of *CR1* had a stronger effect on dementia risk among individuals with

the lowest CpG island methylation level (Figure 3).

Target gene	Instrument	OR (95%CI)	*P* value
PILRA	rs1859788	0.94 (0.93-0.96)	1.16×10^{-17}
C1S	rs12146727	1.07 (1.04-1.10)	6.41×10^{-06}
SIGLEC9	rs2075803	1.03 (1.02-1.04)	4.30×10^{-05}
CR1	rs679515	1.28 (1.23-1.33)	5.65×10^{-33}
PLOD2	rs148118826	0.59 (0.46-0.76)	6.18×10^{-05}
CTSH	rs2289702	1.04 (1.03-1.06)	3.10×10^{-06}
GRN	rs5848	0.74 (0.68-0.81)	2.19×10^{-12}

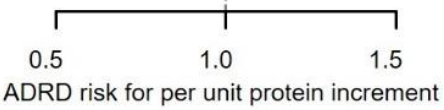

Figure 2. The effect of genetic variation in target genes on ADRD risk using the *cis*-MR analysis

OR, odds ratio; ADRD, Alzheimer's disease and related dementia; MR, Mendelian randomization.

The candidate causal variant identified through colocalization analysis is leveraged as the genetic instrument to proxy the perturbation of the target protein. Combining genetic associations of the instrument with the protein and ADRD, the Wald ratio test is used to estimate the effect of genetic variation in the target gene on ADRD risk. MR estimates are scaled to ORs of ADRD per unit increment of the protein encoded by the target gene.

Table 1. The effect of HyPr-GRS on the risk of incident dementia and main subtypes

Endpoint	Low HyPr-GRS	Medium HyPr-GRS	High HyPr-GRS
All-cause dementia			
Case/participants	23/158	23/155	36/155
HR(95%CI)	1.00 (Ref.)	1.09 (0.57-2.10)	1.82 (1.00-3.32)
ADRD			
Case/participants	12/147	12/144	16/135
HR(95%CI)	1.00 (Ref.)	0.82 (0.30-2.22)	1.45 (0.55-3.80)
Vascular dementia			
Case/participants	5/140	8/140	17/136
HR(95%CI)	1.00 (Ref.)	1.67 (0.53-5.28)	4.45 (1.59-12.50)

ADRD, Alzheimer's disease and related dementia; GRS, genetic risk score.
The effect of HyPr-genetic risk score on the risk of dementia and subtypes are estimated by Cox proportional hazard model. The model adjusts for age, sex, APOE genotypes, educational level and smoking status, and uses twin pair as the random effect.

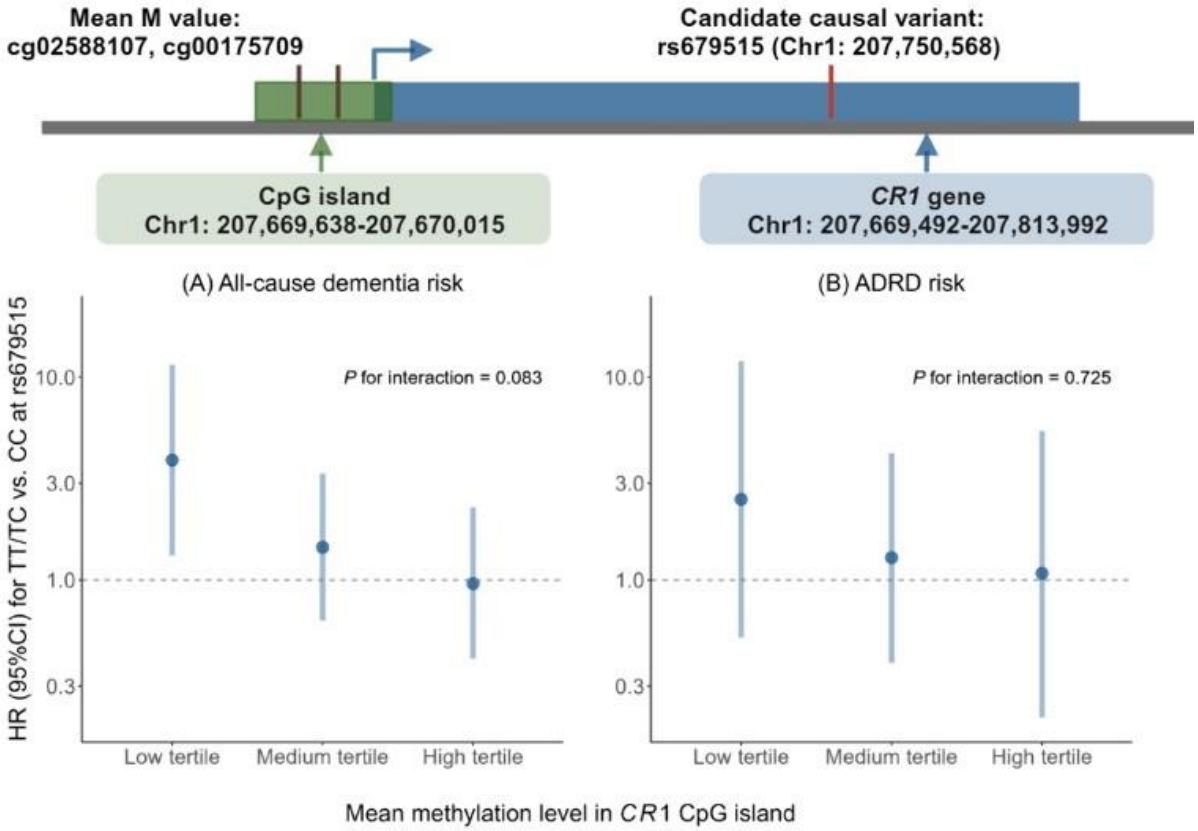

Figure 3. The effect of the candidate causal variant in *CR1* gene on dementia risk in groups with different methylation levels of *CR1* CpG island

ADRD, Alzheimer's disease; HR, hazard ratio; CI, confidence interval.

The upper panel illustrates positions of CpG island and the candidate causal variant in the *CR1* gene region. The lower panel shows the candidate causal variant on dementia risk in three methylation levels of the CpG island of the *CR1* gene. The Cox proportional hazard model uses twin pair as the random effect and adjusts for age, sex, APOE genotypes, educational level, smoking status, and HyPr-genetic risk score excluding the candidate causal variant of the *CR1* gene. The *P* value indicates the significant level of the interaction between the candidate causal variant and CpG island methylation tertiles.

Conclusions: Seven potential targets for ADRD were found. Individuals with lower DNA methylation in the *CR1* CpG island may have greater ADRD risk reduction through inhibiting plasma CR1 protein.

Hussman Institute For Human Genomics, Miami, United States of America, [2]Universidad Central del Caribe, -, Bayamón, Puerto Rico, [3]Clinica de la Memoria, -, San Juan, Puerto Rico, [4]Uniformed Services University of the Health Sciences, Department Of Anatomy, Physiology, And Genetics, Bethesda, United States of America, [5]University of Miami Miller School of Medicine, Department Of Neurology, Miami, United States of America

Aims: Puerto Ricans (PR), the second-largest Hispanic group in the mainland US, remain underrepresented in Alzheimer disease (AD) genetic studies. Including diverse ancestral populations is important for understanding the genetic underpinnings of AD. To bridge this gap, we conducted a genome-wide association study (GWAS) in the PR population to identify novel AD susceptibility loci and characterize known AD genetic risk loci.
Methods: The PR dataset includes Whole Genome Sequencing (WGS) and phenotype data from 639 individuals (334 cases; 305 cognitively unimpaired (CU)). We employed a generalized linear mixed model using SAIGE software. Two separate models were analyzed; the first model accounted for sex, age, population substructure and relatedness, and the second model also included the dosage of *APOEe4*. We assessed the polygenic risk scores (PRS) using non-Hispanic White (NHW) GWAS summary statistics results.
Results: We identified a promising signal on chromosome 12q13.13 with suggestive significance (rs10783462 OR=1.9, CI(1.7-2.3); $8.6x10^{-7}$) localized on the *SCN8A* gene in both models. Additionally, we replicated four known AD-associated loci (Kunkle et al. 2019, same reported markers), at the *APOE*, *TREM2*, *CLU*, and *FERMT2* genes. The PRS showed a good predictive power with the area under the curve of 0.62.
Conclusions: PR GWAS identified a potential risk locus in the *SCN8A* gene, which was previously identified as having a significant linkage with AD in NHW family studies and was associated with decreased AD pathogenesis in mouse models. The good predictive capacity of PRS might be attributed to the high European ancestral background in PRs.

AN INTEGRATED TOOLKIT FOR MICROGLIAL FUNCTIONAL GENOMICS REVEALS DIVERGENT ROLES OF AD-ASSOCIATED GENE SORL1 IN NEURODEGENERATION

POSTERS: A05.C. GENETICS, EPIDEMIOLOGY: GWAS, GENETIC ASSOCIATIONS, SUSCEPTIBILITY & PROTECTIVE GENES

Falak Sher
Columbia University, Neurology, New York City, United States of America

Aims: Microglia, the central nervous system's resident immune cells, play pivotal roles in brain functions and diseases like Alzheimer's (AD). However, a robust human microglia in vitro model is lacking, hampering our understanding of genes linked to neurodegeneration. Aims: 1. Streamline microglia functional genomics by improving differentiation protocols. 2. Validate the model through extensive genomics studies and functional assays. 3. Investigate the role of AD-associated gene, SORL1, in microglia.
Methods: 1. We developed an efficient two-step protocol to differentiate human induced pluripotent stem cells into microglia (iMG). 2. The iMGs were validated using single-cell RNA-sequencing, proteomics, and functional assays. 3. An integrated toolkit, including a drug-inducible CRISPR system, was also introduced. 4. Data is available on an online platform.
Results: Leveraging our state-of-the-art integrated microglia functional genomics toolkit, in tandem with primary human microglia samples, we delved deeply into understanding the role of the AD-associated gene, SORL1, in microglial cells. Our comprehensive approach, which combined cutting-edge genomics techniques with conventional methods, revealed the intricate ways SORL1 influences disease associated microglial phenotypes. A salient finding was that SORL1-deficient microglia exhibited defective phagocytosis of brain-associated substrates. Moreover, these deficient cells showed impaired immune responses. Significantly, the role of SORL1 in microglia was distinct from its function in neurons, highlighting the cell-specific effects of this gene in the neural milieu
Conclusions: Our innovative toolkit highlights the distinct role of the AD-associated gene, SORL1, in microglia. SORL1-deficient microglia present with impaired phagocytosis and altered immune responses. Crucially, SORL1 functions differently in microglia compared to neurons, emphasizing the value of cell-type specific AD research. Our toolkit facilitates translating genetic insights into molecular mechanisms, and the newfound role of SORL1 in microglia paves the way for tailored neurodegenerative disease therapies.

Aims: A polygenic risk score (PRS) is a metric which captures an individual's genetic susceptibility to a particular trait, condition, or disease based on multiple genetic variants or single nucleotide polymorphisms (SNPs) across their genome. PRS is a concept primarily used in the field of genomics and genetics, and it has gained significant attention in recent years due to advances in genetic research and the availability of large-scale genome-wide association studies (GWAS). To date, it is being used to predict an individual's risk of developing Alzheimer's disease or the individual Alzheimer-free survival.
Methods: Here, we will evaluate several machine learning approaches to incorporate ancestry information and several genomic platforms, developing ancestry-specific predictions for both overall disease risk and disease-free survival. We will compare the approaches in simulation studies and by application to the NIAGEDS data set.
Results: We developed an improved PRS with respect to predicting the development of Alzheimer's disease and an individual's Alzheimer-free survival.
Conclusions: These improvements have applications in calculating PRSs to predict the onset of diseases other than Alzheimer's, including cardiovascular disease and type 1 diabetes.

REVISITING THE ABCA7 EXON 18 VNTR IN ALZHEIMER'S DISEASE USING LONG-READ SEQUENCING

POSTERS: A05.C. GENETICS, EPIDEMIOLOGY: GWAS, GENETIC ASSOCIATIONS, SUSCEPTIBILITY & PROTECTIVE GENES

Ilaria Stewart[1], Lia Talozzi[1], Yann Le Guen[2], John Gorzynski[3], Michael Greicius[1]

Aims: The *ABCA7* (ATP binding cassette subfamily A member 7) gene has been previously associated with Alzheimer's disease (AD) (Bellenguez et al.2022). However, the genetic causes driving this association remain unclear. A variable number tandem repeat (VNTR) expansion flanking exon18 may play a driving role (as the top single nucleotide polymorphism (SNP) in Bellenguez is in intron18). The VNTR's expansion has been shown to be enriched in AD cases OR=4.5 (De Roeck et al.2018). The risk-increasing SNPs in De Roeck were also significantly associated with AD risk in Bellenguez. Here, we leveraged long-read sequencing (LRS) to further elucidate this locus, focusing on VNTR size and heterogeneity.
Methods: All participants underwent whole-genome LRS (~15x coverage) and a subgroup (82%) short-read sequencing (SRS). Among 571 participants, 114 were diagnosed with AD or mild cognitive impairment, 97 a synucleinopathy (either Parkinson's or Lewy Body disease), and 358 were controls. VNTRs were called with Vamos which provides quantification of length and polymorphic motifs. Motif composition was modeled using dimensionality reduction and hierarchical clustering.
Results: Using all Bellenguez SNPs within the *ABCA7* gene, we calculated associations with VNTR length, which are reported in Fig.1-2. Notably, we find no correlation between the top Bellenguez SNP and VNTR length and the strongest correlation with intronic SNP rs4807499. VNTR length and motif composition are reported in Fig.2-3. VNTR length did not differ between cases and controls. However, we identified five VNTR clusters, one of which appeared to be enriched in AD cases (Fig.4). This may implicate motif heterogeneity in increased AD
risk.

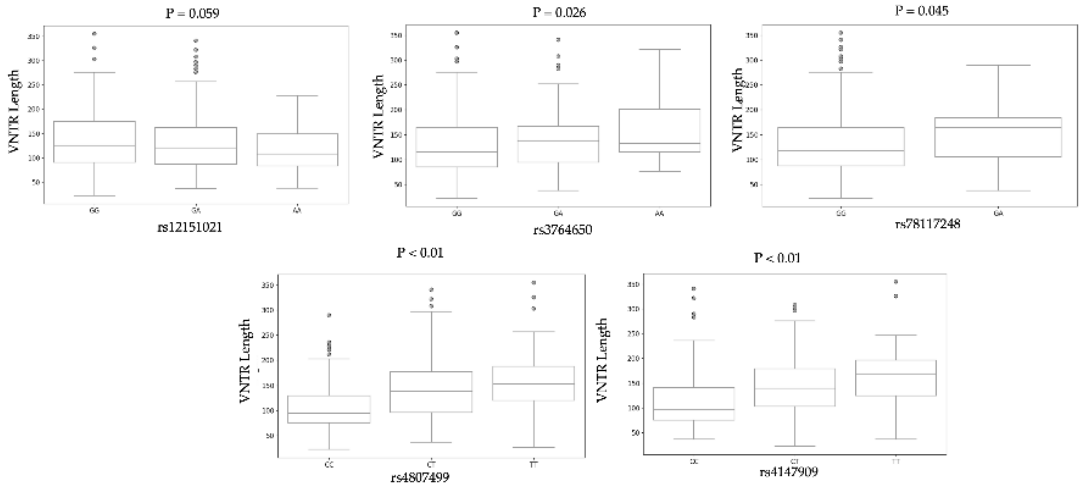

Figure 1. Correlating Bellenguez and De Roeck SNPs with VNTR length. Using Spearman's rank correlation coefficient, we report the associations (p-val) between SNP dosage and VNTR length. The top Bellenguez SNP (rs12151021) does not significantly correlate with VNTR length. The two intronic risk-increasing SNPs (rs3764650 and rs78117248) in De Roeck were significantly correlated with VNTR length, but not as strongly as rs4807499 (p−1.08E-16) and rs4147909 (p−3.28E-16), which are intronic variants on introns 44 and 10, respectively.

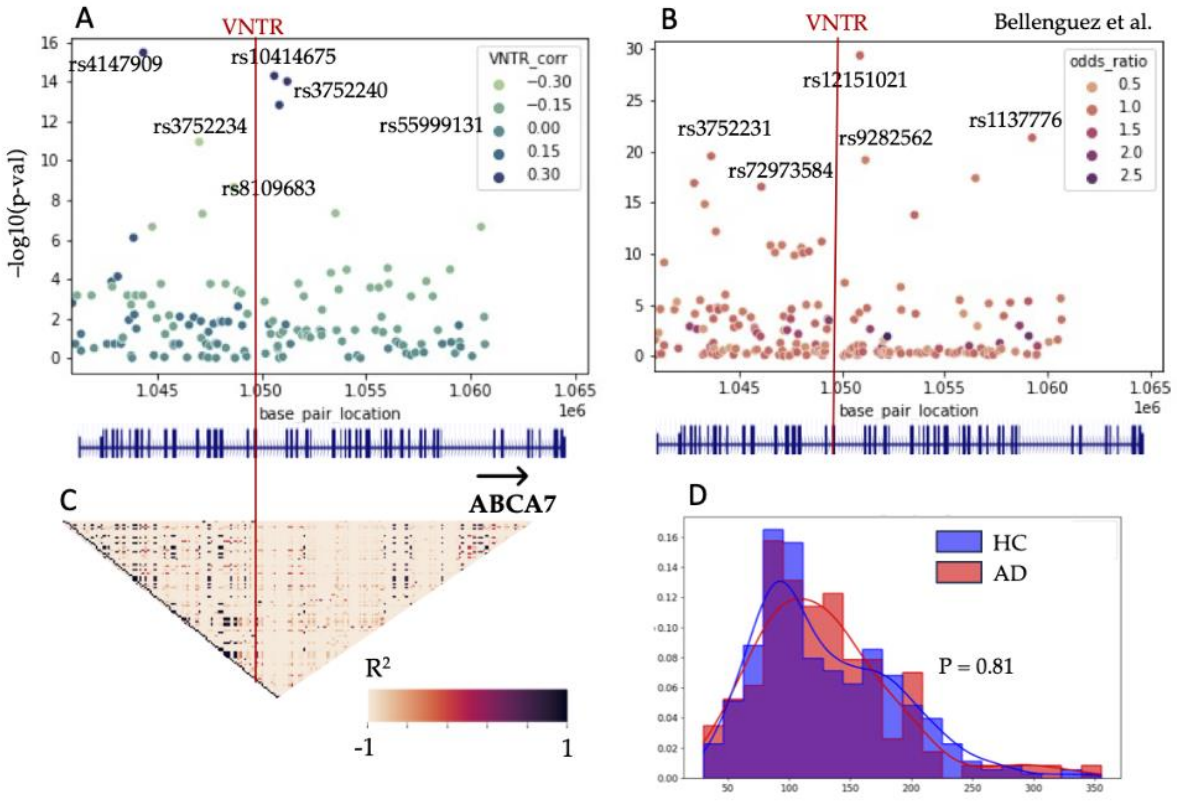

Figure 2. Variable Number Tandem Repeat (VNTR) length correlation with SNPs and diagnosis. A) Plot showing Spearman's correlations between *ABCA7* SNPs and VNTR length. **B)** Locus Zoom from Bellenguez et al. showing p-vals and odd ratios associated with AD. In A and B, the SNPs previously reported in Figure 1 are colored in blue. **C)** Linkage disequilibrium matrix showing R^2 correlations across the *ABCA7* locus. The blue colored SNPs rs4147909 and rs4807499 had an $R^2 = 0.591$. **D)** Histogram depicting VNTR length in base pairs in Alzheimer's disease (AD) cases and controls (HC). There is no significant difference in length between AD cases and controls (T-statistic = 0.24).

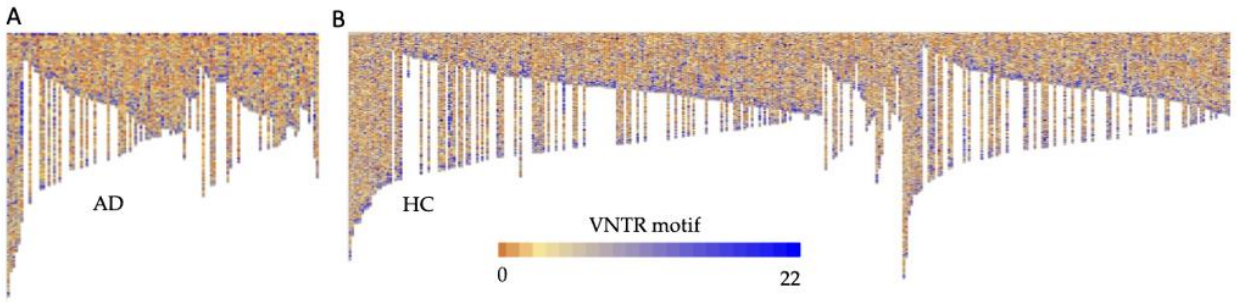

Figure 3. Visualizing *ABCA7* Variable Number Tandem Repeat (VNTR) Motif Polymorphisms in Alzheimer's disease (AD) and healthy controls (HC). Each column in the table is a participant and each cell is a particular motif. The motif frequency classification heat map is included on the right, where the most common motifs are orange, and the least are blue.

	HC (%)	AD (%)
C1	33	27
C2	14	13
C3	19	15
C4	16	16
C5	18	29

Figure 4. Dimensionality Reduction and Clustering. A) The Variable Number Tandem Repeat (VNTR) input. **B)** Principal Component Analysis (PCA) plot of the first two components. **C)** Hierarchical clustering dendrogram illustrating 5 distinct clusters (C1-5). **D)** PCA plot colored by VNTR length. **E)** PCA plot colored by the number of repeats with motif 1 normalized by the VNTR length. **F)** PCA plot colored by the dendrogram clusters. The red line divides the two main ramifications. **G)** Table depicting the percentage of participants that fall into each cluster separated by diagnosis HC and AD.

Conclusions: Our study highlights the potential importance of VNTR motif characterization. We utilized the increased read length of LRS to identify specific motifs enriched in AD cases.

[1]Washington University School of Medicine in Saint Louis, Psychiatry, Saint Louis, MO, USA, United States of America, [2]Universitat Internacional de Catalunya, Ace Alzheimer Center Barcelona, Barcelo, Spain, [3]Germans Trias i Pujol Research Institute, Neurogenerative Diseases, Badalona, Spain, [4]UTHealth, School Of Public Health, Houston, Spain

Aims: Clear sex differences exist in Alzheimer's and Parkinson's diseases. While sex-stratified eQTLs by GTEx show genetic differences between males and females, they primarily focus on cis regions. Therefore, the molecular mechanisms that underlie sex differences remain elusive. This study aims to investigate sex-specific genetic regulation of proteomics in neurologically relevant cerebrospinal fluid (CSF).
Methods: We recently identified 3,373 pQTL for 1,961 proteins of which 1,131 were unique to CSF, demonstrating genetic regulation specific to CSF. For 7,028 aptamers (SOMAscan), we performed sex-stratified pQTLs (in 1,640 males and 1,713 females). We examined pQTL in either males or females for both cis (at $P < 5\times10^{-8}$) and trans regions (at $P < 3.45\times10^{-11}$).
Results: We identified 1,702 significant pQTLs (1,065 cis; 637 trans) in either males or females. There were 393 (23.1%) sex-biased pQTLs (sb-pQTLs), showing association in females only (173), or in males only (220), but not in both. Among them, 141 showed effect differences between males and females ($P < 0.05$). We identified a pleotropic region chr19q13.32 near *APOE* that were enriched for neuron-specificity and neurological development. This *APOE* region regulated several AD genes (including APOE, NEFL, NECTIN2, APOC2, NRXN2) with stronger associations in males, as well as several AD proteins (SMOC1, YWHAB, YWHAZ, PPP3R1, VSNL1) with stronger associations in females. In addition, we found the *LRRK2* region chr12q12 regulated several PD genes (GRN, GPNMB, ITGB2) with stronger associations in males.
Conclusions: This large sex-stratified CSF protein QTL study uncovered distinctive sex-specific genetic regulation of CSF proteome. Our findings identified novel pQTL in both cis and trans, providing insights on dissecting the underlying biological causes and mechanisms contributing to sex differences in neurodegenerative disorders. More detailed characterizations is underway.

Aims: To characterize the Alzheimer's disease (AD) genetic risk at preclinical stages to understand the underlying biological mechanisms.
Methods: We included 2,527 cognitively unimpaired (CU) individuals from the ALFA study and 1,333 participants from ADNI (Controls=530, MCI=598, AD=205). In all participants, A+ was based on CSF Aβ42 levels and cohort-specific pre-established cut-off values. We characterized the genetic risk to AD and other neurological/age-related conditions using various polygenic risk scores (PRSs). We compared AD predisposition in ALFA with the entire ADNI disease spectrum using median tests, stratifying by Aβ status.
Results: The ALFA study exhibited a high prevalence of *APOE-ε4* carriers compared with the general European population (35.6% vs. 14%; $p < 0.001$) [Figure 1]. PRS-AD showed the highest variability in the sample (IQR=0.25) [Figure 2]. The median value of the PRS-AD increased along the AD continuum ($p_{corrected}<0.05$) [Figure 3]. Genetic predisposition to AD in ALFA was higher than in ADNI CN ($p<0.001$). ALFA A+ CU showed a higher genetic predisposition than MCI A+ in ADNI. When removing the *APOE* region, genetic predisposition was significantly lower in CN compared to AD. Also, we consistently observed a higher median score between CN, ALFA A+, MCI and AD. Furthermore, ADNI groups had a higher genetic predisposition to frontotemporal dementia than ALFA, with no significant differences for life expectancy [Figure 4].

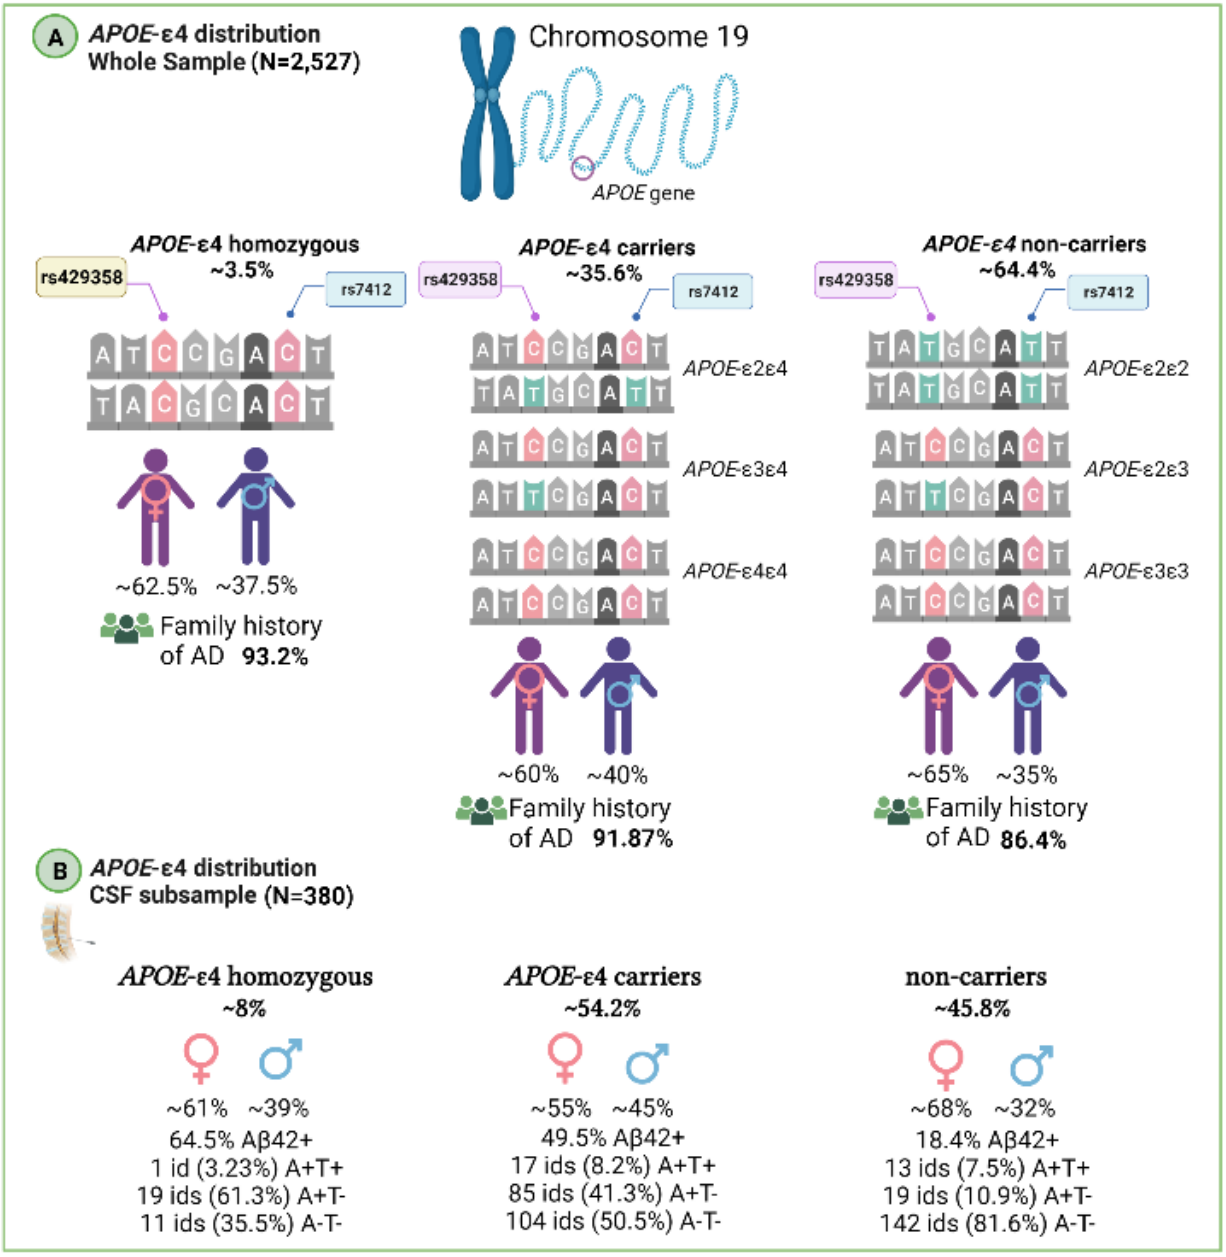

Figure 1. Distribution of *APOE*-ε4 carriership in the ALFA and ALFA+ samples.

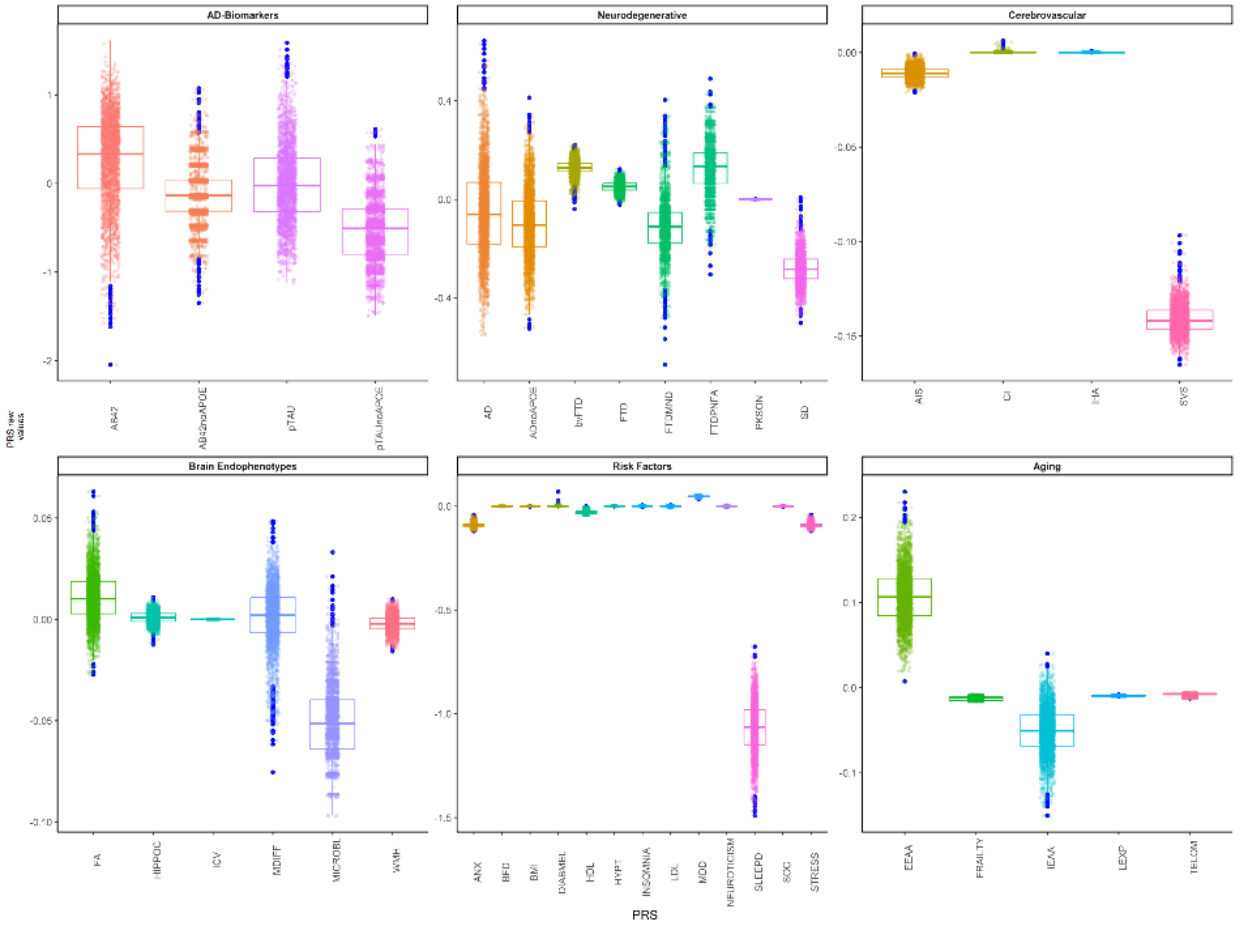

Figure 2. Distribution of genetic scores in the ALFA parent cohort.

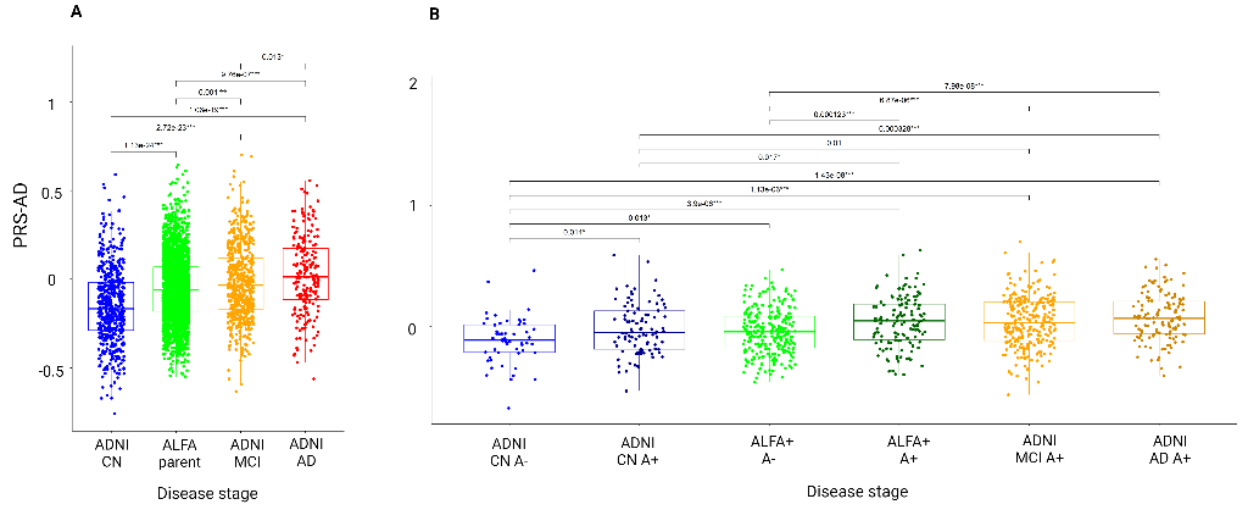

Figure 3. Distribution of genetic scores of Alzheimer's disease along the AD continuum. A) Subgroups from ALFA and ADNI within the AD continuum. B) Subgroups within the AD continuum stratifying ALFA participants by amyloid status. Pairwise comparisons are assessed to compare the median PRS-AD (Wilcoxon test) among groups. Significant results at nominal p-value are displayed (p-value <0.05 *; p-value <0.01 **, p-value <0.001 ***).

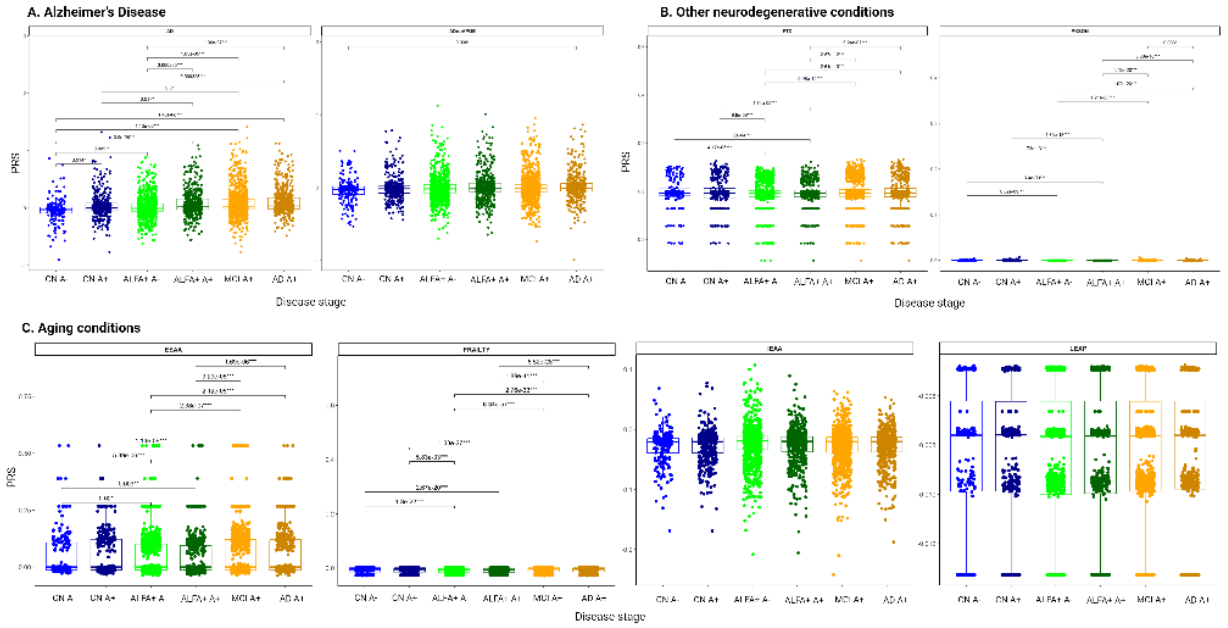

Figure 4. Distribution of genetic scores of Alzheimer's disease (A) and other neurodegenerative (B) and aging (C) conditions along the disease continuum stratifying by amyloid status. Pairwise comparisons are assessed to compare the median (Wilcoxon test) of the PRS among groups. Significant results at nominal p-value are displayed (p-value <0.05*; p-value <0.01**; p-value <0.001***).

Conclusions: The ALFA project successfully established a cohort of CU individuals with a high genetic risk for AD, ideal for studying early pathophysiological changes in preclinical AD. These results emphasize *APOE*'s pivotal role in early AD pathogenesis and imply the involvement of other genetic variants in the overall genetic risk profile.

Aims: Genetic risk for Alzheimer Disease (AD) varies across populations with different ancestry. 3D genome architecture regulates gene transcription. African American (AA) individuals are admixed with European (EU) and African (AF) ancestry, thus it is important to include local ancestry (LA) in their analyses. We hypothesize that variations of 3D genome features on different ancestry background could offer novel epigenetic understanding of ancestry-specific AD risk.
Methods: Hi-C was done in frontal cortex from *APOEε4* homozygotes (4 AA/ 4 Non-Hispanic White (NHW)). LA was calculated using RFMix. Compartmentalization was measured by the first principal component (PC1) of Hi-C contact matrices and compared at a 500kb-resolution. *DeepLoop* was used to call chromatin loops. Population-enriched loops were identified using pairwise T-test (P value<0.05, with an absolute fold change >2).
Results: 2~3% of compartments were switched between AF and EU. *APOE* confers higher risk in NHW than AA and the PC1 value over *APOE* is higher on the EU than the AF genome, suggesting it is more active on the EU genome. In contrast, the PC1 value over *RBFOX1(*AA susceptibility locus) is higher on the AF than the EU genome. 12,082 loops are enriched in NHW and 2885 loops are enriched in AA. NHW-enriched loops are larger than the AA-enriched loops (median size= 496 kb and158 kb, respectively). AA-loops were enriched for co-localization with H3K27ac and H3K4me3 (score=1.2~1.53). Many of the NHW-enriched long-range interactions are mediated by CTCF, 30 of them are absent in AA due to AA specific SNPs in the CTCF motif.
Conclusions: 3D genome regulatory maps could explain the known ancestral differences in AD risk and will be essential to identifying causal genes in GWAS in both NHW and AA populations.

VALIDITY AND CORRELATION OF THE ELECTRONIC FRAILTY INDEX AGAINST SEVERITY ASSESSMENT OF VETERANS WITH ALZHEIMER'S DISEASE

POSTERS: A05.D. GENETICS, EPIDEMIOLOGY: AGING

Joel Reisman[1], Byron J Aguilar[2], Qinqing Li[3], Megan Cheslock[1], Maureen O'Connor[2], Peter Morin[4], Dan Berlowitz[5], Raymond Zhang[6], Amir Tahami Monfared[7], Quanwu Zhang[8], Weiming Xia[2,9,10]
[1]VA Bedford Healthcare System, Geriatric Research and Clinical Center, Center For Healthcare Organization & Implementation, Bedford, United States of America, [2]VA Bedford Healthcare System, Geriatric Research Education And Clinical Center, Bedford, United States of America, [3]Univ. of Edinburgh, Mathematics, Edinburgh, United Kingdom, [4]Boston University Chobanian & Avedisian School of Medicine, Department Of Neurology, Boston, United States of America, [5]University of Massachusetts, Department Of Public Health, Lowell, MA, United States of America, [6]Eisai, Inc., Alzheimer's Disease And Brain Healthe, Nutley, United States of America, [7]McGill Univ., Epidemiology, Biostatistics And Occupational Health, Montreal, Canada, [8]Eisai, Inc., Alzheimer's Disease And Brain Healthe, Nutley, NJ, United States of America, [9]University of Massachusetts, Department Of Biological Sciences, Lowell, MA, United States of America, [10]Boston University Chobanian & Avedisian School of Medicine, Department Of Pharmacology, Physiology & Biophysics, Boston, United States of America

Aims: Electronic frailty indices expand measurement of frailty in clinical assessment of patients with Alzheimer's disease (AD). We aim to determine its correlation with AD severity and define its predictive validity in associations with clinical outcomes.
Methods: Veterans who underwent Mini-Mental State Examination (MMSE) and/or Montreal Cognitive Assessment (MoCA) between fiscal year (FY) 2017-2019 within the Department of Veterans Affairs Healthcare System were identified and their corresponding testing results were extracted in addition to clinicians' judgment on disease severity. The test scores were extracted using a rule-based natural language processing (NLP) system to support and define patients with mild, moderate and severe AD. Harvard claims-based frailty index was calculated based on the structured data of these Veterans.
Results: There were 223,420 Veterans without a record of MMSE or MoCA scores ("untested"). A total of 14,940 Veterans had MMSE or MoCA scores within "normal" range, and the numbers of Veterans with "mild", "moderate" and "severe" AD were 17,747, 12,596, and 9,981, respectively. Age-dependent increases of frailty indices were found among male (0.156-0.167) and female (0.151-0.175) Veterans, and there was no statistically significant difference between male and female subjects, adjusted by age. Every unit increase in frailty indices was associated with an increase in the AD severity from untested, normal, mild, moderate to severe subjects.
Conclusions: Veterans not suspected of AD ("untested" group, i.e., absence of MMSE/MoCA scores) have the best frailty index. Performance on MMSE and MoCA tests correlates with frailty indices, suggesting a predictive value in associations with clinical outcomes from future disease modifying therapy.

HIGHER GENETICALLY PREDICTED TIMP2 PLASMA LEVELS ARE ASSOCIATED WITH BETTER COGNITIVE PERFORMANCE IN INDIVIDUALS AT RISK OF ALZHEIMER'S DISEASE

POSTERS: A05.D. GENETICS, EPIDEMIOLOGY: AGING

Federica Anastasi[1], Patricia Genius[1], Blanca Rodríguez-Fernández[1], Armand González Escalante[1], Luigi Lorenzini[2], Iman Sadeghi[1], Marta Del Campo Milán[1], Gonzalo Sánchez Benavides[1], Carolina Minguillón[1], Manel Esteller[3], Arcadi Navarro[1], Juan Gispert[1], Marc Suárez[1], Natalia Vilor-Tejedor[1]

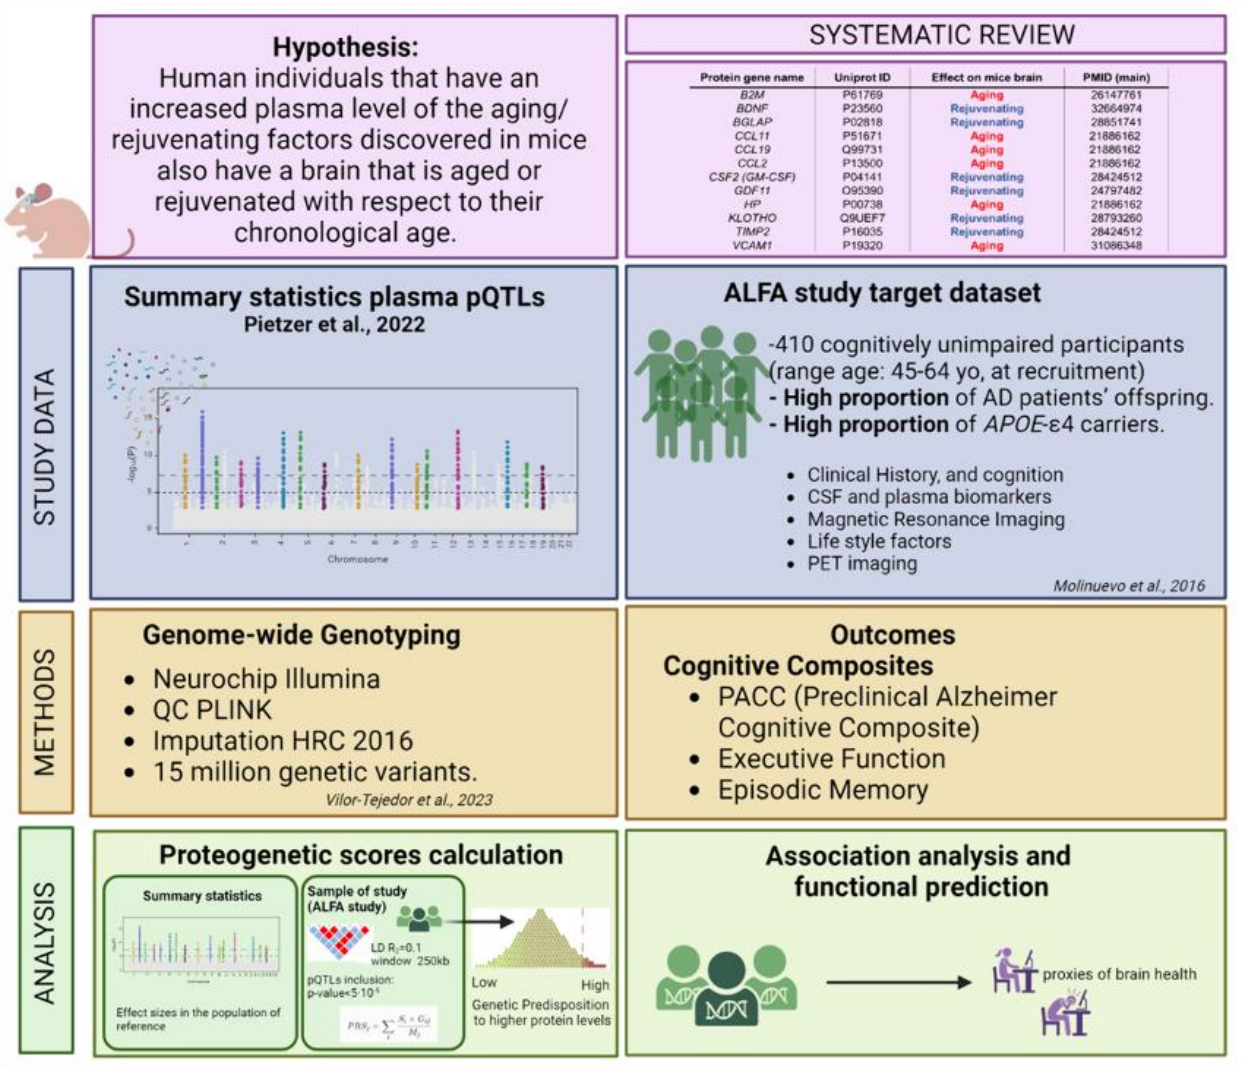
Aims: Mice studies have identified blood proteins that influence brain aging, but translating these findings to humans remains a challenge. Here, we report an innovative approach that leverages genetic data to predict the plasma levels of these proteins in humans and assess their association with cognitive performance (Fig1).

Figure 1. Summary of project workflow.



Methods: Through a systematic review, we identified 13 circulating proteins with an aging/rejuvenating effect on the mouse brain. We retrieved data on summary statistics of protein quantitative trait loci (pQTLs) associated with these proteins in human plasma (Pietzner et al.,2021). We used these DNA variants to compute protein-based genetic scores (PRS) of each protein for 410 cognitively unimpaired individuals at risk of Alzheimer's disease of the ALFA cohort (60% women; 55% *APOE*-ε4 carriers, Fig2). We assessed the associations between each PRS and cognitive performance through general linear models stratified by sex, amyloid-β (Aβ) status (based on CSF Aβ42/40 ratio) and *APOE*-ε4 carriership.

Figure 2. Participants characteristics of the ALFA+ study cohort.
*Aβ positivity (A+) is defined by CSF Aβ42/40 < 0.071.

Variable	**N** [410]
Age (years), Median (IQR)	61.64 (58, 64.8)
Sex, n(%)	
Men	163 (39.8%)
Women	247 (60.2%)
Education Years, Median (IQR)	12 (11, 17)
CSF Aβ42/40 status*, n(%)	388
Aβ-negative (A-)	255 (65.7%)
Aβ-positive (A+)	133 (34.3%)
APOE-ε4, n (%)	
non-carriers	179 (44.8%)
carriers	221 (55.2%)
PACC, Median (IQR)	0.055 (-0.44, 0.46)
Episodic Memory, Median (IQR)	0.063 (-0.42, 0.47)
Executive Function, Median (IQR)	-0.043 (-0.52, 0.50)

Results: Our main results revealed that genetic predisposition to elevated plasma levels of TIMP2 (Metalloproteinase inhibitor 2), a protein with a rejuvenating effect on mice brain, is associated with better cognitive performance as measured by the preclinical Alzheimer cognitive composite (PACC) and episodic memory composite scores. TIMP2-PRS association with PACC was also significant in the stratified models. Only the Aβ-positive group did not survive FDR correction (Fig3). In addition, the TIMP2-PRS significantly predicted the actual levels of TIMP2 protein in plasma (Fig4).

Figure 3. Results of the association analysis of the computed PRS with cognitive composites PACC and EM. Colors represent the direction of the association effect, where blue, refers to a rejuvenating effect and red to an aging effect. Significance is reported at group-correction (two experimental aging groups) and cluster-correction levels (** p<0.025, ***p<0.0125 respectively).

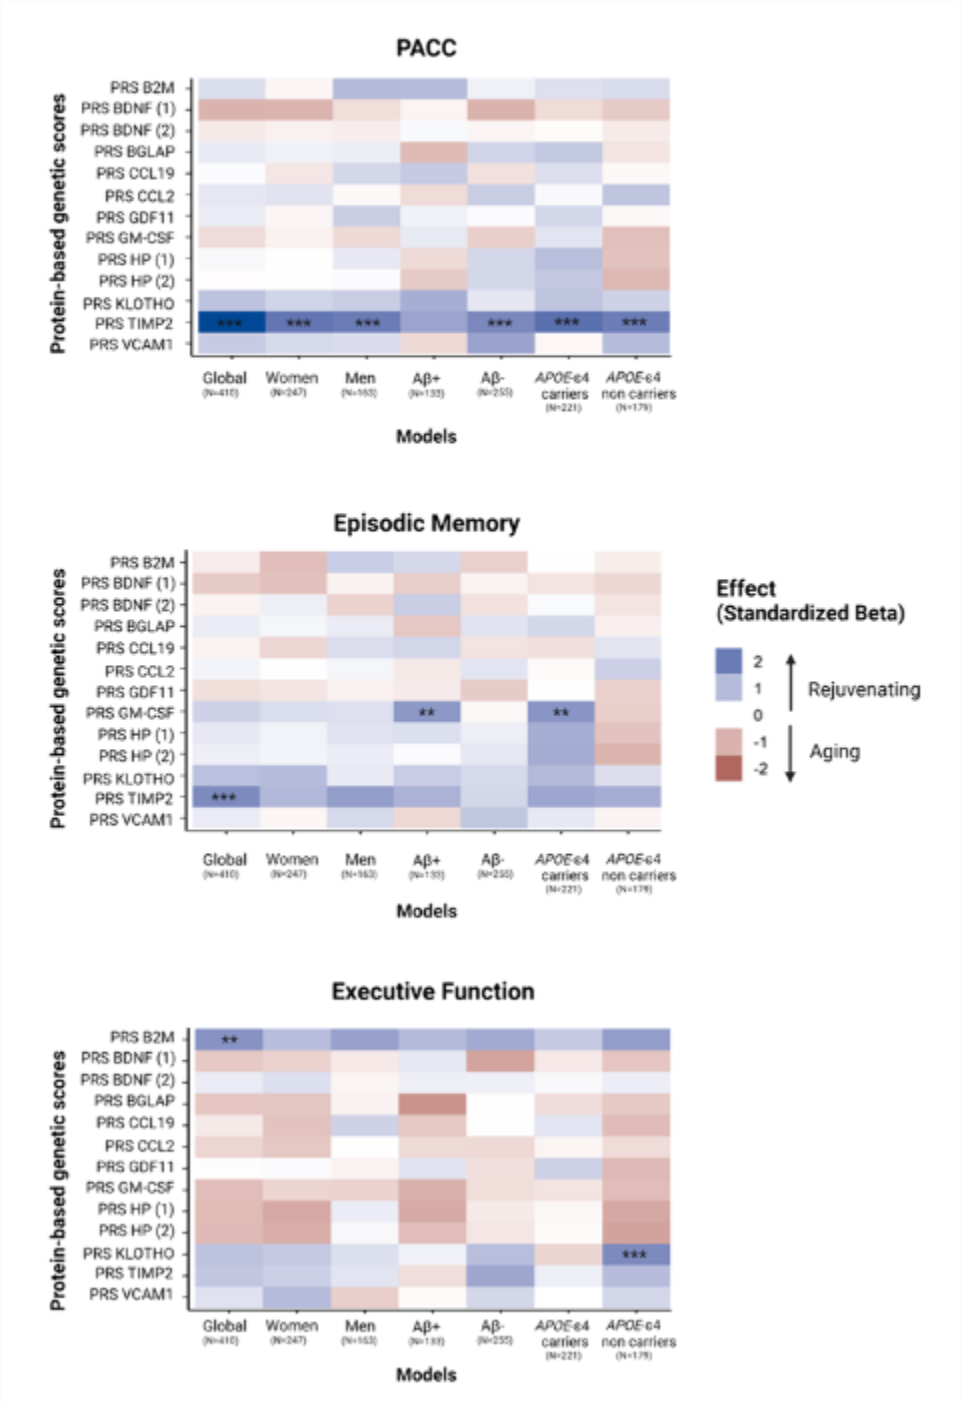


Figure 4. Associations between genetically predicted plasma levels of TIMP2 and TIMP2 actual protein levels as measured by R&D DuoSet® commercial Elisa assay.

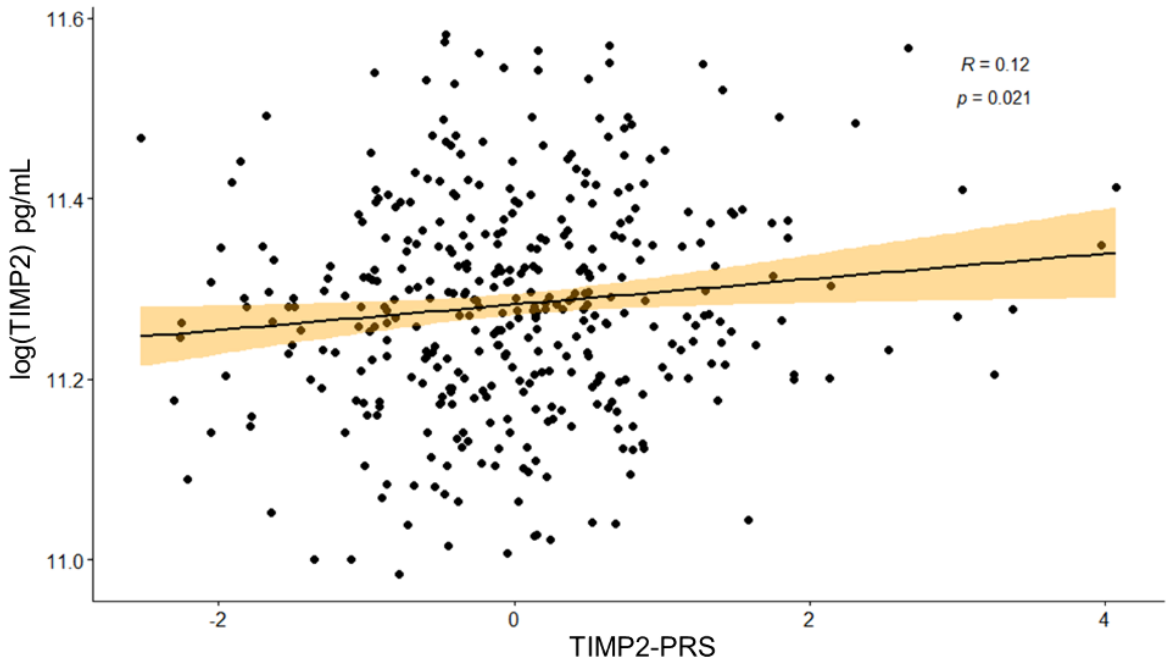

Conclusions: This innovative use of protein-based PRS computation may overcome translational challenges encountered in animal studies. Specifically, our study provides a complementary means to investigate the association of TIMP2 with brain performance in humans, suggesting TIMP2 as a potential therapeutic target in brain aging and cognitive function.

GENETIC BIOMARKERS AND BIOLOGICAL AGING PREDICT THE RISK OF DEMENTIA IN THE UK BIOBANK

POSTERS: A05.D. GENETICS, EPIDEMIOLOGY: AGING

Shayan Mostafaei, Jonathan Mak, Chenxi Qin, Sara Hägg
Karolinska Institutet, Department Of Medical Epidemiology And Biostatistics, Stockholm, Sweden

Aims: This study aims to explore the links between genetic biomarkers, their combinations, biological aging markers (BA), and their potential in predicting dementia risk among UK Biobank (UKB) participants.
Methods: In this study, we analyzed 328,047 dementia-free UK Biobank participants. We calculated an individual's polygenic risk score (PRS) based on 75 dementia-related risk loci. Additionally, we employed three biological aging measures (KDM, PhenoAge, HD) and the frailty index (FI) for dementia risk prediction. To make these predictions, we used a support-vector-machines (SVM) algorithm with a sigmoid kernel. The model's performance was assessed using the area-under-ROC curve (AUROC) through holdout validation (2/3 training and 1/3 testing samples). All models were adjusted for age, sex, ethnicity, smoking, alcohol consumption, and the top 10 genetic principal components.
Results: We studied 328,047 dementia-free participants at baseline (mean age: 56.4 [SD=8.1] years, 54.1% female). They were followed for a median of 6.9 (SD=2.0) years, with 1,617 individuals (0.49%) eventually developing dementia. In univariate analysis, the predictors ranked in importance as follows: PhenoAge, KDM, HD, PRS, and FI. The PRS model's predictive accuracy on the testing set, both with and without the APOE region, was AUROC=0.759 (95% CI: 0.749, 0.769) and 0.721 (95% CI: 0.710, 0.731), respectively. Combining PRS and BA predictors raised the AUROC to 0.793 (95% CI: 0.783, 0.803). Including the frailty index in the model increased the AUROC to 0.80 (95% CI: 0.791, 0.810). Statistically, the AUROCs of the PRS+BA+FI model and PRS+BA model significantly outperformed the PRS model (both P-values<0.01).
Conclusions: Our findings highlight the value of combining genetic and biological aging markers, along with assessing frailty, to improve dementia risk prediction accuracy. These insights hold significant promise for early detection and preventive measures in dementia.

Aims: Chronic traumatic encephalopathy (CTE) is a neurodegenerative tauopathy associated with repetitive head impact (RHI) exposure. We conducted a genome-wide association study (GWAS) of CTE neuropathological endophenotypes in individuals with RHI exposure.
Methods: 458 brain donors [mean age: 68.3 (16.1 SD); 313 (68.3%) with CTE] from the UNITE Brain Bank were included. All donors had exposure to RHI from contact sports or military service. Neuropathologists conducted semiquantitative assessments of CTE stage (0-IV, IV most severe) and phosphorylated tau (ptau) burden (0-3, 3 most severe) across 11 brain regions commonly affected in CTE. We tested the association of genome-wide genotyped and imputed single nucleotide polymorphisms with CTE stage and ptau burden in each region using ordinal logistic regression models adjusted for age at death and 10 principal components of population substructure.
Results: One locus (top hit: rs6910517; MAF=0.12) achieved genome-wide significance for ptau burden in the CA2 region of the hippocampus (OR=5.4; p=4.84E-13). Located within the major histocompatibility complex (MHC) class 1 region of chromosome 6, rs6910517 is intergenic, ~50KB downstream of HLA-A and ~70KB downstream of RNF39. In the hippocampus, rs6910517 is a cis eQTL for RNF39, which has been associated with early phase synaptic plasticity and prolonged long term-potentiation maintenance. The hippocampus CA2 region is preferentially affected in high stage CTE, differing from CA1 and the subiculum, which are preferentially affected in Alzheimer's disease.

Conclusions: In the first GWAS of CTE endophenotypes, one locus in the MHC class I region of chromosome 6 achieved genome wide significance with ptau pathology in the CA2 region of the hippocampus, implicating immune pathophysiology and neuronal function. In addition to RHI exposure, genetic architecture may alter an individual's risk profile for CTE-related outcomes.

PHYSICAL EXERCISE MODULATES ADAM10 METHYLATION IN ACUTELY HOSPITALIZED ELDERLY PATIENTS

POSTERS: A05.D. GENETICS, EPIDEMIOLOGY: AGING

Amaya Urdánoz-Casado[1], Fabricio Zambom-Ferraresi[2,3], Mónica Macías[1], Idoia Blanco-Luquin[1], Miren Roldan[1], Eneko Cabezon-Arteta[1], Nicolás Martínez-Velilla[2,3], Maite Mendioroz[1,4]
[1]Navarrabiomed, Hospital Universitario de Navarra-IdiSNA (Navarra Institute for Health Research), Universidad Pública de Navarra (UPNA), Neuroepigenetics Laboratory, Pamplona, Spain, [2]Navarrabiomed, Hospital Universitario de Navarra, Universidad Pública de Navarra (UPNA), IdiSNA, Department Of Geriatric Medicine, Pamplona, Spain, [3]Instituto de Salud Carlos III, Ciber Of Frailty And Healthy Aging (ciberfes),, Madrid, Spain, [4]Hospital Universitario de Navarra-IdiSNA (Navarra Institute for Health Research), Neurology, Pamplona, Spain

Aims: Acute hospitalization of elderly patients leads to bed rest, which in 20-50% of patients triggers an accelerated ageing process, manifested as rapid functional and cognitive decline. Physical exercise (PE) during hospitalization can prevent it. The expression of ADAM10, a protein involved in the non-amyloidogenic pathway of amyloid precursor protein (APP), increases with PE. In this study we wanted to explore potential dynamic changes in *ADAM10* gene methylation after 3 days of PE in hospitalized patients.
Methods: A randomized clinical trial of 37 controls (no PE) and 36 subjects undergoing PE intervention was established. Blood samples were obtained before and 3 days after PE program or without. Genomic DNA isolated from PBMCs was bisulfite converted. Three CpG methylation levels of the *ADAM10* promoter were analyzed by pyrosequencing. For each study group the % methylation median changes due to intervention (or control) were calculated as follows: % methylation post-intervention - % methylation pre-intervention. Mann-Whitney U tests were performed with IBM SPSS v20.
Results: After PE, the changes observed in methylation levels at the *ADAM10* CpG_1 and 2 positions were greater in the intervention group than in the control group. However, there were no differences in the CpG_3 position or in the average for the 3 CpGs.

***ADAM10* methylation Median changes % (IQR)**	**Intervention**	**Controls**	**P-value**
CpG1	0.52 (-0.12–1.43)	-0.05 (-0.36–0.34)	0.041
CpG2	0.00 (-3.17–1.63)	0.00 (-0.02–2.78)	0.028
CpG3	0.00 (-1.36 - 1.62)	0.00 (-0.25–1.07)	0.946
Average	-0.20 (-1.1–1.08)	0.14 (-0.29–0.93)	0.356

Conclusions: Three days of PE is sufficient to induce changes in DNA methylation levels in *ADAM10* gene. Furthermore, *ADAM10* methylation levels could be postulated as a biomarker to quantify the response to PE intervention in hospitalized elders.

ROLE OF DEPRESSION AS A RISK FACTOR CONCERNING AMYLOID AND P-TAU STATUS

POSTERS: A05.E. GENETICS, EPIDEMIOLOGY: ENVIRONMENTAL RISK FACTORS

Gábor Csukly, Zsolt Huszár
Semmelweis University, Department Of Psychiatry And Psychotherapy, Budapest, Hungary

Aims: Preventing dementia involves taking early action to address modifiable risk factors like depression. However, the extent of the significance of risk factors such as depression when beta-amyloid or phosphorylated-tau (p-tau) changes are present remains uncertain. In this current investigation, our objective was to investigate the potential impact of depression as a modifiable risk factor on conversion separately among individuals who are either Amyloid and Tau positive or negative.
Methods: Utilizing the ADNI database, we examined how depression influenced the progression to dementia in two distinct cognitive groups: cognitively unimpaired (CU) and mild cognitively impaired (MCI) individuals, with beta-amyloid negative (A-) and positive (A+), as well as beta-amyloid and p-tau negative (A-T-) and positive (A+T+) protein status. This investigation involved a total of 367 CU subjects and 619 MCI subjects. The Cox proportional hazard model was applied for the survival analyses.
Results: Among MCI subjects, there was a significant increase in conversion for subjects with depressive symptoms at baseline compared to those without (HR= 1.4 (CI 1.2; 1.6) in the A- group, HR= 1.7 (CI 1.2; 2.5) in the A+ group). In the A+T+ group, subjects with depressive symptoms at baseline showed a significantly higher conversion: HR=1.4 (CI 1.2; 1.6), whereas, in the A-T- group, depressive symptomatology did not affect conversion, HR=1.1 (CI 0.6; 1.9). Among CU individuals, a history of depression was associated with a significantly increased conversion to MCI or dementia compared to those without depression (HR= 1.6 (CI 1.1, 2.3) in the A- group and HR= 1.6 (CI 1.1, 2.5) in the A+ group.
Conclusions: Our research reinforces the importance of addressing modifiable risk factors, even in cases where amyloid or p-tau pathology has already manifested.

MEDICATION EXPOSURE AND NEURODEGENERATIVE DISEASE RISK ACROSS NATIONAL BIOBANKS

POSTERS: A05.E. GENETICS, EPIDEMIOLOGY: ENVIRONMENTAL RISK FACTORS

Gracelyn Hill, Hampton Leonard, Kristin Levine, Michael Nalls, Hirotaka Iwaki, Andrew Singleton
Center for Alzheimer's and Related Dementias, National Institute On Aging, Bethesda, United States of America

Aims: We examined potential links between medication exposures and neurodegenerative disease risk In order to determine possible risk associations between medications and neurodegenerative diseases, and to identify medications with a possible protective effect.
Methods: Using time series data from the UK Biobank (UKB), we used the Cox proportional hazards model to test the association between medication exposure and NDD diagnosis during the study period, adjusting for age, sex, Townsend deprivation index, and number of times prescribed. We additionally compared PRS scores for Alzheimer's and Parkinson's between those who took medications of interest, and the average PRS scores in UKB.
Results: After conducting multiple test corrections, we found 81 medications with protective associations and 162 associated with increased risk across 6 neurodegenerative diseases: Alzheimer's, Parkinson's, motor neuron disease (ALS), multiple sclerosis, general dementia and vascular dementia. Association between Donepezil and Alzheimer's was confirmed (p=4.28E-52) as a positive control. Drugs with psychotropic and anticholinergic properties with established associated risk for Alzheimer's disease were found across multiple other neurodegenerative diseases. Prescriptions of these drugs were associated with significant shifts in PRS score distribution in Alzheimer's and Parkinson's patients; cases with lower PRS had higher attributable risk due to non-genetic factors.
Conclusions: Our observations support the evidence for high risk groups of medications known to interact with NDD phenotypes and provide new findings for drug interactions across several neurodegenerative disorders. Multiple common vaccines for viruses were found to be protective against neurodegenerative diseases, further underscoring the importance of vaccination and the risk that viral infections may impose for dementia.

SEX-SPECIFIC EFFECTS OF MIND DIET ON DEMENTIA RISK: INSIGHTS FROM UK BIOBANK DATA WITH USUAL INTAKE ESTIMATION

POSTERS: A05.E. GENETICS, EPIDEMIOLOGY: ENVIRONMENTAL RISK FACTORS

Jiyun Hwang[1], Young Ho Park[2], Joohon Sung[3], Dong Woo Kim[4]
[1]Seoul National University, Public Health Science, Seoul, Korea, Republic of, [2]Seoul National University Bundang Hospital, Neurology, Seongnam, Korea, Republic of, [3]Seoul National University, Department Of Public Health Science, Seoul, Korea, Republic of, [4]Korea National Open University, Division Of Human Ecology, Seoul, Korea, Republic of

Aims: The relationship between the Mediterranean-Dietary Approach to Systolic Hypertension (DASH) diet Intervention for Neurodegenerative Delay Diet (MIND diet) with cognitive function and dementia has been inconclusive. In previous studies, there often was a failure to consider the shortcomings of the 24-hour recall method, particularly in regard to non-consumption days and day-to-day variability. This study aimed to investigate the relationship between the MIND diet and dementia using usual intake estimations and a sex-specific analysis within the UK Biobank Study.
Methods: We excluded wine, olive oil, and butter/margarine-ingredients that are subjects of going health debates or ambiguously defined in the UK Biobank-from the evaluation of the remaining 12 MIND diet components. Usual food group intakes were estimated by Multiple Source Method (MSM program). Each diet component received 0, 0.5 or 1 based on the original MIND criteria. Dementia diagnosis was ascertained from hospital and death register data recorded by ICD coding system, and self-reported data. We used Cox proportional-hazards regressions adjusted for age, sex, socioeconomic status, education, smoking status, sleep duration, physical activity, and MIND*sex interaction, to explore the associations between the MIND diet and dementia.
Results: Among 68,963 participants aged 60 or older, 1,620 individuals (2.35%) developed dementia during an average follow-up of 10.7 years. Overall, MIND diet was not significantly associated with reduced dementia risk (HR=0.9507, 95% CI: 0.9032-1.0006). However, lower risk was observed in females (HR=0.9475, 95% CI: 0.8997-0.9978), but not in males (HR=0.9998, 95% CI: 0.9564-1.045).
Conclusions: Our study suggests that the effectiveness of MIND diet in reducing dementia risk differs by sex. This finding was made possible through a refined analytical approach that factored in usual dietary intakes and sex differences. Further investigation with advanced modeling could elaborate on these associations.

CONSEQUENCES OF NEUROTOXIANT EXPOSURE IN MOUSE MODELS OF LATE-ONSET ALZHEIMER'S DISEASE

POSTERS: A05.E. GENETICS, EPIDEMIOLOGY: ENVIRONMENTAL RISK FACTORS

Kevin Kotredes[1], Olga Minaeva[2], Ravi Shanker Pandey[3], Alaina Reagan[1], Juliet Moncaster[2], Gregory Carter[1], Bruce Lamb[4], Lee Goldstein[2], Gareth Howell[1]
[1]THE JACKSON LABORATORY, The Jackson Laboratory, Bar Harbor, United States of America, [2]Boston University School of Medicine, Bu Alzheimer's Disease & Cte Center, Boston, United States of America, [3]THE JACKSON LABORATORY, For Genomics Medicine, FARMINGTON, United States of America, [4]Indiana University School of Medicine, Stark Neuroscience Research Institute, Indianapolis, United States of America

Aims: Recent human datasets have revealed LOAD (late-onset Alzheimer's disease) genetic risk factors that are correlated to the degree of AD burden. These risk factors are modulated by exposure to environmental toxicants such as lead (Pb), cadmium (Cd), and arsenic (As). While the toxicants-LOAD association is known, the molecular mechanisms that underpin gene-environmental interactions are unknown. Examination of these risk factors in animal models provides essential insight into the heterogeneity observed in human disease and may reveal more appropriate targets for therapy development.
Methods: Mouse models of LOAD were exposed to Pb, Cd, As, or a mixture in drinking water. Toxicants and endogenous biometals were assayed by ICP-mass spectrometry in the brain, blood, and urine. Spatial profiling by high-resolution metallomic imaging mass spectrometry (MIMS) confirmed brain mapping of toxicants. Transcriptional profiling of brains revealed specific changes in LOAD-related gene expression indicating mechanisms of LOAD progression. Transcriptional and proteomic profiling was used to identify human-aligned genes and protein networks predicted to drive LOAD risk.
Results: Neurotoxicants were detected in all tissue samples collected. Pb, Cd, and As accumulated in the brain and altered expression of LOAD-relevant genes in a toxicant-specific manner. We detected changes in LOAD-relevant gene expression, including a decrease in *Vgf* and an increase in *App*. Reduced *VGF* expression has been observed and reported in all four independent AMP-AD studies and nominated as a key therapeutic target in each and *APP* encodes amyloid precursor protein (APP) from which the Aβ peptides are generated.
Conclusions: These experiments provide critical feedback related to exposures of specific toxicants as environmental factors in novel LOAD models. Collectively these data suggest a direct effect of neurotoxicant exposure related to LOAD progression in patients.

Aims: We examined the association between long-term exposure to $PM_{2.5}$ and NO_2 with neuropathologic changes of Lewy-body related pathology (LRP) in a large autopsy sample.
Methods: 843 participants from the Adult Change in Thought study, a community-based cohort study, underwent autopsies. LRP was assessed in multiple brain regions. A spatiotemporal model was used to generate 10-year average air pollution (AP) exposure values prior to the date of death, linked to participants' residential addresses. Inverse probability weighted multiple logistic regression was used to evaluate the association between exposure to $PM_{2.5}$ or NO_2 and LRP. Additional analyses examined if the association between AP exposure and LRP differed significantly across the levels of sex, smoking history, or age-at-death (< 90 vs 90+ years).
Results: The average age at death in the sample was 89.2 years. Of the 843 individuals autopsied, a majority were female (57.3 %), White (94.1%), and had a history of smoking (55.0%). LRP was identified in 21.4% of the sample and there were no differences in LRP across sex or smoking history.
$PM_{2.5}$ exposure was not associated with the presence of LRP (OR = 1.03, 95% confidence interval 0.90-1.19) after adjusting for study cohort, age-at-death, sex, race, education, neighborhood deprivation index, year of death, smoking history, and APOE genotype. Similarly, NO_2 exposure was not associated with LRP (OR=1.01, 0.91-1.12). There was no evidence for any modification of the association between either pollutant and LRP based on age-at-death, sex, or smoking history.
Conclusions: We did not find any significant associations between long-term exposure to $PM_{2.5}$ or NO_2 and increased risk of Lewy-body pathologies in the brain.

Aims: Given the established association between DNA methylation and the pathophysiology of dementia and its plausible role as a molecular mediator of lifestyle and environment, blood-derived DNA methylation data could enable early detection of dementia risk. in this study we aimed to establish a blood-derived DNA methylation-based model to predict prospective onset of cognitive decline and dementia.
Methods: In conjunction with an extensive array of machine learning techniques, we employed whole blood genome-wide DNA methylation data as surrogate for 14 modifiable and non-modifiable factors in the assessment of dementia risk.
Results: Using methylation profile scores (MPS) generetd for 14 known modifible and unmodifiable risk

facors for dementia, we established a multivariate methylation risk score (MMRS) to identify the status of mild cognitive impairment (MCI) cross-sectionally, independent of age and sex (AUROC = 0.68). Polygenic scores (PGSs) for the corresponding risk factors exhibited limited predictive power, and their addition to MPSs did not significantly enhance MCI prediction. The incorporation of cerebrospinal fluid (CSF) biomarkers significantly improved MCI prediction (AUROC = 0.88). We further demonstrated significant predictive capability of this score for the prospective onset of cognitive decline in two independent cohorts of Alzheimer's disease (AD) and Parkinson's disease (PD). The top-performing MMRS modle relied on 10 of the 14 MPSs, with depression, HDL cholesterol, physical inactivity, and low education MPSs playing pivotal roles.

Conclusions: Our work shows the potential of employing blood-derived DNA methylation data in the assessment of dementia risk. Our established MMRS model may act as a starting point for future studies, aiming at further improving the model's predictive performance by testing novel feature selection and machine learning methods, incorporating more omics layers, as well as performing model training on larger datasets.

Aims: The cognitive reserve hypothesis presumes higher tolerance of Alzheimer's disease (AD)-related pathology without functional decline for those with higher education. However, some studies found the reverse: more rapid decline after AD onset in this population. Evidence accounting for these contradictory results remained limited. Thus, we assessed the relationship between education and cognitive decline in a multi-national cohort of AD patients.
Methods: We analyzed data from patients recruited into the GERAS-EU cohort study from AD clinics in the United Kingdom, Germany, and France. Generalized linear mixed models were employed to assess the effects of education on rate of cognitive decline, i.e., change in Mini-Mental State Examination (MMSE) scores (range: 0-30 points) per 6-month period, over 1.5 to 3 years of follow-up. Education was dichotomized using a 12-year cutoff (approximately U.S. secondary school equivalent); age at diagnosis, gender, disease duration, country, and baseline comorbidities were included as covariates.
Results: A total of 1,330 AD patients were analyzed, with mean age of 77.3 years (SD=7.6), 726 (54.6%) females, 10.4 (SD=3.2) years of education, and 28.6% having lower education (<12 years). Higher education (≥12 years) was associated with 0.19 more points in MMSE decline per 6-month period than lower education ($p<0.001$). Stratified analyses by AD severity at baseline showed that higher education was associated with 0.26 ($p<0.001$) and 0.31 ($p=0.005$) points more decline in MMSE score in mild and severe AD groups.
Conclusions: Our results contribute to evidence contradicting the cognitive reserve hypothesis. One factor that warrants further exploration is whether ceiling effects for cognitive measures (e.g., MMSE) in those with higher education result in delayed AD detection. If so, more sensitive assessment methods are needed to detect early-stage AD in this population.

THE CHEMICAL EXPOSOME OF NEURODEGENERATIVE DISEASES

POSTERS: A05.E. GENETICS, EPIDEMIOLOGY: ENVIRONMENTAL RISK FACTORS

Cécilia Samieri[1], Sophie Lefèvre-Arbogast[1], Jade Chaker[2], Robert Barouki[3], Xavier Coumoul[3], Gary Miller[4], Arthur David[2]
[1]INSERM, Bordeaux Population Health Research Center, Université Bordeaux Segalen, Bordeaux, France, [2]EHESP, Irset (institut De Recherche En Santé, Environnement Et Travail), Rennes, France, [3]Université Paris Cité, T3s, Inserm Umr-s 1124, Paris, France, [4]Columbia University Mailman School of Public Health, Department Of Environmental Health Sciences, New York, United States of America

Aims: A specific vulnerability of the brain throughout the life-course to environmental chemical stressors has been established. Yet, only a tiny fraction of the tens of thousands of chemicals present on the market has been investigated in neurology research. We provide here a critical review of epidemiological and experimental evidence relating the so-called chemical exposome to neurodegenerative diseases, and we present all the promises that omics-based methodologies could provide to uncover unknown chemical signatures associated with neurodegenerative diseases.
Methods: In total, >150 epidemiological studies investigating chemical exposures and the risk of AD/cognitive impairment and PD, and >270 experimental studies assessing their impact on neurodegeneration-related pathways were considered. We focused on pollutants mostly resulting from anthropic activities including pesticides, volatile organic solvents, metal trace elements, combustion air pollutants, dioxins, flame retardants, fluorosurfactants, plastic components and food and cosmetic additives. We identify gaps and pitfalls in existing research and then formulate a roadmap for next generation exposome studies in the field.
Results: Overall, current evidence is heterogeneous, with a majority of research focused on occupational exposure to pesticides, solvents and metals trace element and, regarding non-occupational exposures, ambient air pollution. Many chemicals, including pesticides of emerging concern (e.g., pyrethrinoids, neonicotinoids) and ubiquitous contaminants (dioxins, flame retardants, plasticizers, food/cosmetic additives, etc.) have received little attention so far in epidemiology in spite of evidence of their involvement in neurodegeneration-related pathways. There is an acute need to push towards future application of high throughput omics-based molecular approaches in population studies to reveal novel chemical signatures associated with neurodegenerative diseases.
Conclusions: We intend with this state of the art to serve as a basis knowledge for the development of new-generation exposomics research in neurosciences.

ASSESSING THE RELATIONSHIP BETWEEN EARLY LIFE STRESS AND NEURODEGENERATION: A SYSTEMATIC REVIEW AND META-ANALYSIS

POSTERS: A05.E. GENETICS, EPIDEMIOLOGY: ENVIRONMENTAL RISK FACTORS

Angus Shorthouse, Arthur Brookes, Holly Spence, Jenna Gregory, Fergal Waldron
University of Aberdeen, Institute Of Medical Sciences, Aberdeen, United Kingdom

Aims: Parkinson's Disease (PD), Amyotrophic Lateral Sclerosis (ALS) and Alzheimer's Disease (AD) collectively share hallmark characteristics of protein aggregation and progressive loss of nerve cell structure and function. Several studies have indicated that early life stress (ELS) may increase the incidence of neurodegenerative conditions. The purpose of this review and meta-analysis was to evaluate the pathological changes caused by ELS and their links to neurodegenerative disease.
Methods: A priory protocol was published (https://www.protocols.io/private/797679561B2411EEAFD80A58A9FEAC02) and searches were performed on Pubmed and Medline & Embase to identify potential studies for data extraction and screened against an inclusion & exclusion criteria. For applicable studies, individual outcomes as well as data related to the type & timing of the ELS was retrieved. Where three or more studies had assessed the same quantitative variable, a meta-analysis was performed.
Results: 51 out of 774 studies were suitable for data extraction. Numerical outcomes were then categorised into biochemical, phenotypic, and histological subsets. In ELS individuals, there was a significant increase in lipid peroxidation, Amyloid-beta 42, total tau levels, caspase-3 and amyloid plaque deposition relative to non-ELS controls. Impaired limb use in PD mice, dopamine, neuronal cell counts, and ChAT fibres were significantly decreased in ELS exposure groups. No significant differences were found for alpha-synuclein, Amyloid-beta 40 levels, and hippocampal amyloid plaque deposition.
Conclusions: In this study we identify protein misfolding pathology and brain region specific changes in response to early life stress, positing lipid peroxidation as a driving mechanistic link with neurodegeneration in later life. In light of this review and in order to mitigate disease in those at risk, there is now an added emphasis on early life stress as a driving factor influencing later life brain health.

MORTALITY IN HYPERTENSIVE PATIENTS WITH DEMENTIA TREATED WITH RENIN-ANGIOTENSIN-ALDOSTERONE SYSTEM (RAAS) INHIBITORS. A LONGITUDINAL NATIONWIDE COHORT STUDY.

POSTERS: A05.F. GENETICS, EPIDEMIOLOGY: METABOLIC AND CARDIOVASCULAR

Marta Villa Lopez[1,2,3], Hong Xu[4], Minjia Mo[5], Maria De La Luz Cuadrado Pérez[2,6], Maria Eriksdotter[5,7,8], Sara Garcia-Ptacek[5]
[1]Karolinska Institute, Division Of Clinical Geriatrics, Department Of Neurobiology,, Stockholm, Sweden, [2]Complutense University, Department Of Medicine, Madrid, Spain, [3]University of Alberta, Medical Genetics, EDMONTON, Canada, [4]Karolinska Institutet, Department Of Neurobiology, Care Sciences And Society (nvs), Karolinska Institutet, Huddinge, Sweden, [5]Division of Clinical Geriatrics, Department Of Neurobiology, Care Sciences And Society (nvs), Karolinska Institutet, STOCKHOLM, Sweden, [6]Hospital Clinico San Carlos, Department Of Neurology, Madrid, Spain, [7]University of Gothenburg, Wallenberg Centre For Molecular And Translational Medicine, Gothenburg, Sweden, [8]Institution for Neuroscience and Physiology, Department Of Neurochemistry And Psychiatry, Gothenburg, Sweden

Aims: This study evaluates the impact of the use of renin-angiotensin-aldosterone system (RAAS) inhibitors on mortality rates in hypertensive patients diagnosed with dementia, aiming to inform treatment strategies for this growing patient population.
Methods: In a longitudinal nationwide cohort study, we scrutinized data from the Swedish national health registers, specifically examining individuals diagnosed with hypertension up to 2018. We conducted a comparative analysis of RAAS inhibitor users and non-users, employing propensity score matching to account for potential confounding factors. Additionally, we stratified the results by dementia status for further insight.
Results: In a study of 158,176 hypertensive patients, 21,152 of whom initiated RAAS inhibitors, their use was linked to reduced mortality risk (HR=0.92, 95% CI: 0.90-0.94) across the entire cohort. This effect was even more significant when concentrating on patients with confirmed clinical dementia, where the HR decreased to 0.86 (95% CI: 0.77-0.96). Comparing the two major classes of RAAS inhibitors, angiotensin receptor blockers (ARBs) showed a lower mortality risk in the overall cohort (HR=0.89, 95% CI: 0.83-0.94) compared to angiotensin-converting enzyme inhibitors (ACEIs). However, this advantage disappeared when evaluating the subgroup with clinically confirmed dementia, as the HR for the comparison between ACEIs and ARBs was 1.04 (95% CI: 0.92-1.17).
Conclusions: In conclusion, our analysis reveals a significant reduction in all-cause mortality among hypertensive patients, even when specifically considering those with dementia, who are prescribed RAAS inhibitors. While these findings point to a potential survival advantage, it is essential to approach these conclusions with caution given their derivation from observational studies. Nevertheless, these results offer valuable insights that should inform personalized treatment strategies for hypertensive patients with dementia, and they may serve as a foundation for designing future clinical trials in this area

LIGHT POLLUTION IS ASSOCIATED WITH ALZHEIMER'S DISEASE

POSTERS: A05.E. GENETICS, EPIDEMIOLOGY: ENVIRONMENTAL RISK FACTORS

Robin M Voigt[1], Bichun Ouyang[2]
[1]Rush University Medical Center, Internal Medicine, Chicago, United States of America, [2]Rush University Medical Center, Neurological Sciences, Chicago, United States of America

Aims: Alzheimer's disease (AD) prevalence has increased dramatically in the last century. Extension of lifespan due to improved sanitation and health care certainly contribute to the observed increase in prevalence, but data demonstrate that environment also influences AD development and progression. Artificial light at night (i.e., light pollution) is pervasive in modern day society and could be a factor that influences AD. The objective of this study was to evaluate the relationship between outdoor nighttime light intensity and AD prevalence in the United States.
Methods: AD and covariate prevalence were obtained from Medicare Chronic Conditions Database or the Centers for Disease Control and Prevention and nighttime light intensity data were calculated from satellite acquired images.
Results: Light pollution was associated with higher prevalence of AD at the state level and when comparing counties of approximately equal population and population density. This observation was true in those above the age of 65, below the age of 65, in men and women, and across race/ethnicity (except Asian Pacific Islander). While atrial fibrillation, diabetes, hyperlipidemia, hypertension, and stroke were associated more strongly with AD prevalence than light pollution, average nighttime light intensity was more strongly associated with AD prevalence than alcohol abuse, chronic kidney disease, depression, heart failure, and obesity. Startlingly, light pollution was more strongly associated with AD prevalence in those under the age of 65 than any other factor examined.
Conclusions: The data suggest a relationship between nighttime light exposure and AD, but there is a need to carefully investigate how exposure to light at night (outdoor and indoor) influences AD pathogenesis and evaluate mechanisms. Such information may guide public policy and individual recommendations about exposure to light at night.

CARDIOVASCULAR RISK SCORES EVALUATION TO PREDICT ALZHEIMER'S DISEASE THROUGH MACHINE LEARNING MODELS

POSTERS: A05.F. GENETICS, EPIDEMIOLOGY: METABOLIC AND CARDIOVASCULAR

Juan Pardo[1], Gemma Garcia-Lluch[2,3,4], Angélica Resendiz[1], Lucrecia Moreno[2,3], Miguel Baquero[2,4], Consuelo Cháfer-Pericás[2,4], Lourdes Álvarez[2]
[1]Universidad Cardenal Herrrera CEU, Embedded Systems And Artificial Intelligence Group, Valencia, Spain, [2]Cátedra DeCo, Research, Valencia, Spain, [3]Universidad Cardenal Herrera CEU, Pharmachology, Valencia, Spain, [4]Instituto de Investigación Sanitaria La Fe, Grupo De Investigación En La Enfermedad De Alzheimer (ginea), Valencia, Spain

Aims: The present work aims to identify the relevant factors to predict Alzheimer's Disease (AD) presence, mainly focused on cardiovascular risk scales and related variables.
Methods: Patients between 50 and 75 years old with AD screened between 2017 and 2020 in a Cognitive Disorders Unit of a Hospital in Valencia, Spain, were included. Patients were classified as AD when the t-tau/Abeta42 was >0.51 or the Abeta42/Abeta40 ratio was <0.069. In addition, non-AD patients who failed a maximum of one neuropsychological test were included as a control group. Medications were classified according to the ATC/DDD guidelines 2021 and grouped according to their 3rd ATC level. Machine learning techniques were assessed to determine the most influential variables for AD presence.
Results: A highly imbalanced dataset was obtained, with 177 diagnosed subjects and 50 controls. Ensemble models resulted in better F1-Score metrics, and cardiovascular risk factors were essential to the prediction algorithms. Drugs like anticholinergics, antidepressants, or angiotensin-converting enzyme inhibitors seem positively related to AD prediction, whereas non-steroidal anti-inflammatory drugs and angiotensin receptor blockers showed the opposite effect. Finally, ensembled models considering age, educational level, cardiovascular risk as SCORE2, and specific treatments resulted in interest in AD risk detection.
Conclusions: Machine Learning techniques may improve the identification of patients at risk of AD, allow personalized rationalizing of healthcare costs and improve preventive patient care.

IMPACT OF MULTIPLE INFECTION ON RISK OF INCIDENT DEMENTIA ACCORDING TO SUBJECTIVE COGNITIVE DECLINE STATUS: A NATIONWIDE POPULATION-BASED COHORT STUDY

POSTERS: A05.G. GENETICS, EPIDEMIOLOGY: INFECTIOUS AND INFLAMMATION

Dong Woo Kang
Seoul Saint Mary's hospital, Department Of Psychiatry, Seoul, Korea, Republic of

Aims: The significant roles of both single and multiple infections, coupled with subjective cognitive decline (SCD), as prominent contributors to dementia development are increasingly acknowledged. Yet, their combined effect remains unexplored. This study investigates the influence of infections like Helicobacter pylori, Herpes simplex virus, Varicella-zoster virus, and Human papillomavirus on dementia risk, categorized by cognitive status.
Methods: Utilizing data from a nationwide health screening program (2009-2020) involving 1,100,540 individuals aged 66, participants were categorized as cognitively preserved (CP, n=825,405) or experiencing subjective cognitive decline (SCD, n=275,135). We evaluated the adjusted hazard ratios to ascertain the impact of infection count and cognitive status on dementia types within each group.
Results: Preliminary results indicate an escalated risk of dementia and Alzheimer's disease (AD) with single to triple infections in the CP group in unadjusted analyses. In the SCD group, triple infections significantly amplified the risk for AD dementia. However, risk was slightly mitigated with single and dual infections after adjusting for covariates. A noticeable trend revealed increasing incidence rates per 1000 person-years with a rising count of infectious agents in both groups. Notably, the SCD group faced a twofold increase in dementia risk compared to the CP group.
Conclusions: The study suggests that dementia risk, heightened by single or multiple infections, is potentially less than the risk presented by SCD. The CP group exhibited a comparatively higher risk for infection-triggered AD compared to a nonsignificant risk in the SCD group. Further meticulous research is necessary to affirm these initial findings.

GENETIC RISK FACTOR CLUSTERING OF NEURODEGENERATIVE AND AUTOIMMUNE DISEASES

POSTERS: A05.G. GENETICS, EPIDEMIOLOGY: INFECTIOUS AND INFLAMMATION

Mathew Koretsky[1], Nicole Kuznetsov[1], Sara Bandres-Ciga[1,2], Jeffrey Kim[1,2], Michael Nalls[1,2,3], Hampton Leonard[1,2,3,4]
[1]Center for Alzheimer's and Related Dementias, National Institutes Of Health, Bethesda, United States of America, [2]Laboratory of Neurogenetics, National Institute on Aging, National Institutes Of Health, Bethesda, United States of America, [3]DataTecnica LLC, Datatecnica Llc, Washington, United States of America, [4]DZNE, Dnze, Tuebingen, Germany

Aims: In an effort to find alternative drug targets for neurodegenerative diseases (NDDs), evidence that autoimmunity and inflammation have an effect on NDD etiology has been established. Here, we use a clustering approach to investigate overlapping genetic risk factors between NDDs and autoimmune and inflammatory diseases to further elucidate the potential of inflammation-based drug targets as a treatment for NDDs.
Methods: UK Biobank imputed genotype data for patients with two NDDs (Alzheimer's disease [AD] and Parkinson's disease [PD]) and five autoimmune and inflammatory diseases (multiple sclerosis [MS], rheumatoid arthritis [RA], type 1 diabetes [T1D], ulcerative colitis [UC], and Crohn's disease [CD]) were used. Genome-wide association study (GWAS) summary statistics were used to identify and extract risk variants for each disease, as well as calculate polygenic risk scores (PRS). UMAP was used to perform dimensionality reduction. Clustering was performed to identify patterns in the genotype data in an unsupervised manner, without the use of disease labels.
Results: Preliminary multi-disease analysis identified three clusters that each contained members from all studied diseases (Supplementary Figure 1). Regressions of PRS against cluster membership were performed to identify groups of patients who are generally genetically protected or at risk for the studied diseases. Individuals in cluster 0 generally showed significant genetic protection from both AD and T1D and significant risk for PD based on the PRS associations. Cluster 1 contained patients who had genetic risk for AD and T1D.

Conclusions: Planned analyses to further investigate the genetic overlap between these diseases include single-disease clustering and genomic structural equation modeling. We will also run regressions to determine variants that drive the establishment of the clusters, and perform OpenTargets and omicSynth searches to nominate inflammation-based drug targets for downstream analyses.

Aims: Several *in vitro* or animal studies have shown that inoculation with herpes simplex virus type 1 (HSV-1) could lead to the appearance of amyloid deposits, hyperphosphorylation of the Tau protein or neuronal loss. Our objective was to study a potential impact of HSV-1 on biomarkers of Alzheimer's disease in humans (in whom such studies are rare).
Methods: Our sample included 182 subjects at risk of cognitive decline from the MAPT trial and having HSV-1 plasma serology (at inclusion) and an amyloid PET scan (during follow-up). Among these, 164 subjects benefited from plasma assays of the aβ42/40 ratio and NfL (at 12 months) and 138 subjects of p-tau181 (at inclusion and at 36 months). Multivariate linear regressions were performed to investigate associations between HSV-1 serostatus and Alzheimer's disease biomarkers. Analyzes were also stratified by APOE4 genotype.
Results: The median age was 74.0 years, 85.2% were infected with HSV-1 and 42.9% had a cortical amyloid load above the positivity threshold. Infected participants tended to have a lower cortical amyloid load than uninfected participants (β=-0.08 p-value=0.06), especially those suspected of reactivating HSV-1 most frequently (i.e. with a high anti-HSV-1 IgG level; n=58, β=-0.09 p-value=0.04). After stratification, the association was only significant in APOE4 carriers (n=43, β=-0.21 p-value=0.01). No association was found between HSV-1 serostatus and any of the studied plasma biomarkers.
Conclusions: Our results regarding cortical amyloid load are unexpected and may be due to the exclusion of demented subjects at inclusion in the MAPT trial. Our results concerning plasma biomarkers are consistent with the rare pre-existing results on the topic. Nevertheless, the discrepancies between data *in vitro*, in animals and in humans are not easily explained and will require additional investigations.

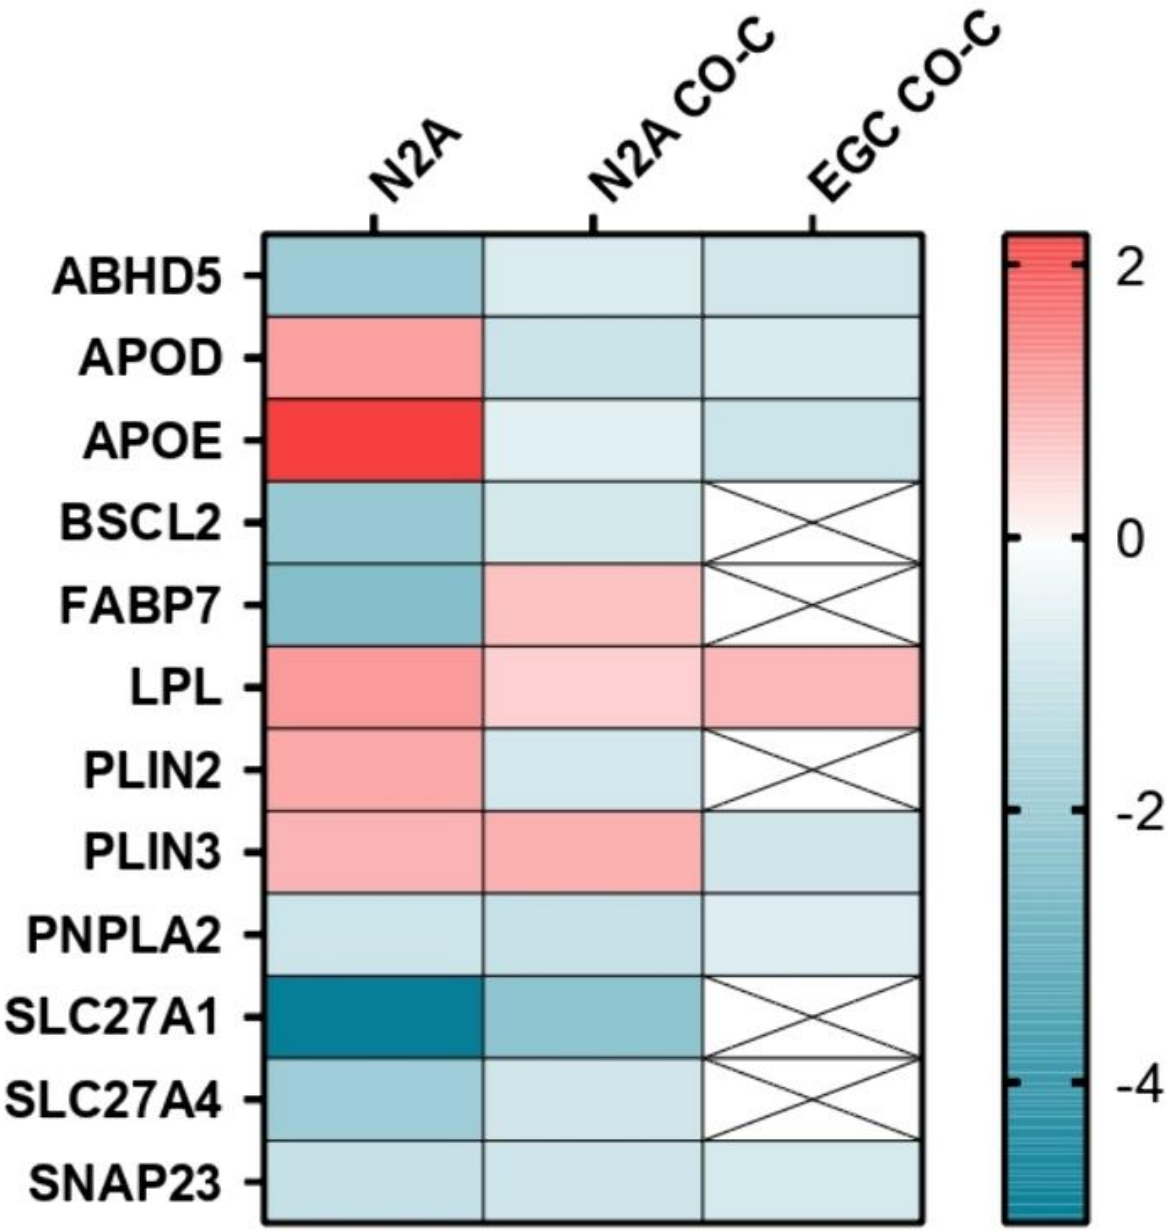
LIPID DROPLETS AS THE LINK BETWEEN HSV-1 INFECTION, OXIDATIVE STRESS AND NEUROPATHOLOGY

POSTERS: A05.G. GENETICS, EPIDEMIOLOGY: INFECTIOUS AND INFLAMMATION

Veronica Zatta[1], Massimo Bellato[2], Alice Pegoraro[1], Paola Brun[1], Ignazio Castagliuolo[1]
[1]University of Padua, Department Of Molecular Medicine, Padua, Italy, [2]University of Padua, Department Of Information Engineer, Padua, Italy

Aims: In the last decades the involvement of Herpes Simplex Virus 1 (HSV-1) infection in Alzheimer's Disease (AD) has emerged. HSV-1 is considered a possible agent triggering neurodegeneration due to its neuro-tropism and ability to undergo multiple cycles of latency and reactivation in neurons. Lipid droplets (LDs) seem to be related to several viral infections and their increased abundance in ageing and neurodegenerating neurons has been reported. In this study we investigated the role of LDs in HSV-1 induced neurodegeneration.
Methods: Mice were inoculated intranasally with a replication deficient HSV-1 (HSV-MUT) (10^2 pfu), intragastrically after 4 weeks (W) (10^8 pfu) and sacrificed after 4W to determine Amyloid Precursor Protein (APP), β-amyloid, and LDs presence in LMMP (Longitudinal Muscle/Myenteric Plexus) by confocal microscopy. Neuro2A cells were infected with HSV-MUT to assess both the induction of LDs in vitro and the impact on the expression of LDs-related genes by qRT-PCR. Finally, HSV-1 MUT-infected Neuro2A were co-cultured with enteric glial cells (EGCs), isolated from healthy mice, to assess the expression of LDs-related genes by qRT-PCR.
Results: Persistent HSV-MUT infection induced neuronal accumulation of APP, β-amyloid and LDs in the LMMP. Moreover, HSV-MUT infected Neuro2aìA show increased ROS production and lipid peroxidation, as well as differential expression of LD-related genes (Figure1): bioinformatic analysis disclosed that such alterations involve several genes implicated in neurodegeneration. EGCs co-cultured with HSV-MUT infected Neuro2A show significantly increased LDs and alteration in the gene expression signature of LDs-related genes, as well as increased peroxidated lipids.



Conclusions: HSV-MUT infection causes the appearance of neurodegeneration markers, oxidative stress and LDs in neurons, in vivo and in vitro. Moreover, EGCs seem to act as "sponge" for LDs thus potentially counteracting HSV-MUT-induced effects.

PROGRESSION FROM ALL-CAUSE MILD COGNITIVE IMPAIRMENT TO ALZHEIMER'S DISEASE DEMENTIA IN UK BIOBANK: EPIDEMIOLOGY, HEALTHCARE RESOURCE UTILISATION AND COSTS

POSTERS: A05.H. GENETICS, EPIDEMIOLOGY: OTHER

Craig Ritchie[1], Sophie Edwards[2], Dominic Trepel[3], Julie Hahn-Pedersen[4], Mei Sum Chan[5], Ben Bray[5], Alice Clark[6], Christian Wichmann[7], Alex Mourer[6], Marc Evans[8]
[1]Scottish Brain Sciences, Neuropyschology, Edinburgh, United Kingdom, [2]Barts Health NHS Trust, Geriatrics, London, United Kingdom, [3]Trinity College Dublin, School Of Medicine, Dublin, Ireland, [4]Novo Nordisk A/S, Payer Evidence Generation, Søborg, Denmark, [5]Lane Clark & Peacock LLP, Health Analytics, London, United Kingdom, [6]Novo Nordisk A/S, Real World Science, Søborg, Denmark, [7]Novo Nordisk A/S, Global Medical Affairs, Søborg, Denmark, [8]University Hospital Llandough, Endocrinology, Llandough, United Kingdom

Aims: To describe the natural history, healthcare resource utilisation and costs of progression from all-cause mild cognitive impairment (MCI) to Alzheimer's disease dementia (ADD).
Methods: UK Biobank participants were followed until end of primary care or hospital record linkage or loss to follow-up. Cognitive tests at baseline were utilised to identify participants with cognition scores consistent with MCI, using principal component analysis. Participants with and without MCI were matched using propensity scores to compare healthcare utilisation and costs. ADD diagnosis was defined using diagnostic codes in electronic health records.
Results: Of 502,394 UK Biobank participants, 33% (164,508) underwent cognitive assessments of which 6,605 (4%) were classified as having all-cause MCI. ADD incidence rates for participants with MCI were 9.5 times (95% CI, 7.9-10.9) higher than participants without MCI at 5 years (67.5 versus 7.1 per 100,000 person-years). The mean time to ADD in those with MCI who progressed to ADD was 6.9 years. 5,419 participants with MCI were matched to 21,676 participants without MCI, 40% of which had linked primary care records. Hospital inpatient costs were £866 (Standard Deviation, SD £3,205) per person per year in the MCI population versus £789 (SD £3,479) in matched participants without MCI at baseline, and £1,978 (SD £8,890) versus £1,669 (SD £9,096) 10 years after baseline, whilst primary care and prescription costs over 6 years were 9.6% higher in those with MCI. The difference in cumulative inpatient costs over 10 years between those with (n=75) and without (n=5344) eventual ADD diagnosis was £20,200 per participant with MCI.
Conclusions: Hospital and primary care costs in individuals with cognition scores consistent with MCI are modestly higher overall and much higher in individuals who subsequently develop ADD.

DEATH RATES OF ALZHEIMER DISEASE AND OTHER DEMENTIAS IN PSYCHIATRIC HOSPITALS.

POSTERS: A05.H. GENETICS, EPIDEMIOLOGY: OTHER

Kengo Sato, Katsutoshi Shioda, Shiro Suda
Jichi Medical University, Department Of Psychiatry, Tochigi, Japan

Aims: We presume that this includes cases in which Alzheimer disease or other dementias are frequently associated with cause of death, or in which Alzheimer disease or other dementias should be the cause of death.This study examined death certificates and medical records in psychiatric hospitals in Japan to clarify instances where the cause of death could have been Alzheimer disease or other dementias.
Methods: We examined death certificates from three psychiatric hospitals in Japan from 2010 to 2020 for cases in which senility, pneumonia, aspiration pneumonia, multiple organ failure, urinary tract infection, and heart failure were listed as disease or condition directly leading to death, and investigated whether dementia was diagnosed or whether the patient might have had dementia in those cases. We further examined the medical records of each of these cases to determine whether dementia played a significant part in their cause of death.
Results: Of the 496 total deaths, 124 patients (75 pneumonia, 17 aspiration pneumonia, 13 heart failure, 12 multi-organ failure, 4 senility, and 2 urinary tract infection) had dementia on the death certificate. All patients had such advanced dementia that they had to be admitted to a psychiatric hospital. Despite being admitted to a psychiatric hospital, 35 patients had no psychiatric diagnosis listed on their death certificates. However, in their medical records, they had been diagnosed with dementia or were thought to have dementia.
Conclusions: In about one-third of the patients who died in psychiatric hospitals, the cause of death was related to dementia. The study suggested that dementia may in fact be the leading cause of death, with a potentially high number of cases in which dementia should be the cause of death in Japan.

Aims: This study aims to investigate the transcription patterns in peripheral monocytes in relation to amyloid-β (Aβ) and tau biomarkers in individuals with memory impairments.
Methods: RNA was extracted from peripheral blood mononuclear cells (PBMCs), and mRNA expression profiles were generated using RNA-sequencing technology. The data were subsequently analyzed using bioinformatics tools to identify differentially expressed genes associated with amyloid-β (Aβ) and tau pathology.
Results: A total of forty-four subjects visiting a memory clinic were enrolled in this study. The mean age of the participants was 64 years, with a male-to-female ratio of 17:27. Our analysis revealed that the cellular components of the transcripts overlapped between Aβ and tau pathology, but the biological processes differed.
Conclusions: The distinct transcription patterns observed in peripheral monocytes in response to Aβ and tau pathology suggest the existence of separate processes through which systemic immune function interacts with these pathologies.

CAG REPEATS WITHIN THE NON-PATHOLOGICAL RANGE IN THE HTT GENE INFLUENCE PLASMA NEUROFILAMENT LIGHT CHAIN CONCENTRATION IN PRODROMAL ALZHEIMER'S DISEASE

POSTERS: A05.H. GENETICS, EPIDEMIOLOGY: OTHER

Assunta Ingannato[1], Chiara Crucitti[1], Salvatore Mazzeo[1,2], Silvia Bagnoli[1], Giulia Giacomucci[1], Valentina Moschini[2], Juri Balestrini[1], Carmen Morinelli[2], Giulia Galdo[1], Filippo Emiliani[1], Arianna Cavaliere[1], Daniele Frigerio[1], Diletta Piazzesi[1], Sonia Padiglioni[2], Sandro Sorbi[2], Valentina Bessi[2], Benedetta Nacmias[1]
[1]University of Florence, Department Of Neuroscience, Psychology, Drug Research And Child Health, Firenze, Italy, [2]Azienda Ospedaliero-universitaria Careggi, Research And Innovation Centre For Dementia-cridem, Firenze, Italy

Aims: Objectives: The Huntington's gene (HTT) contains a key region of CAG repeats that, when expanded beyond 39 repeats, Huntington's Disease (HD) develops. Intermediate alleles (IAs) are the CAG triplet expansion in the range between 27 and 35 repeats. Recent data showed an association between IAs and an increased risk of Alzheimer's disease (AD). Moreover, in a previous study, we reported a correlation between IAs and a higher risk to progress from SCD to MCI. Here, we investigated if a possible association does exist between CAG number repeats and CSF biomarkers and plasma neurofilament light chain (NfL) in AD patients.
Methods: Methods: *HTT* genotype, CSF biomarkers and plasma NfL concentration measurement were analyzed in ninety-six patients (36 SCD and 60 MCI). Study patients were classified as AP+ when A+, T+ and N+, as AP– when A– (regardless of T and N classification), or as A+/T-/N (A/T(N) system).
Results: Results: A significant relationship emerged between HTT length and plasma NfL concentration (p=0.009) in AP+ group, characterized by a nonlinear distribution. The IAs carriers were four in ATN+ group. A linear regression analysis was performed, considering plasma NfL as dependent variable, while age at baseline, age at onset, *APOE* ε4^{+}, CSF biomarker concentration and CAG number repeats as covariates. The final model was significant (p=0.031) and included only HTT CAG repeats (p=0.031) as significant variable.
Conclusions: Conclusions: Our results suggest that increasing number of CAG repeats, below the IAs threshold, may protect against neurodegeneration in AD patients.

APOE4, IN-HOSPITAL DELIRIUM AND LONG-TERM COGNITIVE IMPAIRMENT: A LONGITUDINAL MEMORY CLINIC STUDY

POSTERS: A05.H. GENETICS, EPIDEMIOLOGY: OTHER

Chi-Hun Kim[1], Jong Hun Kim[2]
[1]Hallym University Sacred Heart Hospital, Neurology, Anyang, Korea, Republic of, [2]Ilsan Hospital, National Health Insurance Service, Neurology, Goyang, Korea, Republic of

Aims: To examine the association of *APOE*ε4 allele with in-hospital delirium and long-term cognitive outcomes following the delirium
Methods: DESIGN Retrospective cohort study **SETTING** Electronic medical records (EMRs) from the Ilsan Hospital memory clinics in South Korea were linked to the Korean National Health Insurance Service (NHIS) database, which contains hospitalization, medication, and diagnosis records of all citizens in South Korea from January 2002 to July 2019. **PARTICIPANTS** 1057 memory clinic visitors with *APOE* genotype, longitudinal neuropsychological tests, and hospitalization records. **MEASUREMENTS** Incident in-hospital delirium was defined as the initiation of antipsychotics during hospitalization after excluding prevalent users. Longitudinal outcomes were three cognitive scales and two functional measurements. Incidence analysis was conducted using Cox proportional hazards models, while longitudinal outcomes were analyzed using multivariable mixed models with an interrupted time series design.
Results: At baseline, *APOE*ε4 carriers (N=298, 28.2%) performed poorly cognitive tests compared to non-carriers (CDR-SB mean ± SD: 3.3 ± 3.5 vs 2.8 ± 2.9, *P*=0.016; MMSE 22.3 ± 5.8 vs 23.2 ± 5.2, *P*=0.029). Over the 17-year follow-up, the carriers developed more in-hospital delirium than non-carriers after covariate adjustments (hazard ratio 1.96, 95% confidence intervals 1.30–2.96, *P*=0.0015). The *APOE*ε4 allele also had a more detrimental impact on four out of the five cognitive and functional measurements after the delirium (beta estimates of post-delirium change by *APOE*e4 for CDR-SB = 3.20, *P*<0.0001; CDR=0.60, *P*<0.0001; KIADL = 0.99, *P*<0.0001; SIADL = 14.07, *P*<0.0001). These findings remained robust even after adjusting for covariates.
Conclusions: Throughout the 17-year follow-up, *APOE*ε4 carriers demonstrated robust associations with in-hospital delirium and exhibited more post-delirium cognitive and functional impairment compared to non-carriers. Individuals with *APOE*ε4 allele may need more attention to prevent in-hospital delirium and post-delirium cognitive impairment.

INCREASED RISK OF DEMENTIA AFTER TRANSIENT GLOBAL AMNESIA: A NATIONWIDE POPULATION-BASED, LONGITUDINAL FOLLOW-UP STUDY IN SOUTH KOREA

POSTERS: A05.H. GENETICS, EPIDEMIOLOGY: OTHER

Seung-Jae Lee[1], Yoon-Jong Bae[2]
[1]Soonchunhyang University Bucheon Hospital, Department Of Neurology, Bucheon, Korea, Republic of, [2]Hanmi Pharm. Co., Ltd., Data Science Team, Seoul, Korea, Republic of

Aims: Long-term cognitive outcome after transient global amnesia (TGA) is contradictory in the literature to date. Our study aimed to longitudinally investigate the association of TGA with incident dementia, using the long-term data of nationwide population-based cohort in South Korea.
Methods: From the database of the Korean National Health Insurance Service between 2002 and 2018, study population was recruited using International Classification of Diseases, Tenth Revision codes. Cumulative incidence curve was plotted to compare the incidence rate of dementia between the TGA (G 45.4; n=10,276) and the non-TGA (n=27,389) groups determined using a 1:3 propensity score matching. Using Cox proportional hazard regression models, we obtained crude and adjusted hazards ratios (aHRs) and 95% confidence intervals (CIs) for the incident dementia in patients with TGA compared with non-TGA control. To exam independent variables determining dementia in TGA group, logistic regression analysis was performed, and adjusted odds ratios (aORs) and 95% CIs were produced. All statistical tests were two-tailed, and p values <0.05 were considered statistically significant.
Results: The TGA group had higher cumulative incidence of dementia than the non-TGA group ($p < 0.001$ by long-rank test). TGA was significantly associated with incident dementia in the univariate and multivariate Cox models (HR 1.34, 95% CI 1.28–1.39 and aHR 1.40, 95% CI 1.34–1.46, respectively). The adjusted logistic regression showed that age (per 1 year, OR 1.09, 95% CI 1.09–1.10), female sex (OR 1.31, 95% CI 1.18–1.45), diabetes (OR 1.21, 95% CI 1.08–1.35), stroke (OR 1.30, 95% CI 1.16–1.46), depression (OR 1.53, 95% CI 1.33–1.76), anxiety (OR 1.24 , 95% CI 1.01–1.39), and rural residence (OR 1.24, 95% CI 1.10–1.41) were independently associated with the incident dementia.
Conclusions: Our results suggest the longitudinal association of TGA with incident dementia.

PERSISTENT HSV-1 INFECTION IN MOUSE ENTERIC NEURONS TRIGGERS ALZHEIMER'S DISEASE-LIKE NEURODEGENERATION HALLMARKS

POSTERS: A05.G. GENETICS, EPIDEMIOLOGY: INFECTIOUS AND INFLAMMATION

Veronica Zatta, Paola Brun, Ignazio Castagliuolo
University of Padua, Department Of Molecular Medicine, Padua, Italy

Aims: A growing body of evidence is supporting the profound link between Alzheimer's disease (AD) onset and infectious agents. The neurotropic Herpes simplex virus type 1 (HSV-1) is extremely attractive for a number of experimental and clinical observations, however the absence of a handy *in vivo* model hampers further investigations. The current study was designed to investigate whether persistent HSV-1 infection of enteric neurons would cause neuropathology suggestive of neurodegenerative diseases.
Methods: Mice were inoculated intranasally with HSV-1 (10^2 pfu), intragastrically after 4 weeks (W) (10^8 pfu)* and sacrificed after 4-6-8-10 W. In the ileum LMMP (Longitudinal Muscle/Myenteric Plexus) we determined: a) Amyloid Precursor Protein (APP), β-amyloid, synaptophysin expression by IHC and IF; b) inflammatory cytokines and α-, β- and γ-secretase mRNA by qRT-PCR; c) content of Ach in myenteric neurons by LC-MS/MS. Neurons from myenteric plexus were isolated and cultured and levels of free radicals determined using specific probes.
Results: APP and β-amyloid immunoreactivity progressively increased and peaked at 10W of infection. In contrast, the strong neuronal immunoreactivity for synaptophysin progressively vanished. Ach content in the myenteric plexus was significantly reduced starting at 6W. BACE1 and PSEN2 mRNA significantly increased starting at 4W, whereas ADAM10 transcripts were not significantly affected. IL-1β and IL-6 mRNA levels significantly increased in myenteric plexus starting at 4W. Moreover, redox homeostasis analysis in cultured enteric neurons, obtained from *in vivo* infected mice, revealed peroxidation of membrane lipids and increased mitochondrial production of free radicals.
Conclusions: Persistent HSV-1 infection of enteric neurons causes synaptic damage, accumulation of APP and β-amyloid, neuroinflammation and oxidative damage in neurons: hallmarks of neurodegeneration. Overall our data further support an involvement of HSV-1 in the pathogenesis of neurodegenerative diseases. * Brun et. al. Front Microbiol. 2018

CHARACTERISTICS AND CO-MORBIDITIES OF PATIENTS WITH ALZHEIMER'S DISEASE AT DIAGNOSIS, PRE- AND POST-DIAGNOSIS VERSUS NON-ALZHEIMER´S-DISEASE CONTROLS IN ISRAEL

POSTERS: A05.H. GENETICS, EPIDEMIOLOGY: OTHER

Olga Sánchez-Soliño[1], Yael Barer[2], Lisa Vinikoor-Imler[1], Gabriel Chodick[2]
[1]AbbVie Inc., R&d, North Chicago, United States of America, [2]Maccabi Institute for Research and Innovation, R&d, Tel-Aviv, Israel

Aims: To characterize patients with Alzheimer's Disease (AD) versus matched controls in Israel, at diagnosis, 10 years prior and 2 years post-AD diagnosis.
Methods: This longitudinal, patient-level, retrospective cohort study using the Maccabi healthcare services (MHS) database included adult patients diagnosed with AD, as per the ICD-9 code 331.0 or corresponding MHS internal codes. Date of first AD diagnosis was defined as the Index date (ID). Patients were included if they had at least 10 years prior ID and at least 2 years post ID (apart from death) of continuous MHS enrollment. MHS members without AD diagnosis were matched to patients with AD by age and sex. The ID was required to occur during 01-01-2010 to 31-12-2019.Comparison between groups was performed using standardized mean difference [SMD]. Risk of morality was assessed using COX proportional hazard model adjusted to baseline characteristics.
Results: 44,128 subjects (22,064 AD and 22,064 matched non-AD) were included in the analysis. Mean age at ID was 80.02 (SD 8.4) years and 57.6% were female. At ID, patients with AD were more likely to have mild cognitive impairment, cerebrovascular-disease, type 2 diabetes, depression and/or anxiety, recurrent seizures, falls, psychosis, post-traumatic brain degeneration and other neurological conditions. Patients with AD had a 1.76-fold increased risk of mortality compared to those without. The most common dementia-related diagnoses other than AD prior and post-ID were vascular dementia and dementia due to medical condition.
Conclusions: A higher proportion of AD patients were diagnosed with prior neurological conditions and type 2 diabetes compared to non-AD controls. Patients with AD had an increased risk for death throughout follow-up. Comorbidities should be considered when providing care for patients

ARE PREDICTIONS OF PHENOTYPIC COGNITIVE SCORES BY POLYGENIC COGNITIVE SCORES DRIVEN BY THE COGNITIVE COMPLEXITY OF PHENOTYPIC MEASURES? A META-ANALYSIS

POSTERS: A05.H. GENETICS, EPIDEMIOLOGY: OTHER

Jan Te Nijenhuis, Balaji Kannappan, Kun Ho Lee
Chosun University, Biomedical, Gwangju, Korea, Republic of

Aims: Intelligence is highly heritable and crucial in biomedical research. Recent genome-wide association studies (GWASs) have identified SNPs that account for a modest portion of the heritability of intelligence. There are many studies where cognitive polygenic scores (PGSs) are used to predict scores on intelligence tests; the resulting rs are all over the place. Various unconvincing explanations are offered for this high variability in resulting rs. The most important difference between intelligence tests is their difference in cognitive complexity. We hypothesize that the predictions of phenotypic cognitive scores by polygenic cognitive scores are a function of the cognitive complexity of the phenotypic cognitive scores.
Methods: We carried out a meta-analysis of studies reporting 1) cognitive polygenic scores (IQ, Cognitive achievement, Educational attainment) and 2) the correlation between cognitive polygenic scores and at least four cognitive test scores. We computed the cognitive complexity of the cognitive tests. We then computed the correlation between 1) the cognitive complexity of the cognitive tests and 2) the correlation between cognitive polygenic scores and at least four cognitive test scores. A strong positive correlation means that the predictions of phenotypic cognitive scores by polygenic cognitive scores are strongly driven by the cognitive complexity of the phenotypic measures.
Results: A substantial number of studies were found and many of them were based on a large number of subjects. The studies analyzed so far show large to very large correlations, strongly confirming the hypothesis.
Conclusions: Cognitive polygenic scores predict most strongly for difficult IQ tests and least strongly for easy IQ tests. So, we conclude that the predictions of phenotypic cognitive scores by polygenic cognitive scores are strongly driven by the cognitive complexity of the phenotypic measures

NOVEL KNOCKIN MICE LACKING THE ALPHA- AND BETA-SECRETASE SITES

POSTERS: A06.A. CELL, MOLECULAR AND SYSTEMS BIOLOGY: APP, APLP, ABETA

Lara Kilian[1], Marija Banicevic[1], Jennifer Just[2], Michaela Back[3], Irmgard Amrein[4], Jakob Von Engelhardt[3], David Wolfer[4], Stefan Kins[5], Martin Korte[2], Ulrike Müller[1]
[1]Ruprecht-Karls Universität Heidelberg, Institute Of Pharmacy And Molecular Biotechnology (ipmb), Heidelberg, Germany, [2]TU Braunschweig, Zoological Institute, Braunschweig, Germany, [3]Johannes Gutenberg-Universität Mainz, Universitätsmedizin, Institute Of Pathophysiology, Mainz, Germany, [4]University of Zurich, Institute of Anatomy, Division Of Functional Neuroanatomy, Zurich, Switzerland, [5]TU Kaiserslautern, Department Of Human Biology And Human Genetics, Kaiserslautern, Germany

Aims: The pivotal role of the amyloid precursor protein (APP) in the pathogenesis of Alzheimer's Disease is well established. However, the precise physiological role of APP and its various proteolytical fragments is still not fully understood. Both, transmembrane APP signaling and secreted APP ectodomain fragments are required for normal development of the nervous system. Previous studies indicated that cell surface APP and the APLPs mediate synaptic adhesion, which is important during development and in the adult for processes that require synaptic stabilization. However, proteolytic cleavage of cell surface APP leads to APPsα secretion, which has been shown to support both structural and functional synaptic plasticity. Our goal is to understand the interdependence and regulation of these processes at the synapse *in vivo*.
Methods: Here, we have generated novel APP knockin mice expressing solely a secretion-deficient APP variant by introducing a genomic deletion (APPΔS622) encompassing the α- and β-secretase cleavage sites.
Results: APPΔS622 mice proved fully viable. Western blot analysis of APP processing in brain lysates indicated an accumulation of full-length, uncleaved APP at the cell surface that was paralleled by a prominent reduction of secreted, soluble APPs fragments and APP-CTFs. Intriguingly, the levels of post-synaptic proteins PSD-95 and Homer1 were significantly reduced. Moreover, electrophysiological recordings conducted in the hippocampus of adult APPΔS622 mice revealed a synaptic phenotype characterized by pronounced deficits in the induction and maintenance of hippocampal Long-Term Potentiation (LTP).
Conclusions: APPΔS622 mice represent a novel mouse line which will be further used to gain a deeper understanding of the role of APP as a soluble ligand. Collectively, our findings suggest that soluble APPs plays a fundamental role in modulating and regulating the dynamic processes underlying synaptic plasticity.

TARGETED CO-EXPRESSION NETWORKS PRECISELY DELINEATE THE PATHWAYS ASSOCIATED WITH THE AMYLOID BETA PRECURSOR PROTEIN WITHIN ALZHEIMER´S BRAINS

POSTERS: A06.A. CELL, MOLECULAR AND SYSTEMS BIOLOGY: APP, APLP, ABETA

Juan Botia[1], Alicia Gómez-Pascual[1], Guillermo Rocamora[1], Laura Ibanez[2]
[1]University of Murcia, Information And Communications Engineering, Espinardo, Spain, [2]Washington University School of Medicine in Saint Louis, Psychiatry, Washington, United States of America

Aims: We investigated the gene expression context of the beta-amyloid precursor protein (APP) gene in Alzheimer´s Disease (AD) brains, using its gene expression as the target of a targeted co-expression network.
Methods: Gene co-expression networks (GCNs) on transcriptomes are too coarse grain models to specifically investigate associations of gene expression with phenotypes of interest. Targeted GCNs (TGCNs) are a new modelling approach we designed that creates more specific networks, focused on a phenotype, APP in this case. A TGCN tries to explain as much variation of the phenotype as possible within the sample while describing, functionally, the genes involved (available at https://github.com/aliciagp/TGCN). We created APP-TGCNs on the ROSMAP gene expression profiles and replicated results on the MSBB cohort.
Results: The APP-TGCN has 25 modules 880 genes size. The hubs explain most of the gene expression variation in APP (R^2 0.96). Within the hubs we find the ATP1B1 gene (leading a module enriched for *dopaminergic* neurons and GO terms like synaptic vesicle cycle). ATP1B1 replicates as hub in the MSBB TGCN. ABCD3 leads genes enriched for astrocytes and activity located mainly in the cell plasma membrane. FRZB is hub in a module enriched for endothelial and mural cells. NFASC module is enriched for oligodendrocytes and neuron development related terms, and replicates in the MSBB TGCN. In association to AD as a phenotype, the APP-TGCN shows APP involvement through the HNRNPA2B1 module (enriched with mRNA metabolism and splicing annotations), and ATP1B1 and NFASC module.
Conclusions: We show that APP expression in brain plays cell-specific key roles in several biological processes: neuron development through oligodendrocytes and in regulation of the synaptic vesicle cycle in dopaminergic neurons, which we found associated with AD pathobiology.

TMCC2 PATHOLOGY IN ALZHEIMER'S DISEASE AND DOWN SYNDROME

POSTERS: A06.A. CELL, MOLECULAR AND SYSTEMS BIOLOGY: APP, APLP, ABETA

Paul Hopkins[1], Claire Troakes[2], Andrew King[2], Guy Tear[1]
[1]King's College London, Centre For Developmental Neurobiology, London, United Kingdom, [2]King's College London, Institute Of Psychiatry, Psychology And Neuroscience, London, United Kingdom

Aims: To investigate the apoE-binding and APP-interacting protein TMCC2 in post-mortem human brain.
Methods: We compared TMCC2 immunoreactivity and pathology in post-mortem brain of late onset AD cases as well as in age-matched non-demented controls. We also investigated TMCC2 immunoreactivity in post-mortem brain tissue from cases with early onset AD associated with Down syndrome.
Results: In both early and late onset AD, TMCC2 immunoreactivity was closely associated with neuronal APP, as well as found specifically in dense cored senile plaques. In Down syndrome AD, TMCC2 immunoreactivity was also found prominently associated with putative amyloid having a spicular or thread-like appearance. This TMCC2- and methoxy-X04-positive was not observed in the 10 late onset AD cases examined. Our observations may recapitulate those previously made using thioflavin S, variously named "birds nest plaques" or "fibrous plaques" which showed Aβ- and tau-negative amyloid in Down syndrome that was not observed in AD associated with other genetic risk factors.
Conclusions: Association of TMCC2 with APP-related pathology in both early and late onset AD positions this protein as mediator between apoE and APP in AD pathogenesis. The association of TMCC2 immunoreactivity with an amyloid-dye reactive pathological feature potentially enriched in Down syndrome AD suggests that TMCC2 may be a target of chromosome 21 genes, and have the potential to adopt a β-pleated sheet amyloid conformation.

IN-DEPTH DNA METHYLATION PROFILING OF AD ASSOCIATED LOCI.

POSTERS: A05.H. GENETICS, EPIDEMIOLOGY: OTHER

Greg Wheildon[1], Adam Smith[2], Darren Soanes[1], Rebecca Smith[1], Karen Moore[3], Paul O'Neill[3], Kevin Morgan[4], Paul Francis[5], Jonathan Mill[6], Ehsan Pishva[7], Katie Lunnon[2]
[1]University of Exeter, Clinical And Biomedical Sciences, Exeter, United Kingdom, [2]University of Exeter, Department Of Biomedical And Clinical Sciences, Exeter, United Kingdom, [3]University of Exeter, Biosciences, Exeter, United Kingdom, [4]University of Nottingham, Life Sciences, Nottingham, United Kingdom, [5]University of Exeter, Medical School, Exeter, United Kingdom, [6]University of Exeter Medical School, Department For Clinical And Biomedical Sciences, Exeter, United Kingdom, [7]University of Maastricht, Department Of Psychiatry & Neurophysiology, Maastricht, Netherlands

Aims: Recent epigenome-wide association studies (EWAS) identified loci in specific genes showing robust DNA methylation alterations in Alzheimer's disease (AD) brain samples. Microarrays used in these studies target a limited number of methylation sites in each gene. We performed targeted bisulfite sequencing (TBS) for genes associated with AD, aiming to determine the exact extent of methylation changes in disease within these loci, and to conduct technological comparisons between the Illumina EPIC array and TBS.
Methods: Prefrontal cortex (PFC) brain samples from 58 individuals were selected and grouped by Braak stage (Control 0-II; intermediate III-IV; AD V-VI). DNA was extracted, before 14 AD genomic regions of interest, were captured using Agilent SureSelect target baits. The DNA was bisulfite sequenced, aligned and CpG methylation called. Differentially methylated positions (DMPs) were analysed across the three groups. We also compared the data to EPIC array data generated in the same samples
Results: Methylation levels were quantified, and group differences were examined using a one-way ANOVA, controlling for co-variation. Sites in several genes showed differential DNA methylation, with several of the most robust sites not being present on current methylation arrays. Enrichment of nominally significant sites at genomic features was observed. Non-linear changes in methylation with AD pathology were also observed. Correlation of effect sizes showed concordance at shared CpGs between the two technologies, particularly when stratifying by strength of association.
Conclusions: This work provides further evidence that methylation dysregulation is associated with AD pathology in the PFC. That sites not presented on existing methylation arrays showed significant changes suggests the need for better characterisation. Future work should focus on long-read sequencing methods to allow full characterisation of DNA methylation on native DNA, overcoming issues associated with short-read sequencing.

THE REGION 35-HAEE-38 OF ALPHA4 SUBUNIT PLAYS A KEY ROLE IN THE BINDING OF ALPHA4BETA2 NICOTINIC ACETYLCHOLINE RECEPTOR TO BETA-AMYLOID

POSTERS: A06.A. CELL, MOLECULAR AND SYSTEMS BIOLOGY: APP, APLP, ABETA

Olga Kechko[1], Lucy Ojomoko[2], Vladimir Mitkevich[1], Alexander Makarov[1]
[1]Engelhardt Institute of Molecular Biology RAS, Laboratory Of Protein Conformational Polymorphism In Health And Disease, Moscow, Russian Federation, [2]Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry RAS, Department Of Molecular Neuroimmune Signaling, Moscow, Russian Federation

Aims: Progression of Alzheimer's disease is accompanied by the dysfunction of cholinergetic system and massive loss of cholinergetic neurons containing the nicotinic acetylcholine receptors (nAChRs). NAChRs agonists protect neuronal cells against amyloid toxicity, eliminate the senile plaques and improve learning and memory of transgenic mice. Moreover, nAChRs antagonists, that blocks binding of Abeta to the receptor, inhibits Abeta-induced tau protein phosphorylation in neuronal cells. It is mean that the toxicity of Aβ is mediated through a direct interaction between Abeta and nAChRs. The most abundant form of nAChRs in the brain is alpha4beta2 nAChR. It is known that Abeta binds alpha4beta2 nAChR and inhibits its function but little known about this interaction.
Methods: Microscale thermophoresis and isothermal titration calorimetry were used to measure the binding of Abeta and extracellular domain (32-242aa) of nAChR alpha4 subunit. *Xenopus laevis* oocytes expressed alpha4beta2 nAChR or its mutant alpha4(35-HAAA-38) were used to define inhibition effect of Abetas on the receptor. The acetylcholine-induced ion currents were measured by two-electrode voltage clamp. Dynamic light scattering was used to evaluate the aggregation of Abeta.
Results: Abeta forms a strong complex with alpha4 nAChR through the region 35-HAEE-38 of alpha4. Isomerization of Asp7, the well-known pathogenic modification of Abeta, enhance this interaction 10-fold. Mutation 35-HAAA-38 completely abolishes the binding of alpha4 nAChR and Abetas, as well as Abeta-induced inhibition of alpha4beta2 nAChR in oocytes. The initial binding of Abeta peptides to the alpha4 nAChR promotes their aggregation on the receptor matrix.
Conclusions: The region 35-HAEE-38 of alpha4 nAChR is essential for interaction with Abeta. Increase of Abeta level induces its aggregation on the receptor and results in the inhibition of the nAChR.

AUTOPHAGY DEFICIENCY ALTERS INTRACELLULAR APP TRANSPORT, LEADS TO INCREASED APP PROCESSING AND SOLUBLE APP SECRETION

POSTERS: A06.A. CELL, MOLECULAR AND SYSTEMS BIOLOGY: APP, APLP, ABETA

Johanna Mayer[1], Dominik Boeck[1], Michelle Werner[1], Makoto Shimozawa[1], Hesso Farhan[2], Per Nilsson[1]

Aims: Alzheimer's disease pathology is characterized by amyloid beta (Abeta) plaques and dysfunctional autophagy as seen by an accumulation of autophagic vacuoles in patient brains. Abeta is generated by sequential proteolytic cleavage of amyloid precursor protein (APP) and the site of intracellular APP processing is highly debated and may include autophagosomes.
Methods: Here we investigated the involvement of autophagy in APP intracellular trafficking and processing by applying the retention using selective hooks (RUSH) system. Thereby we could follow the transport of fluorescently labeled mCherry-APP-EGFP in a systematic way starting from the endoplasmic reticulum. Autophagy-deficient, ATG9 knockout HeLa cells stably expressing the RUSH mCherry-APP-EGFP system were investigated by live-cell imaging, immunofluorescence, and Western blot.
Results: We found that mCherry-APP-EGFP passed through the Golgi faster in ATG9 knockout cells potentially due to a fragmented Golgi. ATG9 depletion further resulted in an intracellular relocation of mCherry-APP-EGFP away from early endosomes and towards the plasma membrane. Eventually, the intracellular re-routing of mCherry-APP-EGFP resulted in an increased amount of secreted mCherry-soluble APP and intracellular C-terminal fragment-EGFP.
Conclusions: These findings contribute to the understanding of the role of autophagy in APP metabolism and could potentially have implications for new therapeutic approaches for AD.

Aims: We previously reported that membrane-tethered APP intracellular domain (mAICD) interacts with GalphaS and activates adenylate cyclase. We established that mAICD expression in the brain since birth rescued cognitive impairment observed in 5XFAD, an effect that required mAICD interaction with GalphaS protein. Here, we explored if mAICD expression in adult mouse brains with advanced AD conditions is sufficient to preserve spatial memory and sleep, underlying AD pathology, which can interfere with cognitive behavior.
Methods: We expressed mAICD or mAICDmutAAA variant (lacking the GalphaS interacting site) in the brain of amyloidogenic 5XFAD and tauopathy PS19 mouse models using AAV brain delivery strategy. We injected the AAV plasmids in neonates, young and old adults, and performed sleep and cognitive behaviors 3-6 months later.
Results: We observed that 5XFAD mice sleep less than non-transgenic (NTg) littermates. mAICD expression since birth in 5XFAD prevented sleep disturbance, an effect not seen in 5XFAD mice expressing mAICDmutAAA. NTg mice expressing mAICDmutAAA exhibit an overall reduction of sleep, which was correlated with cognitive impairment. Noteworthy, NTg mice expressing mAICD in the dentate gyrus since a young age exhibited cognitive impairment, an effect not seen in older cohorts. 5XFAD mice did not improve their cognitive behaviors when expressing mAICD in the dentate gyrus, whereas they showed less memory decline if injected in the CA3. We also found that expression of mAICDmutAAA in the suprachiasmatic nucleus markedly reduced contextual fear conditioning responses in PS19 and 5XFAD mice.
Conclusions: Our results suggest that altered APP-mediated cAMP/PKA downstream signaling could contribute to the sleep pattern discrepancy seen in AD mouse models, therefore impacting memory performance. mAICD overexpression in select brain areas at a given period during lifespan might affect cognition.

MOLECULAR PATHWAYS OF PATHOGENIC SORLA PROTEIN IN ALZHEIMER'S DISEASE DEVELOPMENT.

POSTERS: A06.A. CELL, MOLECULAR AND SYSTEMS BIOLOGY: APP, APLP, ABETA

Jan Raska[1,2], Petr Fojtik[1,2], Klara Plesingrova[1], Veronika Pospisilova[1], Simona Bartova[1], Jiri Sedmik[1], Tereza Vanova[1,2], Sona Kadakova[1], Hana Hribkova[1], Victorio Devoto[1,2], Marko Mecava[1], Miriam Satkova[1], Olav Andersen[3], Dasa Bohaciakova[1,2]

Aims: Alzheimer's disease (AD) is a progressive neurodegenerative disorder characterized by a gradual decline in memory function and the presence of distinct pathological features, including amyloid-β plaques and Tau neurofibrillary tangles. While most AD cases are sporadic, a subset of cases is linked to specific mutations in genes such as *APP*, *PSEN1*, and *PSEN2*, which lead to early-onset AD. More recently, genetic variations in the *SORL1* gene, which encodes the SORLA protein, have also been associated with the development of AD, suggesting that *SORL1* may be considered the fourth AD causative gene. We aimed to investigate the mechanisms underlying the development of AD-related pathology caused by pathogenic *SORL1* mutations.
Methods: We used CRISPR/Cas9 technology to introduce several pathogenic *SORL1* mutations into induced pluripotent stem cells and employed advanced *in vitro* models to produce 2D inducible neurons and 3D neural organoids. SORLA was investigated by WB, and endosome morphology, and APP accumulation were investigated using confocal microscopy and the Proximity ligation assay.
Results: We successfully adapted advanced 2D and 3D *in vitro* models and introduced mutations in the *SORL1* gene to investigate the molecular consequences of pathological SORLA in AD development. As controls, we utilized wild-type and complete *SORL1* knock-out cells. Using these novel disease models, we observed how decreased maturation and the total SORLA protein level was unifying feature of all tested pathogenic variants. A concomitant decrease in mutant SORLA shedding was observed. Notably, we identified the presence of enlarged endosomes with increased accumulation of APP, a major pathological marker in these cell models.
Conclusions: We have successfully validated the utility of stem-cell *in vitro* models for SORLA research, paving the way for more in-depth investigations into the molecular pathways underlying SORLA-associated AD development.

EVALUATING ALZHEIMER'S DISEASE PHENOTYPES IN APOE ALLELIC VARIANTS ENGINEERED INTO IPSC-DERIVED NEURONS

POSTERS: A06.B. CELL, MOLECULAR AND SYSTEMS BIOLOGY: APOE

Amr Othman[1], Scott Schachtele[2], Rebecca Fiene[1], Megan Livingston[1], Carole Crittenden[3], Oksana Sirenko[3], Coby Carlson[1]
[1]FUJIFILM Cellular Dynamics, Applications, Madison, United States of America, [2]FUJIFILM Cellular Dynamics, Product Management, Madison, United States of America, [3]Molecular Devices, LLC., Applications, San Jose, United States of America

Aims: Apolipoprotein E (APOE) is a gene involved in cholesterol transport and has a well-known link to Alzheimer's Disease (AD). An individual's composition of APOE alleles (e.g., epsilon(E)2, E3, E4) is related to AD risk; inheriting two APOE E4 alleles increases risk of AD compared to individuals containing just one E4 allele. Conversely, two APOE E2 alleles reduces risk of developing AD. Understanding the functional role of APOE allele combinations may identify new methods for prevention or delay of AD. In this study, we investigated phenotypes of common APOE allele combinations in GABAergic neurons derived from human induced pluripotent stem cells (iPSCs) and cultured in either 2D or advanced multi-cell 3D neurospheres.
Methods: A human iPSC donor with APOE 3/3 (wild-type) was engineered to create isogenic APOE E2/2, E3/4, and E4/4 iPSCs. iPSCs were differentiated into GABAergic neurons (iCell GABANeurons) at scale and across multiple lots. We monitored the effect of APOE allele combinations on neurite outgrowth and alpha-synuclein production. iCell GABANeurons were cultured with other iPSC-derived brain cells (i.e., glutamatergic neurons, astrocytes) to generate 3D neurospheres. Using a high-throughput calcium oscillation assay, baseline activity was measured in APOE allele AD-based neurospheres. Neurosphere cultures were subsequently screened with neuromodulatory and AD-relevant compounds.
Results: Neurospheres containing APOE allele GABANeurons yielded unique functional differences using the calcium oscillation assay. APOE E4/4 GABANeurons displayed the strongest deviation compared to control APOE E3/3 neurons. Preliminary data showed memantine treatment returned APOE4/4 neuron calcium oscillations back to control cultures.
Conclusions: Human iPSC-derived neurons composed of AD-relevant APOE allele combinations present phenotype differences in culture and can be a useful model for identifying mechanism of AD pathogenesis and potential targets for therapeutic treatments.

THE INTERRELATION BETWEEN APOE AND MATRIX METALLOPROTEINASE-9 WITH HIPPOCAMPAL VOLUMETRY IN PATIENTS WITH ALZHEIMER'S DISEASE

POSTERS: A06.B. CELL, MOLECULAR AND SYSTEMS BIOLOGY: APOE

Jelena Bašić[1], Vuk Milošević[2], Branka Đorđević[1], Vladana Stojiljković[1], Milica Živanović[3], Tatjana Jevtović Stoimenov[1], Ivana Stojanović[1]
[1]Faculty of Medicine, University of Niš, Department Of Biochemistry, Niš, Serbia, [2]University Clinical Center Niš, Clinic Of Neurology, Niš, Serbia, [3]University Clinical Center Niš, Radiology Center, Niš, Serbia

Aims: Although APOE ε4 carrier status, matrix metalloproteinases-9 (MMP-9), and its tissue inhibitor (TIMP-1) are associated with the disruption of blood-brain barrier integrity, prolonged neuroinflammation, and Aβ clearance, the role of matrix remodeling enzymes in neurodegeneration remains unclear. This study aimed to investigate the influence of APOE ε4 carrier status on plasma MMP-9, TIMP-1 levels, and hippocampal volume, and to assess the correlation between MMP-9/TIMP-1 ratio with hippocampal volumetric measurements in patients with dementia due to Alzheimer's disease (AD).
Methods: We enrolled 53 patients with probable dementia due to AD. The positivity of selected CSF AD biomarkers was determined using the A/T/N classification. Brain magnetic resonance imaging (MRI) was performed according to the dementia protocol, and hippocampal volumetry was analyzed using Vol2Brain. Plasma MMP-9 and TIMP-1 levels were determined by ELISA. APOE rs429358 and rs7412 were analyzed using the Real-Time PCR method with allele-specific TaqMan assays, followed by the analysis of APOE ε2/ε3/ε4 allele carrier status.
Results: Volumetric analysis based on brain MRI scans showed that APOE ε4+ patients exhibited a decline in hippocampal volume, including total volume (p=0.008), total/intracranial volume (ICV)(p=0.008), right hippocampus (p=0.002), right/ICV (p=0.000), and left hippocampus (p=0.033), when compared to APOE ε4- patients. Although we didn't find a significant difference in levels of plasma MMP-9, TIMP-1, and MMP-9/TIMP ratio between APOE ε4+ and APOE ε4- patients, we observed a positive correlation between the plasma MMP-9/TIMP-1 ratio and the Asymmetry Index (AI) of hippocampus in volumetry, as a neuroradiological biomarker of disease progression (r= 0.437; p=0.018).
Conclusions: Our findings suggest that the MMP-9/TIMP-1 ratio may be involved in neurodegeneration and could potentially serve as a promising plasma biomarker for monitoring disease progression in AD.

MOLECULAR AND BEHAVIORAL EFFECTS OF APOE4 FRAGMENTATION IN TRANSGENIC ZEBRAFISH

POSTERS: A06.B. CELL, MOLECULAR AND SYSTEMS BIOLOGY: APOE

Troy Rohn, Emily Egan, Sofi Leon-Gonzalez, Alex Lafollette
Boise State University, Biological Sciences, Boise, United States of America

Aims: Of the genetic risk factors identified, the 34 kDa protein, apolipoprotein (Apo) E4, is of significant importance as *APOE4* carriers account for 65-80% of all AD cases. Although ApoE4 plays a normal role in lipoprotein transport, how it contributes to AD pathogenesis is currently unknown. The overall objective of this project is to determine the potential deleterious effects of an endogenously generated 151 amino-terminal fragment of ApoE4 ($nApoE4_{1-151}$) Zebrafish.
Methods: We propose to generate a new zebrafish strain that expresses $nApoE4_{1-151}$ to determine whether low-level chronic expression leads to developmental and behavioral impairments. By employing a Tol2 transposase method, we have generated a permanent transgenic zebrafish line that can now be bred indefinitely to allow for the study of deleterious effects from embryos into adulthood. Using such a model, we hypothesize that the $nApoE4_{1-151}$ fragment will demonstrate significant developmental abnormalities, motor dysfunction, and memory impairments that will further support a novel role of this fragment in the etiology associated with AD.
Results: •Confocal microscopy showed strong immunofluorescent labeling of the $nApoE4_{1-151}$ within the CNS of mutant zebrafish •T-maze behavioral studies indicated both color preference and enriched environment of wild-type zebrafish as compared to $nApoE4_{1-151}$ fish. •$nApoE4_{1-151}$ zebrafish show a significant decrease in survivorship as compared to wild-type fish
Conclusions: Although it is well established that inheritance of the *APOE4* allele increases the risk of AD the mechanism of how this protein contributes to AD pathogenesis remains unknown. Our findings in $nApoE4_{1-151}$ mutant zebrafish provide proof-of-concept *in vivo*, that this amino-terminal fragment induces toxicity and behavior deficits. These data provide further support for the novel role of this important risk factor in the etiology associated with AD.

DETERMINING HOW COMPLEX INTERACTIONS BETWEEN APOE ALLELIC SERIES AND GENETIC BACKGROUND CONTRIBUTE EARLY TO ALZHEIMER'S DISEASE RISK

POSTERS: A06.B. CELL, MOLECULAR AND SYSTEMS BIOLOGY: APOE

Kristen Onos[1], Asli Uyar[2], Kelly Keezer[1], Kevin Elk[1], Ravi Shanker Pandey[2], Kierra Eldridge[3], Scott Persohn[3], Amanda Bedwell[3], Mike Sasner[1], Gregory Carter[2], Paul Territo[3], Gareth Howell[1]
[1]The Jackson Laboratory, Research, Bar Harbor, United States of America, [2]The Jackson Laboratory, Research, Farmington, United States of America, [3]Indiana University, School Of Medicine, Indianapolis, United States of America

Aims: OBJECTIVES: Apolipoprotein E4 is the strongest genetic risk factor for late-onset Alzheimer's disease(AD), leading to an 3-12x increase dependent on copy number, and significant decrease in age of onset. APOE is implicated to play central roles in multiple pathways such as neuroinflammation, lipid metabolism and vascular health. E4 has also been identified as an independent risk factor for Type-2 diabetes and cardiovascular disease. Here, we aimed to identify how differences in copy number and genetic context may interact to elevate risk for AD.
Methods: METHODS: We performed a comprehensive analysis of neurovascular coupling in aging in $APOE^{3/3}$, $APOE^{4/4}$ and $APOE^{3/4}$ animals. PET/MRI measures of ^{64}Cu-PTSM, blood-flow and ^{18}F-FDG, glucose uptake were utilized. Furthermore, we introduced APOE4 into genetically diverse mouse strains that had previously been shown to be resilient or susceptible to amyloid-induced neuronal loss. Neuropathology and brain transcriptomics were performed across multiple strains.
Results: RESULTS: PET/MRI data collected across 27 brain regions was analyzed per tracer as well as combined into a novel measure of neurovascular metabolic uncoupling. Age, sex and APOE genotype directly contributed to significant disruptions in blood-flow and metabolism, with $APOE^{3/4}$ exhibiting earlier and more severe Type II uncoupling. In genetically diverse strains carrying $APOE^{4/4}$, the PWK background showed the greatest transcriptomic change and impact to neuronal health despite previously being shown to be resistant to age-related synaptic loss and resilient to amyloid-induced neuronal loss.
Conclusions: CONCLUSIONS: Overall, these combined data highlight new ways to identify early metabolic changes in novel mouse models of APOE, as well as the importance of assessing risk alleles for AD in a variety of genetic contexts. These approaches hold great promise for identification and development of novel therapeutic targets.

APOE ISOFORM-DEPENDENT MODULATION OF HIGH-FAT DIET EFFECTS IN THE MOUSE BRAIN

POSTERS: A06.B. CELL, MOLECULAR AND SYSTEMS BIOLOGY: APOE

Sun Ah Park[1,2], Kyeong Jae Lee[1], Pyeong Jun Choi[1], Hyuna Jeon[1], Jin Kim[1]
[1]Ajou University School of Medicine, Anatomy, Suwon, Korea, Republic of, [2]Ajou Univeristy, Neurology, Suwon, Korea, Republic of

Aims: Alzheimer's disease (AD) is influenced by both genetics and environmental factors. Among genetic risk factors, ApoE4 allele is the most significant predictor of AD. Additionally, midlife obesity is known to increase the risk of AD. This study aims to investigate the interplay between a high-fat diet (HFD)-induced obesity and the ApoE4 isoform in the brain.
Methods: We utilized human ApoE3 knock-in, ApoE knockout (KO), and ApoE4 knock-in mice to distinguish the effects specific to the ApoE isoform from those specific to ApoE itself. These mice were either fed a HFD or a normal regular diet (ND) for six months, starting at three months of age. We conducted behavioral tests, magnetic resonance imaging (MRI) with diffusion tensor imaging (DTI), and tissue analysis to assess the impact of chronic HFD on the brain, depending on the ApoE isoform.
Results: Weight gain due to HFD was observed in all ApoE genotype groups. However, HFD led to an increase in glycated hemoglobin levels only in ApoE4 mice, not in ApoE3 and KO mice. Nest-building performance declined in ApoE4 and KO mice on HFD. DTI-MRI revealed disrupted neural integrity in response to HFD, primarily in ApoE4 knock-in mice. Western blot analysis showed consistently lower levels of lipidation and apoE protein in the cortex of ApoE4 mice compared to ApoE3 mice, regardless of HFD intake. Furthermore, synaptic and inflammatory markers exhibited apoE isoform-specific differences, not HFD-dependent changes. In different to these, the examination of axon skeletal proteins revealed a HFD-specific change: reduced levels in ApoE4 mice in response to HFD.
Conclusions: It provides the evidence that HFD feeding has differential effects on the mouse brain depending on the ApoE isoform, particularly increasing white matter pathology in ApoE4 mice.

THE MITOCHONDRIAL PHOSPHATASE PGAM5 IS A NOVEL INTERACTOR OF THE AMYLOID PRECURSOR PROTEIN

POSTERS: A06.A. CELL, MOLECULAR AND SYSTEMS BIOLOGY: APP, APLP, ABETA

Kriti Shukla[1], Zhi Zhang[2], Charles Lacy[1], Dylan Barber[1], Samah Houmam[1], Jialing Lin[2], Heather Rice[1]

Aims: In ongoing clinical trials, APP is being targeted by RNAi to reduce amyloid-beta levels to treat AD. However, not only does this reduce amyloid-beta but also full-length APP and its other fragments, such as CTF and sAPP. Thus, it is critical that we fully understand the functions of APP and its proteolytic products. In our previous study (Rice et al., 2019), we performed an unbiased proteomics screen for interactors of the APP ectodomain and found that the GABA B receptor and phosphoglycerate mutase family member 5 (PGAM5) were among the top candidates. Here, we aimed to investigate PGAM5, a mitochondrial phosphatase, as a candidate interactor of the APP ectodomain.
Methods: In vitro binding assays were used to confirm binding of APP and PGAM5 and to determine the domains required for binding. Subcellular fractionation of HeLa cells were performed to determine the subcellular localization of these proteins. Proximity ligation assays were used to determine the subcellular location of this interaction in mouse primary cell cultures and brain slices.
Results: The N-terminal region of PGAM5 interacts with the linker region of APP in vitro. PGAM5 is enriched in mitochondria and mitochondrial associated ER membranes (MAMs), full-length APP is enriched in MAMs, and APP CTF is enriched in mitochondria. APP and PGAM5 interact in primary neurons and astrocytes as well as brain slices, and this interaction likely occurs in MAMs.
Conclusions: We demonstrate that endogenous APP interacts with PGAM5 in multiple cell types of the brain. Ongoing work is aimed at determining the effect of this interaction on mitochondrial dynamics in health and in AD. This will lead to a better understanding of the potential consequences of targeting APP for the treatment of AD.

RECOGNITION OF ISLET AMYLOID POLYPEPTIDE'S EPITOPES IS IMMUNOGLOBULIN- AND APOE ISOTYPE-DEPENDENT

POSTERS: A06.B. CELL, MOLECULAR AND SYSTEMS BIOLOGY: APOE

Dovile Poceviciute[1], Anders Olofsson[2], Bodil Roth[3], Malin Wennström[1]
[1]Lund University, Department Of Clinical Sciences, Malmö, Sweden, [2]Umeå University, Department Of Medical Biochemistry And Biophysics, Umeå, Sweden, [3]Lund University, Internal Medicine, Malmö, Sweden

Aims: Autoantibody clearance of oligomeric islet amyloid polypeptide (IAPPo) is crucial as increased plasma levels of IAPPo can induce microvascular alterations and amyloid beta depositions in the brain. The clearance is dependent on the exposure and specificity of epitopes, where epitopes in the N-terminal, but not C-terminal, are exposed when the peptide oligomerizes. Previously, we have showed that individuals carrying the *APOE4* demonstrate reduced amounts of IgA (but not IgG or IgM) against IAPPo, suggesting a specific impediment in IgA clearance of IAPPo in these individuals. Currently, we aim to investigate if this Ig- and *APOE* isotype-dependent impact can be explained by differences in epitope recognition.
Methods: The plates were coated with six IAPP peptides (P) representing the following fragments of the IAPP (1-37) sequence: P1 (1-15), P2 (6-20), P3 (11-25), P4 (16-30), P5 (21-35), P6 (26-37). Thereafter, plasma from non-demented controls (NCs) carrying *APOE33* (n=6) and AD patients carrying *APOE33* (n=6) and *APOE44* (n=6) was applied, followed by an incubation with either anti-IgA or anti-IgG secondary antibodies.
Results: While IgG in plasma from all individuals bound solely to P6, IgA bound to all six peptides, but with an increasing binding towards the C-terminal (P1<P2<P3<P4<P5<P6). Levels of IgA against P1 and P2 in AD with *APOE44* were lower (p=0.0887) and significantly lower, respectively, than the levels in NC with *APOE33.*
Conclusions: Our data indicate an Ig isotype-dependent binding to IAPP epitopes and that some IgA-specific epitopes are still exposed when IAPP oligomerizes. However, the binding to these exposed epitopes is decreased in *APOE44* carriers. We, therefore, speculate that the reduction in IAPPo-IgA levels seen in our previous studies is due to IgA-IAPP epitope specificity which is affected by oligomerization and *APOE* isotype.

METALS MODULATE PROTEIN PHOSPHATASES IMPACTING ALZHEIMER'S DISEASE RELATED PROTEINS

POSTERS: A06.D. CELL, MOLECULAR AND SYSTEMS BIOLOGY: NETWORK BIOLOGY, CONNECTOME, PROTEIN-PROTEIN INTERATIONS

André Nadais, Steven Alves, Ana Gabriela Henriques, Odete Da Cruz E Silva
Institute of biomedicine, Department Of Medical Sciences, University Of Aveiro, Aveiro, Portugal

Aims: Alzheimer´s Disease (AD) is histopathologically characterized by hyperphosphorylation of tau protein and Aβ peptide deposition, thus forming intracellular neurofibrillary tangles (NFTs) and extracellular senile plaques (SPs), respectively. Moreover, the hyperphosphorylated states that occur in amyloid β-precursor protein (APP) and tau can result from imbalanced activities of protein phosphatases (PPs) and protein kinases (PKs) observed in AD. Additionally, SPs found in AD patients contain Zn2+, Cu2+, Al3+ and Fe3+ and previous studies have demonstrated that some metals affect both PPs and PKs activity impacting tau and APP phosphorylation. However, the correlation between metals, protein phosphorylation and AD pathology has not been fully elucidated and will be addressed in the work here presented.
Methods: *In vitro* (cell-based experiments and protein analysis) and *in silico* methods were employed to unravel the potential role of metals in AD relevant proteins.
Results: The results showed that Zn2+ and Cu2+ promote an increase in protein phosphatase 2A (PP2A) activity as well as a decrease of Glycogen Synthase Kinase 3β (GSK3β), resulting in decreased tau phosphorylation. On the other hand, with Al3+ and Fe3+, APP phosphorylation and metabolism were compromised as well as an increase in tau phosphorylation. These effects can be potentially mediated by alteration of PP1/PP2A and GSK3β activity. Moreover, using bioinformatic tools, 81 metal binding proteins, that also bind to PP1 or PP2 and that are associated with AD were identified. These represent interesting candidates for future studies among them the Glutamate Receptor Ionotropic, NMDA 2B (GluN2B).
Conclusions: This study opens the door to the use of Zn2+ and Cu2+ as potential modulators of protein phosphatases and NMDAR activity, preventing the excitotoxicity, synaptic dysfunction, and tau hyperphosphorylation observed in AD.

DEEP LEARNING RESOLVES CELL-TYPE SPECIFIC TRANSCRIPTOMES IN MOUSE HIPPOCAMPUS AND UNVEIL SYNAPTIC CHANGES AFTER EXPOSURE TO AN EXCITOTOXIN.

POSTERS: A06.D. CELL, MOLECULAR AND SYSTEMS BIOLOGY: NETWORK BIOLOGY, CONNECTOME, PROTEIN-PROTEIN INTERATIONS

Eloise Berson[1], Amalia Perna[2], Thanaphong Phongpreecha[2], Nima Aghaeepour[3], Thomas Montine[2]
[1]Stanford, Pathology, Palo Alto, United States of America, [2]Stanford, Pathology, PaloAlto, United States of America, [3]Stanford, Anesthesia, PaloAlto, United States of America

Aims: Single nucleus RNA sequencing (snRNA-seq) has revolutionized our ability to dissect transcriptional profiles in specific cell types. However, it captures only 20-50% of the cellular transcriptional information, limiting our comprehensive understanding of the cellular transcriptional ensemble. Therefore, we propose a computational approach to extract the cellular signal from brain tissue bulk transcriptomic data, allowing us to investigate cell type-specific transcriptomic programs underlying neurodegeneration.
Methods: We adapted Cellformer - a deep learning deconvolution model for ATAC-seq data - to RNA-seq data. We leverage an excitotoxicity mouse model to detect cell-type specific transcriptomic responses to injury.
Results: Cellformer accurately deconvoluted mouse brain bulk RNA into 9 major cell types (mean Pearson correlation of 0.97) (Figure 1A). Validation with single nucleus datasets reveals a significantly higher correlation (0.85) within the same cell type compared to different cell types (0.20) (P-value < 1e-6) (Figure 1B). We applied Cellformer to bulk RNAseq data obtained from both tissue and nuclei isolated from the same mouse hippocampus. We compared these cell-type-specific transcriptomic signatures between healthy mice and those exposed to a low dose of Kainic Acid (KA), a potent toxin for excitatory neurons (Figure 1C). More shared information was found between snRNA and deconvoluted RNA from nuclei compared to deconvoluted tissue (Figure 1D). Interestingly, differential expression analysis revealed a greater effect of low-dose KA exposure on deconvoluted bulk tissue compared to nuclei, pinpointing synaptic and lysosomal signaling to excitatory neuronal cells (Figure 1E-F).
Conclusions: We introduce a computational approach using Cellformer to deconvolute bulk RNA sequencing data into cell-type-specific profiles, enabling in-depth analysis of bulk RNAseq. By comparing deconvoluted profiles between healthy and injured hippocampi, we unveil insights previously masked by the limitations of snRNA-seq, revealing intricate synaptic signaling dynamics.

EXPLORING ORGANELLE-SPECIFIC ROLES FOR PRESENILINS USING INTERACTOME PROFILING

POSTERS: A06.D. CELL, MOLECULAR AND SYSTEMS BIOLOGY: NETWORK BIOLOGY, CONNECTOME, PROTEIN-PROTEIN INTERATIONS

Céline Vrancx[1], Rosanne Wouters[1], Ragna Sannerud[1], Iván Ramos Calvo[1], Anika Perdok[1], Francis Impens[2], Wim Annaert[1]
[1]VIB KU Leuven Center for Brain & Disease Research, Laboratory For Membrane Trafficking, Leuven, Belgium, [2]VIB-UGent Center for Medical Biotechnology, Proteomics Expertise Core, Ghent, Belgium

Aims: Presenilins (PSEN) 1 and 2 act as the catalytic core of γ-secretase, playing a pivotal role in the onset and progression of Alzheimer's disease (AD). We previously demonstrated that, opposed to the broad localization of PSEN1/γ-secretase at the cell surface and in endosomes, PSEN2 is restricted to late endosomes/lysosomes (LE/Lys). Interestingly, the endolysosomal system has been recognized a central vulnerable mechanism in AD for decades, owing to its early defects and functionally related genetic risk variants. This project aims to unravel whether the homologue-specific subcellular localization reflects PSEN1- and PSEN2-specific functions in organellar homeostasis.
Methods: We generated cell lines expressing either GFP- or APEX2-tagged versions of PSEN with the aim to identify specific interactors hinting at functional roles in distinct organelles. This allowed us to combine two orthogonal interactomics methods, i.e. affinity purification with the GFP-tag and proximity-dependent biotinylation with the APEX2-tag. Identified hits were prioritized based on their functional relevance to organellar homeostasis and next validated for their interaction using biochemical approaches and super-resolution imaging.
Results: Although some common interactors were identified, we found the PSEN1 interactome being more enriched for cell surface localized proteins whereas PSEN2/γ-secretase interactors related more to endolysosomal functions, including lysosomal transport/motility and nutrient sensing. Using super-resolution imaging and functional assays, we confirmed that PSEN2 participates in lysosomal positioning in response to e.g. nutrient availability, with its deficiency impairing these two intrinsically connected molecular pathways.
Conclusions: Our observations specifically link PSEN2/γ-secretase to endolysosomal functioning, providing new starting points for a better understanding on the etiology of endolysosomal dysfunctions which appear at early, preclinical stages of AD.

SEX-LINKED TRANSCRIPTION FACTORS ZFX AND ZFY REGULATE MICROGLIAL EXPRESSION STATES AND DISEASE-RELATED GENES

POSTERS: A06.D. CELL, MOLECULAR AND SYSTEMS BIOLOGY: NETWORK BIOLOGY, CONNECTOME, PROTEIN-PROTEIN INTERATIONS

Logan Brase[1], Yanbo Yu[1], Oscar Harari[1], Bruno Benitez[2]
[1]Washington University in St. Louis, Psychiatry, St. Louis, United States of America, [2]Harvard Medical School and Beth Israel Deaconess Medical Center, Neurology, Boston, United States of America

Aims: Objectives: Microglia can exhibit different expression states in Alzheimer disease (AD). Using gene regulatory networks, we sought to determine the key regulatory elements for specific microglia states and how these regulatory differences could influence AD.
Methods: Methods: We ran pySCENIC 100 times for each of five unique microglia states in discovering and replicating single nucleus RNA-seq datasets to identify consensus transcription factors (TF) and their target genes. We accessed ChIP-seq data from ChIP-Atlas[1] and isolated the MACS2 binding scores for TFs *ZFX* and *ZFY* in the HepG2 cell line. We compared the binding affinity across all target genes and the transcriptome, then used Cook's Distance to identify genes deviating from the line of best fit.
Results: Results: We identified 78 TFs that replicated across all microglia states, including TFs unique to each resting, activated, *TREM2*-reduced activation, *MS4A*-proinflammatory, and necroptosis states. *ZFX* uniquely regulated the activated state, and *ZFY* the *MS4A*-proinflammatory. These are orthologous TFs on the sex chromosomes that encode zinc-finger proteins with known residue differences in 5 of the 13 zinc-finger domains[2]. We compared the binding affinity for *ZFX* and *ZFY* to the target genes identified by pySCENIC. In general, we observed a stronger affinity from *ZFY* than *ZFX* (slope = 1.08), including for *RALGAPB,* an autism-linked gene[3]. A transcriptome-wide version of this analysis identified the strongest binding affinity difference in *NPAS4,* a gene negatively associated with Tau Braak stage[4], regulated by *APP*[5], and responsible for regulating neuronal plasticity[6].
Conclusions: Conclusions: We discovered that *ZFX* and *ZFY*, two TFs on the sex chromosomes, regulate microglia states and disease-related genes, *RALGAPB* and *NPAS4*. These findings may have implications for sex differences and therapeutic strategies in AD.

PATHWAY TRACING: KNOWLEDGE GRAPHS FROM GENE LISTS

POSTERS: A06.D. CELL, MOLECULAR AND SYSTEMS BIOLOGY: NETWORK BIOLOGY, CONNECTOME, PROTEIN-PROTEIN INTERATIONS

Stephen Keegan[1], Gregory Cary[1], Jesse Wiley[2], Gregory Carter[1]
[1]The Jackson Laboratory, The Jackson Laboratory, Bar Harbor, United States of America, [2]Sage Bionetworks, Sage Bionetworks, Seattle, United States of America

Aims: The TaRget Enablement to Accelerate Therapy Development for AD (TREAT-AD) consortium is missioned to provide tools to the Alzheimer's research community for the discovery of novel therapeutics. Here we establish methods for developing knowledge graphs summarizing Alzheimer's disease (AD) endophenotypes.
Methods: The Pathway Commons Database contains information about biological pathway and interaction data. Using genes as nodes and the pathway and interaction data as edges, the topography of the network is established. A query gene list is used as input and the shortest path network reconstruction is the output. Data from the Accelerating Medicines Partnership® Program for Alzheimer's Disease (AMP-AD) is encoded into the knowledge graph as node and edge features. Filters, like cell type specificity, can be used to constrain the scope of the graph reconstruction.
Results: Analysis of genetic targets for AD is enhanced by constructing pathway interaction networks describing the relationships between genes. Using a reconstructed network as the basis for a suite of network analysis tools identifies relationships between genes and potential therapeutic targets. Networks derived from genes involved in the biological domains such as lipid metabolism, autophagy, and synapse are more informative than a random set of genes being traced.
Conclusions: Knowledge graphs derived from a list of genes are generated to enable network level understanding of the genes of interest. The relationships between genes that are annotated to a phenotype can be visualized and analyzed further as a network than they can in just a list form. Understanding the network effects of gene targets is imperative for identifying AD therapeutic targets.

ENRICHMENT OF SYNCHRONOUS GENES RELATED TO ALZHEIMER'S USING DUO

POSTERS: A06.D. CELL, MOLECULAR AND SYSTEMS BIOLOGY: NETWORK BIOLOGY, CONNECTOME, PROTEIN-PROTEIN INTERATIONS

Bryce Paubel, Olivia Biswas, Divine Akinjiyan, Sharlee Climer
University of Missouri-St. Louis, Computer Science, St. Louis, United States of America

Aims: WGCNA, weighted correlation network analysis, is a network analysis tool that is widely used to identify combinations of genes that appear to have correlated expressions in the presence of a given phenotype. However, its network model conflates high and low expression and the correlation metric utilized doesn't adapt to phenotype heterogeneity. Herein, we apply a robust network analysis tool, Duo, to analyze gene expression data in the context of late-onset Alzheimer disease (AD).
Methods: AD gene expression dataset GSE132903 was downloaded from GEO Omnibus and split into Discovery (58 cases and 49 controls) and Validation (39 cases and 39 controls) such that sex was evenly balanced. Duo generated a network with communities of inter-correlated genes and identified significant communities. Finally, these communities were tested on the unseen Validation data.
Results: We identified five statistically significant groups of highly synchronized genes. The cardinalities of these communities ranged from 2 to 23 genes and exhibited odds ratios of **0.17** [95%CI: 0.05,0.54], **15.56** [95%CI: 3.88,16.00], **7.86** [95%CI: 3.43,18.03], **4.11** [95%CI: 1.89,8.95], **12.11** [95%CI: 4.82,30.43] in the Discovery data and **0.21** [95%CI: 0.05,0.83], **3.18** [95%CI: 1.13,8.97], **4.02** [95%CI: 1.56,10.32], **3.20** [95%CI: 1.27,8.09], **5.26** [95%CI: 1.69,16.30] in the Validation data.
Conclusions: Two of the significant communities included genes with known AD associations. Community 3 with 23 nodes includes *TTBK1*, which is a kinase that phosphorylates tau. Additional interesting genes include *UBTD1*, which is involved in cellular senescence, and *MKNK2* and *CACTIN*, which are involved in stress response. Community 10 with 6 nodes includes both *PRKX* and *TNS1*, which have been previously associated with AD risk. These results reveal highly synchronous genetic patterns that are significantly associated with AD in both Discovery and Validation datasets.

NOVEL KLOTHO MOUSE MODELS TO EXAMINE PROTECTION AGAINST APOE4 RISK FOR ALZHEIMER'S DISEASE

POSTERS: A06.B. CELL, MOLECULAR AND SYSTEMS BIOLOGY: APOE

Mike Sasner[1], Christoph Preuss[1], Dylan Garceau[1], Kevin Kotredes[1], Ravi Shanker Pandey[2], Gregory Carter[1]
[1]THE JACKSON LABORATORY, The Jackson Laboratory, Bar Harbor, United States of America, [2]THE JACKSON LABORATORY, For Genomics Medicine, FARMINGTON, United States of America

Aims: Several large-scale genetic studies have identified a common haplotype of the aging factor *klotho* that modifies disease risk specifically in APOE4 carriers. In humans, *klotho* harbors two common missense variants (*rs9536314*, p.F352V; *rs9527025*, p.C370S) that define the *klotho* V/S (KL-V/S) haplotype, which is protective against LOAD in APOE4 carriers, and the *klotho* F/C (KL-F/C) haplotype, which is not. We sought to understand this genetic interaction using novel mouse models.
Methods: We replaced the native mouse haplotype with protective KL-V/S and common KL-F/C haplotypes. To validate the effects of these *klotho* haplotypes, soluble klotho serum levels of young mice were compared using ELISA. We also measured klotho in amyloidogenic *App*^{SAA} mutant mice. Transcriptomic analysis on brain hemispheres was performed at 4 and 12 months of age.
Results: Secreted klotho was decreased in KL-F/C mice harboring the novel mouse risk haplotype when compared to B6 controls and KL-V/S mice. In contrast, KL-V/S mice showed no significant differences in soluble klotho serum levels when compared to B6 controls. Secreted klotho levels in KL-V/S mice were significantly elevated when compared to the *App*^{SAA} mice, whereas KL-F/C mice showed similar levels to the aged *App*^{SAA} model. Transcriptomic analysis revealed significant differential gene expression between the homozygous klotho genotypes, particularly in genes involved in metabolic pathways and in genes associated with AD.
Conclusions: Taken together, these data suggest the native mouse *klotho* allele acts similarly to the protective KL-V/S haplotype, while the KL-F/C haplotype leads to lower secreted klotho and potentially greater disease risk. These models are therefore suitable to elucidate how *klotho* variants protect from LOAD pathologies and will enable detailed studies of how this protection is specific to the APOE4 genotype.

INTERACTION BETWEEN HIPPO PATHWAY ELEMENTS AND THE E3-LIGASE CHIP REGULATES A POTENTIAL MARKER OF ALZHEIMER`S DISEASE

POSTERS: A06.D. CELL, MOLECULAR AND SYSTEMS BIOLOGY: NETWORK BIOLOGY, CONNECTOME, PROTEIN-PROTEIN INTERATIONS

Melek Suluova, Kathryn Ball, Erisa Nita
The University of Edinburgh, Institute Of Genetics And Cancer, Edinburgh, United Kingdom

Aims: Aim: CHIP has a role in the ubiquitin-proteasome system to maintain cellular proteostasis in stress conditions. VGF is a neuronal precursor protein whose peptide-derivatives have various roles in the neuronal cells including energy homeostasis and synaptic plasticity. The transcriptional coactivator YAP1, a known CHIP substrate, that has a role in the regulation cell proliferation, tissue homeostasis and stem cell maintenance, was investigated as a potential link between CHIP and VGF which is 10X higher in CHIP KO neuroblastoma cells (our unpublished data).
Methods: Method: (1) Previously, CRISPR-Cas9 method was used to create CHIP KO neuroblastoma cell line. Then proteomic data of CHIP KO and WT neuroblastoma cells was obtained by SWATH-MS. VGF data was validated by immunoblot and IF. (2) YAP1 level and localization were assessed in both cell group. (3) RNAi method was used for YAP1 silencing, then analysis was done via immunoblot and IF. (4) Additionally, pathway analysis of upregulated and downregulated hits of the proteomics data plus YAP1 was applied.
Results: Result: (1) Based on proteomic data, CHIP KO neuroblastoma cells have 10X more VGF protein level than isogenic WT cells, validation was done by immunoblot and IF. (2) YAP1 expression and nuclear localization are higher in CHIP KO neuroblastoma cells. (3) YAP1 manipulation showed impact on the VGF expression in CHIP KO neuroblastoma cells. (4) Pathway analysis of proteomics hits plus YAP1 showed both VGF and YAP take role in organismal development pathways and stress response.
Conclusions: Conclusion: CHIP modified Hippo element YAP1 potentially can have role in VGF regulation. As VGF is an Alzheimer's disease biomarker, discovering new elements of its regulation mechanisms could support efforts to find new targets for the development of disease modifying drugs."

Aims: Methionine oxidation is a frequent occurrence in the ROS-rich brain, which can be reversed by methionine sulfoxide reductase (Msr). Since Msr is downregulated in AD patients and causes accumulation of methionine-oxidation, we believe that characterizing the methionine-oxidized proteome will provide clinically relevant information regarding AD pathogenesis.
Methods: The present research provides label-free methionine-oxidized proteome measurements of mouse hippocampus with a design including variables of: time (3, 6, and 9 months), genetic background (5XFAD vs. WT) and sex (male and female).LC-MS/MS was acquired by Waters NanoAcquity UPLC coupled to a Thermo Scientific™ Elite Orbitrap Elite™ mass spectrometer. Raw LC-MS/MS data was processed using Peaks, Scaffold and Protmap.
Results: We detected an age-dependent increase in global oxidation in both WT and 5XFAD mice, corroborating previous studies that found accumulation of oxidized proteins in healthy older adults. Additionally, 5XFAD mice show significantly higher expression of oxidized peptides at six and nine months, meaning that the oxidation burden is both age and disease dependent in this model. Enrichment pathway analysis revealed that glucose metabolism, recycling pathway of L1, and neurotransmitter release cycle are the main pathways involved in the AD-dependent oxidation as reflected by methionine sulfoxide profiling. While exploring our dataset of significantly expressed oxidized peptides, we found multiple proteins to be almost exclusively expressed in 5XFAD mice in oxidized forms. Using Protmap, we further validated which of these ox-peptides display a significantly higher oxidized fraction than all other proteins detected to be oxidized.
Conclusions: We have longitudinally characterized the methionine sulfoxide abundance and stoichiometry speciation in 5XFAD mice. Altogether, our characterization of 5XFAD's oxidized proteome provides insight on oxidation-impacted molecular mechanisms and identifies several methionine-oxidized proteins as a potential clinical target for antioxidant AD therapy.

Aims: The brain is complex and heterogeneous where cell function and cell-to-cell communication are critical for rapid and accurate performance. The ability to explore protein-driven activities at high resolution within the spatial context of their immediate environment is critical to gaining comprehensive pictures of brain development, activity, aging, disease or dysfunction, and inflammatory responses. Many existing approaches for high-plex single-cell spatial proteomics face issues around simplicity, speed, scalability, and big data analysis.
Methods: Here, we present an integrated workflow that addresses key concerns around high-plex proteomics. The CosMx™ Spatial Molecular Imager and AtoMx™ Spatial Informatics Platform comprise an end-to-end workflow that efficiently handles highly multiplex protein analysis at plex-sizes >68 targets. The CosMx protein assays use oligonucleotide-conjugated antibodies, that are detected using universal, multi-analyte CosMx readout reagents. The CosMx Mouse Neural Cell Typing and Alzheimer's Pathology panels, are optimized to comprehensively profile neural cell lineages across the brain as well as the progression of Alzheimer's disease.
Results: The CosMx protein assay reagents were validated on the FFPE adult mouse brain, mouse embryo, and Alzheimer's positive human brain. We used the CosMx protein panels with the CosMx SMI to identify multiple neuronal subtypes, reactive states of astrocytes and microglia, cell degeneration and proliferation. In a single-cell exploration of mitochondria, we noted distinct patterning of key immune targets based on their immediate microenvironment.
Conclusions: CosMx SMI is a high-plex spatial multi-omics platform that enables the detection of >68 proteins at subcellular resolution. In combination with the high-plex CosMx Mouse Neural Cell Typing and Alzheimer's Pathology panels, we present a robust solution for comprehensive neural and disease phenotyping that captures the complexity of neuronal and glial cellular activity with full spatial context.

Aims: It remains unclear whether serum metabolomic signatures can differentiate early accumulation of *in vivo* cerebral beta-amyloid (Aβ), a hallmark neuropathology of AD, before onset of dementia. We investigated serum metabolomic signatures of *in vivo* cerebral Aβ deposition in nondemented individuals using comprehensive metabolomic profiling.
Methods: We recruited nondemented older adults from the Korean Brain Aging Study of the Early Diagnosis and Prediction of Alzheimer's Disease. All participants underwent comprehensive clinical assessment and ^{11}C-PiB-PET, as well as the collection of serum samples from overnight fasting blood. Participants were classified into the Aβ positive (Aβ+) and Aβ negative (Aβ-) groups after quantification of brain regional PiB uptake. For comprehensive metabolomic profiling, we conducted global metabolomics using gas chromatography time-of-flight mass spectrometry and targeted metabolomics using the AbsoluteIDQ® p400 kit (BIOCRATES Life Science AG) with an ultra-high-performance liquid chromatography-quadrupole orbitrap mass spectrometry system.
Results: A total of 247 nondemented older adults were included in the final analysis. Among them, 102 individuals were classified into the Aβ+ group, and 145 individuals were in the Aβ- group. From global metabolomic profiling and targeted metabolomics, we first identified metabolite candidates that showed significant differences between the Aβ+ and Aβ- groups after multiple comparison corrections (FDR-corrected $p<0.05$). Then, we selected five metabolic biomarkers, including Methionine, Threonic acid, 1,3-Butaneiol, L-Phenylalanine and PC-O (25:0) by adjusting a VIP score in the PLS-DA model. The diagnostic accuracy of this metabolic panel to discriminate Aβ positivity among nondemented older adults was 84.2% (CI: 79.2%-89.1%).
Conclusions: Our comprehensive metabolomic profiling found differences in serum metabolic profiles between the Aβ+ and Aβ- groups in nondemented older adults, indicating the serum metabolic signature may reflect *in vivo* cerebral Aβ deposition in this population.

Aims: We generated a pipeline to analyze lipidomic data and the association with amyloid load, imaging and fluid biomarkers as well as cognitive measures in participants from Alzheimer's Disease Neuroimaging Initiative (ADNI).
Methods: We analyzed lipidomic data from ADNI which included targeted lipidomics and a metabolic panel based on nuclear magnetic resonance (NMR)including endogenous nanoparticles (eNP) composed of apolipoproteins. We determined the association of lipid dysregulation with amyloid load, imaging and fluid biomarkers including hippocampal volume and cognitive metrics including SPELL OUT (CDR-SB) AND MMSE (MMSE). Statistical models were built using linear regression and stratified by ApoE4 status (ApoE4+, harboring one or two ApoE4 alleles and ApoE4-, lacking the E4 allele). and diagnosis, including cognitively normal (CN), Mild Impairment Cognitive (MCI) and AD.
Results: In ApoE4+ individuals, several eNP, including low-density lipoprotein cholesterol ester (LDL-CE), increased with cortical amyloid burden in the temporal, parietal, and cingulate lobe regions. From targeted lipidomic data, both ApoE4+ and ApoE4-, were associated of sphingomyelin (SM) and phosphatidylethanolamine (PE). Several species of lysophosphatidylcholine (LPC) were associated with hippocampal volume, implicating changes in acyl chain remodeling. SM lipids were positively associated with CSF Abeta42 in AD+ participants and was negative associated with cognition in MCI+ participants.
Conclusions: Our findings indicate that eNP and the lipid content are associated with amyloid burden, hippocampal volume, and cognitive outcomes amongApoE4 carriers and non-carriers . Molecular mechanisms and potential for clinical intervention can be revealed by future research of the lipid signature and changes in endogenous nanoparticle content of biofluids.

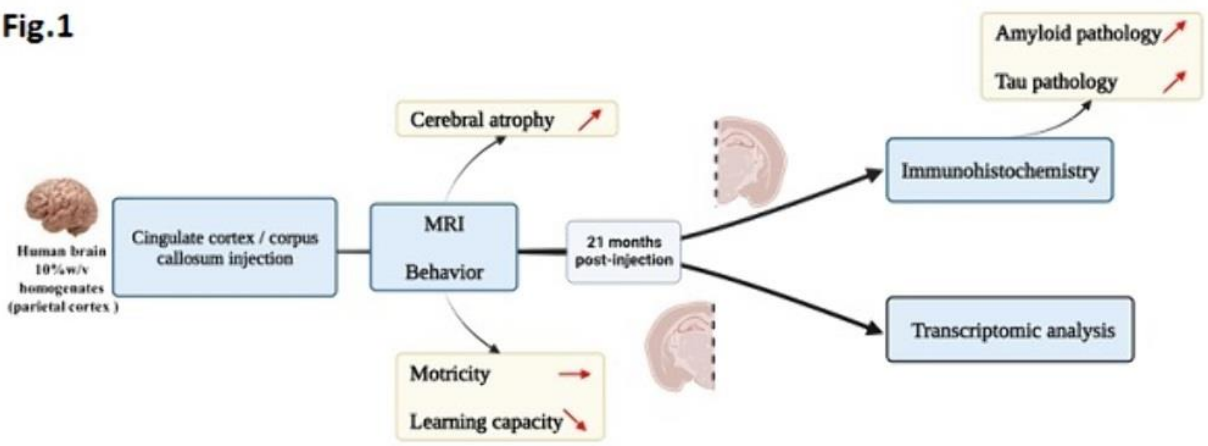
Aims: Transcriptomic approach is widely used to study changes of gene expressions in reaction to Alzheimer's Disease (AD) pathology. Most studies involve rodents but their transcriptomic profile is relatively different from humans during AD. In consequence, animal models closer of the humans are required. This work aims to study the impact of AD human brain inoculation on the transcriptomic expression of a primate model.
Methods: We induced β-amyloid (Aβ) and tau lesions in a primate (Microcebus murinus) following intracerebral inoculation of AD brain extracts (n=12)(Lam, Acta Neuropathol Com, 2021)(Fig.1). Animals inoculated with control brain extracts were used as controls (n=6). They did not display amyloid or tau lesions. Bulk transcriptomic expression was assessed by RT-qPCR 21 month after brain extracts inoculation (Fig.2). We focused on the hippocampus, entorhinal cortex, frontal cortex and caudate nucleus using selected genes for microglia (AIF1, TREM2, CD68, CX3CR1), complement (C3, C1QBP), astrocytes (GFAP, Vimentin), oligodendrocytes (Sox10, MBP, PLP, APC, PDGFR-alpha) and neurons (Bassoon, Synaptophysin, Scl17a7, Homer1, Gria1 and Dlg4).

Fig.1



Results: Mann-Whitney statistical test revealed an up-expression of MBP, GFAP and Vimentin in the entorhinal cortex in AD animals (this region displayed only tau pathology) compared to controls. Analysis

of frontal cortex (that displayed only Aβ pathology) showed a down-expression of AIF1 and an up-expression of CD68 and Gria1 in AD animals compared to control. Analysis in hippocampus (that displayed both tau and Aβ) revealed a down-expression of AIF1 and an up-expression of Bassoon in AD animals compared to control.

Aims: Unbiased data-driven omic approaches are revealing the molecular heterogeneity of Alzheimer disease (AD). It has been hypothesized that by combining multiple signals from various molecules, novel significant biological pathway changes in AD will emerge that are otherwise missed with single-omic analyses. We sought to investigate whether multi-omics integration of AD brains can provide novel molecular insights into AD progression and identify potential biomarkers for synaptic dysfunction, cognition, and AD staging.
Methods: We leveraged machine learning approaches to integrate high-throughput transcriptomic, proteomic, metabolomic, and lipidomic profiles with clinical and neuropathological data from multiple AD cohorts and brain regions to identify cross-omics molecular profiles of AD, genes and pathways affected at multiple stages of AD. These profiles were then integrated with data from established mouse models of neurodegeneration to clarify the role of genes and pathways altered in these profiles in AD pathophysiology.
Results: We discovered four unique multimodal molecular profiles, one showing signs of poor cognitive function, a faster pace of disease progression, shorter survival with the disease, severe neurodegeneration and astrogliosis, and reduced levels of metabolomic profiles. This profile shows similar cellular and molecular profiles in multiple affected cortical regions associated with higher Braak tau scores and significant dysregulation of synapse-related genes and pathways altered in AD early and late stages. To monitor AD progression, the multimodal clusters uncovered cerebrospinal fluid synaptic biomarkers, including *IGF1*, *NRXN3*, and *YWHAZ*, which can be employed for early detection of synaptic dysfunction, cognition, and AD staging. Integrating AD multi-omics profiles with A53T aSyn-APOE transgenic mice transcriptomic data revealed an overlapping signature.
Conclusions: Multi-omics analyses capture molecular heterogeneity among AD cases and provide novel critical molecular insights into AD that are typically missed with single-modality omics approaches.

PSEUDO-TEMPORAL MODELS OF ALZHEIMER'S DISEASE ACROSS BRAIN-DERIVED TRANSCRIPTOMICS AND PROTEOMICS REVEAL UNIQUE INSIGHTS INTO EARLY MOLECULAR CHANGES LEADING TO DISEASE

POSTERS: A06.E. CELL, MOLECULAR AND SYSTEMS BIOLOGY: METABOLOMICS, TRANSCRIPTOMICS, LIPIDOMICS, PROTEOMICS

Laura Heath[1], Gregory Cary[2], Jesse Wiley[1], William Poehlman[1], Abby Vander Linden[1], Gregory Carter[2], Anna Greenwood[1]
[1]Sage Bionetworks, Sage Bionetworks, Seattle, United States of America, [2]The Jackson Laboratory, The Jackson Laboratory, Bar Harbor, United States of America

Aims: We applied pseudotemporal models to brain-derived transcriptomics and proteomics data from an AD case-control study to better understand the ordering and nature of the earliest molecular changes in the brain.
Methods: Manifold learning algorithms 'order' samples based on similarity of expression patterns, and then place each sample across a 'trajectory' of disease progression. We applied this approach to transcriptomic (N=1078) and TMT-proteomic (N=602) data from human postmortem brain samples from the ROS/MAP study within the Accelerating Medicine Partnership-AD consortia (AMP-AD). Analyses were stratified by sex, which resulted in four lineages, each of which successfully recapitulated disease and neuropathological endpoints. We calculated differential expression (DE) within 'states' along each trajectory. We used gene set enrichment analyses to identify significant GO terms changing along the trajectories and grouped them into 19 AD-relevant biological domains. We compared state-specific DE to case-control analyses of DE.
Results: We identified up- and down-regulated pathways involved in biodomains encompassing immune response, synaptic function, lipid metabolism, and other realms, in sex-stratified AD case-control analyses. We then tracked them state-by-state along the lineages and identified early 'transition' states at which biodomain regulation began to resemble the case-control analysis. In these transition states, we also observed significant changes in other biodomains that were not identified in the case-control analysis. Major pathways were largely conserved between males and females.
Conclusions: Pseudotemporal modelling provided unique insights into the ordering of molecular changes leading to AD, and potentially uncovered new genes and pathways implicated in early-stage disease processes. While most major pathways were conserved between sexes, more subtle differences, especially those noted early in disease trajectories, may provide crucial insights into key processes driving disease in women and men.

THE NEUTROPHIL LANDSCAPE OF COGNITIVE IMPAIRMENT IN ALZHEIMER'S DISEASE

POSTERS: A06.E. CELL, MOLECULAR AND SYSTEMS BIOLOGY: METABOLOMICS, TRANSCRIPTOMICS, LIPIDOMICS, PROTEOMICS

Kilian Kleemann[1,2], Neta Rosenzweig[2], Madeline Grucci[3], Hyun-Sik Yang[3], Reisa Sperling[3], Oleg Butovsky[2]
[1]Bonn University Hospital, Institute Of Clinical Chemistry And Clinical Pharmacology, Bonn, Germany, [2]Brigham and Women's Hospital, Harvard Medical School, Neurology, Boston, United States of America, [3]Massachusetts General Hospital, Harvard Medical School, Department Of Neurology, Boston, United States of America

Aims: Neutrophils were shown to play a negative role in Alzheimer Disease (AD) mice and their depletion improved cognitive functions. In AD patients, increased neutrophil-to-lymphocytes ratio was observed. Here we aimed to dissect the neutrophil transcriptomic signature associated with cognitive impairment in AD relative to sex, age and APOE-genotype.
Methods: We utilized a balanced cohort (totalling 160 samples) of male and female patients with AD or mild cognitive impairment (MCI) across APOE genotypes. Age-matched cognitively unimpaired individuals, were analyzed as healthy controls (HC). Top differentially expressed genes were identified, and the core neutrophil signature associated with MCI/AD, adjusted for covariates, was investigated using supervised machine learning (Random-Forest-Classifier). Validation was performed on public bulk-RNAseq of blood samples from 422 patients. Bulk-RNAseq profiles were screened using immune-cell-type deconvolution. Gene-regulatory-network, upstream-regulator and custom gene-set enrichment analysis were implemented to decipher underlying neutrophil changes according to patient subgroup.
Results: We identify strong sex-dependent neutrophil gene signature changes during cognitive impairment. While neutrophils from both sexes were enriched for TGFb-signaling during MCI/AD, only female samples upregulated gene expression modules associated with IL-1 and IL-17. Utilizing neutrophil expression profile and machine learning approaches, we identified top molecular perdictors of cognitive impairment, which are enriched in carriers for the strongest AD risk gene; APOE4, and to a greater extent in female APOE4 carriers.
Conclusions: The core transcriptional signature of neutrophils associated with cognitive impairment, was predominantly sex-dependent and to a lesser extent APOE4 driven. We identify targets for therapeutic intervation, as well as molecular biomarkers of the transition to cognitive imapirment and dementia. This may result in precise therapeutic interventions for AD according to sex and APOE4 genotype, providing an alternative strategy for an unmet clinical need.

CHARACTERIZING THE MOLECULAR MECHANISMS IN THE HUMAN AMYLOID PLAQUE NICHE USING SPATIAL TRANSCRIPTOMICS

POSTERS: A06.E. CELL, MOLECULAR AND SYSTEMS BIOLOGY: METABOLOMICS, TRANSCRIPTOMICS, LIPIDOMICS, PROTEOMICS

Hans-Ulrich Klein, Berke Karaahmet, Laurine Duquesne, Ya Zhang, Alina Sigalov, Christina Yung, Alexandra Kroshilina, Mariko Taga
Columbia University Irving Medical Center, Neurology, New York, United States of America

Aims: Glial cells exhibit distinct transcriptional responses to β-amyloid. Single-nucleus RNA-sequencing studies have carefully characterized glial cell subpopulations in the human Alzheimer's disease (AD) brain and described their association with AD pathology burden. However, without spatial information, the multicellular response at amyloid plaques remains largely unknown. Here, we combined spatial transcriptomics (ST) with immunohistochemistry to explore the molecular mechanisms in the amyloid plaque niche.
Methods: A total of 32 sections from the prefrontal cortices of 15 AD and 2 control cases were applied to ST arrays with spatially barcoded probes (spots) of 55 µm diameter. Each of the 59,588 tissue-covered spots in our dataset detected a median of 2,202 genes and included a median of 4 nuclei. Amyloid plaques in the same tissue sections were stained with Thioflavin S and then projected onto the ST profiles.
Results: Clustering the spots reconstructed the cortical layer structure. We detected 263 amyloid plaques, and spots within 150 µm of plaques were compared to distant spots (>500 µm), adjusted for cortical layer and donor. This approach confirmed plaque-associated genes reported in mice, including *GFAP*, *CLU*, *MBP* and *MOBP*. Interestingly, the two AD risk genes *RBFOX1* and *SERPINA3* were upregulated at plaques. *SERPINA3* is a marker of an inflammatory astroglial subpopulation (Ast_5). Indeed, computationally predicting the Ast_5 locations from the ST data confirmed an enrichment at plaques. Further, we found a downregulation of metallothioneins, expressed by astrocytes, indicating a potential dysfunction of zinc ion homeostasis.
Conclusions: Our unbiased approach revealed 182 plaque-associated genes, enhancing our understanding of the molecular mechanisms within the amyloid plaque environment. Many of these genes are transcribed by astrocytes and oligodendrocytes and point towards inflammatory processes and ion transport and homeostasis.

INVESTIGATING ABCA7-MEDIATED PHENOTYPES IN A HUMANIZED, LATE-ONSET ALZHEIMER'S DISEASE MOUSE MODEL

POSTERS: A06.E. CELL, MOLECULAR AND SYSTEMS BIOLOGY: METABOLOMICS, TRANSCRIPTOMICS, LIPIDOMICS, PROTEOMICS

Kevin Kotredes[1], Adrian Oblak[2], Ravi Shanker Pandey[3], Paul Territo[4], Mike Sasner[1], Gregory Carter[1], Bruce Lamb[5], Gareth Howell[1]
[1]THE JACKSON LABORATORY, The Jackson Laboratory, Bar Harbor, United States of America, [2]Indiana University School of Medicine, Stark Neurosciences Research Institute, Indianapolis, United States of America, [3]THE JACKSON LABORATORY, For Genomics Medicine, FARMINGTON, United States of America, [4]Indiana University School of Medicine, Medicine, Indianapolis, United States of America, [5]Indiana University School of Medicine, Stark Neuroscience Research Institute, Indianapolis, United States of America

Aims: The Model Organism Development and Evaluation for Late-onset AD (MODEL-AD) Center aims to develop, validate, and distribute novel mouse models of late-onset Alzheimer's disease (LOAD). Accordingly, risk factors associated with the etiology of LOAD were identified and expressed in a novel mouse model to investigate their impact on aging phenotypes and AD progression. Genetic studies have demonstrated that a locus containing the ATP binding cassette subfamily A member 7 (*ABCA7*) gene is correlated with increasing risk for AD. Here, we investigated the effects of the *Abca7*A1527G* humanized risk allele on LOAD phenotypes and biomarkers to better align the biology of mouse models with those observed in human disease.
Methods: Two genetic risk factors of LOAD were incorporated into C57BL/6J mice along with humanized amyloid-beta to produce the 'LOAD2' (B6.*APOE4.Trem2*R47H*.hAbeta) baseline strain. To investigate the impact of the *ABCA7*A1527G* risk factor, littermate carrier (LOAD2. Abca7*A1527G) and non-carrier (LOAD2) mice were extensively aged and an animal phenotyping pipeline was employed to correlate outcomes with phenotypes observed in human patients, including i*n vivo* PET/CT imaging and behavior assays. Post-mortem analyses of blood and brain tissue for risk-factor-related alterations in neuropathology, transcriptomics, metabolomics, and proteomics were performed.
Results: Mice expressing *Abca7*A1527G* revealed individual and synergistic transcriptional effects with genetic risk factors correlated with human AMP-AD modules. LOAD2.*Abca7*A1527G* mice showed an uncoupling of brain glycolysis and regional perfusion. Neuropathology analysis in brain tissue is in progress, as are cytokine panels in brain homogenates and plasma. Further transcriptomic, neuropathological, and histological analyses are currently underway.
Conclusions: Initial characterization of aged mice expressing genetic risk factors of LOAD indicates that *Abca7*A1527G* expression increases susceptibility to disease through interactions between cerebrovasculature, microglia and peripheral immune cells.

Aims: Late-onset Alzheimer's disease (LOAD) comprises more than 95% of all AD cases. Legacy transgenic, overexpression animal models do not effectively produce the heterogeneity observed clinically in LOAD patients and thus are not appropriate subjects for preclinical therapeutic development. We therefore generated and investigated novel LOAD mouse strains designed to better phenocopy the heterogeneity of human disease and reveal more appropriate molecular targets for treatment. Results from the Alzheimer's Disease Neuroimaging Initiative (ADNI) revealed that alterations in *MTHFR* expression produce changes in brain volume, white matter, and vascular inflammation. Understanding the effects of the *MTHFR*C677T* allele expression in mouse strains subjected to additional LOAD risk alleles will inform biomarker discovery and potential clinical therapeutics.
Methods: Mice expressing *Mthfr*C677T*, on a humanized *App*, *APOEe4*, and *Trem2*R47H* background, were assessed over multiple ages for indications of disease. Regular behavior measurements and biometric samples were collected longitudinally to 24 months. Upon endpoints blood and brain tissue was collected for transcriptomic, proteomics, and neuropathological, correlation and analyses.
Results: Initial studies in an aged mouse model with a LOAD-relevant genetic background showed that *Mthfr*C677T* produced a transcriptional signature in the brain more similar to those seen in human AD patients, supporting observations from public datasets. The enzymatic activity of MTHFR*C677T is known to be diminished, preventing homocysteine conversion, increasing blood homocysteine levels, and inducing vascular inflammation. Neuropathological and transcriptomic analysis of advanced age cohorts is underway along with more detailed, CNS-specific characterization of the many aspects of MTHFR function.
Conclusions: We observed strong correlations to human disease transcripts in AMP-AD expression modules with the expression of *Mthfr*C677T*. Here we show the evidence of emerging disease pathology in a novel LOAD2.*Mthfr*C677T* mouse strain.

Aims: Lipidomic data from autopsy brain, human plasma and animal models shows severe lipid dyshomeostasis in AD, thus, indicating a crucial role of the lipids in the development of Alzheimer's pathology. Previous studies have shown that the loss of polyunsaturated fatty acids among multiple phospholipid classes is common in AD affected human brain and mouse models.
Methods: We employ untargeted Desorption Electrospray Ionization (DESI) Imaging Mass Spectrometry to investigate spatial profiling of lipids between normal-aging and AD-affected mouse brains across various ages (6, 12 and 22 months old). Using PYTHON and R-studio, we developed a new pipeline to process spatially acquired data of several thousand precursor ions of lipids and to perform statistical analysis to determine the differential content of lipids among specific anatomical regions.
Results: By using Mass Spectrometry and applying appropriate lipid standards we show for the first time that specific lipid species including sphingomyelins, phospholipids and polyunsaturated fatty acids, such as docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA) are highly enriched in the globus pallidus region of AD-affected mouse brains compared to wild type brain. This phenomenon is observed prior to amyloid plaque accumulation and behavioral deficits.
Conclusions: Untargeted DESI Imaging Mass Spectrometry facilitates spatial profiling of thousands of lipids in mouse brain. Our newly developed pipeline fosters comprehensive statistical analysis to compare specific regional lipid alterations and to discover lipids that are relevant to AD etiology and disease progression. The pipeline also facilitates distribution pattern recognition allowing spatial cluster analysis to identify lipids with similar regional distribution and changes due to genetic disposition and age. Ultimately, discovery of new differentially expressed lipids will lead to identification of new lipid-based biomarkers and mechanistic changes in lipid metabolism relevant to disease.

COMPUTATIONAL ANALYSIS OF SNRNA-SEQ DATA OF TBK1E696K MICE TO DISCOVER THE AGE-GENOTYPE IMPACT ON THE PROGRESSION OF AMYOTROPHIC LATERAL SCLEROSIS

POSTERS: A06.E. CELL, MOLECULAR AND SYSTEMS BIOLOGY: METABOLOMICS, TRANSCRIPTOMICS, LIPIDOMICS, PROTEOMICS

Babak Loghmani[1], Volker Ast[2], David Brenner[1,2], Rüstem Yilmaz[1], Angelika Duda[3], Rosanna Parlato[1], Jochen Weishaupt[1]
[1]Medical Faculty Mannheim, University Clinic Mannheim, Division Of Neurodegeneration, Mannheim, Germany, [2]Ulm University Medical Faculty, Neurology, Ulm, Germany, [3]University Medicine Mannheim, Clinical Chemistry, Mannheim, Germany

Aims: Mutations in the pleiotropic TANK1-binding kinase 1 (*TBK1*) are responsible for the onset of Amyotrophic Lateral Sclerosis (ALS), a lethal neurodegenerative disease. Specifically, the missense mutation p.E696K distinctly disrupts the TBK1 protein's interaction with the autophagy adaptor optineurin. We developed knock-in mice, referred to as *Tbk1*^{E696K}, which carry the p.E696K mutation. This mutation results in a hindrance of the autophagic process. In this study, we conducted a comprehensive computational analysis in two dimensions, namely age and genotype, using single-nuclei RNA sequencing, to understand the individual and combinatorial (age-associated) effect of the p.E696K homozygous mutation in the mouse spinal cord, mostly affected in ALS.
Methods: We compared the single-nuclei transcriptomics of wild-type and Tbk1^{E696K} knock-in mice in the spinal cord. The data were analysed at two levels: 1) single-nuclei and 2) pseudo-bulk. Moreover, multiple pathway analysis algorithms based on various databases were applied to identify the impact of the p.E696K mutation in specific cell-types at different ages (6 and 19 months), also corresponding to different disease stages.
Results: We found that age has a greater impact on the gene expression profile compared to genotype, and the effects caused by genotype (namely, by the p.E696K mutation), to some extent mimic the aging process. This finding is reflected for example by the number and the identity of differentially expressed genes, the dysregulated pathways, and cell type-specific dysregulated genes (e.g. in microglia)
Conclusions: The results suggested that the progression of TBK1-ALS has similarities with preponed or accelerated aging at the gene expression level, even at the early presymptomatic stages (6 months). Moreover, changes in cell-subtype identity can be used to dissect the hallmarks of the disease based on differentially expressed genes.

ASSOCIATION BETWEEN PLASMA PROTEOMICS AND DEMENTIA NEUROPATHOLOGY AT AUTOPSY

POSTERS: A06.E. CELL, MOLECULAR AND SYSTEMS BIOLOGY: METABOLOMICS, TRANSCRIPTOMICS, LIPIDOMICS, PROTEOMICS

Minerva Martinez-Castillo[1], Pamela Martino-Adami[2], Alberto Rábano[1], Alfredo Ramirez[2,3,4,5,6], Pascual Sanchez-Juan[1]
[1]Alzheimer's Centre Reina Sofia-CIEN Foundation-ISCIII, Cien Foundation, Madrid, Spain, [2]University Hospital Cologne, Psychiatry And Psychotherapy, Cologne, Germany, [3]German Center for Neurodegenerative Diseases (DZNE), Psychiatry, Bonn, Germany, [4]University of Cologne, Cluster Of Excellence Cellular Stress Responses In Aging-associated Diseases (cecad), Cologne, Germany, [5]Glenn Biggs Institute for Alzheimer's and Neurodegenerative Diseases, Psychiatry, San Antonio, United States of America, [6]University Hospital Bonn, Neurodegenerative Diseases And Geriatric Psychiatry, Bonn, Germany

Aims: Determine neuropathological correlates of ante-mortem plasma proteins in demented patients.
Methods: Plasma levels of ~2000 proteins from Centro Alzheimer-Fundación Reina Sofía ante-mortem samples (N=133) were quantified using Olink®Explore 3072 and passed the quality control. Patients were all demented (Alzheimer's disease [AD], N=103; vascular dementia, N=14; dementia with Lewy bodies, N=12; frontotemporal dementia, N=2; hippocampal sclerosis, N=1; tauopathy, N=1), had an average disease duration of 12 years, and were classified into the different AD neuropathologic change (ADNC) scores. Association between brain weight and plasma protein levels was evaluated using a linear model adjusted for age and sex, and correlation between brain weight and plasma protein levels in each ADNC score using correlational clustering. Protein–protein association networks were identified using STRING database.
Results: Linear regression analysis identified 290 proteins significantly associated with brain weight (corrected *p*-value, $q<0.05$). Next, correlation between significant protein levels with brain weight in each ADNC score group was calculated. Clustering of these correlation profiles showed that ADNC scores 1 (low-AD probability) and 3 (high-AD probability) were clustered together. To understand the similarity, proteins were classified considering the direction of their correlation coefficient in each ADNC score group. Group of 130 proteins was the only one where the direction of the relationship in ADNC score 2 was different from the others, it was selected for gene ontology enrichment analysis. Protein-protein network analysis revealed the top associated biological processes, including ESCRT-III complex disassembly ($q=2.3\text{x}10^{-3}$), and extracellular matrix assembly regulation ($q=0.02$).
Conclusions: Mixed forms of AD (ADNC score 2) may exhibit a different proteomic profile compared to non-AD dementias (ADNC score 1) and the purer forms of AD (ADNC score 3) that could be related to changes in biological processes involving the extracellular matrix.

Aims: Objective: Emerging studies from lipidomic and genetic data have repeatedly identified lipid metabolism as a major driver of etiology and progression of Alzheimer's disease. However, a system-wide understanding of the consequences of lipid dysregulation has not yet been addressed.
Methods: Using a candidate based genetic screen, we identified a network of genes involved in lipid metabolism which prevented synapse loss triggered by β-amyloid peptide (Aβ) suggesting coordination of lipid levels in response to Aβ challenge. We interrogated the disease associated changes in lipid metabolism from multiple data sets including the Religious Order Study, Memory Aging Project (ROS-MAP) and the Alzheimer's Disease Neuroimaging Initiative (ADNI). Finally, using Nuclear Magnetic Resonance (NMR), circular dichroism and novel lipid binding assays, we identified specific lipid binding activity of Aβ.
Results: We found that deficits in acyl chain remodeling were able to model changes we found in lipidomic studies from human brain and endogenous nanoparticles (eNP) isolated from cerebral spinal fluid (CSF). Further, we found associations among characteristic clinical outcomes and fluid biomarkers with specific eNP identified by the Nightingale platform based on NMR detection of metabolites and apolipoproteins in ADNI. The composition of eNP is enriched in phospholipids containing polyunsaturated fatty acyl chains which we show bind Aβ directly and affect oxidation as well as aggregation of the peptide supporting a critical functional role.
Conclusions: We have identified acyl chain remodeling as a driver of lipid dyshomeostasis in AD progression. Further, we report specific functional consequences of Aβ binding to phospholipids harboring polyunsaturated acyl chains. Our studies support the specificity, necessity and sufficiency of polyunsaturated lipids for driving Aβ eNP formation and function.

Aims: Alzheimer's disease (AD) is a complex, multifactorial pathology with high heterogeneity in biological alterations. Our understanding of cellular and molecular mechanisms from disease risk variants to various phenotypes is still limited. Therefore, it is required to integrate the information from multiple data modalities for thorough exploration of endophenotype networks, biological interactions related to disease and thus accelerate our understanding of heterogeneity in Alzheimer's disease.
Methods: We performed multi-level omics in a cohort of mouse models expressing humanized Abeta and two genetic risk factors (APOE4 and Trem2*R47H), termed as LOAD2, and mice harboring additional risk variants *Abca7*A1527G* and *Mthfr*677C>T* on to LOAD2 background at multiple ages for both sexes. Data from multiple omics platforms were integrated in an unbiased fashion, considering interaction between modalities using bioinformatics approaches. We also systematically aligned multimodal mouse data to relevant human studies cohort.
Results: Multi-omics integration identified major components of heterogeneity explaining the variance within the cohort and differentially associated with age, sex, and genotype. Enrichment analysis of genes and protein associated with these components were significantly enriched for multiple AD-related processes. Multi-omics profiling showed expression changes that are similar to those observed in human AD. In addition, we observed weak correspondence between change in protein and RNA expression in mouse models compared to controls, similar to recent results from the ROSMAP cohort, which reported weak correlation between protein and RNA expression.
Conclusions: We identified axes of variation within a cohort of LOAD mouse models using integrative multi-omics approach. Our analysis revealed interaction between distinct multi-omics molecular signatures associated with Alzheimer's disease. This study highlighted that assembling multi-omics measurements reveal interrelated pathway alterations in AD and the ability to identify biomarkers combinations that may inform clinical practice.

Aims: Alzheimer disease (AD) is an heterogeneous and complex disease with different pathophysiological mechanisms involved, which could trigger in AD clinical subtypes. AD subtypes have been described according to atrophy patterns, CSF biomarkers, symptoms evolution. Regarding biochemical pathways, lipid metabolism plays an important role in AD, so the lipid levels have been evaluated as potential AD diagnosis biomarkers, and their levels could be studied to define AD subtypes. Therefore, the aim of this work is to describe AD subtypes according to the lipid profile in plasma samples from early AD patients and to evaluate the clinical significance of these subtypes.
Methods: Untargeted plasma lipidomic analysis was carried out in early AD patients (n = 31) diagnosed by CSF biomarkers (amyloid β42, total Tau, phosphorylated Tau). Then, an unsupervised cluster analysis was carried out to define early AD subgroups according to plasma lipid levels. After that, the clinical significance of each lipid profile subgroup was studied analysing differences for clinical variables (cognitive status, CSF biomarkers, medication, comorbidities, age, gender). In addition, a progression substudy (n=14) was carried out analysing the evolution in cognitive status in each subgroup.
Results: These AD patients were divided into 2 groups. Group 1 showed higher levels of plasma lipids and better cognitive status (neuropsychological tests RBANS.DM, CDR sum of boxes, and MMSE) than Group 2. However, not differences were found for other variables (age, gender, medication, comorbidities, cholesterol, triglycerides levels) between both groups. In addition, a substudy showed a trend to a slower decline along time in group 1.
Conclusions: Plasma lipid levels could differentiate two early AD subgroups, which showed different cognitive status and a trend to differential progression. However further research with a large cohort is required.

[1]NIH, Center For Alzheimer's And Related Dementias (card), Bethesda, United States of America, [2]Data Tecnica International, Data Science, Washington DC, United States of America, [3]The Jackson Laboratory for Genomic Medicine, The Jackson Laboratory For Genomic Medicine, Farmington, United States of America, [4]National Institute on Aging and National Institute of Neurological Disorders and Stroke, National Institutes of Health, Center For Alzheimer's And Related Dementias, Bethesda, United States of America, [5]National Institutes of Health, Molecular Genetics Unit, Laboratory Of Neurogenetics, Center For Alzheimer's And Related Dementias, Bethesda, United States of America, [6]NIH, Lab Of Neurogenetics, National Institute On Aging, Bethesda, United States of America, [7]NIH, National Institute Of Neurological Disorders And Stroke, Bethesda, United States of America

Aims: The growing scale of genetic studies has led to the identification of many genetic variants that contribute to risk for developing Alzheimer's Disease and Related Dementias (ADRDs), but how these variants contribute to disease risk remains poorly understood. The iPSC Neurodegenerative Disease Initiative (iNDI) is the largest-ever induced pluripotent stem cell (iPSC) genome engineering project, modeling over 100 ADRD mutations in high-quality isogenic human iPSCs. iNDI will generate foundational iPSC tools and datasets to study fundamental mechanisms of ADRDs and identify new therapeutic targets.
Methods: Phase 1: A parental iPSC line was selected based on growth characteristics, pluripotency, p53 pathway integrity, genetic risk, genomic integrity, and differentiation potential. All mutant lines are generated by the Jackson Laboratory (JAX) by CRISPR editing in the parental iPSC line. Phase 2: We characterize the downstream effects of ADRD mutations on iPSC-derived neuron biology using multi-omic readouts.
Results: To-date, iNDI has generated 107 cell lines modeling 37 ADRD-relevant mutations. 270 labs worldwide have requested iNDI lines, and 2 manuscripts utilizing iNDI cell lines have already been published. We recently completed pilot experiments demonstrating the iNDI phase 2 workflow, from highly paralleled iPSC thawing, culturing, expansion, and differentiation of a subset of iNDI mutant iPSC lines into cortical-like neurons. We now begin to explore multi-omic datasets of ADRD mutant iPSC-derived neurons to help understand proximate transcriptome and proteome phenotypes associated with ADRD mutations. We are now actively developing custom automated cell culture robotics for future large-scale experiments.
Conclusions: iNDI is the largest-ever iPSC genome engineering project and has distributed isogenic ADRD-relevant mutant iPSCs to labs worldwide. The resultant iPSC tools and datasets will be foundational for the study of ADRDs, and all datasets generated will be freely available.

Aims: Alzheimer's disease (AD) is a neurodegenerative disorder with an increasing incidence worldwide. There are currently no treatments to cure or effectively slow the progression of AD. To address this, patient-derived cell models of AD that co-relate with early clinical features observed in AD could be valuable to gain a better understanding of the disease and develop new treatments. Impaired olfaction is one of the earliest symptoms and a significant predictor of conversion to AD from mild cognitive impairment (MCI), a prodromal AD condition. Found deep within the naris, olfactory stem cells provide a window into the brain. Their inherent ability to form neuroglia makes these cells potentially an ideal model system to examine the early pathophysiological changes that take place in AD.
Methods: Human olfactory neurosphere-derived (ONS) cell lines were generated using olfactory mucosal biopsies from age-, gender- and ApoE genotype-matched cognitively healthy individuals (HC), patients with AD, and individuals with MCI (*n*=6 for each group). Omics analyses were performed to identify global gene and protein changes and associated pathways between HC, MCI and AD ONS cells, and to discover potential disease biomarkers.
Results: Transcriptomic results revealed several differentially expressed genes associated with cognitive changes, *AKAP6* being the most significantly altered. Proteomics analysis highlighted especially differentially expressed proteins, such as NDUFS4 and ENO1, and disease pathways associated with altered cell metabolism and mitochondrial function in AD ONS cells compared to MCI and HC.
Conclusions: This study demonstrated the potential of patient-derived ONS cells to provide a cell-based model for AD biomarker discovery. It revealed potential novel genes, proteins, and disease pathways that may have a role in AD, especially MCI to AD transition, and should be further examined.

Aims: Pathological hallmarks of Parkinson's Disease (PD) are degeneration of dopaminergic neurons (DANs) in the substantia nigra (SN) and intraneuronal α-Synuclein inclusions known as Lewy bodies. DANs can be categorized into distinct subpopulations based on location, physiological functions and expression profiles. Over 60% of nigral DANs express Aldehyde Hydrogenase 1A1 (ALDH1A1). This subpopulation has been identified as selectively vulnerable in post-mortem PD tissue and is over-represented in pathways underpinning vulnerability in PD models. Other findings suggest more complex mechanisms of vulnerability that, during pathological processes, may include changes in neuronal phenotypic and expression profiles. In this study, distribution and transcriptome of midbrain ALDH1A1+ and ALDH1A1- DANs were elucidated in an animal model of α-Synuclein pathology.
Methods: Mice received intra-nigral injections of AAV-expressing human-α-Synuclein (SNCA) or GFP. Brain slices were collected 3- and 8-weeks post-injection. Neuroanatomical regions were delineated and DAN subtypes were identified using immunofluorescence. Spatially-resolved transcriptomics was performed on midbrain ALDH1A1+ and ALDH1A1- DANs using NanoString's GeoMx Digital Spatial Profiler. Bioinformatics [e.g., clustering, differential expression, enrichment analyses] was performed in R.
Results: Increased midbrain SNCA expression was accompanied by diffuse α-Synuclein pathology at both timepoints. Significant DAN loss was observed in the SN at 8 weeks but not in the ventral tegmental area (VTA). Cell counting did not detect overt differences in vulnerability between ALDH1A1+ and ALDH1A1- neurons. Differential expression analysis identified distinct transcriptomic signatures of ALDH1A1+/- subtypes at early and late timepoints and indicated that α-Synuclein pathology may reduce transcriptional differences over time. Enrichment analysis identified critical pathways associated with each subtype [e.g., synaptic transmission, calcium transport], underscoring the functional impact of α-Synuclein pathology.
Conclusions: Development of α-Synuclein pathology significantly affects expression profiles of midbrain dopaminergic subpopulations, likely bearing important functional consequences.

Sergievsky Center, College Of Physicians And Surgeons, New York, United States of America, [4]Pontificia Universidad Catolica Madre y Maestra Santiago, School Of Medicine, Santiago, Dominican Republic, [5]CEDIMAT, Department Of Neurosurgery, Santo Domingo, Dominican Republic, [6]Columbia University Irving Medical Center, Taub Institute For Research On Alzheimer's Disease And The Aging Brain, New York, United States of America

Aims: We investigated the relationship between cerebrospinal fluid (CSF) proteome in Alzheimer's disease (AD) with clinical and biomarker-assisted diagnosis.
Methods: CSF was collected in 250 individuals of non-Hispanic white, African Americans, and Caribbean Hispanic individuals from Dominican Republic and New York City. CSF biomarkers of AD were measured including P-tau181, Aβ40, Aβ42, total-tau, neurofilament light chain (NfL) and glial fibrillary acidic protein (GFAP). CSF was depleted of abundant proteins followed by precipitation, cysteine reduction/alkylation, and proteolytic cleavage by trypsin. Peptides were measured using a Q Exactive HF mass spectrometer (Thermo Scientific). Association of individual and co-abundant modules of proteins were tested with the clinical diagnosis of AD, as well as biologically defined AD pathological process based on CSF P-tau181 and other biomarker levels.
Results: We detected 22,778 peptides in 865 protein groups (with greater than or equal to 2 peptides per protein), yielding an overall data completeness value of 97%. CSF levels of phospholipase D3 (PLD3, p=1.52E-07) and osteopontin (OSTP, p=2.16E-06) were increased and ceruloplasmin (CERU, p=6.88E-06) was decreased among individuals with high P-tau181 levels. These proteins were also associated with CSF Aβ42/Aβ40 ratio and total Tau levels but not with NfL. OSTP was also nominally associated with CSF levels of GFAP (p=4.6e-04). We did not identify any protein associations with clinical AD. Among proteins associated with P-tau181 levels, pathways related to axon development (p=1.39E-09), axonogenesis (p=5.31E-08) and regulation of axon regeneration (p=8.76E-06) were enriched. We are analyzing the CSF proteome in additional 250 participants for validation of identified proteins.
Conclusions: Unbiased profiling of circulating CSF proteins identified key proteins associated with β-amyloid and phosphorylated tau pathology. Biologically based diagnostic criteria may aid in the identification of unique pathogenic mechanisms.

Aims: Dysregulation of lipid homeostasis and the acyl chain remodeling pathway, along with depletion of specific lipid acyl species, are implicated in Alzheimer's Disease (AD) pathogenesis. We aimed to study the contribution of acyl chain remodeling pathways in the dysregulation of the lipidome over aging and in a mouse model of AD by integrating spatial lipidomic and coordinated spatial transcriptomic analyses.
Methods: Serial brain slices from a mouse model of AD were analyzed for lipid content using imaging mass spectrometry and for gene expression using RNAscope, and spatial gene expression. Wild type mice and those overexpressing amyloid precursor protein with the Swedish mutation (APPsw) were analyzed during aging at, 6, 12 and 22 months.
Results: We found regional changes in globus pallidus (GP) which showed an age-related increase in GFAP andACSL6 copy number. In the APPsw model, ACSL6 and GFAP copy number was elevated at 12 months, with a slight reduction at 22 months. The neuronal protein, NeuN decreased over time, with a more pronounced effect in the APPsw. Microglia, Iba-1 exhibited increased expression at 12 months and decreased at 22 months in APPsw. Spatial transcriptomics revealed differences in gene expression related to lipid metabolism. Imaging mass spectrometry detected regional lipid content differences in the GP, consistent with deficits in acyl chain remodeling in the AD model.
Conclusions: Dysregulation of lipid metabolism, including changes in the expression of enzymes involved in fatty acid metabolism such as ACSL6, has been linked to AD development. It is likely that astrogliosis in the GP area contributes to the observed lipid alterations detected through imaging mass spectrometry and spatial transcriptomics, revealing deficiencies in the Lands cycle acyl chain remodeling in lipid metabolism.

Aims: Several molecular processes, such as posttranslational modifications (PTMs), contribute to the formation of the Alzheimer's disease (AD) hallmarks amyloid-beta (Aβ) plaques and tau neurofibrillary tangles. The aim of this explorative proteomic study was to identify novel peptides, including PTMs, in cerebrospinal fluid (CSF) associated with AD pathologies throughout the disease continuum.
Methods: We performed a cross-sectional TMT proteomic study of CSF samples from the Translational Biomarkers in Aging and Dementia (TRIAD) cohort (young adults (n=22), cognitively unimpaired (n=54), cognitively impaired (n=45), AD (n=19)); a cohort covering the AD continuum, highly profiled by clinical assessment, Aβ and tau positron emission tomography (PET), and fluid biomarkers. Exploiting the unbiased nature of MS-based proteomics, we performed all analyses on the peptide level. To determine pathology-associated peptides, we built linear regression models, performed correlation analyses, and assessed peptide abundances across the disease continuum.
Results: Preliminary results show a strong association between Aβ PET and, among others, peptides mapping to the following proteins: CORT (β_{std}=-0.52; p<0.001), SMOC1 (β_{std}=0.48; p<0.01), C3 (β_{std}=-0.33; p<0.01), and AQP4 (β_{std}=0.51; p<0.01), many of which have been shown to co-localize with Aβ plaques. In addition, we determined peptides stemming from the following proteins to be strongly related to tau pathology: 14-3-3 proteins YWHAZ (β_{std}=0.53; p<0.001), and YWHAE (β_{std}=0.51; p<0.001), as well as MDH1 (β_{std}=0.47; p<0.001), and OTUB1 (β_{std}=1.30; p<0.01). The 14-3-3 proteins displayed a stepwise increase in abundance across the AD continuum. Future analyses will elucidate disease associated PTMs and cleavage sites of the identified peptides.
Conclusions: Leveraging MS-based proteomics, we identified several peptides strongly associated with Aβ and tau pathology. Furthermore, we discovered diverging abundance patterns of these markers across the AD continuum, identifying both early- and late-stage CSF biomarker candidates.

Aims: We performed gene set enrichment analysis (GSEA) on the Accelerating Medicine Project-Alzheimer's Disease (AMP-AD) transcriptomic and proteomic datasets within the Target Enablement to Accelerate Therapy Development for AD (TREAT-AD) bioinformatics pipeline. The enrichment is mapped onto the 19 biological domains and the subordinate subdomains to show disease specific process involvement in AD across parallel datasets.
Methods: The TREAT-AD informatics pipeline ingests large datasets and scores them based upon genetic, transcriptomic and proteomic AD risk association. The scored genes are aligned with their gene ontology terms. The biological domains describe 19 core areas of endophenotypic investigation in AD based upon systematic alignment of GO terms defining each domain. In order to more accurately and specifically identify disease processes within each biological domain, we developed risk-associated subdomains for each biological domain. The AMP-AD transcriptomic and proteomic data was aligned to both the biological domains and subdomains, with preliminary characterization of cell-type specificity mapping.
Results: The biological domain and subdomain enrichment across datasets demonstrated unique signatures of disease process. We were able to stratify previously observed signal in core down-regulated processes (Synapse and Mitochondria) and up-regulated processes (Immune Response, Structural Stabilization, and Lipid Metabolism) to more specific areas such as electron transport chain function and mitochondrial transport within the Mitochondria biological domain, core synaptic signaling and processing pathways in Synapse, and activation of innate immune response and adaptive immune response in the immune response biological domain.
Conclusions: The biological domain and subdomain mapping of AD-risk associated process may facilitate an open-source, open-science shareable resource for comparison of large datasets integrated into specific biological areas for identification of future therapeutic targets and hypotheses.

Aims: ADmit has developed a cutting-edge technology based on next-generation sequencing (NGS) analysis of mitochondrial DNA (mtDNA) epigenetic biomarkers present in the blood of patients with mild cognitive impairment (MCI). It provides a percentage of progression to Alzheimer's disease dementia (ADD) using a machine learning approach. The aim is to analyze the stability of mtDNA methylation: a) in blood stored at room temperature (RT), b) in different DNA freeze-thaw cycles, and c) in sample replicates.
Methods: Extracted DNA from whole blood recruited at Bellvitge University Hospital (Barcelona, Spain) was treated with bisulfite. Libraries were generated and sequenced by NGS using the MiSeq Illumina platform. a) From the blood of 5 patients, we extracted DNA immediately and stored other blood aliquots at RT for 2, 6, and 12 days prior to DNA extraction, b) we completed the following freeze-thaw cycles in DNA from 8 patients: 1, 3, 6 and 12 cycles, and c) we used DNA from 10 patients and replicate the bisulfite treatment 8 times.
Results: DNA methylation patterns in D-loop and ND1 mitochondrial regions are stable in the different conditions showing no significant statistical differences (FWER> 0.05) and no technical batches associated with systematic variation. We showed replicability in samples from the same patient. These results demonstrated the repeatability and reproducibility of our method within our facilities.
Conclusions: The storage conditions that samples may encounter during normal shipping and handling processes do not impact on mtDNA methylation. Therefore, our mtDNA mitochondrial approach is a feasible prognostic tool for the progression of ADD at the MCI stage.

Aims: CpG-related single nucleotide polymorphisms (CGS) are special types of single nucleotide polymorphism (SNP) because they change the sequence of CpG dinucleotides, the targeted methylation sites. CGS might have special importance to Alzheimer's disease (AD) since both genetic variants and epigenetic features contribute to AD pathogenesis. We studied the effects of CpG variants in AD among a cohort of Caribbean Hispanics.
Methods: We annotated the CGS by checking the three base pairs flanking each SNP and derived the dosage of the CpG site-creating allele of multiple CGSs in each 1 Kb window across the genome. We conducted the genome-wide sliding window-based association analysis across 7,155 individuals, of which 3,194 (44.6%) were diagnosed as clinical AD. We used generalized linear mixed models (GLMMs) implemented in GMMAT with adjustments for age, sex, population structure, genomic relation matrix, and genotyping batches. For those genome-wide significant windows (P<5.0x10^{-8}), we conducted functional analyses using human brain DNA methylation and gene expression data in tissue from 116 Hispanic individuals.
Results: There were three independent genome-wide significant regions, which were located at *APOE* (Score=75.1, P=7.26x10^{-26}), *ADAM20* (Score=55.2, P=4.06x10^{-8}), between *VRTN* (Score=-19.6, P=1.47x10^{-8}) and *SYNDIG1L* (14q24) (Score=-37.7, P=2.25x10^{-9}), and *SPG7* (16q24.3) (Score=40.5, P=2.23x10^{-8}). Significant mQTL signals at *ADAM20* and *SPG7* were associated with reduced mRNA expression levels (P<0.05).
Conclusions: The CpG-related loci identified above in *APOE, ADAM20, VRTN-SYNDIGIL* and *SPG7* appear to act as functional hubs that could contribute to the effects of these genes in AD. *APOE, ADAM20,* and *SPG7* have been previously associated with AD in other populations, thus further investigation of CpG-related sites is warranted.

Aims: Recent studies show that Alzheimer's disease (AD) patients harbor specific methylation marks in the brain. The main goal of the present study was to characterize circulating cell-free DNA (cfDNA) as a novel source of AD-specific epigenetic biomarkers to aid non-invasive diagnosis of AD by liquid biopsy procedures.
Methods: cfDNA was isolated from 2 mL plasma of 35 AD patients and 35 age- and gender-matched cognitively healthy controls by using QIAmp Circulating Nucleic Acid Kit (Qiagen) and bisulfited converted. Subsequently a genome-wide methylation analysis was executed using the Illumina Infinium® MethylationEPIC BeadChip microarray in the Illumina HiScan System (Illumina). Methylation data was fully preprocessed using the *minfi* package in R software. Differentially methylated regions (DMRs) between AD patients and controls were identified using linear regression models defined in *limma* package and *limma p*-values were fed in the *comb-p* function of the *EN*mix package. Bisulfite cloning sequencing was performed to validate methylation results obtained from the microarray.
Results: cfDNA was readily isolated from AD patients and controls. Differential analysis revealed 17 DMRs comparing AD *APOE* ε4 carriers and controls *APOE* ε4 non-carriers and 4 hypermethylated DMRs between AD *APOE* ε4 non-carriers and controls *APOE* ε4 non-carriers (Sidak-corrected $p<0.05$). Interestingly, several DMRs were annotated to AD-related genes. A DMR annotated to *HKR1* gene was further validated and DNA methylation levels were shown to be strongly increased in AD patients compared to controls (82 ± 10% vs 17 ± 11%; $p<0.001$).
Conclusions: These results suggest that liquid biopsy technique would provide access to AD-specific information in a non-invasive way. The availability of blood sampling makes the analysis of epigenetic alterations in cfDNA a promising source of biomarkers in AD during patients' lifetime.

THE EPIGENETIC CODE OF ALZHEIMER'S DISEASE

POSTERS: A06.F. CELL, MOLECULAR AND SYSTEMS BIOLOGY: EPIGENETICS, HISTONE MODIFICATION, DNA METHYLATION

Alexi Nott, Philippa Wells, Kevin Ziegler
Imperial College London, Brain Sciences, London, United Kingdom

Aims: Interpreting Alzheimer's disease (AD) genetic risk variants is a major challenge because they are mostly located outside of genes and likely localise to gene regulatory regions called enhancers. Enhancers are sensitive to pathological changes and are dysregulated in the brains of AD patients. Recent studies have shown that AD-risk genes are expressed across vascular cell-types, as well as immune cells, however, epigenomic analysis of these rare cell-types is lacking. Our hypothesis goal is that the epigenetic landscape of vascular-associated cell-types in AD will define cell-type-specific disease-risk genes and will identify transcriptional regulators associated with pathology.
Methods: We have established florescence-activated nuclei sorting approaches to enrich nuclei from human vascular-associated cell-types (microglia, endothelial cells and pericytes), as well as neurons and oligodendrocytes. Acetylation of histone H3 Lysine 27 (H3K27ac) is located at active enhancers and is sensitive to changes in disease pathology. H3K27ac signal was assessed for our cell-type-enriched nuclei using chromatin immunoprecipitation and for rarer cell-types using single nuclei CUT&Tag.
Results: Epigenomic analysis of the neurovascular unit has identified a vascular-immune gene regulatory network. While AD genetics is predominantly associated with immune cells, we found that AD genetic risk is partially shared between immune and vascular cell-types and several loci are specific to the vasculature. Cell-type-specific epigenomic analysis in the AD brain has shown that gene regulatory regions are dysregulated across brain cell-types, in particular in glia and immune cell-types. AD-associated epigenomic changes mirror transcriptional changes and have now highlighted cell-type transcription factors that drive disease.
Conclusions: Collectively, these studies reveal cell-type-specific gene networks and transcription factors important for AD and highlight candidate targets that are dysregulated in disease.

DECIPHERING THE ROLE OF A NOVEL LONG NON-CODING RNA IN ASTROCYTE REACTIVITY AND ALZHEIMER'S DISEASE

POSTERS: A06.F. CELL, MOLECULAR AND SYSTEMS BIOLOGY: EPIGENETICS, HISTONE MODIFICATION, DNA METHYLATION

Sophie Schröder[1], Ulrike Fuchs[1], Dennis Krüger[1], Verena Gisa[1], André Fischer[1,2,3]
[1]German Center for Neurodegenerative Diseases (DZNE), Department For Epigenetics And Systems Medicine, Göttingen, Germany, [2]University Medical Center, Department Of Psychiatry And Psychotherapy, Göttingen, Germany, [3]University of Göttingen, Cluster Of Excellence "multiscale Bioimaging: From Molecular Machines To Networks Of Excitable Cells" (mbexc), Göttingen, Germany

Aims: Due to their diverse functions, long non-coding RNAs (lncRNAs) are emerging as important regulators of neuronal plasticity and have recently been linked to the onset and progression of neurodegenerative diseases such as Alzheimer's Disease. However, our knowledge about the role of tissue- and cell type-specific lncRNAs in the central nervous system is still limited. Therefore, the aim of this project was to identify astrocyte-specific lncRNAs in the human and mouse brain in the context of neurodegeneration and astrocyte reactivity and to characterize their function.
Methods: Single-nucleus total RNA sequencing data from brains of two non-demented humans were generated. From there, astrocyte-enriched lncRNAs were identified and their regulation in activated astrocytes and cognitive diseases was evaluated. The most intriguing candidate, here named AstroLNC, was then further characterized regarding its role in astrocytes.
Results: AstroLNC was found to be the most astrocyte-specific lncRNA in the human brain that has a mouse homologue. It was downregulated in reactive primary astrocytes and in Alzheimer's Disease. The knockdown of AstroLNC led to the acquisition of a pro-apoptotic and pro-inflammatory phenotype. At the same time, important astrocytic functions such as the uptake of glutamate and release of lactate were reduced, leading to the impaired support of primary neurons.
Conclusions: Astrocytes provide important metabolic support functions for neurons and can furthermore also tightly interact with synapses. The lncRNA AstroLNC is important for maintaining the expression levels of many synaptic genes and, at the same time, inhibiting the acquisition of a pro-apoptotic and pro-inflammatory phenotype. The downregulation of AstroLNC in activated astrocytes and in Alzheimer's Disease might contribute to disease progression and could be, due to its high cell-type specificity, an attractive drug target.

Aims: While the aetiology of familiar Alzheimer´s Disease (fAD) is determined by genetic mutations in well-characterised genes, sporadic AD (sAD) arises from a complex interplay between genes and environment that remains poorly understood. This project rises from the hypothesis that early causative disease states, triggered by genetic and external factors, highly difficult to model, can be defined by transcriptomic fingerprints that functionally drive the cells into the disease phenotype. In this context, we aimed to integrate such fingerprints in human cells for the generation of sAD models.
Methods: We have developed a pipeline for the validation of early transcriptomic alterations identified from post-mortem patient samples which hold the potential to be causative of sAD. Bioinformatically-predicted candidates were analysed in human neuroblastoma SH-SY5Y cells to assess the effect of their knockdown (KD) on Aβ aggregation. Shortlisted candidate genes were then validated in iPSC-derived cortical neurons to study whether AD relevant phenotypes were triggered upon early expression perturbation.
Results: Our SH-SY5Y pre-screening assay identified 12 candidates which increased Aβ aggregation upon KD. FBXO2, a subunit of the ubiquitin protein ligase complex SCF, was chosen for further validation. The early downregulation of *FBXO2* in wild-type human cortical neurons triggered amyloidopathy, tauopathy and both functional and structural network impairment, hence enabling the generation of a comprehensive model of sporadic AD.
Conclusions: We report a neuronal model of sAD that recapitulates a set of key molecular AD hallmarks. We envision to expand our strategy towards the generation of panels of preclinical models that faithfully capture the molecular complexity of the full spectrum of AD patients, steering the drug discovery field towards personalised medicine.
