Aims: The cause of Alzheimer's disease (AD) remains unidentified, but it is likely the result of a combination of genetic and environmental factors. One significant risk factor for AD is traumatic brain injury (TBI). Several AD-associated pathological features, including Aβ deposition, elevated phosphorylated tau levels, acetylcholine deficits, blood-brain barrier disruption and memory decline have been detected in TBI-affected brains. The aim of this study was to investigate functional and pathological effects of a single closed head injury (CHI) in a mouse model of amyloid and tau pathology, the 3xTg-AD mouse, with the hypothesis that TBI may lead to memory impairments and in a raise on deposition of Aβ and tau phosphorylation, potentially exacerbating the progression to AD.
Methods: We induced a CHI in 6-month-old male and female 3xtg-AD mice using a 5mm flat steel tip electromagnetic impactor (Leica Impact One). The impact was aimed at bregma point (ML=0.0mm, AP=0.0mm), at a 4.0m/s with a 100ms dwell time and a 1mm impact. After a 28-day post-injury period, cognitive and locomotion functions were evaluated, and various inflammatory, neurodegenerative, and blood-brain barrier (BBB) markers were assessed using immunohistochemistry and immunofluorescence methodologies.
Results: Our findings reveal that CHI in 3xtg-AD mice leads to significant deficits in learning and memory when compared to sham animals by fear conditioning and novel object recognition tests. Additionally, we observed a 38% rise in intraneuronal amyloid beta (Aβ) accumulation and disruptions in the blood-brain barrier within the pericontusional cortex following CHI. In addition, we observed sexual dimorphisms in these effects.
Conclusions: In conclusion, our study demonstrates that the closed head injury model aggravates behavioural impairments and Aβ pathology in 3xtg-AD brain pathology 28 days after injury.

INVESTIGATION OF THE CELL TYPE SPECIFIC PFC ENHANCER AND PROMOTER LANDSCAPE IN ALZHEIMER'S DISEASE

POSTERS: A06.F. CELL, MOLECULAR AND SYSTEMS BIOLOGY: EPIGENETICS, HISTONE MODIFICATION, DNA METHYLATION

Philippa Wells[1], Paulina Urbanavicicute[1], Reuben Yaa[1], Christian Nickl[2], Inge Holtman[3], Aydan Askarova[1], Sarah Marzi[1], Chris Glass[2], Alexi Nott[1]
[1]Imperial College London, Brain Sciences, London, United Kingdom, [2]UCSC, Dept. Of Cellular & Molecular Medicine, San Diego, United States of America, [3]University of Groningen, Department Of Biomedical Sciences Of Cells & Systems, Groningen, Netherlands

Aims: Alzheimer's disease is a complex progressive neurodegenerative disease, having major lifespan and societal implications in the context of the ageing worldwide population. Sporadic Alzheimer's disease is highly heritable (~70%) and it has been shown that the majority of risk loci in AD are located within non-coding regions and are likely to drive regulation of gene expression. Concurrently, differences in histone acetylation have been observed in the AD brain, likely secondary to genetic and non-genetic factors. There is a requirement to understand these processes in a cell-type specific manner.
Methods: We undertook a large-scale study to delineate the promoter and enhancer landscape in Alzheimer's disease (AD), using cell type enriched nuclei populations from post-mortem pre-frontal cortex (PFC). We investigated differentially acetylated regions as revealed by ChIPseq at (H3K27ac) within neurons, oligodendrocytes and microglia. We profiled differences in histone acetylation in AD compared to non-AD individuals, whilst controlling for potential biological and technical confounders and integrated profiles with genomic and chromatin conformation data.
Results: Differentially acetylated regions were identified within oligodendrocytes (2131 hyper-acetylated and 1310 hypo-acetylated), neurons (121 hyper and 148 hypo acetylated), and microglia (1511 hyper and 908 hypo acetylated) in AD cases versus control samples (EdgeR; $q < 0.05$). Functional investigation of the differentially acetylated regions via gene pathway analysis and motif analysis identifying putative transcription factors in AD demonstrated cell type specific roles in numerous disease pertinent processes including oxidative stress, immune response, excitotoxicity and circadian rhythm.
Conclusions: We have demonstrated cell type specific histone acetylation differences in the AD PFC, which are particularly evident within microglia and oligodendrocytes, giving much needed insight into mechanisms of disease in a cell type specific manner. Our work highlights mechanisms which may reflect useful therapeutic targets.

MORPHOLOGICAL, BIOCHEMICAL AND RESPIRATORY EFFECTS OF DIFFERENTIATION ON SH-SY5Y CELLS

POSTERS: A06.G. CELL, MOLECULAR AND SYSTEMS BIOLOGY: OTHER

Rachel Cruickshank, Lisa Chakrabarti, Kevin Gough
University of Nottingham, School Of Veterinary Medicine And Science, Loughborough, United Kingdom

Aims: In cellular models of Alzheimer's disease (AD), the neuroblastoma derived cell line SH-SY5Y is commonly used. Various methods exist to differentiate SH-SY5Y cells into a mature neuron-like phenotype. The main objective of this study is to assess the morphological, biochemical and respiratory changes of three SH-SY5Y differentiation protocols and evaluate their effectiveness as potential AD models.
Methods: Cells were differentiated according to previously described protocols using insulin like growth factor 1 (IGF-1), retinoic acid (RA), or RA combined with brain derived neurotrophic factor (BDNF). Immunocytochemistry was performed to assess morphological changes. Western blots were performed to assess protein level changes. High resolution respirometry was used to assess respiratory changes. Statistical analysis was performed with T-tests and ANOVA.
Results: Morphologically, ~90% of RA/BDNF and IGF-1 differentiated cells displayed neurites equal to or greater in length than the cell body, compared to 65% of RA differentiated cells and 25% of undifferentiated cells. RA and RA/BDNF differentiated cells had significantly higher levels of choline acetyl transferase and synaptophysin proteins than undifferentiated and IGF-1 differentiated cells. IGF-1 differentiated cells displayed significantly increased beta-III-tubulin protein levels compared to other cell types. Rotenone-induced inhibition of respiration was less pronounced in RA differentiated cells, suggesting that RA differentiation decreased the proportional contribution of complex I to respiration.
Conclusions: Morphologically, RA/BDNF and IGF-1 cells display a more mature neuronal phenotype than RA differentiated and undifferentiated cells. Biochemically, both RA and RA/BDNF differentiated cells display the same cholinergic phenotype, making them ideal for AD modelling. Mitochondrial dysfunction is an early hallmark of AD neurotoxicity, so an understanding of the way differentiation affects respiration is an important consideration in cellular modelling of AD. The novel respiratory differences presented provide insight into these developmental changes.

USING COMPLEX GENETICS IN MICE TO UNLOCK THE SECRETS OF RESILIENCE TO DEMENTIA

POSTERS: A06.G. CELL, MOLECULAR AND SYSTEMS BIOLOGY: OTHER

Julia Rosander[1], Vivek Philip[2], Niran Hadad[2], Timothy Hohman[3], Vaibhav Janve[3], Yiyang Wu[3], Vilas Menon[4], Catherine Kaczorowski[1]
[1]The University of Michigan, Neurology, Ann Arbor, United States of America, [2]The Jackson Laboratory, Genetics, Bar Harbor, United States of America, [3]Vanderbilt University Medical Center, Vanderbilt Memory & Alzheimer's Center And Vanderbilt Genetics Institute, Nashville, United States of America, [4]Columbia University, Neurology, New York, United States of America

Aims: Cognitive resilience to AD is a phenomenon whereby and individual presents with normal cognitive function despite harboring familial Alzheimer's disease (FAD) mutations and corresponding brain neuropathologies. Determination of the underlying mechanisms of cognitive resilience to AD will likely offer novel disease modifying therapeutics for individuals at-risk for AD.
Methods: To determine transcriptional changes associated with resilience, we profiled the hippocampal transcriptome at the single cell level in top resilient and susceptible strains from the AD-BXD mouse reference panel, a genetically diverse mouse model of AD that better mimics human AD. Here, we used contextual fear memory paradigm to assess short-term memory function in AD-BXDs carrying the 5XFAD mutation. Resilience was defined based on age-related change in cognitive function relative to that of the entire AD-BXD population, where strains showing no or lower than average decline were considered resilient.
Results: We show that cognitive resilience is characterized by a transcriptional signature that diverges from that of susceptible strains in excitatory neurons of CA1, dentate gyrus and intratelencephalic neurons in layer 3 and 6 of the entorhinal cortex. We found that the transcriptional profile of resilient strains is enriched for regulation of transmembrane transport in presymptomatic stages that included a notable upregulation of Reln and Ntng2, whereas translation at the CA1 synapse corresponded to an upregulation of ribosomal genes in neurons from resilient AD mutation carrier mice.
Conclusions: Our findings suggest that resilience is conferred in memory-relevant regions through unique transcriptional changes in a cell-specific manner and provide a foundation for mechanistic studies required for resilience-based drug development.

Sergievsky Center, College Of Physicians And Surgeons, New York, United States of America, [11]Mayo Clinic, Department Of Neurology, Jacksonville, United States of America

Aims: Genetic variations have emerged as crucial players in the etiology of Alzheimer's disease (AD), and they serve for a better understanding of the disease mechanisms; yet the specific roles of these genetic variants remain uncertain. Animal models with reminiscent disease pathology could uncover previously uncharacterized roles of these genes. Therefore, we generated zebrafish models for AD variants to analyze their function.
Methods: Using CRISPR/Cas9, we generated a knockout model for *abca7,* orthologous to human *ABCA7*. We performed single cell transcriptomics and analyzed the altered genes and molecular pathways in zebrafish. We leveraged data from multiethnic AD cohorts at Mayo Clinic and Columbia University, to perform genetic association studies, co-expression analyses, in silico interaction mapping, family based variant segregation analyses and epigenetic mQTL studies, and the functional and histological investigations in human and zebrafish.
Results: The *abca7*$^{+/-}$ zebrafish reduced astroglial proliferation, synaptic integrity, and microglial response after Aβ42 treatment. We found that the *abca7* loss-of-function (LOF) reduced neuropeptide Y (*npy*) expression as well as *bdnf* and *ngfr*. Human brain analysis showed reduced *NPY* in AD, regulatory interaction between *NPY* and *BDNF*, genetic variants in *NPY* associated with AD, and segregation of variants in *ABCA7*, *BDNF* and *NGFR* in families. *ABCA7* variants altered the epigenetic codes in *NPY*, *BDNF,* and *NGFR* promoter regions. Human results paralleled with zebrafish findings. NPY administration to zebrafish rescued the phenotypes in *abca7* knockout.
Conclusions: Our results demonstrate a previously unknown link between *ABCA7* and *NPY* in regulation of synaptic integrity and astroglial proliferation in AD. We show that zebrafish is a useful functional genomics model for investigating the roles of genetic variants found in humans.

Aims: This study aims to assess the complex interplay between age, sex, and APOE genotypes in regulating cell-type-specific transcriptional profiles in a mouse model of Alzheimer's Disease (AD).
Methods: Hippocampal samples of a sex-balanced cohort of APOE3-KI and APOE4-KI mice at 6, 12, and 18 months of age were collected for single-nuclei RNA-sequencing (snRNA-seq). Quality assurance, count normalization, clustering, cell type identification, and differentially expressed gene (DEG) analysis were performed using the Seurat package in RStudio.
Results: The snRNA-seq dataset comprises 527,395 cells covering 27,153 genes. 35 cell clusters were identified, representing six major brain cell types: astrocytes, microglia, oligodendrocytes, oligodendrocyte precursor cells (OPCs), and excitatory and inhibitory neurons. We found that sex significantly influenced cell fraction variance in astrocyte and inhibitory neuron clusters, while APOE genotype and its interaction with age significantly impacted cell fraction variability in the OPC cluster. Analyzing sex and age-stratified DEGs and enriched pathways in APOE4-KI versus APOE3-KI microglia and astrocytes revealed age-dependent inverse effects in males and females dependent on APOE genotypes. At 12 months, proliferation-related genes were upregulated in APOE4-KI males and downregulated in females. At 18 months, synaptic activity and neurogenesis-related genes were downregulated in APOE4-KI males but upregulated in females. Furthermore, males exhibited consistent gene regulation by APOE genotypes across cell types, while females displayed a greater prevalence of opposing DEG regulations. Lastly, cell-cell communication analysis with CellChat revealed sex-biased communication from astrocytes to inhibitory neurons, with an age-dependent augmentation.
Conclusions: There is a clear interplay between age, APOE genotype, and sex in mouse models of AD, with strong sex-biased effects in microglia and astrocytes. This suggests that targeting sex-specific glial cell dysfunction could be a valuable precision medicine approach.

Aims: Alzheimer's disease (AD) is a progressive neurodegenerative disorder that lacks any kind of effective treatment options. A critical barrier to overcome right now is understanding disease pathogenesis to identify new neurotherapeutic opportunities. AD is canonically characterized by the buildup of amyloid plaques and tau tangles, which is thought to lead to neurodegeneration and progressive loss of cognitive function. Although there has been a concerted effort to investigate these pathological mechanisms, we still lack therapeutic success. Therefore, we aim to identify new targets through the primary cilium, which is a widely overlooked neuronal signaling hub that might offer insights into the pathophysiology of AD.
Methods: To help investigate the etiology of neurodegeneration in AD, we conducted unbiased analysis of differentially expressed genes (DEGs) in postmortem brains from AD subjects, compared to age-matched non-AD control subjects. Differentially expressed genes related to the primary cilia were further investigated in pre-symptomatic and post-symptomatic 5xFAD mice, an amyloid-driven mouse model of AD that carries five human mutations in the amyloid precursor protein and presenilin 1 genes.
Results: This effort revealed a unexpectedly high number of DEGs that were related to the neuronal primary cilia, an organelle that has received very little attention in the field of AD. Gene ontology analysis revealed dysregulation of cilium biogenes and degredation. Notably, we found significant downregulation of that primary cilia specific adenylate cyclase 3 (AC3) in both 5xFAD mice and humans with AD.
Conclusions: In conclusion, our research has unveiled a novel perspective on AD by bringing the neuronal primary cilia to the forefront of investigation. These findings position the primary cilia as a previously unrecognized locus of injury in AD pathology which could serve as new neurotherapeutic targets.

UNDERSTANDING THE MOLECULAR MECHANISMS THAT DRIVE NEURONAL LOSS IN PARKINSON'S DISEASE

POSTERS: A06.G. CELL, MOLECULAR AND SYSTEMS BIOLOGY: OTHER

Joe Park, Wayne Carter
University of Nottingham, Medical School, nottingham, United Kingdom

Aims: While Parkinsons disease (PD) proteomic changes have been established in the context of Lewy body and α-synuclein aggregates this study aimed to investigate further changes in Protein I-isoaspartyl methyltransferase (PIMT) and Microtubule Associated Protein 2 (MAP2) . With the changes in expression of these proteins in different regions of the PD brain being less understood.
Methods: A cohort of 10 PD and 10 control (CO) age and sex matched post-mortem samples were used with samples from the prefrontal cortex (PFC) , hippocampus and corpus callosum (CC) . These underwent protein assays, SDS-PAGE and western immunoblotting for PIMT and MAP2 detection for each brain region. The proteins were detected and quantified using imageLab6.0 before being normalised to the housekeeping protein Glyceraldehyde 3-phosphate dehydrogenase (GAPDH) and total lane protein (TLP). A Mann-Whitney U test was used to calculate statistical significance.
Results: MAP2 expression increased by a statistically significant 650% (p-value = 0.0052 normalised to TLP) in the PFC. While PIMT expression decreased by a statistically significant 42% (p-value = 0.0040 normalised to TLP) in the same brain region when comparing PD to CO samples. For the hippocampus and CC no statistically significant results were achieved. It is worth noting this data is preliminary and these protein changes may also be validated using an alternative method such as immunohistochemistry .
Conclusions: These results show the potential importance of normal regulation of MAP2 and PIMT in preventing neurodegeneration in the PD brain. These insights provide basis for the potential future use of MAP2 and PIMT as biomarkers. Additionally, the proposed mechanisms by which cytosolic dopamine (DA) affects PIMT and post translational modifications affect MAP2 may provide possible mechanisms to utilise for therapeutic benefit.

A COMPARATIVE ANALYSIS OF IPSC-DERIVED NEURAL PROGENITOR CELLS AND ADULT HUMAN NEURAL STEM/PROGENITOR CELLS

POSTERS: A06.G. CELL, MOLECULAR AND SYSTEMS BIOLOGY: OTHER

Yu-Mi Shim[1,2,3], Sooyeon Yoo[1,2], Kwanghoon Lee[1,2], Seoug-Ik Kim[1,2,3], Jae-Kyung Won[1,2], Sung-Hye Park[1,2,3]
[1]Seoul National University Hospital, Dementia Brain Bank, Seoul, Korea, Republic of, [2]Seoul National University Hospital, Pathology, Seoul, Korea, Republic of, [3]Seoul National University, Pathology, Seoul, Korea, Republic of

Aims: Neuroscience increasingly uses iPSC-derived NPCs and aNSPCs for brain research, offering new perspectives but presenting developmental challenges. Our study aims to compare these cell types, clarifying their properties and applications to aid in selecting the right model for specialized neuroscience investigations.
Methods: aNSPCs were sourced from epilepsy patients' ependymal layer near the hippocampus and postmortem SVZ samples. iPSCs were cultured, induced to form EBs, then underwent neural induction via dual SMAD inhibition. RNA sequencing was performed on various SNUH samples using the Illumina platform (TruSeq)
Results: Bulk RNA sequencing revealed that samples within similar groups had nearly identical gene expression patterns, as depicted in an MDS plot. Notably, iNPC and aNSPC samples closely clustered, suggesting shared neurodevelopmental and functional attributes. However, differences exist. While both cell types show similar developmental potential, ICC analysis indicates that aNSPCs are more mature than iNPCs. This is evident from aNSPCs expressing CD133, PAX6, and NESTIN. In contrast, iNPCs also express SOX2, a neural stem cell marker. Neither cell type expressed common neuronal markers like OCT4, NANOG, MAP2, NeuN, GFAP, or OLIG2.
Conclusions: Our study compares iPSC-derived neural progenitor cells (iNPCs) and adult human neural stem/progenitor cells (aNSPCs) using RNA sequencing and ICC experimentation. Results show shared neurodevelopmental attributes between these cell types, but also differences in maturity and developmental markers. This ongoing study plans to include additional iNPC samples for further analysis. The insights gained can potentially guide future research into therapeutic applications of these cells in neurodegenerative disease.

DOPAMINE STIMULATES L-LACTATE PRODUCTION IN SINGLE PRIMARY ASTROCYTES

POSTERS: A06.G. CELL, MOLECULAR AND SYSTEMS BIOLOGY: OTHER

Keita Sugiyama[1], Anemari Harvot[1,2], Nina Vardjan[1,2], Robert Zorec[1,2]
[1]Laboratory of Neuroendocrinology - Molecular Cell Physiology, Institute of Pathophysiology, Faculty Of Medicine, Ljubljana, Slovenia, [2]Laboratory of Cell Engineering, Celica Biomedical, Ljubljana, Slovenia

Aims: Dopaminergic signaling is associated with various neurodegenerative diseases, including Alzheimer's and Parkinson's disease, and has garnered attention as a potential target for astrocytes. However, the regulatory role of dopamine in astroglial metabolism, especially L-lactate production is poorly understood. Previous research shows that astroglial aerobic glycolysis with the end product L-lactate is regulated by both Ca^{2+} and cAMP signaling influenced by noradrenaline binding to adrenergic receptors. In this research, we, therefore, investigated the effect of dopamine on astroglial aerobic glycolysis.
Methods: Primary astrocyte cultures were derived from the cortex of 2–3-day-old Wistar rats, and we used the inverted fluorescence microscope system (Colibri, Zeiss) to employ the fluorescence resonance energy transfer (FRET) technique. To evaluate the response of astrocytes to dopamine at the single-cell level, astrocytes were transfected with the FRET cAMP nanosensor (Epac1-camps) and the FRET L-lactate nanosensor (Laconic). Using agonists and antagonists, we targeted the D1 receptors but also β-adrenergic receptors, monitoring the concentrations of intracellular cAMP ($[cAMP]_i$) and L-lactate ($[lac]_i$).
Results: Dopamine induced a dose-dependent increase in $[cAMP]_i$ largely via D1 receptor activation, which was confirmed by a D1 receptor agonist (SKF81297) and inhibited by a D1 receptor antagonist (SCH23390). When dopamine was applied in the presence of a β-adrenergic receptor antagonist (Propranolol), the increase in $[cAMP]_i$ was partially inhibited. Moreover, dopamine application increased $[lac]_i$ in astrocytes.
Conclusions: Our results suggest that (i) dopamine modulates $[cAMP]_i$ via not only the D1 receptors but also possibly through the β-adrenergic receptors, and that (ii) dopamine facilitates aerobic glycolysis via these receptors. Future work will delve into the dopamine-induced dynamics of intracellular glucose and Ca^{2+} in astrocytes to further elucidate the regulatory role of dopamine in astroglial metabolism.

EXCITATORY AND INHIBITORY NEURONS PRODUCE DISTINCT AMYLOID STRUCTURES IN MOUSE MODELS OF APP OVEREXPRESSION

POSTERS: A07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Gabriella Perez, Rong Zhao, Danish Uddin, Joanna Jankowsky
Baylor College of Medicine, Neuroscience, Houston, United States of America

Aims: We investigated how the cellular localization of pathogenic amyloid precursor protein (APP) might influence amyloid accumulation in the brain. Our primary objective was to understand how different neuronal subtypes contribute to the heterogeneity of amyloid beta (Aβ) plaque development.
Methods: We generated transgenic mouse models to overexpress APP either in excitatory neurons using the CaMKII promoter, or in inhibitory neurons using the GAD2 promoter. We immunostained brain sections from each model to measure Aβ plaque load, identify fibrillar plaques using thioflavin-S, evaluate microglial activation around plaques using Iba1, and detect dystrophic neurites using LAMP-1. We also measured Aβ40 and Aβ42 levels from the cortices of these models using the Luminex platform.
Results: We found significant differences in Aβ aggregation patterns between the two models. Plaque formation appeared earlier in the CaMKII-APP model than in the GAD2-APP model, beginning at 3 and 18 months respectively. The GAD2-APP model exhibited primarily diffuse Aβ deposits and lacked fibrillar plaques throughout the cortex, while the CaMKII-APP mice displayed extensive fibrillar deposits. Microglial activation and dystrophic neurites were prominent around plaques in the CaMKII-APP mice, but these responses were absent in the cortex of GAD2-APP animals. Remarkably, although both models expressed the same APPswe/ind transgene, GAD2-APP mice deposited a much greater level of Aβ42 relative to 40 than CaMKII-APP mice.
Conclusions: Our findings suggest that distinct neuronal subtypes process APP in distinct ways to produce different Aβ structures. This diversity of Aβ aggregation may contribute to the heterogeneity observed in Alzheimer's disease pathology, clinical presentation, and disease progression.

AGE- AND SEX-DEPENDENT CHANGES IN SLEEP AND NESTING BEHAVIOR IN AN ALZHEIMER'S DISEASE MOUSE MODEL, APP-SAA KNOCK-IN MICE

POSTERS: A07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Marilyn Duncan[1], Haleigh Whitlock[1], Jayden Alcorn[1], Will Briones[1], Michael Murphy[2], Sridhar Sunderam[3], Bruce O'Hara[4], Adam Bachstetter[1]
[1]University of Kentucky Medical School, Dept. Of Neuroscience, Lexington, United States of America, [2]University of Kentucky Medical School, Dept. Of Biochemistry, Lexington, United States of America, [3]University of Kentucky College of Engineering, Dept. Of Biomedical Engineering, Lexington, United States of America, [4]University of Kentucky College of Arts and Sciences, Dept. Of Biology, Lexington, United States of America

Aims: Aims: To investigate if the APP^{SAA} knock-in mouse model of Alzheimer's disease exhibits age- and sex-dependent changes in sleep and nesting, an activity of daily living that enhances sleep.
Methods: Methods: Using a longitudinal design, sleep and nesting were monitored in male and female APP^{SAA} and wild-type (WT) mice (N=8/genotype/sex) from 4-17 months of age, because previous studies indicate that APP^{SAA} mice exhibit amyloidosis and running behavior alterations during this age range. Every 2-3 months, the mice were transferred to individual cages for piezoelectric sleep recording for one week. Each cage contained cotton squares, allowing construction of nests that were scored on a 5-point scale (5=best nest). Sleep percentages during the light, dark, and 24-hour periods were assessed with SPSS 28.0, using 2-way ANOVA to test for the main effects of sex and genotype. Kruskal Wallis was used to asses nesting scores.
Results: Results: At all ages tested, female mice of both genotypes slept less than male mice. APPSAA mice showed significantly less daytime and total sleep percentages than WT mice at 15 and 17 months. Nesting scores were not significantly affected by sex but decreased as the mice aged (P<.001), with APPSAA mice showing lower scores at 15 and 17 months.
Conclusions: Conclusions: Female sex deleteriously affects sleep in the APPSAA mice, as previously observed in other AD mouse models. At older ages, the APPSAA mice exhibit a loss of daytime (rest phase) sleep, mimicking the condition in AD patients. Nesting, a mouse activity of daily living, also declines with age, more prominently in the APPSAA than WT mice. In summary, APPSAA mice exhibit age-related behavioral changes that are similar to those observed in AD patients.

COMBINED REDUCTION OF AMYLOID-BETA AND TAU PRODUCTION RESCUES NEURONAL CIRCUIT DYSFUNCTION IN A MOUSE MODEL OF ALZHEIMER'S DISEASE.

POSTERS: A07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Robert Ellingford[1], Samuel Harris[1], Rikesh Rajani[1], Lindsay Welikovitch[2], Eric Jacobi[3], Sonia Ruggieri[3], Rhiannon Laban[1], Amanda Heslegrave[1], Dervis Salih[1], Umran Yaman[1], Henrik Zetterberg[1], Jakob Von Engelhardt[3], Bradley Hyman[2], Marc Aurel Busche[4]

Aims: The memory deficits and cognitive decline associated with Alzheimer's Disease (AD) become evident when both amyloid-beta and tau pathology are widespread across cortical-hippocampal circuits. However, the causes of dysfunction within these circuits in AD, and whether this dysfunction is reversible, remains unknown. We aimed to assess the impact of amyloid-beta and tau accumulation upon the function of cortical-hippocampal circuits and determine whether any associated deficits can be rescued following reduced expression of these proteins.
Methods: We used two-photon calcium imaging and multi-region Neuropixels electrophysiology to record neuronal activity within cortical-hippocampal circuits of the APP/PS1xTg410 mouse model of AD, before and after treatments to suppress amyloid-beta and/or tau production. We employed additional immunohistochemistry, blood plasma analysis and nucleated patch electrophysiology to assess the effect of treatment on AD biomarkers and investigate the mechanisms underlying treatment effects.
Results: Accumulation of amyloid-beta and tau caused a strong reduction in neuronal firing across cortical-hippocampal circuits. Importantly, combined reduction of both pathogenic proteins was sufficient to reinstate normal activity patterns while reducing individually proteins had no impact on neuronal dysfunction. Combination treatment prevented the accumulation of soluble AD-associated biomarkers but had no impact on the density of neuropathological plaques and tangles in cortical tissue. Finally, restoration of neuronal activity was concurrent with increased density and function of NMDA receptors.
Conclusions: Our data suggest both amyloid-beta and tau elicit effects via NMDA receptors that act to suppress neuronal activity. These effects are likely mediated by soluble forms of both proteins. Crucially, our data suggest that at advanced stages of AD, where both amyloid-beta and tau pathology are widespread, therapeutic strategies repressing both proteins simultaneously may provide greater clinical benefits to cognitive function in patients.

BRAIN AREAS LIPIDOMICS IN FEMALE TRANSGENIC MOUSE MODEL OF ALZHEIMER'S DISEASE

POSTERS: A07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Laura Ferré González[1], Ángel Balaguer[2], Marta Roca[3], Artemis Ftara[4], Ana Lloret[4], Consuelo Cháfer-Pericás[1]
[1]Instituto de investigación La Fe, Grupo De Investigación En Enfermedad De Alzheimer, Valencia, Spain, [2]University of Valencia, Faculty Of Mathematics, Valencia, Spain, [3]Instituto de investigación La Fe, Analytical Unit, Valencia, Spain, [4]University of Valencia, Physiology, Valencia, Spain

Aims: Lipids are the major component of the brain with important structural and functional properties. Lipid disruption could play a relevant role in Alzheimer's disease (AD), as recent research pointed out. Therefore, a comprehensive analysis of brain lipid composition would improve the pathogenesis knowledge. Some brain lipidomic studies showed significant differences compared to controls, but few studies have focused in different brain areas related to AD. Furthermore, AD is more prevalent in females, but there is a lack of studies focusing on this sex. Therefore, the aim of this work is to perform a lipidomic study in selected brain areas (cerebellum, amygdala, hippocampus, cortex) from wild-type (WT, n=10) and APPswe/PS1dE9 transgenic (AD, n=10) female mice of 5 months of age, as model of early AD, to identify alterations in lipid composition.
Methods: A lipidomic mass spectrometry-based method was optimized and applied for brain tissue.
Results: As result, several lipid variables were detected in the positive ionisation mode (n=252) and in the negative ionisation mode (n=196). Of these, some lipids showed statistically significant differences between mice groups in cerebellum (n=68), amygdala (n=49), hippocampus (n=48) and cortex (n=22). In addition, some lipids (n=15) from the glycerolipid, phospholipid and sphingolipid families were statistically significant in several brain areas simultaneously between WT and AD mice.
Conclusions: A selection of lipid variables was made to develop a multivariate approach to assess their discriminant potential, showing high diagnostic indexes, especially in cerebellum and amygdala (sensitivity 70 – 100%, sensibility 80 – 100%).

A NOVEL 3D IMAGING PIPELINE FOR ANALYZING EFFICACY OF THERAPEUTIC COMPOUNDS ON AMYLOID-BETA PATHOLOGY IN PRECLINICAL ALZHEIMER'S DISEASE ANIMAL MODELS

POSTERS: A07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Gianna Ferron[1], Stefan Linehan[1], Tim Ragan[1], Kevin Elk[2], Dylan Garceau[2], Mike Sasner[2]
[1]TissueVision Inc., Imaging, Newton, United States of America, [2]The Jackson Laboratory, Model-ad Center, Bar Harbor, United States of America

Aims: Standard laboratory approaches assessing amyloid-beta (Aβ) lack the ability to provide region-specific quantitation with high-throughput whole-organ imaging and often require destructive homogenization of tissue. We developed a novel Serial Two-Photon Plus (STP^2) pipeline to quantify Aβ plaque progression as a function of brain region, resulting in indexed brain sections for secondary analysis using MALDI HiPLEX-IHC with imaging mass spectrometry (IMS).
Methods: 5XFAD (JAX #8730) and APP SAA (JAX #34711) mouse brains labeled with methoxy-X04 were serially imaged and sectioned on the STP^2 platform. Resulting datasets were registered to the Allen Mouse Brain Common Coordinate Framework (CCFv3) and region-specific plaque analysis was conducted. Using MALDI HiPLEX-IHC staining, fourteen (14) protein signatures were imaged on select sections and aligned to the corresponding STP^2 sections using a registration pipeline. The intensity of each signal was assessed quantitatively for all processed 2D sections and summarized across major 3D brain regions in the Allen CCFv3.
Results: The analysis of plaque distribution revealed distinct spatial-temporal changes across the whole-brain datasets. STP^2 imaging and CCFv3 mapping allowed for targeted evaluation of Aβ plaques and a comparison of regional changes occurring with age or treatment. Using data from 4 time points, we can observe a progressive increase in plaque accumulation in regions such as the hippocampal formation, thalamus, and cortical subplate, providing a baseline for targeted additional analysis and comparison to treated brains.
Conclusions: This novel technology has great promise for both quantifying the spatial-temporal Aβ plaque efficacy of AD animal models and producing translatable preclinical AD data for drug discovery. The high sensitivity and precision of the STP^2 platform and high multiplexity of MALDI HiPLEX-IHC secondary analysis provides data-rich results to assess the difficult research questions surrounding AD disease progression.

UNC5C T835M MUTATION-MEDIATED NEURODEGENERATION IN LATE-ONSET ALZHEIMER'S DISEASE IN A NOVEL MOUSE MODEL

POSTERS: A07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Devi Krishna Priya Karunakaran[1], Makenna Ley[1], Joanna Guo[1], Mai Khatri[1], Katherine Sadleir[1], Jelena Popovic[1], Arun Upadhyay[1], Ryan Watts[2], Jasvinder Atwal[3], Daniele Procissi[4], Jeffrey Savas[1], Robert Vassar[1]
[1]Feinberg School of Medicine, Northwestern University, Neurology, Chicago, United States of America, [2]Denali Therapeutics Inc.,, Neuroscience, South Sanfrancisco, United States of America, [3]Genentech Inc., Neuroscience, South San Francisco, United States of America, [4]Northwestern University, Center For Preclinical Imaging Core Facility, Chicago, United States of America

Aims: Recently, a rare autosomal dominant coding mutation, T835M, was discovered in the Un-coordinated 5c (UNC5C) netrin receptor gene that segregated with late-onset AD (LOAD). T835M alters a conserved amino acid in the hinge region of the Unc5c death domain, suggesting the mutation may increase apoptosis. Indeed, in primary hippocampal neurons, overexpression of T835M increased cell death in response to neurotoxic stimuli including beta-amyloid (Aβ) suggesting a mechanism by which T835M may confer increased risk of LOAD, however the molecular mechanism of T835M-mediated cell death has not yet been explored. Understanding the molecular mechanism of cell death in regions susceptible to neurodegeneration such as hippocampus could shed light on the players and pathways involved in cell death in AD pathogenesis.
Methods: We generated a mouse knock-in (KI) model of Unc5c T835M Mutation and employed biochemical and histological analyses to understand the molecular mechanism of T835M-mediated pathogenesis in late onset Alzheimer's disease.
Results: We show that homozygous KI mice have significantly reduced hippocampal volume, increased ventricular volume, dendritic disorganization (CA1 region) and reduced Unc5c protein level by 12-18 months of age. Further, we show that the neuronal cell death is observed in the KI mice by 12 months of age by TUNEL analysis and activated Caspase 3/7 activity assay. KI mice also show morphological changes in the astrocytes with reduced GFAP levels and significantly increased activation of microglia. Proteomics analysis of hippocampal samples corroborate the biochemical and histological results which showed upregulation of oxidative stress and downregulation of chaperone proteins at 18 months.
Conclusions: Overall, these results suggest that T835M mutation causes neurodegeneration by creating an oxidative stress environment leading to synaptic degeneration and weakened astrocytes, thereby leading to neuronal cell death via apoptosis.

ANALYSIS OF MOTOR FINE FUNCTION IN THE 5XFAD MOUSE MODEL OF ALZHEIMER'S DISEASE

POSTERS: A07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Ioanna Kousiappa[1], Stylianos Valiantis[1], Nikolas Perentos[2], Savvas Papacostas[1], Avgis Hadjipapas[3], Andreas Koupparis[1]
[1]Cyprus Institute of Neurology and Genetics, Neurobiology, Nicosia, Cyprus, [2]University of Nicosia, School Of Veterinary Medicine, Engomi, Cyprus, [3]University of Nicosia, Medical School, Nicosia, Cyprus

Aims: Alzheimer's disease (AD) is characterized by deficits in memory, cognition and motor function that are proportional to the disease's progression. AD mouse models have shown similar motor difficulties based on motor behavioral tests. The main objective of this project was to investigate the fine motor skills of the 5xFAD Alzheimer's mouse model.
Methods: 3- and 9-month-old transgenic 5xFAD mice were compared to their wild-type (WT) littermates with three motor behavioral assays (n=48 mice). Rotarod test was used to assess the motor coordination. Balance beam test was conducted at three different beams (15, 10 and 6 mm-width) to evaluate the fine motor coordination and balance, while single-pellet reaching test was performed to assess the fine skilled limb movement.
Results: Findings showed a motor deficit of 9M 5xFAD mice in the rotarod test, since they fell at lower rotation speed compared to 9M WT mice. Results from the balance beam test exhibited that 9M 5XFAD mice traverse each beam at significantly greater time and slower speed. A motor performance scoring of the data revealed that 9M 5xFAD mice was the most affected group with a significant impairment at 6 mm with increased presence of dragging and foot slips. Single-pellet reaching test revealed an impairment in fine limb movement mostly in 9M 5xFAD mice, since 3M, 9M WT and 3M 5xFAD mice achieved significantly higher success rate and speed compared to 9M 5xFAD mice to reach successfully the food.
Conclusions: This research provided the first concrete proof of fine motor deterioration in 9M 5xFAD mice. Collectively, older transgenic mice presented the most impaired performance at each behavioral assay, proposing that advanced AD-related pathology may has a role to play in motor function, especially in skilled movements.

PF-04691502, A PI3K/MTOR DUAL INHIBITOR, IMPROVES LEARNING DEFICITS IN APP/PS1 MICE

POSTERS: A07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Marika Lanza, Giovanna Casili, Rossella Basilotta, Alberto Repici, Salvatore Oddo, Salvatore Cuzzocrea, Emanuela Esposito

Aims: Aging is the greatest risk factor for several neurodegenerative disorders, including Alzheimer's disease (AD). Overwhelming evidence indicates that reducing mTOR signaling improves health span and lifespan in a multitude of organisms. PI3K is a key regulator of mTOR activity; the PI3K/mTOR signaling pathway regulates several key biological mechanisms related to cell development, cell survival, protein synthesis, autophagy, metabolism, and learning and memory. To this end, up-regulation of the PI3K/mTOR signaling contributes to AD neuropathology and causes neurodegeneration and learning and memory deficits. In this study, we sought to determine the molecular correlates of memory deficits in APP/PS1 mice, a widely used animal model AD.
Methods: 18-month-old APP/PS1 and WT mice were dosed orally with 1 mg/Kg PF-04691502, an ATP-competitive PI3K/mTOR dual inhibitor, for 12 weeks. At the end of the treatment, we assessed changes in spatial learning and memory using the Morris water maze. We then processed their brains for neuropathological and biochemical assessment of amyloid-β (Aβ).
Results: We found that PF-04691502 improved learning and memory in APP/PS1 mice. Currently, we are processing the tissue to assess potential changes in brain Aβ deposits and soluble and insoluble Aβ levels. We will also assess the effects of reducing PIK3/mTOR signaling on inflammation.
Conclusions: These results provide preclinical data indicating that PF-04691502 may be a valid therapeutic approach for AD and other neurodegenerative disorders associated with aging and mTOR hyperactivity.

CEREBRAL PERFUSION AND METABOLISM ACROSS THE LIFESPAN OF THE NOVEL HUMAN AMYLOID BETA KNOCK-IN MOUSE MODEL OF ALZHEIMER'S DISEASE

POSTERS: A07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Andre Obenaus[1], Amandine Jullienne[1], Charles Burton[2], Scott Persohn[2], Rojina Pad[1], Ayati Mishra[1], Tia Ketsan[1], Aditya Singh[1], Paul Territo[3]
[1]University of California Irvine, Pediatrics, Irvine, United States of America, [2]Indiana University School of Medicine, Stark Neuroscience, Indianapolis, United States of America, [3]Indiana University School of Medicine, Medicine, Indianapolis, United States of America

Aims: To elucidate the role of genetics, age and environmental risk factors on Alzheimer's disease (AD), the human amyloid beta knock-in (hAβKI) was developed and deeply phenotyped by MODEL-AD for cerebral perfusion and metabolism.
Methods: hAβKI mice were imaged at 6-24mo (n=6/sex/age/genotype) via dynamic contrast-enhanced MRI at 9.4T, while 18F-FDG was acquired via Siemens Inveon PET/CT. Using established protocols, images were processed, registered, segmented, and quantified for cerebral blood flow (CBF) and volume (CBV), glycolytic metabolism, connectomics, and neurovascular uncoupling.
Results: Hippocampal CBF was elevated in 24mo-old males hAβKI ($p=0.024$), while females exhibited reduced CBF ($p=0.018$) relative to WT controls. CBV was significantly decreased in the male temporal lobes ($p=0.048$), but not in females ($p=0.59$) compared to WT. Hippocampal 18F-FDG was decreased in hAβKI males ($p=0.042$) but not females compared to WT mice. In contrast, male hAβKI mice showed reduced hippocampal 18F-FDG compared to hAβKI females ($p=0.02$). In the entorhinal cortex, only female hAβKI mice showed elevated 18F-FDG uptake ($p=0.039$) compared to WT. PET connectomics revealed significant ($p<0.05$) alterations in 5 of 7 functional modules between female hAβKI and WT controls. At 12 mo, axial cortical vascular density was reduced in hAβKI compared to WT mice (53.08 vs. 59.6%), but similar amongst sexes. Further analyses for regional neurovascular uncoupling are underway.
Conclusions: These data suggest sex-dependent regional differences in CBF and CBV of hAβKI compared to WT mice. Glycolytic uptake across most brain regions were divergent, with females increasing while males decreased. Moreover, hAβKI mice show phenotypic changes in regions known to be vulnerable in AD and are consistent with neurovascular uncoupling and network reorganization observed with sex and age in the clinic.

Aims: 17β-Estradiol (E2) was previously demonstrated to have neurotherapeutic effects on animal models of Alzheimer's disease (AD). However, the clinical trials on E2 replacement therapy for preventing AD onset yielded inconsistent results. Therefore, it is necessary to clarify the therapeutic effects of E2 on human cells. This study explored the therapeutic effects of E2 on the in vitro model from human iPSCs.
Methods: A systematic review and meta-analysis using a random-effects model of the previously reported AD clinical trials was conducted to summarize the effects of E2 replacement therapy on AD prevention. Then, the iPSCs from the donors of the 2 healthy control lines, 2 familial AD lines (APP V717L and APP KM670/671NL), and 3 sporadic AD lines (APOE e3/e3, APOE e3/e4, and APOE e3/e3) were induced into neurons. In addition to the mono-culture model of the neurons, we examined the effects of E2 on the co-culture model of the iPSC-derived neurons and astrocytes.
Results: The meta-analysis concluded that E2 replacement therapy reduced the risk of AD onset (OR, 0.69; 95% confidence interval [CI], 0.53–0.91; I^2 = 82%). Neural models from the AD iPSC lines demonstrated an elevation in secreted Aβ levels and astrogliosis-like phenotype compared to the control lines. E2 treatment to the neurons increased neuronal activity and promoted neurite complexity. Furthermore, E2 treatment to the co-culture model ameliorated the astrogliosis-like phenotype. However, contrary to the previous reports, E2 treatment did not alter the levels of Aβ secretion and pTau accumulation.
Conclusions: E2 treatment to the human cellular model did not affect Aβ secretion and pTau accumulation, but promoted neuronal plasticity and mitigated the astrogliosis-like phenotype. This study demonstrated the molecular effects of E2 on neuronal plasticity and AD pathogenesis utilizing human iPSCs.

Aims: The IU/JAX/PITT MODEL-AD Center's primary focus is to characterize mouse models that express significant genetic risk factors, namely the APOE4 allele of apolipoprotein E and the R47H allele of triggering receptor expressed on myeloid cells (Trem2*R47H).
Methods: To achieve this, we established the LOAD2 strain, which was double homozygous for humanized amyloid-beta, APOE4 and Trem2R47H on the C57BL6J (B6) genetic background. We employed a comprehensive phenotyping approach, which included in vivo imaging, multi-omics analysis, and immunofluorescence. Furthermore, we explored the impact of a high fat/high sugar diet (HFD) on the alignment of mouse models with human LOAD.
Results: Findings indicate that, when compared to LOAD2 mice fed a regular diet, LOAD2 mice on an HFD exhibit increased levels of insoluble Aβ, cortical neuronal cell loss, elevated levels of neurofilament light chain (NfL) in both the plasma and brain. Intriguingly, gene expression profiles and proteomic signatures of aged LOAD2+HFD mice aligned with 'omics signatures of AD patients in the absence of core neuritic plaques, which were not detected up to 24 months of age. Additionally, positron emission tomography and computed tomography (PET/CT) scans using 64Cu-PTSM and 18F-FDG reveal more pronounced disruptions in blood flow and glucose uptake in LOAD2 HFD mice.
Conclusions: Mice with genetic risk for LOAD coupled with environmental risk factors demonstrate aging-dependent changes in line with a spectrum and trajectory of features of clinical LOAD. From a precision medicine approach, our Preclinical Testing Core is prioritizing LOAD2+HFD mice as an important model system for evaluating the therapeutic potential of non-amyloid targeting therapeutics as well as for prophylactic interventions initiated prior to significant amyloid accumulation.

DEVELOPMENT OF A NOVEL ALZHEIMER'S DISEASE MOUSE MODEL BASED ON CHRONIC PLASMALOGEN DEFICIENCY IN ADULTHOOD

POSTERS: A07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Shawn Ritchie[1], Tara Smith[1], Kaeli Knudsen[2]
[1]Med-Life Discoveries LP, Therapeutics, SASKATOON, Canada, [2]Med-Life Discoveries LP, Therapeutics, Saskatoon, Canada

Aims: Plasmalogens are vinyl-ether-containing membrane phospholipids involved in many functions, particularly neurotransmission. Plasmalogen deficiency has been associated with Alzheimer's disease (AD), leading to the hypothesis it underlies the disease process. However, the lack of an animal model displaying a chronic plasmalogen deficiency beginning in adulthood has made it impossible to understand the effects of the deficiency in brain structure and function as it relates to AD. We therefore developed and characterized a novel plasmalogen-deficient knockout mouse model of AD containing a conditional *Gnpat* deletion that can be induced postnatally.
Methods: We introduced loxP sites flanking exon 4 of *Gnpat,* a plasmalogen biosynthetic gene. Upon tamoxifen administration, a recombination and deletion of the region occurs, resulting in loss of plasmalogen biosynthesis. Following tamoxifen treatment, the animals were characterized by functional assessments (open field, sleep monitoring, and nerve conduction), neuroimaging (anatomical MRI and mass spectrometry imaging (MSI), and for neuroinflammatory markers (NfL).
Results: Within one month of tamoxifen treatment in adult *Gnpat* cKO animals, there was a clear reduction in plasmalogen levels in serum and multiple tissues including brain. Activity levels, sleep architecture, nerve conduction, and NfL levels were all altered in deficient animals. Brain and white matter volumes were reduced, which correlated with reduced brain plasmalogen levels as detected by MSI. Preliminary results following treatment with PPI-1011, an oral plasmalogen therapeutic precursor, showed normalization of brain structure and lipid composition.
Conclusions: Our *Gnpat* conditional mouse model confirms for the first time that plasmalogen reductions in adulthood, comparable to the chronic situation observed in individuals with AD, are sufficient to impair function, alter sleep architecture, increase neuroinflammatory markers and reduce brain volumes. This model therefore represents a critical tool in the evaluation of future plasmalogen-targeted therapeutics.

MECHANISMS UNDERLYING REDUCTIONS OF SEROTONERGIC AXON PROJECTIONS TO THE CORTEX IN APP KNOCK-IN MOUSE MODEL OF AB PATHOLOGY

POSTERS: A07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Yasufumi Sakakibara[1], Yu Hirota[1,2], Kyoko Ibaraki[1], Kimi Takei[1], Risa Nishijima[1], Michiko Sekiya[1,3], Koichi Iijima[1,3]
[1]National Center for Geriatrics and Gerontology, Department Of Neurogenetics, Obu City, Aichi, Japan, [2]Japan Society for the Promotion of Science, Jsps Research Fellow, Tokyo, Japan, [3]Nagoya City University, Graduate School Of Pharmaceutical Sciences, Nagoya, Aichi, Japan

Aims: Dorsal raphe nucleus (DRN) is a nucleus containing the cell bodies of serotonergic neurons in the brainstem and is one of the earliest regions affected by Alzheimer's disease (AD). Defects in serotoninergic system is thought to be related to cognitive declines and behavioral and psychiatric problems in the early stage of AD and has been a drug target to improve clinical symptoms. However, mechanisms underlying degeneration of serotonergic system in AD remain elusive. In this study, we analyzed structural changes of serotonergic system upon accumulation of amyloid-β (Aβ) pathology in cortical areas using *App*$^{NL\text{-}G\text{-}F/NL\text{-}G\text{-}F}$ knock-in mice.
Methods: We compared the density of serotonin (5-HT)-positive axons in the cortex and the number of serotonergic neurons in the DRN between *App*$^{NL\text{-}G\text{-}F/NL\text{-}G\text{-}F}$ and wild-type (WT) C57BL/6J mice at 6 and 24 months of age. We also asked whether tau pathologywas formed in the serotonergic axons and in the DRN in *App*$^{NL\text{-}G\text{-}F/NL\text{-}G\text{-}F}$ mice.
Results: Immunohistochemical analyses revealed that *App*$^{NL\text{-}G\text{-}F/NL\text{-}G\text{-}F}$ mice exhibited age-dependent decreases in the density of 5-HT-positive axons in the cortex compared to WT mice. In contrast, *App*$^{NL\text{-}G\text{-}F/NL\text{-}G\text{-}F}$ mice did not display loss of 5-HT-positive neurons in the DRN even at 24 months of age. Furthermore, phosphorylated tau was not accumulated in either the nerve terminals or the cell bodies of DRN neurons in the brains of *App*$^{NL\text{-}G\text{-}F/NL\text{-}G\text{-}F}$ mice.
Conclusions: This study demonstrates that cortical Aβ pathology reduces the density of serotonergic axons independent of neuron loss and tau pathology in the DRN. These results also suggest that age-dependent accumulation of Aβ in the cortex chronically damages serotonergic axons during the preclinical period, which may lead to death of DRN neurons accumulated tau during aging in AD pathogenesis.

Aims: The hippocampus is a primary region affected in Alzheimer's disease (AD). Because AD postmortem brain tissue is not available prior to symptomatic stage, we lack understanding of early cellular pathogenic mechanisms.
Methods: To address this issue, we examined the cellular origin and progression of AD pathogenesis by comparing proteomic changes in patient-based model systems including iPSC-derived brain cells transplanted into the mouse brain hippocampus.
Results: Proteomic analysis of the graft enabled the identification of pathways and network dysfunction in AD patient brain cells, associated with increased levels of Aβ-42 and β-sheet structures. Interestingly, the host cells surrounding the AD graft also presented alterations in cellular biological pathways. Furthermore, proteomic analysis across human iPSC-based models and human post-mortem hippocampal tissue projected longitudinal cellular changes indicative of early to end stage AD cellular pathogenesis.
Conclusions: Our data showcase patient-based models to study the cell autonomous origin and progression of AD pathogenesis

Aims: Our understanding of early pathogenic processes within the hippocampus, a primary brain region severely impacted in Alzheimer's disease (AD), is hampered by the unavailability of pre-symptomatic postmortem brain tissue. Our goal was to develop advanced iPSC-based models closely mimicking human AD pathology and emphasize the utility of patient-based models, such as humanized chimeric mice, for understanding the cell-autonomous origin and progression of AD.
Methods: We developed a chemical approach to rapidly generate adherent hippocampal neurons (HNs) and free-floating hippocampal spheroids from human iPSCs. To model AD pathology in vivo, we created humanized chimeric mice by transplanting iPSC-derived brain cells into the mouse hippocampus. We employed Western blotting, immunocytochemistry, qRT-PCR, MSD multi-array, synchrotron-based FTIR, and shotgun proteomics to phenotype these AD models and compared them with postmortem AD human brain tissue.
Results: HNs derived from AD patients revealed complex cellular dysfunctions resembling prodromal pathology in vitro. When grafted into immunodeficient mice, patient HNs integrated into the host environment, creating an in vivo model mimicking patient brain parenchyma, with the advantage of being vascularized. At six months, this novel patient iPSC-based AD model displayed significant alterations in the human proteome, detected with LC-MS/MS, and signs of incipient protein aggregation measured by FTIR microspectroscopy. Importantly, these changes occurred before amyloid plaque formation but with elevated Aβ-42 levels, confirming the model's fidelity to prodromal AD pathology.
Conclusions: Our models offer a valuable platform for studying early pathogenic hippocampal changes in AD patients, providing insights into mechanisms and potential therapeutic targets for early-stage AD. Developing patient-based models provides a robust approach to investigate the cell-autonomous origin and progression of AD pathogenesis across its various stages.

GENOMIC ANALYSIS OF FIBROBLASTS FROM MARMOSETS CARRYING EARLY-ONSET ALZHEIMER'S DISEASE MUTATIONS IN PSEN1

POSTERS: A07.B. ANIMAL MODELS: PRIMATES, NATURALLY OCCURING MODELS AND BRAIN ORGANOIDS

Gregory Carter[1], Annat Haber[1], Duc Duong[2], Nicholas Seyfried[3], Takeshi Murai[4], Laura Schultz[4], Hasi Huhe[4], Sang Ho Choi[4], Julia Kofler[5], David Schaeffer[4], Stephanie Hachem[4], Jung Eun Park[4], Gregg Homanics[4], Stacey Sukoff Rizzo[6], Afonso Silva[4]
[1]THE JACKSON LABORATORY, The Jackson Laboratory, Bar Harbor, United States of America, [2]Emory University School of Medicine, Center For Neurological Disorder, Atlanta, United States of America, [3]Emory University School of Medicine, Department Of Biochemistry, Atlanta, United States of America, [4]University of Pittsburgh, Neurobiology, Pittsburgh, United States of America, [5]University of Pittsburgh, Pathology, Pittsburgh, United States of America, [6]University of Pittsburgh, Medicine, Pittsburgh, United States of America

Aims: We present genetic, genomics, and proteomic analysis of fibroblast lines derived from a colony of marmosets genetically engineered with familial variants in PSEN1.
Methods: We performed whole-genome sequencing on 50 individuals, including eight mutant carriers. We validated the presence of the PSEN1 mutations and assessed variation at multiple other Alzheimer's disease loci. Fibroblast cultures were obtained from 12 animals and assayed using a Nanostring AD gene expression panel and label-free proteomics. This allowed us to quantify 800 transcripts and 2165 proteins per sample.
Results: We detected differential gene expression for genes enriched in neuron development and amyloid-beta regulation, providing strong evidence for the functional relevance of the engineered variants. We quantitatively compared changes in marmoset PSEN1 fibroblasts to similar molecular measures in postmortem brain tissue and induced pluripotent stem cells (iPSCs) from human AD studies. Both gene and protein expression changes in the undifferentiated fibroblasts correlated with changes in iPSCs from human AD carriers reprogrammed into neuronal lineages.
Conclusions: These findings demonstrate that disease-relevant pathways and processes are altered in fibroblasts from mutant marmosets, provide a roadmap for more advanced molecular studies of AD in aging marmosets and marmoset-derived cell models, and outline a strategy to align marmoset models with human disease to facilitate robust translation.

TRANSGENIC INHERITANCE PATTERN MODULATES PLAQUE BURDEN IN THE 5XFAD MOUSE MODEL

POSTERS: A07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Andrew Octavian Sasmita[1], Constanze Depp[1], Taisiia Nazarenko[1], Lena Spieth[2], Stefan Berghoff[2], Klaus-Armin Nave[1]
[1]Max Planck Institute for Multidisciplinary Sciences, City Campus, Neurogenetics, Göttingen, Germany, [2]Technical University Munich, Institute Of Neuronal Cell Biology, Munich, Germany

Aims: The 5xFAD mouse model is one of the most commonly used mouse models of amyloidosis or more specifically, Alzheimer's disease (AD). Sex dimorphism has been reported in many transgenic AD mouse models, but even after stratification of mouse cohorts by sex, the variability of amyloid burden remain staggeringly high. As this line is bred heterozygously, here, we present a jarring relationship between the parental source of the transgene and the amyloid burden that ensued.
Methods: We performed *in toto* amyloid plaque staining with the Congo red dye and imaged whole hemispheres via light sheet microscopy. We grouped our gender-matched data based on whether the mice inherited their transgene paternally or maternally.
Results: Mice that inherit their transgenes paternally develop a much higher amyloid burden, especially within cortical regions where amyloid plaque numbers are twice as many. We further stratified our data based on the parental and grandparental source of the transgene. We saw even more clustering of our data when taking the grandparental origin into account, albeit not as strongly as the direct parental source. This suggests that this transgenic inheritance pattern persists through generations of breeding, highlighting the importance of mouse pedigree in 5xFAD mouse, or perhaps, transgenic mouse research in general. As mice that inherit the transgene would naturally be gestated within 5xFAD mothers, we analyzed offspring of heterozygous breeding pairs. The amyloid burden of the heteroyzgous offspring still clustered into two separate populations, suggesting that it is unlikely that the distinct amyloid plaque populations are the result of maternal immune priming.
Conclusions: We provided a novel outlook on the relationship between the 5xFAD transgenic source and amyloid plaque burden *in vivo. W*e believe that epigenetic analysis of these mice would remain valuable.

[1]University of California Irvine, Pathology And Laboratory Medicine, Irvine, United States of America, [2]Sanders Brown Center on Aging, University of Kentucky, Pharmacology And Nutritional Sciences, Kentucky, United States of America, [3]University of Kentucky, Division Of Laboratory Animal Resources, Kentucky, United States of America, [4]University of Kentucky, Magnetic Resonance Imaging And Spectroscopy Center, Kentucky, United States of America, [5]University of California Irvine, Neurobiology And Behavior, Irvine, United States of America, [6]Aperus Pharma, Aperus Pharma, Szeged, Hungary

Aims: Calcineurin/NFAT signaling increases in Alzheimer disease (AD) and is associated with neurodegeneration, neuroinflammation, amyloid-β (Aβ) production, and cognitive decline. In AD rodent models, calcineurin/NFAT (CN/NFAT) inhibitors improved cognition and ameliorated neuroinflammation and synapse dysfunction, suggesting that CN/NFAT inhibitors (e.g., tacrolimus and Q134R) are attractive potential therapeutics to improve/prevent AD-associated cognitive impairments. We hypothesized that chronic low-dose administration of tacrolimus and Q134R will delay cognitive decline over time in middle-aged beagles, a model of human brain aging and AD.
Methods: We evaluated cognitive outcomes in 37 middle-aged beagles at baseline and during follow-up (years 1-3), including spatial learning [landmark-discrimination (1, 2 and 4cm)], visual discrimination learning, reversal learning (executive function), and spatial working memory (20-, 70-, and 110-second delays). Dogs were ranked for cognition at baseline and randomized into treatment groups: Control/Placebo (n=12), Q134R (n=12), and tacrolimus (n=13).
Results: Accuracy at all landmark-discrimination distances declined 20% faster in control dogs, relative to tacrolimus, and 15% faster than Q134R dogs, at the most difficult distance of 4cm. Accuracy on spatial working memory task declined 21% faster/year among controls than tacrolimus (years 2&3); and 18% faster than Q134R dogs (year 1). Furthermore, performance on visual discrimination and reversal tasks declined with age; however, no treatment effect was found in these tasks.
Conclusions: We found that both tacrolimus and Q134R showed beneficial preventative effects on age-related decline in spatial functions and memory, but not on associative learning nor executive function in a canine model of AD, suggesting that CN/NFAT inhibitors have the potential to reduce or delay cognitive impairment in AD

Aims: While vast majority of AD patients are non-familial, the animal models of AD in common use for studying disease pathogenesis and therapy development - are mostly of a genetic form (transgenic mice). We aimed to develop a non-familial, environmental model for AD, and use it for further studying our new developed therapies.
Methods: To generate an environmental model for dementia/AD, naïve female mice went through ovariectomy (to accelerate aging/ menopause) and fed with high fat-sugar-salt diet - for exposing them to factors associated with increased risk the development of dementia/AD. Sham operated mice fed with standard diet served as normal controls. Behavioral-, biochemical- and histological-studies, as well as blood pressure tests, were performed. In addition, we tested the response of this newly generated dementia/AD model to our newly developed Mitochondrial Transfer Therapy.
Results: The ovariectomized mice fed with high fat-sugar-salt diet showed increased blood pressure, glucose, insulin and lipids in the serum, with impaired cognitive performance in the Y-maze and NOR maze, accompanied with the presence of robust brain pathology of amyloid and tau tangle pathology, gliosis, and reduced blood vessel density. Preliminary results showed that treating this newly developed environmental model for dementia/AD with Mitochondrial Transfer – resulted in reduced amyloid plaques, tau pathology, gliosis and increased blood vessel density in hippocampus, with better cognitive performance in Y-maze.
Conclusions: Ovariectomized mice fed with high fat-sugar-salt diet showed dementia/AD characteristics, providing us an authentic environmental model for AD to represent a high portion of the AD patients. This newly developed AD model showed responsiveness to our newly developed therapeutic approach of Mitochondrial Transfer Therapy for AD, and further supports its value.

Aims: High consumption of Annonacae plant products containing the mitochondrial toxin annonacin has been previously recognized as a risk factor for atypical degenerative parkinsonism in the French Caribbean islands. Our objectives were to further characterize protein amyloid aggregation in this disorder, and determine to what extent annonacin could contribute to this pathogenic process.
Methods: We performed post-mortem histopathological analysis of brain samples from 8 patients, and more specifically assessed the distribution and burden of a-Synuclein (aS) and tau lesions. We also studied the impact of annonacin on a-Syn and tau aggregation using Thioflavin-T (ThT) fluorescent assays with corresponding recombinant human proteins as substrate.
Results: Caribbean atypical parkinsonism (CAP) represents a group of patients with heterogeneous clinical and histopathogical features. A tau/αS co-pathology, with a predominance of either aS or tau lesions, is observed in the majority (5/8) of cases. Annonacin amplifies aS aggregation, and leads to the formation of new fibrillary species having the capacity to seed tau aggregation.
Conclusions: We suggest that annonacin may contribute to degenerative Caribbean parkinsonism by modulating the production of tau and αS pathogenic protein assemblies.

EFFECTS OF P301L-TAU ON POST-TRANSLATIONAL MODIFICATIONS OF MICROTUBULES IN HUMAN IPSC-DERIVED CORTICAL NEURONS AND TAU TRANSGENIC MICE

POSTERS: B01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TAU AGGREGATION, PHOPHORYLATION, ACETYLATION & MODIFICATIONS

Mhd Aghyad Al Kabbani[1], Hans Zempel[2], Christoph Köhler[3]
[1]University Hospital of Cologne, Institute Of Human Genetics, Köln, Germany, [2]University Hospital of Cologne, Center For Molecular Medicine Cologne, Institute Of Human Genetics, Köln, Germany, [3]University of Cologne, Center Anatomy Ii, Medical Faculty, Cologne, Germany

Aims: TAU is a microtubule-associated-protein that promotes microtubule assembly and stability in the axon. TAU is missorted and aggregated in an array of diseases known as tauopathies. Microtubules are essential for neuronal function and are regulated via a complex set of post-translational modifications (PTMs), changes in which affect microtubule stability and dynamics, microtubule interaction with other proteins/cellular structures, and mediate recruitment of microtubule-severing enzymes. Impairment of microtubule dynamics cause neuronal dysfunction and may cause cognitive impairment in human disease. We therefore studied the effects of a disease-causing mutation of TAU (P301L) on the levels and localization of microtubule PTMs indicative of microtubule stability and dynamics.
Methods: To investigate TAU localization, phosphorylation, and effects on tubulin PTMs, we expressed wild-type or P301L-TAU in human *MAPT*-KO induced pluripotent stem cell-derived neurons (iNs) and studied TAU in neurons in the hippocampus of mice transgenic for human P301L-TAU (pR5-mice) via immunostaining and western blotting.
Results: iNs expressing P301L-TAU showed increased TAU phosphorylation at the AT8, but not the p-Ser-262 epitope, increased acetylation and polyglutamylation, but unchanged tyrosination of microtubules compared to endogenous TAU-expressing neurons. P301L-TAU expression was insufficient to trigger TAU mislocalization or aggregation in iNs. Hippocampal neurons in pR5-mice similarly exhibited tauopathy-typical AT8-phosphorylation, decreased acetylation and increased polyglutamylation levels of their microtubules compared to non-transgenic littermates, but also TAU missorting apparent by increased somatodendritic presence of TAU assessed with a total TAU antibody.
Conclusions: In sum, P301L mutant TAU results in changes of microtubule PTMs, suggestive of impairment of microtubule stability. This is accompanied by missorting and aggregation in mice but not in human neurons. Microtubule PTM/impairment may be of key importance in tauopathies.

APP AND TAU PROTEINS ARE DIFFERENTIALLY REGULATED BY VCP INTERACTORS

POSTERS: B01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TAU AGGREGATION, PHOPHORYLATION, ACETYLATION & MODIFICATIONS

Catherine Baud[1], Raphaelle Caillierez[2], Hanane Abouelfarah[2], Adriana Figueroa Garcia[2], Luc Buee[2], Patricia Melnyk[1], Nicolas Sergeant[2]
[1]University of Lille INSERM UMR S-1172, Brain Biology And Chemistry, Lille Neurosciences & Cognition, Lille, France, [2]University of Lille INSERM UMR S-1172, Alzheimer & Tauopathies, Lille Neurosciences And Cognition Center, Lille, France

Aims: Alzheimer's disease (AD) is the most prevalent form of dementia with aging. However there is still no cure. The neuropathological hallmarks of AD are ß-amyloid deposits, derived from cleavages of the amyloid-ß precursor protein (APP) and neurofibrillary degeneration or tangles (NTFs) resulting from the intraneuronal aggregation of the microtubule-associated protein Tau, hyper– and abnormally phosphorylated. A hypothetical mechanism to explain these lesions can arise from the deregulation of protein homeostasis and degradation systems like the unfolded-protein response (UPR), autophagy-lysosome pathway and clearance of protein aggregates at the crossroad of which is the valosin-containing protein VCP/p97. VCP/p97 is a homohexameric AAA-ATPase which, together with its numerous adaptors, recognizes ubiquitylated proteins to address them for degradation by the proteasome or autophagy. Its dysfunctions have been associated with neurodegenerative diseases including inclusion body myopathy with Paget's disease frontotemporal dementia and amyotrophic lateral sclerosis (IBMPFD). Moreover, lower VCP expression levels are observed in AD brains, and there is a growing body of evidence for a link between Tau seeding, aggregation propagation, phosphorylation and VCP in literature. However, the precise mechanism by which VCP/p97 could regulate Tau phosphorylation and aggregation remains poorly understood as well as its contribution to APP metabolism.
Methods: To further decipher the potential mechanism, VCP interactome was achieved by mass spectrometry following immunoisolation from cells treated or not with NMS-873, the most potent and specific VCP pharmacological inhibitor.
Results: We showed that VCP inhibition or silencing increases Abeta production, while repressing Tau aggregation. Bioinformatic analyses determined potent APP or Tau metabolism regulators and will be presented.
Conclusions: Our results suggest that VCP contributes to regulate Tau phosphorylation and APP metabolism, which could represent an attractive therapeutic target for AD.

AGGREGATE-SPECIFIC SINGLE-MOLECULE PROFILING REVEALS HETEROGENEOUS LANDSCAPE OF TAU AGGREGATES IN DISEASE

POSTERS: B01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TAU AGGREGATION, PHOPHORYLATION, ACETYLATION & MODIFICATIONS

Dorothea Böken, Dezerae Cox, Melanie Burke, David Klenerman
University of Cambridge, Yusuf Hamied Department Of Chemistry, Cambridge, United Kingdom

Aims: Hyperphosphorylation and aggregation of the microtubule binding protein tau play a key role in the development of Alzheimer's disease. While the structure of the filamentous aggregates formed in humans has recently been determined to atomic resolution, there is far less information available about the smaller aggregate precursors, thought to be the most neurotoxic. To address this gap, we have developed a single-molecule pull-down (SiMPull) able to detect tau aggregates in clinically relevant human samples, including human brain homogenate and serum.
Methods: This method enables the detection and characterization of individual tau aggregates, as opposed to averaged features obtained from traditional bulk techniques. By adapting the assay to simultaneously detect multiple features in individual aggregates, we were also able to derive compositional profiles for pathological modifications present in individual aggregates, including phosphorylation at different sites and ubiquitination.
Results: We report the number, size and shape of individual aggregates measured via super-resolution microscopy, revealing disease-specific differences in tau aggregate morphology. We further demonstrate that over 80% of tau aggregates in Alzheimer's disease brains had multiple pathological phosphorylation markers (AT8 and T181) simultaneously, compared to only 5% in healthy samples.
Conclusions: Together, tau SiMPull identified distinct subpopulations of large, modified tau aggregates that were invisible to traditional methodologies. These morphological and compositional differences distinguish samples taken from disease cohorts, offering to illuminate underlying disease mechanisms, sand providing a foundation for novel diagnostic strategies.

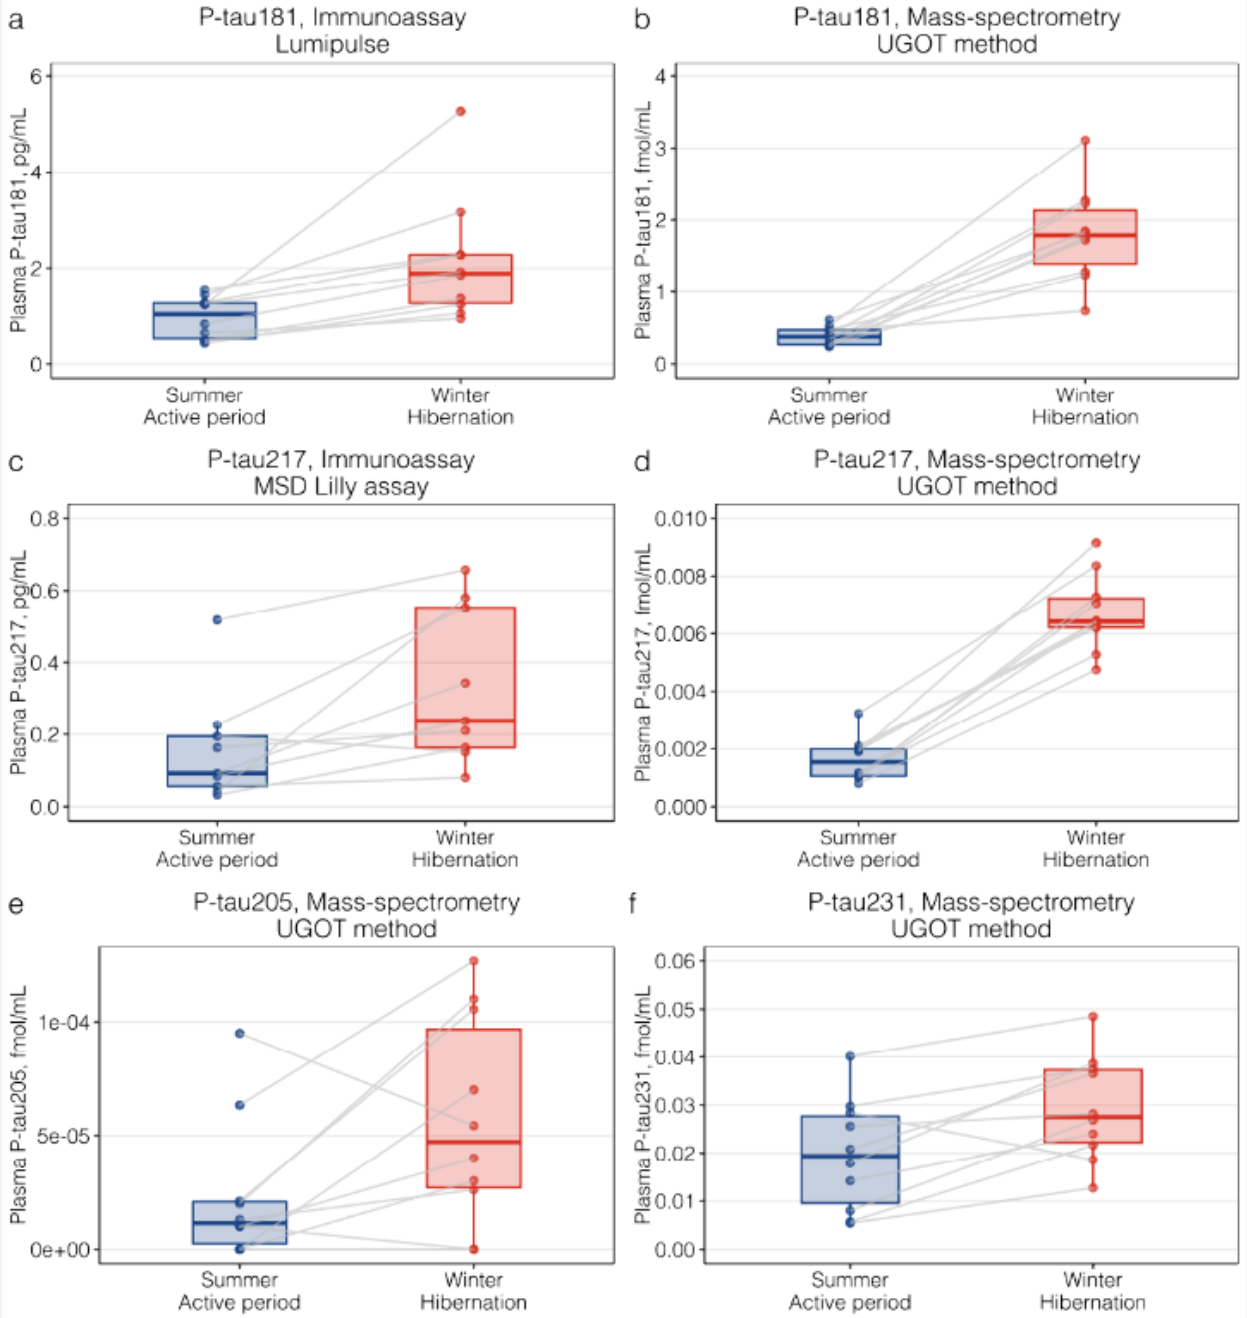
Aims: Tau hyperphosphorylation is one of the key pathological hallmarks of several neurodegenerative diseases, including Alzheimer's disease (AD). While tauopathies have been largely studied in transgenic animals and diseased humans, physiological models of tau hyperphosphorylation remain under-explored. Hibernation-linked tau hyperphosphorylation has been reported in neuropathological studies on various mammal hibernating species, always marked by full de-phosphorylation upon awakening, without signs of insoluble tau deposits. We aimed to evaluate whether these hibernation-linked tau hyperphosphorylation abnormalities could be detected *in vivo* using plasma phosphorylated tau (p-tau) biomarkers.
Methods: Paired plasma samples were collected from free-ranging brown bears (*Ursus arctos*; n=10), during their active state (summer) and hibernation (winter), and human-bear tau sequence homology was evaluated to determine whether currently available tau assays were suitable. With immunoassays (IA), we measured p-tau181$_{IA}$ (Lumipulse, Fujirebio assay) and p-tau217 (MSD; Lilly assay). With a novel validated in-house mass spectrometry (MS; UGOT) assay for simultaneous quantification of tau species in the plasma, we measured p-tau181, p-tau199, p-tau202, p-tau205, p-tau217$_{MS}$, p-tau231. Non-parametric paired tests were used for season comparisons, and percentage change from summer was computed.
Results: During hibernation, significant increases were observed for p-tau181 (IA: +128%, p=0.013; MS: +411%, p<0.0001), p-tau205 (+169%, p=0.012) and p-tau217 (IA: +269%, p=0.047; MS: +371%, p<0.0001) (Figure 1), while no changes were observed for p-tau199 (p=0.49), p-tau202 (p=0.52) and p-tau231 (p=0.12).



Conclusions: We report *in vivo* evidence supporting the previously described hibernation-linked reversible tau hyperphosphorylation process in hibernating brown bears. During hibernation, these p-tau blood biomarkers are changed in the same direction as in AD, but under a physiological phenomenon marked by several adaptive changes, including lowering of neuronal activity. Further translational studies of this phenomenon may provide insights into novel anti-tau treatment strategies in humans.

Aims: Since the underlying mechanisms of early Alzheimer's Disease are not well understood, we aimed to explore plausible extracellular cross-interactions between Tau and Amyloid beta (Abeta) that could condition disease development, as well as the effect of the early-stage chaperone S100B in this context.
Methods: The effect of Abeta on Tau was assessed following the aggregation of a fixed concentration of the Tau AD core (TADC, $Tau_{306-378}$) by monitoring X-34 fluorescence intensity in the presence of Abeta42 monomers under cofactor-free conditions. To study the effect of Tau over Abeta, the *in vitro* aggregation of a fixed concentration of Abeta42 monomers in the presence of increasing proportions of TADC and Tau-K18 ($Tau_{244-372}$) was monitored by ThT fluorescence. Finally, the influence of S100B on TADC aggregation, with and without heparin, was similarly evaluated with the fragment alone and in the presence of Abeta42 monomers. The toxicity of end-point species was assessed by liposome leakage assays.
Results: TADC aggregation was accelerated in the presence of Abeta42 in a concentration-dependent manner, and the end-point species present were fully toxic for liposomes. On the contrary, Abeta42 aggregation was inhibited by both TADC and K18. S100B had a dual-behavior on TADC aggregation, accelerating it at substoichiometric proportions and fully inhibiting it at equimolar proportions, though this inhibition was not complete when heparin was present. Finally, under mixed conditions with Abeta42, the inhibitory effect of S100B over TADC aggregation was lost.
Conclusions: Tau and Abeta have opposite effects on each other's *in vitro* aggregation. S100B, while able to inhibit TADC aggregation and toxicity, showed a concentration-dependent dual-behavior, accelerating its aggregation at lower proportions. These results highlight the complex interplay of events in early-disease scenarios in Alzheimer's Disease.

HS3ST2 EXPRESSION INDUCES THE CELL AUTONOMOUS AGGREGATION OF TAU

POSTERS: B01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TAU AGGREGATION, PHOPHORYLATION, ACETYLATION & MODIFICATIONS

Minh Bao Huynh[1], Nicolas Reberque[1], Heloise Merrick[1], Wilton Gomez-Henao[1], Estelle Jospin[1], Denis Biard[2], Dulce Papy-Garcia[1]

Aims: Heparan sulfates have long been known to intracellularly accumulate in Alzheimer's disease neurons, where they colocalize with neurofibrillary tangles made of abnormally phosphorylated and aggregated tau protein. However, the reasons and consequences of the heparan sulfates accumulation in the Alzheimer's cells are not yet well understood. Previously, we showed that the neural heparan sulfate 3-*O*-sulfotransferase HS3ST2 is critical for the abnormal phosphorylation of tau in Alzheimer's disease-related tauopathy. Using cell models of tauopathy we showed that intracellular 3-*O*-sulfatated heparan sulfates (3S-HS) interact with tau inducing its abnormal phosphorylation. However, it is unknown whether HS3ST2 expression induces the intracellular aggregation of tau in cells. In this work we aim to investigate whether 3S-HS by HS3ST2 can promote the spontaneous sef-agregation of tau in cells.
Methods: Here, by using replicative pEBV plasmids, we engineered HEK293 cells to stably express HS3ST2 together with human tau carrying or not the P301S mutation.
Results: We show that HS3ST2 gain of function induces the cell autonomous aggregation of tau not only in cells expressing tauP301S, but also in cells expressing the wild type tau. Our engineered cells mimicked both the HS intracellular accumulation observed in neurons of Alzheimer's disease and the tau aggregation characteristic of tauopathy development and evolution.
Conclusions: These results give evidence that the neural HS3ST2 plays a critical role in the cell autonomous self-aggregation of tau.

DISCOVERY OF SMALL RNA SPECIES UNDERLYING TAU AGGREGATION AND PATHOLOGY

POSTERS: B01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TAU AGGREGATION, PHOPHORYLATION, ACETYLATION & MODIFICATIONS

Ami Kobayashi[1], Anna Krichevsky[2]
[1]Brigham and Women's Hospital, Harvard Medical School, Neurology, Boston, United States of America, [2]Brigham and Women's Hospital, Neurology, Boston, United States of America

Aims: Several reports and our new data suggest specific small RNA (sRNA) transcripts as the major tau binding partners that may facilitate its aggregation in Alzheimer's diseases and other tauopathies. Distinct classes of sRNA, including snoRNA and tRNA, have been proposed as the primary candidates. Our data suggest that persistent neuronal stress implicated in tauopathies leads to tRNA cleavage and accumulation of specific tRNA-derived fragments (tRFs) in neurons. Despite the established role of tRFs as factors triggering stress granule formation in stress response in various proliferative cells, their neuronal functions are unknown. The goal of our work is to identify endogenous sRNA species contributing to tau pathology and neurodegeneration.
Methods: To discover specific RNA transcripts enriched in tau complexes and aggregates, we optimized Cross-Linking and ImmunoPrecipitation (CLIP) technique coupled with the minimally biased small RNA detection for an array of anti-Tau antibodies. In addition, we developed *in situ* imaging technology (small RNA FISH) to monitor sRNA localization in pathological tau aggregates in rodent and human neurons and brain tissues.
Results: We observed an accumulation of specific tRFs in human Alzheimer's disease brains and the Tau P301S mouse model. Using several models of long-lasting neuronal stress that employ low subtoxic doses of glutamate, H2O2, or Aβ, we identified specific tRFs most strongly accumulating in these conditions in Tau WT and mutant cells. Our data further suggest some of these tRFs as selective and physiological tau-binders.
Conclusions: While we continue to investigate and validate the specificity of tau-tRF interactions, our current study suggests new molecular targets and biomarkers for therapeutic interventions, contributing to our understanding of the complexity and etiology of tauopathies.

UNCOVERING ELEVATED TAU TPP MOTIF PHOSPHORYLATION IN THE BRAIN OF ALZHEIMER'S DISEASE PATIENTS

POSTERS: B01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TAU AGGREGATION, PHOPHORYLATION, ACETYLATION & MODIFICATIONS

Lei Liu[1], Jean-Pierre Bellier[1], Yuqi Cai[1], Sarah Alam[1], Thorsten Wiederhold[2], Arica Aiello[2], Jonathan Vogelgsang[3], Sabina Berretta[3], Jasmeer Chhatwal[1], Dennis Selkoe[1]

Aims: A wide array of post-translational modifications of the tau protein occur in Alzheimer's disease (AD) and are critical to pathogenesis and biomarker development. Several promising tau markers, especially pT181, pT217 and pT231, rely on increased phosphorylation within a common molecular motif - threonine-proline-proline (TPP). Here, we use novel assays to examine systematically the extent to which phosphorylation of the pTPP molecular motif occurs in AD brain and how its differential phosphorylation patterns can be tied to disease staging and progression.
Methods: We validated several new and existing antibodies against pT217 and pT231, pT175, and pT181, then combined immunohistochemistry (IHC) and sensitive immunoassays (ELISA) to broadly examine the phosphorylation of the tau TPP motif across many AD brains.
Results: We find that the pTPP tau burden, as examined by IHC and ELISA, correlates to Braak stages across all TPP sites examined. Moreover, we observed significant regional variability across four TPP motif phosphorylation sites in multiple brains of sporadic, late-onset AD patients.
Conclusions: We conclude that the elevation of TPP tau phosphorylation in AD brains correlates to disease progression. The regional variability of pTPP tau suggests that examining different phosphorylation sites may be needed to assess tau pathology comprehensively.

LEVERAGING CELL-TYPE-SPECIFIC PATHOGENIC TAU REACTIVITY PATHWAYS TO UNCOVER AMYLOID TOXICITY MODIFIERS

POSTERS: B01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TAU AGGREGATION, PHOPHORYLATION, ACETYLATION & MODIFICATIONS

Roman Praschberger, Jeevanjot Singh, Patrik Verstreken

Aims: Tauopathies are characterized by certain neuronal subtypes being more affected than others, giving rise to the disease-defining symptoms. Since tau is expressed brain-wide without an obvious correlation with neuronal vulnerability, we hypothesized that different neurons are differentially susceptible to pathogenic tau toxicity and therefore contributing to the observed selective neuronal vulnerability. We have experimentally confirmed this with brain-wide single-cell RNA-seq across >200 unique neuron types of *Drosophila* models of tauopathy. Here, we investigate whether and how different neurons react differentially to pathogenic tau and assess if these pathways contribute to neuronal vulnerability/resilience to tau.
Methods: We compare differentially expressed genes and pathways in different neuronal subtypes in *Drosophila* models of tauopathy and relate these changes to Alzheimer's disease brains. We also perform scRNA-seq on non-aggregating tau flies harboring a PHF6 deletion in order to extract pathways specific to aggregation toxicity. Finally, we integrate these data and perform an unbiased experimental modifier screen based on the top differentially expressed genes.
Results: While we detect shared deregulations across cell-types – mainly in ribosomal and mitochondrial pathways - we also detect abundant transcriptional changes that are specific to certain neuron types. This underlines the values of single-cell studies to understand tau-induced reactivity pathways, which is further underlined by the observation that at the bulk analysis level we detect several-fold fewer transcriptional changes, potentially due to a dilution effect via unaffected cell-types. This suggests that different neurons react differently to pathogenic tau. Several of the deregulated genes were also potent tau toxicity modifier, indicating causality.
Conclusions: Single-cell RNA-seq derived pathways of tau reactivity might be useful to understand toxicity pathways.

NEURONAL MECP2 PHOSPHORYLATION PRECEDES TAUOPATHY IN HIPPOCAMPUS AND MIDDLE TEMPORAL GYRUS OF SPORADIC ALZHEIMER'S DISEASE

POSTERS: B01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TAU AGGREGATION, PHOPHORYLATION, ACETYLATION & MODIFICATIONS

Qing-Rong Liu[1], Mark Horowitz[2], Qin Yao[2], Min Zhu[2], Qinghua Chen[2], Josephine Egan[2], Christopher Ramsden[2]

Aims: MECP2, an epigenetic transcription repressor, participates in neuron dendritic arborization and its phosphorylation regulates synaptic plasticity. Although MECP2 dysfunction has been implicated in Rett syndrome, its potential role in sporadic Alzheimer's disease (sAD) is largely unknown. We sought to determine whether MECP2-pS423 (pMECP2) can be detected in autopsied human hippocampus and middle temporal gyrus prior to Tau-hyperphosphorylation and whether its expression was increased in mild cognitive impairment (MCI) and sAD cases.
Methods: We developed and validated a rabbit anti-pMECP2 specific polyclonal antibody and carried out immunohistochemistry (IHC) on rapidly-autopsied postmortem hippocampus, entorhinal cortex (ErC), and middle temporal gyrus (MTG) specimens from 30 cases spanning the clinicopathological spectrum of sAD. We used HALO 3.3 to quantify the positive signals.
Results: pMECP2 expression increased in hippocampus, ErC, and MTG throughout the sAD spectrum with minimal, moderate, and strong expression in Controls, MCI, sAD cases, respectively. pMECP2 was primarily localized to soma and to a lesser extent within neurites emanating from affected neurons. Prominent pMECP2 expression was observed in neuron populations that are known to be selectively vulnerable to Tau-related neurodegeneration, including ErC layer II neurons and CA1 pyramidal neurons. pMECP2 expression was significantly correlated with pTau expression in each annotated region. In the hippocampus of Braak stage I-II controls, IHC revealed a small number of pMECP2-positive neurons in a similar distribution as observed for pTau. Multiplex-immunofluorescence revealed prominent cellular colocalization of pMECP2 and pTau. However, in some pyramidal neurons, pMECP2 expression was observed in the soma while AT8 positive pTau was confined to the neuropil thread, suggesting that cytoplasmic translocation of pMECP2 from nuclei may precede neurofibrillary tangle formation.
Conclusions: pMECP2 is elevated in sAD brain and correlates with pTau-associated neurodegeneration.

NUCLEAR ALTERATIONS AND TOXIC TAU CONFORMERS DEPOSITION IN NEURONS, ASTROCYTES AND MICROGLIA OF ALZHEIMER'S DISEASE, PROGRESSIVE SUPRANUCLEAR PALSY, AND DEMENTIA WITH LEWY BODY

POSTERS: B01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TAU AGGREGATION, PHOPHORYLATION, ACETYLATION & MODIFICATIONS

Lajja Majmundar[1], Rakez Kayed[2], Mauro Montalbano[2]
[1]University of Texas Medical Branch, John Sealy School Of Medicine, Galveston, United States of America, [2]University of Texas Medical Branch, Department Of Neurology, Galveston, United States of America

Aims: Tauopathies consist of age-associated neurodegenerative diseases (NDDs) characterized by pathological tau aggregation which leads to progressive neuronal dysfunction and death. Microglia and astrocytes have been described in several NDDs as playing important roles in synaptic spreading of toxic tau. In this study, human brain slices from age-matched non-demented (Control), Alzheimer's Disease (AD), Progressive Supranuclear Palsy (PSP), and Dementia with Lewy Body (DLB) cases were used to explore neuronal and glial nuclear alterations and investigate cell-specific deposition of toxic tau species.
Methods: Systematic macroscopic-histological examination of toxic tau aggregates in cortical human brains, by combinations of immunofluorescence staining were investigated for their association with specific cell types. Moreover, we investigated the nuclear density and chromatin condensation markers in these tissues. The Pearson's colocalization coefficient (PCC) for the different staining combinations were measured and presented as an averaged coefficient of determination, R^2.
Results: In the totality of cortical nuclei, a significantly greater nuclear area and chromatin condensation was seen in AD, and a reduction in nuclear density and chromatin condensation was seen in DLB and PSP. These observations showed that each disease presents varying nuclear phenotypes. Moreover, colocalization of toxic tau conformers showed a positive correlation mainly in neurons, indicating a large deposition of toxic tau in this cell type. A positive correlation in astrocytes was observed for distinct aggregates of neurotoxic phenotypes but not neuroprotective phenotypes. Microglia cells showed positive co-localization with both in varying degrees. In this study, we observed that each disease presents a specific nuclear signature and cell-type specific tau deposition.
Conclusions: This greater understanding of tau aggregation shows a cell-type tropism of toxic tau species and can give greater insight into appropriate more personalized therapeutic frameworks.

Aims: Tau fibrils, abnormal aggregates of the tau protein associated with neurodegenerative diseases, disrupt neuronal function and are primarily linked to brain pathology. However, evidence suggests their presence in the retina, sparking interest in their potential as a model for studying neurodegeneration and as a biomarker for disease diagnosis and progression. This study explores their presence in the retina, proposing it as a model for neurodegeneration research and a potential biomarker for disease. We focused on tau fragment K18, a truncated tau form with high binding and aggregation properties.
Methods: Fibrillation of this fragment was induced with heparin to generate oligomers or medium-length fibrils. Retinal neurons were differentiated from human iPSCs to study the impact of extracellular tau oligomers and fibrils in a controlled environment. Assessing tau seed uptake and concentration, we performed tau k18 seeding and collected samples after 1 and 15 days for immunofluorescence analysis.
Results: showed an increased Cleaved-casp3 positive nuclei in our cultures treated for 15-days, and an alteration in cytoskeleton markers suggested a correlation between tau fibrils exposure and cellular damage. Neurotoxicity effect of tau seeds was also confirmed by live/dead assay.
Conclusions: We concluded that tau fibrils induced cellular stress, disrupted neuronal function, and caused cell death in iPSC-derived retinal neurons. In summary, tau fibrils in the retina represent a burgeoning area of research with potential implications for understanding neurodegenerative diseases. They offer insights into disease mechanisms, diagnostic possibilities, and therapeutic monitoring. The in vitro models developed serve as a valuable tool for investigating the consequences of tau pathology on retinal cells, providing a foundation for exploring interventions to protect retinal health.

DIECKOL AS A NOVEL NEUROPROTECTIVE CANDIDATE WITH COGNITION IMPROVEMENT AND MULTIFACETED MECHANISMS IN ALZHEIMER'S DISEASE MOUSE MODEL

POSTERS: A07.C. ANIMAL MODELS: NON-MAMALIAN MODELS, OTHER

Kumju Youn[1,2], Jeong-Hyun Yoon[3], Mira Jun[1,2,3]
[1]Dong-A University, Center For Food & Bio Innovation, Busan, Korea, Republic of, [2]Dong-A University, Department Of Food Science And Nutrition, Busan, Korea, Republic of, [3]The graduate School of Dong-A University, Department Of Health Sciences, Busan, Korea, Republic of

Aims: Alzheimer's disease (AD) is an age-related neurodegenerative disorder associated with memory and cognitive deficits. Both amyloid β (Aβ) deposition and inflammatory response occur in the early course of AD, but the progression of cognitive impairment and its relationship with Aβ and neuroinflammation have not been fully understood. Dieckol is a phenolic compound from brown algae and has been reported to possess several health benefits. In particular, our previous studies have shown that the compound exerts the neuroprotective effects by inhibiting amyloidogenesis, oxidative stress and inflammatory responses against Aβ injury in cellular system. The aim of the present study was to demonstrate the cognitive improvement effect of dieckol *via* multiple mechanisms in AD mouse model.
Methods: Human $A\beta_{1-42}$ peptide was injected into the hippocampal CA1 region of mouse brains, followed by administration of dieckol (100 mg/kg/day) for 3 weeks, and histological changes and neuroprotective effect of dieckol were evaluated.
Results: Immunostaining showed that Aβ injection dramatically increased Aβ plaques compared to the vehicle injection, while administration of dieckol after Aβinjection decreased Aβ burden through Akt/GSK-3β/Nrf2 regulated amyloidogenic pathway. Dieckol suppressed neuroinflammatory responses in the Aβ group as evidenced by lower tissue levels of IL-1β, GFAP, and iNOS, except for COX-2. Moreover, the compound inhibited both nuclear translocation of NF-kB p65 subunit and IkBα phosphorylation, which significantly attenuated Aβ-mediated cognitive and memory dysfunction.
Conclusions: Overall, the present study provided a novel insight into feasibility of developing the compound as a neuroprotective agent for AD.

PPIA BINDS TAU AND SLOWS AGGREGATION IN VITRO INDEPENDENT OF ISOMERASE ACTIVITY

POSTERS: B01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TAU AGGREGATION, PHOPHORYLATION, ACETYLATION & MODIFICATIONS

Ayde Mendoza-Oliva[1], Bryan Ryder[1], Charles White[2], Valerie Perez[1], Lukasz Joachimiak[1], Marc Diamond[1]
[1]University of Texas Southwestern Medical Center, Center For Alzheimer's And Neurodegenerative Diseases, Dallas, United States of America, [2]University of Texas Southwestern Medical Center, Department Of Pathology, Dallas, United States of America

Aims: Based on evidence linking proline isomerization with tau pathology and since we found association of peptidyl-prolyl isomerase A (PPIA) with tau in Alzheimer's brain, we tested whether PPIA's cis-trans proline isomerase activity modifies tau aggregation *in vitro* and in cells.
Methods: PPIA-tau binding in human brain and in cells was determined using a pull-down assay. Recombinant human PPIA and tau were used for *in vitro* experimentation. The binding affinity was determined using microscale thermophoresis. The effect of PPIA isomerase activity on tau aggregation was analyzed by dynamic light scattering. The PPIA-tau interaction sites were mapped using crosslinking-mass spectrometry and the binding mode was determined by protein modeling. To test PPIA's effect in a cell model of tau aggregation its expression was genetically modified either by overexpression or CRISPR/Cas9 knockout.
Results: PPIA co-purifies with tau in human tauopathy brains. The conformational state of tau is not determinant for its interaction. PPIA affinity for tau is comparable to that shown with other proline isomerases. Proteomics experiments show in molecular detail that PPIA binds tau through its proline-rich domain (PRD). *In vitro,* PPIA delays tau aggregation kinetics independently of its proline isomerase activity. However, in cells, we did not detect any change in tau aggregation when PPIA proline isomerase activity was genetically abolished or when its levels of expression were increased.
Conclusions: PPIA directly binds tau through its PRD. *In vitro*, PPIA's effect on tau aggregation may arise from a function unrelated to its isomerase activity. Since there are multiple aspects of cellular proteostasis that involve PPIA, its role on tau maybe be dependent on cellular state or on the existence of more actors that regulate the PPIA-tau interaction.

Aims: Tau is a protein abundantly expressed in neurons where it modulates the stability of axonal microtubules, thus contributing to the regulation of axonal transport of several organelles. Tau aggregates in a group of neurodegenerative diseases named tauopathies, which include frontotemporal dementia (FTD) and Alzheimer's disease. Our work aimed at studying axonal transport defects induced by tau pathology, both in cultured neurons and *in vivo* in the mouse brain. We also tested the reversibility of these deficits via pharmacological inhibition of the MAPK p38.
Methods: We investigated cultured mouse neurons and tauopathy mouse models *in vivo*, using immunoistochemistry, live imaging and in vivo two photon microscopy.
Results: We found that human tau showed regions of higher density along axons, reminiscent of tau envelopes, a microtubule-bound multimeric state of tau, distinct from pathological aggregates. FTD-linked mutations, known to increase pathological phosphorylation and aggregation of tau, induces larger envelopes, an effect that is reversed by inhibition of p38 MAPK, known to phosphorylate tau at multiple sites. Functionally, axonal transport of BDNF-containing secretory granules is affected by mutant tau envelopes as observed both *in vitro* and *in vivo* by using a new assay based on two-photon microscopy on tauopathy mouse models. Interestingly, this impairment occurred very early on, before overt tau aggregation. Inhibition of p38 MAPK was able to partially rescue the defects in axonal transport both *in vitro* and *in vivo*.
Conclusions: Our data suggests that tau envelopes size regulates axonal transport, an effect dependent on tau phosphorylation. Inefficient organelles transport may have severe consequences on the activity and plasticity of neuronal circuits. The evidence that reducing tau phosphorylation by inhibiting p38 MAPK potentiated axonal transport points towards inhibition of p38 MAPK as a promising therapeutic strategy in tauopathies.

Aims: Synaptic loss is a pathological hallmark in Alzheimer's disease (AD) that correlates with cognitive decline. However, the investigation in human brain is limited by the lack of adequate tools to resolved these small structures. Our primary objective was to combine array tomography (AT) with direct stochastic optical reconstruction microscopy (dSTORM) to achieve an enhanced lateral resolution optimal to resolve synaptic terminals in human postmortem brain and study synaptic tau pathology in AD.
Methods: We used AT samples obtained from controls and sporadic AD patients(n=3) from our AT cohort to study the lateral resolution achieved with the combination of AT+dSTORM. We measured the distance between the pre and post-synaptic markers. We also utilized 2 µm-thick paraffin (FFPE) samples from SAD patients(n=2) to visualize hyperphosphorylated tau using AT8 antibody. This marker was used for resolution comparison in confocal and STORM imaging.
Results: The combination of AT+dSTORM provides a significant improvement in lateral resolution compared to AT alone with conventional microscopy. This combination allowed to visualize the nanoscale architecture of individual synapses, including the synaptic cleft. The median distance between SYPH and PSD95 was 0.064µm±0.061, without overlap at distances of up to 0.008µm. We observed a significant improvement in lateral resolution using FFPE samples with dSTORM compared with confocal microscopy. However the AT+STORM combination offered the best results for visualizing aggregates at the
synapse.

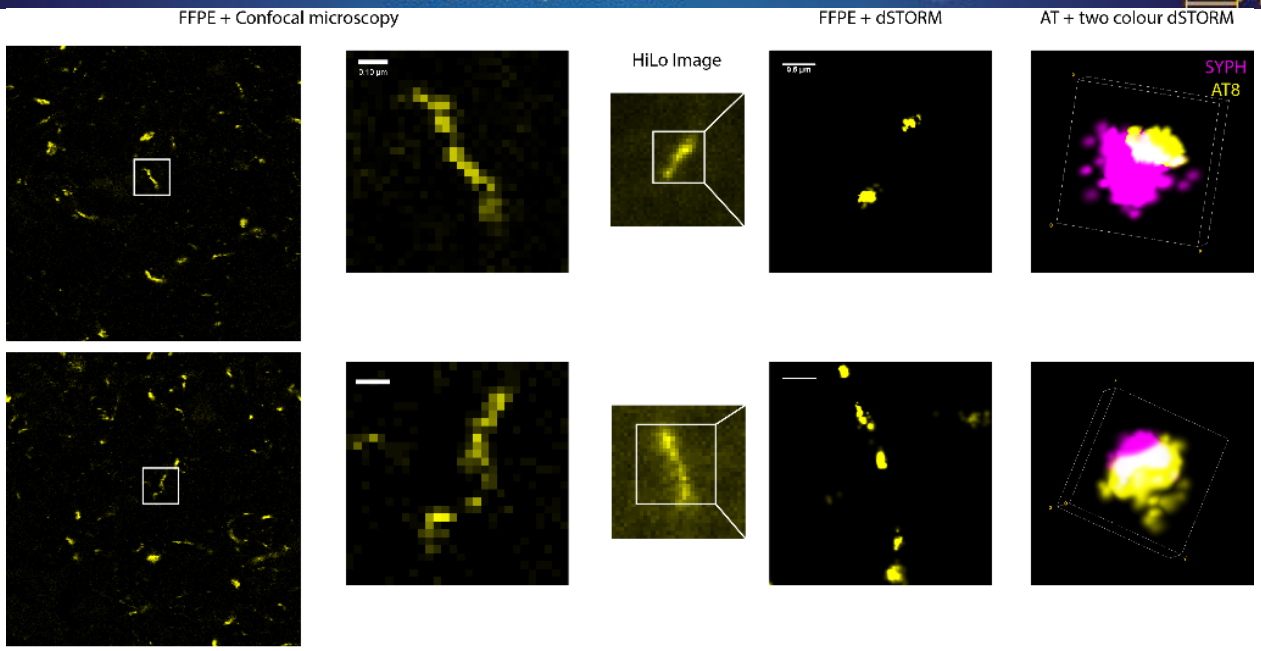

Figure 1. Comparison of Lateral Resolution obtained using confocal microscopy (left) and dSTORM (right).

Conclusions: Our findings highlight the potential of the combination of AT+dSTORM as an optimal condition to visualise tau aggregates at the synapse and to precisely resolve pre- and post-synapse structures in human brain. This innovative approach improves the understanding of synaptic pathology in neurodegenerative diseases, that could facilitate more targeted therapeutic interventions and a deeper understanding of the mechanisms underlying cognitive impairment.

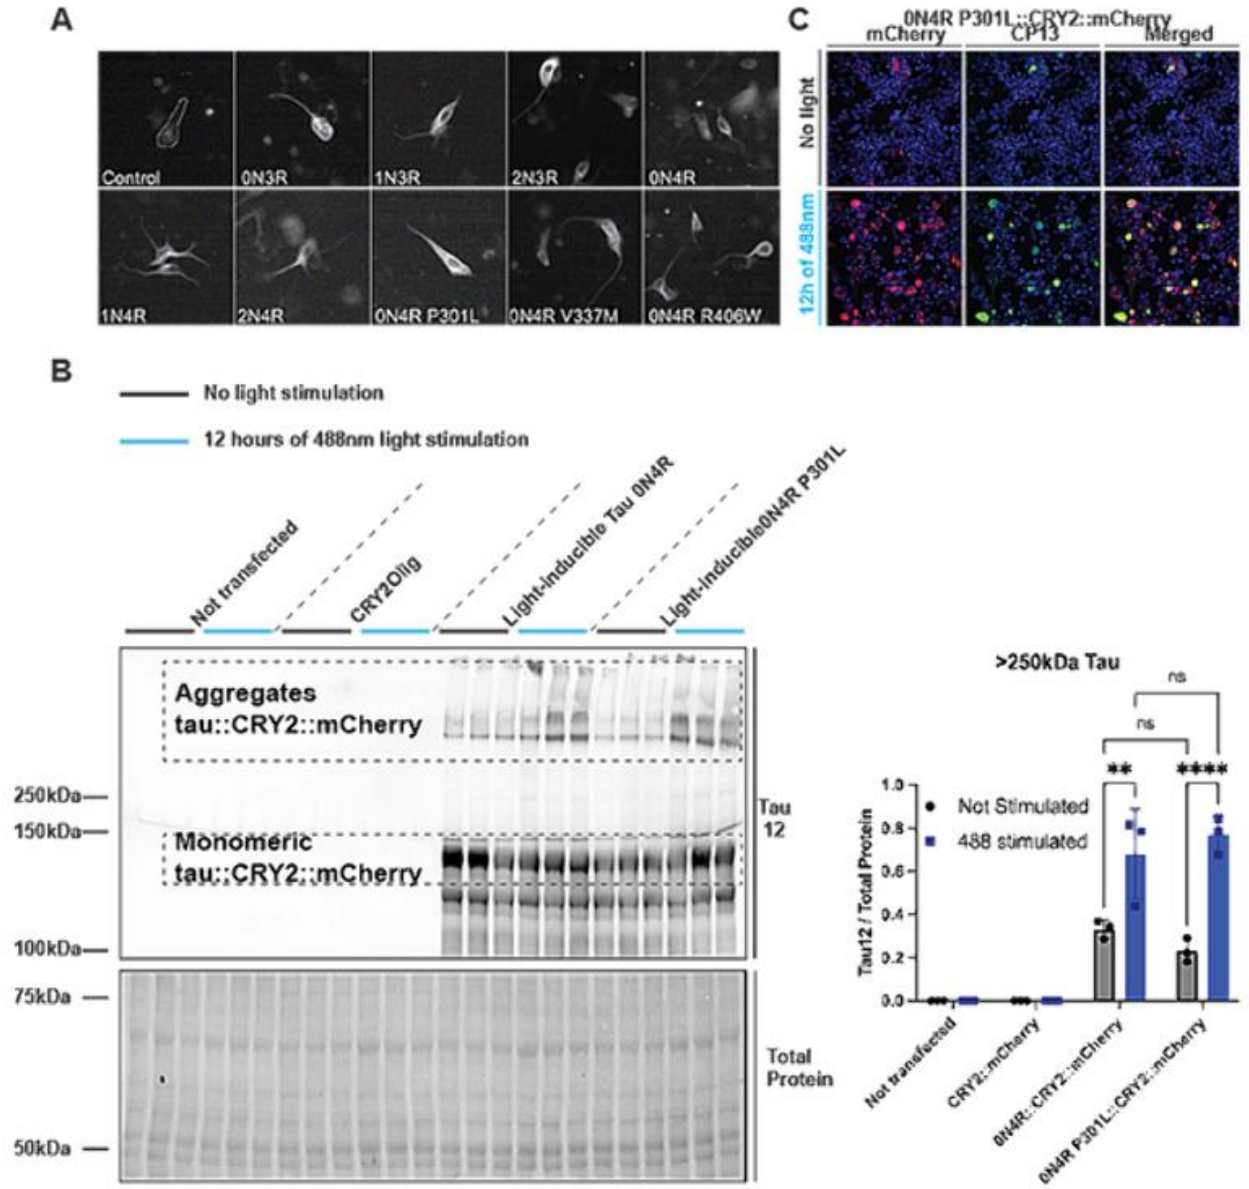
Aims: Tauopathies comprise a broad category of diseases associated with cognitive impairment. The molecular underpinnings of neurofibrillary neurodegeneration remain poorly understood and there is a paucity of robust cellular models for mechanistic studies and drug development. Hence, there is a critical need for new tau aggregation models and for further research to better understand the molecular basis of tauopathies. **OBJECTIVE:** To develop an optogenetics-based cellular model suitable for high-throughput analysis to aid in mechanistic studies of tau mediated cell death.
Methods: We engineered a panel of light-activated CRY2-tau constructs that enables assessment of tau aggregation kinetics and allows to focus on specific tau proteoforms to address questions on tau proteostasis, and associated pathway alterations with precise spatiotemporal control. This panel includes all CNS tau isoforms and a spectrum of mutations as well as mCherry for live cell imaging. This is a departure from the variable tau models available that rely on non-physiological modifiers of tau structure or the utilization of fibrils taken from diseased brains. Cell lines were transfected and assayed following light activation using immunoblotting and live imaging.
Results: Overexpression of CRY2-tau constructs showed stable inclusions after light stimulation, which were absent or markedly diminished in controls (Fig 1). Immunoblotting confirmed the presence of high molecular weight tau aggregates following stimulation. Inclusions were immunopositive for phospho-tau by immunocytochemistry and
immunoblot.



Conclusions: These data demonstrate that this system is capable of generating pathology-relevant tau species and has potential to reveal mechanistic insights into neurofibrillary degeneration. The precise spatiotemporal resolution of the system represents a potentially useful platform for drug screening.

TACKLING TAUOPATHIES: LAMIVUDINE'S PROMISE IN NEURODEGENERATIVE THERAPY

POSTERS: B01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TAU AGGREGATION, PHOPHORYLATION, ACETYLATION & MODIFICATIONS

Laura Vallés Saiz, Jesús Ávila, Félix Hernández
Centro de Biología Molecular Severo Ochoa, Molecular Neuropathology, Madrid, Spain

Aims: 1. Investigate the potential protective effects of the reverse transcriptase inhibitor lamivudine (3TC) in a P301S mouse model of Alzheimer's disease based on the overexpression of tau protein associated with FTDP-17 tauopathy. 2. Assess the relationship between dysregulation of transposable elements and neurodegenerative disorders, specifically abnormal tau accumulation.
Methods: Lamivudine was administered to P301S mice via drinking water. These mice were subjected to the Rotarod test to evaluate motor deficits and the Y-maze test to assess short-term memory. Various immunofluorescence assays were conducted for histopathological evaluation. Experiments in HeLa cells were conducted to assess retrotransposition both with and without tau and lamivudine
Results: Lamivudine treatment showed a 30% increase in survival and improvements in behavior, such as a decrease in motor deficits and enhancement of short-term memory. Additionally, treated mice exhibited significant beneficial effects at the histopathological level, including a reduction in abnormal tau phosphorylation, decreased brain inflammation, decreased neuronal death, and attenuation of hippocampal atrophy in lamivudine-treated mice. Finally, we demonstrated in vitro that there was an increased insertion of LINE-1 in HeLa cells when tau was co-expressed, compared to cells without tau, and lamivudine could inhibit this process.
Conclusions: The data from this study suggest that the progression of tauopathies can be attenuated by the administration of lamivudine when symptoms of neuropathology first appear. This suggests a potential therapeutic approach to mitigate the effects of neurodegenerative disorders associated with dysregulated transposable elements and tau protein abnormalities. A connection exists between tau protein and LINE-1 retrotransposition, with higher retrotransposition in the presence of tau, and lamivudine reduces this

activity.

COGNITIVE DECLINE AND TAU-ASSOCIATED PATHOLOGY WORSEN AFTER LATE-LIFE DEPRESSION IN P301S MICE

POSTERS: B01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TAU AGGREGATION, PHOPHORYLATION, ACETYLATION & MODIFICATIONS

Laura Vegas-Gomez[1], Cristina Gutierrez-Sastre[1], Maria Angeles Arredondo-Alcala[1], Antonia Gutierrez[1,2], Ines Moreno-Gonzalez[1,2,3]
[1]Universidad de Málaga, Departamento De Biologia Celular, Genética Y Fisiologia, Malaga, Spain, [2]Centro de Investigacion Biomedica en Red Sobre Enfermedades Neurodegenerativas, Ciberned, madrid, Spain, [3]The University of Texas Health Science Center at Houston, 3 Department Of Neurology, Houston, United States of America

Aims: Clinical studies suggest that depression could be considered an important risk factor for the future development of cognitive impairment and Alzheimer's disease (AD). In fact, there is a strong association between late-life depression and AD. The age of AD onset has been shown to be accelerated in patients with mild cognitive impairment (MCI) with a history of depression, and women appear to be particularly more vulnerable to this condition. In addition, individuals with MCI who present depressive symptoms have an elevated burden of amyloid-beta (Aβ), the main toxic protein associated with Alzheimer's pathology, and a higher risk of developing AD compared to non-depressed MCI patients. Although it has been described that some transgenic models of AD can develop signs like depression in advanced stages, the induction of Alzheimer's pathology due to a depressive process has not been studied under experimental conditions to emulate late-life depression as a risk factor for AD.
Methods: The objective of this study is to determine, by inducing unpredictable mild chronic stress (CUMS) in tau transgenic P301S mice, whether depression is a cause, rather than a consequence, of AD development.
Results: The results of our study indicate that the induction of CUMS in transgenic animals induces phenotypic changes related to a depressive state. Behavioral and histological studies suggest that depression-like induction can worse AD pathology.
Conclusions: The findings generated in this project could provide evidence of depression as a risk factor for AD.

TAU CLUSTERING ON THE NEURONAL PLASMA MEMBRANE IS IMPEDED BY NA+/K+-ATPASE DERIVED PEPTIDE

POSTERS: B01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TAU AGGREGATION, PHOPHORYLATION, ACETYLATION & MODIFICATIONS

[1]Institut de Biologie de l'ENS(IBENS), Cellular Biology Of The Synapse, Paris, France, [2]Institut Francois Jacob (MIRCen), Cea And Laboratory Of Neurodegenerative Diseases, Fontenay-Aux-Roses cedex, France

Aims: Abnormal accumulation of tau aggregates in the brain is a hallmark of tauopathies. Both monomer and fibril tau are detected in the extracellular environment and internalized by neurons in either free form or inside vesicles. However, whether monomer tau accumulates on the plasma membrane before internalization remains unclear. In this study, we will dissect the diffusion properties of both monomer and fibril tau on the plasma membrane.
Methods: Purified monomer and fibril tau were applied to primary neuronal culture and organotypic slice culture to mimic the pathologic environment. We adopted multiple single-molecule imaging approaches including single-molecule localization microscopy and quantum dots single particle tracking together with confocal imaging to quantitively analysis the clustering and dissociation process of monomer and fibril tau on the neuonal plasma membrane.
Results: Similar to fibril tau, monomer tau forms clusters on the plasma membrane following a time- and concentration-dependent manner. Monomer tau is involved in fibril tau clustering to enhance cluster stabilization and result in dynamic structures on the plasma membrane. Additionally, we describe the different diffusion properties of monomer and fibril tau on the plasma membrane suggesting their different binding partners on the membrane. Meanwhile, based on our previous work, we designed and verified a small peptide derived from Na^+/K^+-ATPase which alters tau clustering process and can be used as a potential therapeutic tool to postpone disease progression.
Conclusions: Monomer tau accumulates to clusters on the plasma membrane and is involved in fibril tau clustering to stabilize its structures, which suggests that monomer tau also plays an important role on tau spreading in tauopathies. The designed short peptide from Na^+/K^+-ATPase alters tau clustering process suggesting a new therapeutic method to postpone disease progression.

Aims: Tauopathies are age-associated neurodegenerative diseases whose mechanistic underpinnings remain elusive, partially due to lack of appropriate human models. Current human induced pluripotent stem cell (hiPSC)-derived neurons express very low levels of 4-repeat (4R)-tau isoforms that are normally expressed in adult brain. Here, aimed to create new iPSC lines that expressed 4R-tau and 4R-tau carrying the P301S *MAPT* mutation when differentiated into neurons, to characterize and dissect the molecular mechanisms of underlying 4R-tauopathy in human neurons.
Methods: We employed the use of CRISPR editing to engineer the iPSC lines, and used molecular biology techniques, bulk and single-cell RNA sequencing, and immunostaining to characterize the lines. We found endogenous tau aggregation in the exclusively 4R-P301S neurons seeded with K18-PL tau seeds. With this, we utilized electrophysiology, transmission electron microscopy, and CRISPRi functional genomic screening to understand the pathways and factors driving tau inclusion formation.
Results: We found 4R-P301S neurons display progressive Tau inclusions upon seeding with Tau fibrils and recapitulate features of tauopathy phenotypes, including shared transcriptomic signatures, autophagic body accumulation, and impaired neuronal activity. A CRISPRi screen of genes associated with Tau pathobiology identified over 500 genetic modifiers of Tau-seeding-induced Tau propagation, including retromer VPS29 and the UFMylation cascade as top modifiers. In AD brains, the UFMylation cascade is altered in neurofibrillary-tangle-bearing neurons. Inhibiting the UFMylation cascade suppressed seeding-induced Tau propagation.
Conclusions: We characterized the 4R and 4R-P301S neuronal cell lines and identified novel genetic modifiers of 4R-tau inclusions, and thus, this model provides a powerful platform to identify novel therapeutic strategies for 4R tauopathy in human neurons.

STUDYING TAU-INDUCED NEURON-ASTROCYTE SIGNALLING

POSTERS: B01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELL TO CELL TRANSMISSION, SPREADING OF PATHOLOGY, PRION-LIKE

Ambika Mahajan[1], Kevin Batenburg[1], Wiep Scheper[1,2]
[1]Amsterdam UMC, Human Genetics, Amsterdam, Netherlands, [2]Centre for Neurogenomics and Cognitive Research, Functional Genomics, Amsterdam, Netherlands

Aims: Tau pathology is strongly associated with neurodegeneration in numerous diseases including Alzheimer's Disease and Fronto-Temporal Dementia. Aggregation of tau disrupts cellular homeostasis and leads to activation of proteostatic stress responses in the neurons, sustained activation of which is toxic. Recent research from our lab has shown that progressive intraneuronal tau aggregation activates the integrated stress response (ISR) and increases reactive oxygen species (ROS) in astrocytes (Batenburg et al., 2022). In this study, we aim to elucidate the mechanism underlying the tau-induced cell non-autonomous response in astrocytes by determining the mode of transfer and the effect of ISR activation on astrocyte function.
Methods: Utilising our extensively validated seed-independent approach to induce tau aggregation (Batenburg et al., 2022; Jorge-Oliva et al., 2022, 2023), we employ direct and sandwich co-culture and monoculture models of human iPSC-derived neurons and human foetal astrocytes and mouse primary neurons and astrocytes to study neuron-astrocyte signalling and astrocyte function. High-content microscopy and confocal microscopy are utilised to determine cell type-specific ISR activation. Molecular and pharmacological interventions are employed to elucidate pathways involved in neuron-glia signalling and its downstream effects.
Results: Our data indicate that extracellular tau is not involved in tau-induced cell non-autonomous ISR activation in astrocytes. We are currently investigating the mode of transfer of the stress response through the transferring of conditioned media, and direct and sandwich co-cultures. Furthermore, we are studying the effects of activation of the ISR on astrocytic physiology.
Conclusions: Identification of the mechanism underlying the astrocytic non-autonomous response will provide insight into the role of astrocytes in tau-induced neurodegeneration. Knowledge of the molecular mechanism involved in tau-induced neuron-glia signalling will potentially provide novel therapeutic targets for neurodegenerative tauopathies.

TAU PATHOLOGY IN HUB REGIONS IS ASSOCIATED WITH HIGHER CONVERSION TO ALZHEIMER'S DISEASE

POSTERS: B01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELL TO CELL TRANSMISSION, SPREADING OF PATHOLOGY, PRION-LIKE

Fardin Nabizadeh
Iran University of Medical Science, Tehran, Iran, School Of Medicine, Tehran, Iran

Aims: Previous studies showed that tau pathology spreads trans-synaptically across interconnected neurons. However, it is not clear whether the individuals who convert to Alzheimer's disease (AD) have higher tau pathology in globally connected hubs. We aimed to perform a study by combining resting-state fMRI and longitudinal tau-PET to investigate the association between tau pathology in globally connected hub regions and conversion to AD.
Methods: The data of 110 patients with mild cognitive impairment (MCI) was obtained from ADNI. Tau-hub ratio was calculated which represents the pattern of tau pathology considering the functional connectivity of each region to other regions.
Results: Our analysis showed that the tau-hub ratio was significantly higher among MCI patients who converts to AD over the follow-up (p:0.002). Moreover, there was a strong correlation between the tau-hub ratio and disease progression in MCI patients ($p<0.001$, r:0.453).
Conclusions: Our findings suggest that the tau pathology in globally connected hub regions may accelerate tau spreading through connected regions, AD progression, and conversion rate to AD.

REMOTE AND LOCAL EFFECT OF AB ON TAU SPREADING THROUGH FUNCTIONAL CONNECTIONS

POSTERS: B01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELL TO CELL TRANSMISSION, SPREADING OF PATHOLOGY, PRION-LIKE

Fardin Nabizadeh
Iran University of Medical Science, Tehran, Iran, School Of Medicine, Tehran, Iran

Aims: Alzheimer's disease (AD) is characterized by the accumulation of Amyloid-beta (Aβ) plaques initiated approximately two decades before the symptom onset followed by buildup and spreading of neurofibrillary tau aggregates. Although it has been suggested that the Aβ amplifies tau spreading the observed spatial disparity called it into question. Yet it is unclear how neocortical Aβ remotely affects early pathological tau, triggering it to leave the early formation area, and how Aβ facilitates tau aggregate spreading throughout cortical regions. I aimed to investigate how Aβ can facilitate tau spreading through neuronal connections in the AD pathological process by combining fMRI normative connectomes and longitudinal in vivo molecular imaging data.
Methods: In total, the imaging data of 317 participants including, 173 Aβ-negative non-demented and 144 Aβ-positive non-demented participants have entered the study from ADNI. Furthermore, normative resting-state fMRI connectomes were used to model tau spreading through functional connections.
Results: It was observed that the Aβ in regions with the highest deposition (Aβ epicenter) is remotely associated with connectivity-based spreading of tau pathology. Moreover, Aβ in regions that exhibit the highest tau pathology (tau epicenter) is associated with increased connectivity-based tau spreading to non-epicenter regions.
Conclusions: The findings provide a further explanation for a long-standing question of how Aβ can affect tau aggregate spreading through neuronal connections despite spatial incongruity. The results suggest that Aβ pathology can remotely and locally facilitate connectivity-based spreading of tau aggregates.

MAPPING OF POSTTRANSLATIONAL MODIFICATIONS OF NEURONAL MICROTUBULES AS MARKERS OF STABILITY DURING HIBERNATION IN HAMSTERS

POSTERS: B01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TAU AGGREGATION, PHOPHORYLATION, ACETYLATION & MODIFICATIONS

Julia Ziegert, Moana Künemuth, Max Holzer, Isabel Hilbrich, Jens Stieler, Markus Morawski, Thomas Arendt
Paul Flechsig Institut, Ag Holzer, Leipzig, Germany

Aims: Abnormal phosphorylation and subcellular translocation of tau protein are hallmarks of a variety of neurological disorders, including Alzheimer's disease (AD). Recently we described the reversible formation of highly phosphorylated tau protein in hibernating hamsters. Despite the extreme conditions during torpor, inducing highly phosphorylated tau protein and the cold-induced instability of microtubules, neuronal processes and associated memory contents remain largely intact upon arousal, necessitating compensation for cold-induced changes. We aim to analyse posttranslational modifications of microtubules during torpor in comparison to euthermic brain reagions in hamsters.
Methods: Posttranslational tubulin modifications such as polyglutamylation, Δ2-tubulin, Δ3-tubulin, tyrosination, detyrosination and acetylation were quantified in relation to total tubulin in brain areas of cerebellum, hippocampus, neocortex and subcortical regions from torpor (5°C) and euthermic (37°C) hamster brains. Western blot analysis is performed using modification-specific antibodies while fluorescence read-out allows simultaneous detection of specific posttranslational modifications and total tubulin. Immunostaining of brain sections will yield information about differentially affected cell types in various brain areas.
Results: In torpor state, I found that the total amount of tubulin decreases in all of the investigated brain regions. Some of the posttranslational modifications such as polyglutamylation and tyrosination are upregulated in some brain regions.
Conclusions: The presence of hyperphosphorylated tau and cold-induced instability may affect microtubule-integrity in brains of hibernating hamsters. The reversibility of cold-induced effects after torpor bouts calls for compensating effects on microtubles and microtubule-associated proteins. We show that posttranslational modification of tubulin may be associated with cold-induced stability.

TAU OLIGOMER-MEDIATED STIMULATION OF THE NADK2-NADPH PATHWAY REWIRES MITOCHONDRIAL METABOLISM AND REGULATES ITS UPTAKE BY HUMAN NEURONS.

POSTERS: B01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELL TO CELL TRANSMISSION, SPREADING OF PATHOLOGY, PRION-LIKE

Evelyn Pardo, Taylor Kim, Xuehan Sun, George Bloom, Andrés Norambuena
University of Virginia, Biology, Charlottesville, United States of America

Aims: Transcellular spread of pathological tau, mitochondrial dysfunction, and neuron loss are key signatures of Alzheimer's disease (AD). The evolutionarily conserved mitochondrial NADP+ kinase (NADK2) has been recently shown to regulate proline synthesis, cell proliferation, and cancer. However, whether dysregulation of mitochondrial NADK2 mediates tau-induced toxicity and propagation in AD remains unexplored.
Methods: Using recombinant (rTauOs) or brain-derived human tau (bdTauOs) oligomers, we evaluated mitochondrial metabolism by two-photon fluorescence lifetime microscopy in live NPC-derived human neurons. Lentiviral-mediated delivery of shRNA was used to downregulate LRP1 expression and CRISPR/CAS9 was used to generate both NADK2 and PYCR1-KO NPCs. A proteomic profile of NADK2-KO neurons was analyzed by mass spectrometry.
Results: Sublethal doses of rTauOs and bdTauOs increased the mitochondrial content of NADPH and the expression of NADK2, P5CS, PYCR1, and proline. These effects were absent in NADK2-KO and PYCR1-KO neurons. Mechanistically, these effects were mediated by LRP1, a major TauO receptor at the plasma membrane. Notably, NADK2 expression was upregulated in human AD brain. To understand the neuronal role of NADK2, we analyzed the proteomic profile of NADK2-KO human neurons using mass spectrometry. Among others, the expression of LRP1 was highly compromised in NADK2-KO neurons. Remarkably, the expression of LRP1 was increased in neurons treated with either rTauOs or bdTauOs and in neurons expressing P301S tau. Finally, the endocytosis of rTauOs was reduced by 50% in NADK2-KO human neurons, suggesting a decreased availability of LRP1 in the plasma membrane surface.
Conclusions: TauO-mediated dysregulation of NADK2 controls the expression of its own receptor, likely regulating a key aspect of TauO toxicity. Dysregulation of the NADK2 could be an early contributor to AD initiation.

NEOCORTICAL TAU PROPAGATION IS A MEDIATOR OF CLINICAL HETEROGENEITY IN ALZHEIMER'S DISEASE

POSTERS: B01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELL TO CELL TRANSMISSION, SPREADING OF PATHOLOGY, PRION-LIKE

Ana Pereira[1], Anjalika Chongtham[2]
[1]Icahn School of Medicine at Mount Sinai, Neurology, New York, NY, United States of America, [2]Icahn School of Medicine at Mount Sinai, Neurology, New York, United States of America

Aims: Heterogeneity in progression of clinical dementia obstructs the general therapeutic potential of current treatments for Alzheimer's disease (AD). Though the mechanisms of this heterogeneity remain unclear, the characterization of bioactive tau species and factors that regulate their seeding behavior might give valuable insight as tau is well correlated with cognitive impairment.
Methods: Here, we investigated the molecular basis involved in widespread, connectivity-based tau propagation that begins in the human post-mortem inferior temporal gyrus (ITG) and spreads to neocortical areas such as the prefrontal cortex (PFC) using tau seeding, several biochemical assays and RNA-sequencing.
Results: Biochemical analysis of postmortem human ITG and PFC tissues revealed considerable variability in tau seeding, which correlated with cognitive decline particularly in the ITG, a region known for promoting accelerated tau propagation. We propose that specific hyperphosphorylated high-molecular-weight and low-molecular-weight tau and its isoforms are likely mediators of seeding and cognitive decline. Further, we investigated the molecular heterogeneity in AD with RNA-seq analyses of ITG tissues with differential seeding potential. Patients with relatively higher levels of seed-competent tau showed more severely impaired synaptic and neural plasticity and increased neuroinflammation.
Conclusions: These findings provide further insights into multiple molecular mechanisms potentially involved in disease progression, highlight targets for early intervention, and improve patient subtyping, which is critical for developing precision medicines.

TRAUMATIC BRAIN INJURY DERIVED PATHOLOGICAL TAU POLYMORPHS INDUCE THE DISTINCT PROPAGATION PETTERN AND NEUROINFLAMMATORY RESPONSE

POSTERS: B01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELL TO CELL TRANSMISSION, SPREADING OF PATHOLOGY, PRION-LIKE

Nicha Puangmalai[1], Nemil Bhatt[1], Alice Bittar[2], Cynthia Jerez[1], Nikita Shchankin[2], Rakez Kayed[1]
[1]University of Texas Medical Branch, Neurology, Galveston, United States of America, [2]University of Texas Medical Branch, Department Of Neurology, Galveston, United States of America

Aims: The misfolding and aggregation of the tau protein into neurofibrillary tangles constitute a central feature of tauopathies. Traumatic brain injury (TBI) has emerged as a potential risk factor, triggering the onset and progression of tauopathies. Our previous research revealed distinct polymorphisms in soluble tau oligomers originating from single versus repetitive mild TBIs. However, the mechanisms orchestrating the dissemination of TBI brain-derived tau polymorphs (TBI-BDTPs) remain elusive.
Methods: We explored whether TBI-BDTPs could initiate pathological tau formation, leading to distinct pathogenic trajectories. Wild-type mice were exposed to TBI-BDTPs from sham, single-blast (SB), or repeated-blast (RB) conditions, and their memory function was assessed through behavioral assays at 2- and 8-month post-injection.
Results: Our findings revealed that RB-BDTPs induced cognitive and motor deficits, concurrently fostering the emergence of toxic tau aggregates within the injected hippocampus. Strikingly, this tau pathology propagated to cortical layers, intensifying over time. Importantly, RB-BDTP-exposed animals displayed heightened glial cell activation, NLRP3 inflammasome formation, and increased TBI biomarkers.
Conclusions: Collectively, our results shed light on the intricate mechanisms underlying TBI-BDTP-induced tau pathology and its association with neuroinflammatory processes. This investigation enhances our understanding of tauopathies and their interplay with neurodegenerative and inflammatory pathways following traumatic brain injury.

ARC MEDIATES THE INTERCELLULAR SPREAD OF TAU

POSTERS: B01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELL TO CELL TRANSMISSION, SPREADING OF PATHOLOGY, PRION-LIKE

Mitali Tyagi[1], Radhika Chadha[1], Bradley Hyman[2], Jason Shepherd[1]
[1]University of Utah, Department Of Neurobiology, Salt Lake City, United States of America, [2]Harvard Medical School, Massachusetts Alzheimer's Disease Research Center, Charlestown, United States of America

Aims: Aggregation of hyperphosphorylated tau is one of the hallmarks of Alzheimer's disease (AD) and correlates with cognitive decline in AD patients. During AD, tau pathology spreads across the brain in a stereotypical pattern. The spread of tau pathology occurs through intercellular transfer of pathological tau, but the underlying mechanisms remain unclear. Intercellular tau transfer may occur either through membrane-bound tau in extracellular vesicles (EVs) or as "naked" tau. Recent studies demonstrate that EV-tau may be more potent at seeding and spreading tau pathology. We recently discovered that the neuronal gene *Arc,* a critical regulator of synaptic plasticity and memory, mediates a novel form of intercellular communication. Arc protein self-assembles into viral-like capsids that are released from neurons in EVs that carry RNA/proteins to neighboring neurons. We hypothesized that Arc EVs may facilitate the release of pathological tau and intercellular spread.
Methods: To test if Arc facilitaes intercellular tau transfer, we virally expressed GFP-2A-human Tau (P301L) in wild-type and Arc knockout primary hippocampal neurons and in 6-month-old mouse entorhinal cortex. We also investigated if Arc and tau bind using GST pulldown assays and co-immunoprecipitation.
Results: We found intercellular tau transfer decreases significantly in the absence of Arc, both *in vitro* and *in vivo*. We also confirmed that Arc binds tau *in vitro* and *in vivo*.
Conclusions: Our findings suggest that Arc facilitates the intercellular spread of tau. We are now investigating the molecular mechanisms underlying Arc-dependent tau transfer.This study will uncover a novel mechanism for tau spread and seeding, potentially opening new therapeutic interventions for AD.

UNVEILING THE STRUCTURAL DIVERSITY OF TAUOPATHY STRAINS THROUGH SYSTEMATIC AMINO ACID PROFILING

POSTERS: B01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELL TO CELL TRANSMISSION, SPREADING OF PATHOLOGY, PRION-LIKE

Jaime Vaquer Alicea[1], Victor Manon[1], Vaibhav Bommareddy[1], Peter Kunach[1], Ankit Gupta[1], Jim Monistrol[1], Valerie Perez[1], Vishruth Mullapudi[1], Du Siling[1], Sushobhna Batra[1], Charles White[2], Lukasz Joachimiak[1], Sarah Shahmoradian[2], Marc Diamond[2]
[1]University of Texas Southwestern Medical Center, Center For Alzheimer's And Neurodegenerative Diseases, Dallas, United States of America, [2]University of Texas Southwestern Medical Center, Department Of Pathology, Dallas, United States of America

Aims: The primary aim of this research is to unravel the structural diversity of tauopathy strains, including those observed in Alzheimer's disease (AD), Corticobasal Degeneration (CBD), and Progressive Supranuclear Palsy (PSP). This involves a systematic exploration of the role of individual amino acids in tau protein assembly, with a focus on understanding the amino acid dependencies within tau aggregates in cellular models. The study also seeks to develop a novel biosensor system for tauopathy classification, assess the fidelity of cellular models in replicating tau strain structures, and provide insights into potential diagnostic and therapeutic strategies.
Methods: To achieve our aims, we developed a cell-based assay that combines comprehensive tau mutagenesis with the detection of tau monomer incorporation into existing aggregates. This approach allowed us to systematically profile the amino acid contributions to tau strain stability and propagation. Synthetic tau strains were scrutinized in our models to assess their fidelity in replicating real-world tauopathy strain features. Furthermore, we extended our analysis to human tauopathy cases, investigating seeding activity profiles.
Results: Our study revealed the remarkable fidelity of simple cellular systems in replicating unique structural features of tau strains associated with specific tauopathies, such as AD, CBD, and PSP. Furthermore, the biosensor system successfully discriminated synthetic tau strains, providing a robust classification tool based on replication requirements. Analysis of human tauopathy cases demonstrated distinct seeding activity profiles for accurate disease differentiation.
Conclusions: We have successfully profiled amino acid contributions to tau strain stability and replication, leading to the development of a reliable classification system. The fidelity of cellular models in replicating tau strain features in patients underscores the potential of these models for future research. These findings have implications for diagnostics and therapeutic strategies.

DIFFERENTIAL EFFECT OF AMYLOID AND TAU PATHOLOGY ON PRO-INFLAMMATORY AND PRO-RESOLVING LIPID MEDIATORS IN TRANSGENIC RAT MODELS OF ALZHEIMER'S DISEASE

POSTERS: B01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Sonia Do Carmo[1], Surjyadipta Bhattacharjee[2], Marie-Audrey Kautzmann[2], Carolyn Steinberg[1], Nicolas Bazan[3], A Claudio Cuello[4]
[1]McGill University, Pharmacology And Therapeutics, Montreal, Canada, [2]School of Medicine, Louisiana State University Health New Orleans, Neuroscience Center Of Excellence, New Orleans, United States of America, [3]School of Medicine, Louisiana State University Health New Orleans andForeign Adjunct Professor of Neuroscience Karolinska Institutet, Stockholm, Sweden., Neuroscience Center Of Excellence, New Orleans, United States of America, [4]McGill University and Visiting Professor at Pharmacology, Oxford University, Pharmacology And Therapeutics, Montréal, Canada

Aims: Brain inflammation is characterized by glial cell activation and by the increased production of cytokines, chemokines, and lipid mediators (LMs) and contributes significantly to the development and progression of Alzheimer's disease (AD). However, little is known about the relative contribution of the amyloid and tau pathologies to the progression of neuroinflammation. Our objective was to investigate the differential impact of tau and amyloid pathology on the levels of cytokines, chemokines and bioactive pro-inflammatory and pro-resolving LMs.
Methods: We examined cohorts of homozygous McGill-R-Thy1-APP transgenic rats at 6 months of age when the amyloid beta (Aβ) pathology is restricted to the intraneuronal space and at 16 months of age when there is extensive Aβ plaque pathology. We also examined cohorts of heterozygous McGill-R962-hTau and McGill-R955-hTau transgenic at 10 and 20 months of age, representing progressive stages of tauopathy. Age-matched wild-type littermates were used as controls. Levels of cytokines, chemokines and LMs in cortical homogenates were probed applying well-established ECLIA, Western blotting and LC-MS/MS protocols.
Results: We found that in APP transgenic rats the cortical production of cytokines was already significantly elevated at pre-plaques stages while, in our rat models of tauopathy, an elevation in inflammatory mediators was only seen at late tau pathology stages. Our analyses also revealed that in our models, amyloid and tau pathologies had differential effects on levels of arachidonic (AA)-derived LMs prostaglandins, of docosahexaenoic acid (DHA)-derived pro-resolving mediators and of AA- and DHA-containing phospholipids.
Conclusions: Amyloid and tau pathology have differential effects on the abundance of bioactive LMs which vary with pathology progression. This suggests that tau and amyloid pathology have a different impact on the membrane properties and consequentially on signal transduction.

NEUROINFLAMMATION, ALPHA-SYNUCLEIN AND BETA-AMYLOID ANTIBODIES IN PARKINSON'S DISEASE AND ALZHEIMER'S DISEASE.

POSTERS: B01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Dmitriy Labunskiy, Svetlana Kiryukhina, Vyacheslav Podsevatkin, Nikolay Kurgaev, Denis Baranov
Ogarev Mordovia State University, Neurology And Psychiatry, Saransk, Russian Federation

Aims: Neuroinflammation plays a very important role in the pathogenesis of a number of neurodegenerative diseases. Autoimmune reactions that come to the fore during neuroinflammation are accompanied by the release of specific antibodies to proteins that cause one or another neurodegenerative pathology. In Parkinson's disease (PD), this protein is alpha-synuclein (Alpha-S). In Alzheimer's disease (AD) it is amyloid beta (Beta-A). The purpose of our work was to identify specific antibodies (AB) to Alpha-S and Beta-A in these two neurodegenerative diseases, to determine the sensitivity and specificity of these antibodies, their affinity and cross-reactivity in patients suffering from BE and AD.
Methods: Under our supervision there were 13 PD and 16 AD patients, men and women aged from 47 to 84 years. The control group consisted of 23 healthy donors representing similar age and gender groups. ELISA and Western blot were used to detect AB to Alpha-S and Beta-A.
Results: AB to Alpha-S was detected in 67 percent of PD patients and 21 percent of AD patients. AB to Beta-A was detected in 74 percent of AD patients and 11 percent of PD patients. As a rule, in patients with each disease, ABs to both antigens (AGs) were detected; one antigen significantly exceeded that of the other antigen.
Conclusions: Analysis of the antibody response is important for assessing neuroinflammation in neurodegenerative diseases in order to develop new drugs for their treatment. Some anti-inflammatory drugs may be used.

LPS INDUCED NEUROINFLAMMATION: MODIFIER OF PHOSPHORYLATION AND TAU TANGLE FORMATION

POSTERS: B01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Tomas Smolek, Neha Basheer, Muhammad Khalid Muhammadi, Norbert Žilka
Slovak Academy of Sciences, Institute Of Neuroimmunology, Bratislava, Slovak Republic

Aims: Tau spreading and neuroinflammation are two intimately connected processes. However, while epidemiological data suggests an early involvement of neuroinflammation in the etiopathogenesis of Alzheimer's Disease (AD), the lack of clinical efficacy observed for nonsteroidal anti-inflammatory drugs (NSAIDs), warrants further research. Consequently, with this study we aspired to apprehend the neuroinflammatory link to tau spreading and associated pathological changes by modulating microglial activation status.
Methods: We used R3m/4 transgenic mouse model expressing truncated 3 repeat tau (3 R tau, aa151-391). We induced chronic neuroinflammation for a period of two months with lipopolysaccharides (LPS). At final time point, animals were perfused, followed by immunohistochemical analysis to visualize hyper phosphorylated tau in hippocampus and tangle load in the brainstem, using tau specific antibody AT8. Glial cells, microglia and astrocytes were visualized using Iba 1 and GFAP antibodies respectively. Semi-automated histopathological quantification was performed on acquired images using open-source software QuPath.
Results: We found that LPS reduced tau phosphorylation in hippocampus and tau tangles load in the brain stem. We reported marginally significant cortical atrophy with no astrocytic reactivity in any of the groups. LPS entice a robust response in the form of microglial activation even a month after the last LPS insult and a directed migration towards the brainstem and hippocampal formation.
Conclusions: In summary, the present study suggests that relationship between inflammation and tau pathology is more complex. Our findings challenge the prevailing notion that chronic inflammation is solely responsible for the development of tau pathology. In fact, there is an active role of microglia in tau spreading and subsequent formation of pathological inclusion in vivo, which could manifest either way. **Acknowledgement:** This work was supported by JPND Multi-MeMo and VEGA 2/0127/22 research grants.

EVALUATION OF HUMAN INDUCED PLURIPOTENT STEM CELL (HIPSC)-DERIVED TRI-CULTURE AS IN VITRO MODEL FOR NEUROINFLAMMATION

POSTERS: B01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Isabel Onofre, Chiara Formica, Leo Smit, Joyson Dcosta, Shushant Jain
Ncardia, Discovery Technologies, Leiden, Netherlands

Aims: Development of physiologically relevant models for neuroinflammation to address the unfilled gap in translatable human-based platforms.
Methods: Ncardia used neurons, astrocytes and microglia derived from iPSCs to set up tri-cultures and treated the cultures with recombinant mutant Tau (pre-formed fibrils) PFFs to establish a tauopathy model. Quantification of Tau aggregation and phagocytosis was performed using High content Imaging and measurement of cytokines and soluble Tau was performed by MSD and ELISA, respectively.
Results: We characterized the tri-culture model for cell type ratio and microglia activation for major biological processes that occur in the human brain: release of pro-inflammatory cytokines (IL-6, TNF-α, IL1-β and IL-18) and phagocytic activity. We observed tri-cultures exposed to lipopolysaccharide (LPS) released higher levels of cytokines and exhibited higher phagocytic activity assessed by uptake of pHrodo bioparticles. In a next step, we induced the phosphorylation (pTau) and aggregation of Tau, using Tau PFFs. This approach enabled a multi-parametric readout of neuronal and glial phenotypes including activation of microglia and astrocytes in the tri-culture. We observed increased levels of phagocyted pTau by microglia, mostly dependent on the phagocytosis of neurons expressing pTau and also increased levels of release of IL-6, TNF-α, IL1-β and IL-18. Together, these observations support a neurodegenerative phenotype, typical of tauopathies in which secreted or engulfed pTau activates microglia initiating the neuroinflammatory cascade.
Conclusions: Ncardia developed a tri-culture model that allow modulation of neuroinflammation and neurodegeneration *in vitro*. This model provides insight on cellular interactions such as microglia-neuron communication that play a role in recognizing apoptotic neurons and modulating neuronal activity which are crucial events in disease progression relevant for a biological disease processes.

Aims: Tauopathy is a group of neurodegenerative diseases characterized by tau deposits in neurons or glial cells. Clinical symptoms of tauopathies include cognitive impairments and motor disorders. From primary to secondary tauopathies, colossal work is underrunning to understand the pathophysiology of tau aggregation and disease progression. The role of inflammation and oxidative stress in the progression of tauopathies is demonstrated in different cellular and animal models. In the current study, we demonstrate that the Nrf2 expression is already impaired at the 8-week-old P301S transgenic mice model of tauopathy compared to the age-matching B6 wild-type mice. This data also takes us to further test Nrf2 activators as potential therapeutic agents for hindering the cognitive and pathological insults associated with disease progression in P301S mice.
Methods: P301S and B6 mice of 2, 4, and 6 months of age are used. Behavioral tests were done to evaluate cognitive and locomotor functions in each age group. Mice performances were recorded and analyzed by ANYMAZE. Following trans-cardiac perfusion, hippocampi were collected for quantitative PCR analysis of inflammation-related genes and interleukins, and other hemispheres were processed for immunohistopathology. For Nrf2 activation, two different Nrf2 activators were administrated IP for 6 weeks duration.
Results: The cognitive impairment of P301S is already evident in some tasks at the age of 2 months, and in all tasks by 6 months. mRNA expression of Nrf2 and its downstream hemoxygenase were already deficient in 2 months in P301S mice, suggesting a possible impaired cellular stress handling due to transgene expression. This proceeds tau aggregation that is only evident by 4 and 6 months.
Conclusions: Inflammation-related molecular changes proceed tau aggregation in P301S mice. Ongoing analysis is testing if increasing the cellular defense via enhancing Nrf2 signaling can be a potential therapeutic option for tauopathy.

DECIPHERING THE ROLE OF THE PERIPHERAL IMMUNE SYSTEM IN THE PATHOLOGY OF FRONTOTEMPORAL DEMENTIA

POSTERS: B01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Nazaret Gamez, Abdulmunaim Eid, Maria Pascual, Joseph Masdeu, Stanley Appel, Alireza Faridar
Houston Methodist Research Institute, Neurology, Houston, United States of America

Aims: Translational and clinical evidence support the contribution of chronic systemic inflammation in the etiopathology and progression of neurodegenerative diseases, including frontotemporal dementia (FTD). However, a comprehensive understanding of the intricate functional and mechanistic implications of how the peripheral immune system participates in neurodegeneration remains elusive. Here, we investigate the status of peripheral immune cells and the activation of inflammatory cascades in FTD individuals.
Methods: 24 FTD and 17 age-matched healthy control (HC) individuals were recruited by the Houston Methodist Nantz National Alzheimer´s Center. The immunophenotype and suppressive function of regulatory T cells (Tregs) were analyzed. The inflammatory transcriptomic changes of peripheral monocytes were assessed on the nCounter Human Panel for 770 immune markers. Plasma proteomics (Olink®) was performed for a total of 48 inflammatory cytokines and Peripheral Blood Mononuclear Cells (PBMCs) were submitted to single-cell mass cytometry by time-of-flight (CyTOF) analysis.
Results: The suppressive function of Tregs was compromised in FTD when compared to HC individuals. This was associated with the dysregulation of 136 inflammation-related transcripts in FTD monocytes. Plasma proteomics analysis identified increased levels of proinflammatory cytokines, including IFNG, CXCL9, CXCL10, and CXCL11 in FTD individuals. By integrating both transcriptomics and proteomics data, we identified the activation of the CXCL9-11/CXCR3 inflammatory cascade in FTD individuals. Moreover, the CyTOF proteomics analysis revealed that the CXCL9-11 ligands were mainly expressed by CD14-classical monocytes, whereas their receptor, CXCR3, was highly expressed by CD4 and CD8 T cells.
Conclusions: FTD individuals exhibit a compromised immunosuppressive function of Tregs along with the systemic activation of CXCL9-11/CXCR3 inflammatory cascade. Our findings demonstrate the activation of a novel inflammatory cascade in the clinical setting of FTD that merits further research as a potential therapeutic target.

Aims: Plastic nanoparticles have become a growing environmental concern due to their potential toxicity to nervous systems, including the brain, spinal cord, and peripheral nerves. The detrimental mechanism is, however, still unknown. This study aims to investigate the effect of nanoplastics on the mechanisms of neuroinflammation and neurodegeneration in the human brain environment.
Methods: Human brain cells were exposed to plain and amine-functionalized polystyrene nanoparticles. The internalization of nanoparticles was observed through live cell holotomography. The levels of chemokines and cytokines were measured using a human cytokine array.
Results: Human glial cells actively internalized PS-NP, resulting in Lc3b, LAMP-1 increase in lysosomes followed by Cathepsin-B. Consequently, the NLRP-3 inflammasome was activated, leading to increased activation of reactive astrocytes evidenced with GFAP and microglia evidenced with CD86 and TREM-2. This neuroinflammation leads to neurotoxic nitric oxides, as well as the release of proinflammatory mediators such as IL-1β, TNF-α, IL-6, IL-8, and chemotactic chemokines. Moreover, mild neuronal losses were observed with a 40% decrease in NeuN levels, accompanied by the occurrence of tau hyperphosphorylation and accumulation of phosphorylated alpha-synuclein.
Conclusions: Thus, this study confirms that polystyrene nano-plastics activate NLRP-3 inflammasomes in astrocytes and microglia, potentially causing neurodegenerative disease.

MOUSE MODELS FOR NEUROINFLAMMATORY AND NEURODEGENERATIVE DISEASES

POSTERS: B01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Gunnar Flik, Mariette Heins, Ilona Vuist, Martha Olthuis
Charles River Laboratories, Discovery, Groningen, Netherlands

Aims: We aim to demonstrate the effects of different treatments, LPS, BzATP, LPS+BzATP or vehicle on neuroinflammation as well as the potential differences in peripheral effects of the tested set ups. Combined data should present us with guidelines for choosing optimal experimental designs for a variety of neuroinflammatory research questions. In addition, we will gain a better understanding of the timing effects of priming and activation of the inflammasome. Allowing better decisions to be made on test article administration for the various set ups.
Methods: A microdialysis probe (PP-PES200 2/3, CRL, the Netherlands) or a microperfusion cannula (Joanneum Research) was positioned in the right cortex of adult male C57Bl/6J mice and an ICV cannula in left ventricle. After several days of recovery, the experiment was initiated and microdialysate of microperfusate samples were collected at a flow rate of 0.5 µL/min in 60-minute intervals At the end of the experiment, terminal tissue samples were collected to serve as controls.
Results: Administration of LPS or LPS+BzATP showed pronounced IL-1β increases, while this is not observed in BzATP or vehicle administered animals. Effects were relatively more pronounced in the left and right cortices than in the striatum and hippocampus tissues. Blood levels of IL-1β were <LLOQ for the vehicle administered animals, while the LPS+BzATP dosed animals showed only a minor elevation in plasma (~60 pg/mL)
Conclusions: Our research has demonstrated that neuroinflammation of mouse brain tissue, without any major peripheral effects is feasible in a reproducible fashion both in an acute setting and in freely-moving cannulated animals. Microdialysis and microperfusion in mouse brain tissue will require further experimental optimization to establish a robust in vivo mouse model for the development of drugs that target neuroinflammatory processes.

Aims: The locus coeruleus (LC) is one of the earliest brain regions affected in tauopathies and synucleinopathies. Non-cognitive clinical symptoms that relate to this early pathology in the LC are not well defined. Sleep disturbances, pathological anxiety as well as olfactory dysfunction can be potential early manifestations. Here, we seek to understand the mechanisms and consequences of LC dysfunction in the context of early symptoms in mouse models of neurodegenerative diseases using new in vivo imaging and molecular tools.
Methods: We employed in vitro and in vivo techniques including immunohistochemistry, behavioral experiments, slice electrophysiology, optogenetics and longitudinal in vivo 2P microscopy in AD and PD mouse models with early LC pathology. Either mouse models like the APPNL-G-F at early time points or induced LC-specific pathology via stereotactic injections of Cre-dependent AAVs carrying human Tau-P301S or α-synuclein preformed fibrils into the LC were analyzed. Mice expressing GFP in the mitochondrial membrane specifically in LC neurons enabled for genetic and proteomic analysis as well as in vivo imaging of mitochondria axonal transport.
Results: Our findings reveal an early loss of LC-noradrenergic axons exclusively in the olfactory bulb of APPNL-G-F mice which coincides with olfactory dysfunction. Moreover, stable, cell-type specific transduction of LC neurons with human P301S Tau recapitulate human LC Tau pathology. Proteomic analysis of isolated LC-mitochondria and in vivo imaging in human-Tau-expressing mice revealed multiple alterations in mitochondrial physiology and axonal transport.
Conclusions: Our study highlights the early-onset loss of LC-noradrenergic axons in the OB and its correlation with olfactory dysfunction in mouse models of neurodegenerative diseases. Moreover, we identified mitochondrial dysfunction and transport as a potential important mechanism in mediating axonal dysfunction.

SYNAPTIC DEGENERATION IN C. ELEGANS TAUOPATHY / AD MODELS

POSTERS: B01.D. DISEASE MECHANISMS, PATHOPHYSIOLOGY: SYNAPSE PATHOLOGY

Jennifer Amrein[1], Brian Ackley[2]
[1]University of Kansas, Department Of Molecular Biosciences, Lawrence, United States of America, [2]The University of Kansas Department of Molecular Biosciences, Department Of Molecular Biosciences, Lawrence, United States of America

Aims: The mechanisms by which tau aggregation and/or mitochondrial function interact to manifest disease phenotypes is not entirely clear. To better understand whether mitochondrial stressors or tau aggregation could manifest disease-relevant phenotypes alone or in combination, we have developed novel *C. elegans* tauopathy models, in which we monitor synaptic integrity as a marker of early disease events.
Methods: Specifically, we developed new transgenic lines that express either wild-type human tau (hTau40), a disease-associated mutation (P301L), or a spontaneously aggregating variant (3PO) selectively in GABAergic neurons. Using a well-characterized synaptic marker (SNB-1::GFP) we have characterized the consequences of tau expression on synaptic integrity.
Results: We find that wild-type tau is well tolerated, causing no obvious changes to synapse numbers as animals age. In contrast, expression of either P301L or 3PO resulted in progressive synapse degeration during aging, with 3PO animals having a more severe phenotype. Separeately, we tested the consequences of treatment with juglone, which induces the formation of mitochondria-damaging reactive oxygen species (ROS). Larval treatment with juglone in otherwise wild-type animals caused synapse degeneration in young adults. Treatment of 3PO tau-expressing animals with juglone did not enhance the rate of degeneration observed, suggesting these may be affecting synaptic integrity via similar mechanisms.
Conclusions: These results suggest that early developmental stress, *i.e.,* tau aggregation and/or ROS production, could bias the development of synapse degeneration during adult aging. These results could indicate that events earlier in life may contribute to dememtias that manifest much later in life.

ANALYSIS OF BRAIN SYNAPSE-ASSOCIATED PROTEINS IN TAUOPATHIES

POSTERS: B01.D. DISEASE MECHANISMS, PATHOPHYSIOLOGY: SYNAPSE PATHOLOGY

Gunnar Brinkmalm[1], Johanna Nilsson[1], Elena Camporesi[1], Juan Lantero-Rodriguez[1], Tammaryn Lashley[2], Henrik Zetterberg[1], Kaj Blennow[1], Ann Brinkmalm[3]
[1]Department of Psychiatry and Neurochemistry, Institute Of Neuroscience And Physiology, The Sahlgrenska Academy, University Of Gothenburg, Mölndal, Sweden, [2]Queen Square Brain Bank for Neurological Disorders, Department Of Clinical And Movement Neuroscience, London, United Kingdom, [3]University of Gothenburg Institute of Neuroscience and Physiology: Goteborgs universitet Institutionen for neurovetenskap och fysiologi, Institute Of Neuroscience And Physiology, The Sahlgrenska Academy, University Of Gothenburg, Mölndal, Sweden

Aims: Alzheimer's disease (AD), progressive supranuclear palsy (PSP), corticobasal degeneration (CBD), and Pick's disease (PiD) are neurodegenerative disorders characterized by aggregation and spreading of tau protein. While there are good diagnostic fluid biomarkers for AD, this is not the case for the other tauopathies. Our aim was to investigate synapse associated proteins in brain for possible translation to fluid biomarkers.
Methods: Seventeen synaptic proteins were quantified in soluble (tris-buffered saline, TBS) brain extracts using two different targeted mass spectrometry assays. Solid-phase extraction and parallel reaction monitoring mass spectrometry were used to quantify a protein panel including AP-2, beta-synuclein, gamma-synuclein, neurogranin, phosphatidylethanolamine-binding protein 1, 14-3-3 proteins, neuronal pentraxin-1 and -2, neuronal pentraxin receptor, and syntaxin-1B and 7. Immunoprecipitation combined with mass spectrometry was used to quantify four proteins, complexin-1 and -2, synptotagmin-1, and SNAP-25.
Results: In general controls had the highest levels followed by PSP, which generally was the least affected disease group. For SNAP25 CBD, followed by AD, had lower abundance. For gamma-synuclein and the neuronal pentraxins PiD, followed by CBD had lowest abundance; neuronal pentraxin-2 had lower abundance of AD and PSP as well. The 14-3-3 proteins also had lower abundance for all disease groups. A combination of selected peptides and previous data from p-tau217 made it possible to separate the five groups from each other.
Conclusions: By combining a few selected peptides PSP, CBD, and PiD could be separated from the other disease groups, which can be exploited to find fluid biomarkers for these tauopathies.

Aims: We have recently developed CSF biomarker panels targeting synaptic dysfunction as well as pathological alterations in the endo-lysosomal and ubiquitin-proteasome systems. Several of the proteins that we have found to be significantly altered in CSF in early stages of AD or PD are synapse-associated membrane-proteins and in some cases, we have identified specific processed protein forms that seem to be disease related. Our aim in this study is to develop a selected reaction monitoring (SRM) mass spectrometry-based panel to characterize and quantify specific forms of synapse associated proteins in brain for possible translation to fluid biomarkers.
Methods: A central methodology in this project is targeted mass spectrometry for identification and quantification of proteins and protein forms. Low-flow liquid chromatography and high-resolution mass spectrometry is used to identify/characterize target peptides and fragments. High-flow liquid chromatography and high-selectivity mass spectrometric quantitation using SRM is used for quantitation. The quantitation is performed by adding heavy stable-isotope labelled peptides (internal standard [IS]) during the sample preparation.
Results: Solid-phase extraction and parallel reaction monitoring mass spectrometry were used to prepare TBS soluble brain homogenate fractions and almost 2000 proteins were identified with low-flow liquid chromatography and high-resolution mass spectrometry. High-flow liquid chromatography and SRM were used to develop a panel including SNAP-25, syntaxin-1A and B, VAMP2, complexin-1 and 2, SV2A, synaptophysin, and synapsin-1.
Conclusions: Differential patterns of CSF biomarkers associated with the synapse are probably due to differences in pathology mechanisms. The presented method could be used to compare the biomarkers' diagnostic and disease monitoring potential as well as to investigate specific pathological molecular patterns across and within neurodegenerative diseases.

TAU AFFECTS POST-SYNAPTIC PROTEIN CONDENSATION

POSTERS: B01.D. DISEASE MECHANISMS, PATHOPHYSIOLOGY: SYNAPSE PATHOLOGY

Aims: Tauopathies associate with deficits in synaptic function and plasticity, which rely on the formation and dynamics of the post-synaptic densities (PSD). Recent studies indicate that PSDs form via liquid-liquid phase separation (LLPS) of scaffold proteins, e.g. PSD95, along with multiple effector proteins, e.g., SynGAP. The microtubule associated protein Tau, an LLPS protein itself, was suggested to interfere with PSD function in Alzheimer's disease by interacting with PSD95 and SynGAP. We hypothesize that the disease-associated interaction of Tau with the PSD is based on interference with functional PSD condensation. We aim to 1) explore the interactions of Tau isoforms and frontotemporal dementia-related mutations with PSD95 condensation in vitro and in cells, and 2) how these interactions affect the functionality of synaptic PSDs in primary neurons.
Methods: The effect of Tau on PSD condensation is investigated in human cells (HEK293 cells) and in in vitro reconstitution using confocal microscopy, fluorescence recovery after photobleaching (FRAP) and other light microscopic techniques. The physiological significance of our findings is verified in primary hippocampal mouse neurons using similar techniques and LTP/LTD paradigms, as well as immunostaining and calcium imaging.
Results: We find that Tau promotes cellular and in vitro LLPS of PSD95 and decreases the mobility of PSD95 in PSD condensates in HEK cells and in synapses of primary neurons. We observe a complex interplay between Tau isoforms, post-translational modifications, and FTD-mutations and the molecular mobility of PSD95 in synaptic condensates.
Conclusions: Pathologically increased Tau concentrations in the post-synapse appear to decrease the molecular mobility of PSD95 within the PSD, which impacts PSD function and, hence, downstream signaling.

STRUCTURAL INSIGHTS INTO THE ACTIVATION OF CDK5 BY SEROTONIN RECEPTOR 7

POSTERS: B01.E. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELLULAR SIGNALLING, KINASES, PHOSPHATASES, CALCIUM

Aims: Aberrant phosphorylation and aggregation of the microtubule-associated protein tau are important neuropathological hallmarks of tauopathies. Several kinases are known to phosphorylate tau, with the Cyclin-dependent Kinase 5 (CDK5) being critically involved in pathological tau hyperphosphorylation. However, how cellular receptors contribute to CDK5 activation is only poorly understood. We have recently shown that the serotonin receptor 7 (5-HT7R) is involved in tau hyperphosphorylation by interacting directly with CDK5, independent of its activation by serotonin. Here, we studied the structural requirements for the interaction of 5-HT7R with CDK5.
Methods: Using an AI-based approach, we created a structural model of the 5-HT7R/CDK5 complex. Receptor mutants were generated by site-directed mutagenesis of potentially important amino acids. Biochemical and microscopic approaches were used to study the impact on CDK5 activation and tau phosphorylation in a cellular model of tauopathy.
Results: Our computational model identified 5-HT7R domains involved in the interaction with CDK5. In particular, two conserved phenylalanine residues, F278 and F281, within the third intracellular loop of the receptor were predicted to be crucial within the interaction interface. Substitution of these residues to alanine resulted in reduced 5-HT7R/CDK5 complex formation, CDK5 activation, and subsequent tau phosphorylation and aggregation. Importantly, G protein-mediated downstream signaling of the receptor was not affected by these mutations.
Conclusions: Our results provide the structural basis for the development of novel drugs targeting the 5-HT7R/CDK5 interaction interface for the selective treatment of tauopathies, including frontotemporal dementia and Alzheimer's disease.

ALZHEIMER'S RISK GENE PTK2B LINKS TAUOPATHY, NEURONAL ELECTRICAL ACTIVITY AND AMYLOID-B IN HIPSC-DERIVED NEURONS

POSTERS: B01.E. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELLULAR SIGNALLING, KINASES, PHOSPHATASES, CALCIUM

Ana Raquel Melo De Farias[1], Alexandre Pelletier[2], Johanna Gadaut[1], Jean-Charles Lambert[3], Marcos Costa[4]
[1]Institut Pasteur de Lille, U1167, Lille, France, [2]Institut Pasteur de Lille, Umr1283-8199 - Cnrs, Lille, France, [3]Institut Pasteur de Lille | Université de Lille, Inserm U1167, Lille, France, [4]Institut Pasteur de Lille, Inserm U1167, Lille, France

Aims: In the human brain, the Alzheimer's disease (AD) risk gene PTK2B is mainly expressed in glutamatergic neurons and its expression declines with AD pathology progression. This reduced PTK2B expression in the brain of patients with AD coincides with the appearance of tauopathy and may contribute to neuronal dysfunctions observed in the disease, such as increased electrical excitability and synaptic loss. In this work, we investigated the impact of reduced PTK2B expression in human-induced neurons (hiNs).
Methods: We used two different isogenic human-induced pluripotent stem cell (hiPSC) lines to generate clones carrying PTK2B knockout (KO) and heterozygous (HET) mutations. These hiPSC lines were differentiated into hiNs expressing different levels of PTK2B in 2D and 3D (cerebral organoids) cultures. We then used functional and molecular assays to investigate the consequences of altered PTK2B expression in both physiological and AD-like contexts.
Results: We show that both PTK2B HET and KO hiNs display altered patterns of neuronal electrical activity when compared to WT. We also show that reduced expression of PTK2B leads to specific changes in gene expression in glutamatergic neurons, and that STAT3 could be a downstream target of PTK2B to regulate activity-dependent genes in hiNs. Reduced expression of PTK2B is also associated with increased phosphorylation of TAU at several epitopes associated with AD. Notably, exposure to $Aß_{1-42}$ increased the frequency of calcium transients in hiNs expressing PTK2B but not in KO hiNs, suggesting a possible role for PTK2B in mediating the effects of Aß on neuronal electrical activity.
Conclusions: Our study suggests that PTK2B may serve as a critical mediator linking amyloidopathy to changes in neuronal electrical activity and tauopathy. They also suggest STAT3 as a potential PTK2B downstream target regulating activity-dependent transcription in neurons.

Aims: NHE6 is an early endosomal cation exchanger where it helps maintain the pH of the lumen. *NHE6/SLC9A6* mutations cause a severe form of X-linked mental retardation. We investigated whether *SLC9A6* variants could contribute CBS/CBD in females and the biological relevance of NHE6 loss-of-function.
Methods: We performed a genetic screen for *SLC9A6* variants in an international cohort of 286 CBS/CBS cases and, 272 matched controls. We derived induced pluripotent stem cells from the fibroblasts of a female CSB patient carrying the p.T489Yfs *SLC9A6* mutation for differentiation into mature neurons. We also used inducible NHE6 knockdown in neuroblastoma cells. To investigate the relevance of NHE6 loss-of-function, we employed high throughput autophagy screening, mass spectroscopy and biochemical analyses of the endosomal-lysosomal system.
Results: There was no formal genetic association of *SLC9A6* variants with CBS, yet the cohort is relatively small since CBS/CBD is a rare neurodegenerative disease. We would therefore like to collect more samples through further collaborations. The T489Yfs NHE6 mutation confers loss-of-function due to truncation of the protein and failure of NHE6 to multimerize. Using p.T489Yfs patient-derived cells and loss-of-function models we report that NHE6 dysfunction causes blockage of the endosomal-lysosomal system and inhibition of autophagy initiation. Furthermore, there is a build-up of hyperphosphorylated Tau, (which was previously observed in *SLC9A6* knockout mice) and we identified specific, novel phosphorylation sites on Tau affected by NHE6 loss-of-function (Ser198 and Ser404) in patient derived neurons.
Conclusions: These data provide insight into possible underlying risk and biology of CBS/CBD, a

neurodegenerative disorder which is currently untreatable and incurable. The link between blockage of the endosomal-lysosomal system and build-up of phosphorylated tau may provide an entry point for the development of potential biomarkers and therapies for CBS.

Aims: Alzheimer's disease (AD) is the most common form of dementia, yet the mechanism triggering the disease remains unclear. AD is characterized by the two main classical hallmarks, senile plaques and neurofibrillary tangles. Among the less known hallmarks, the intracellular accumulation of 3-*O*-sulfated heparan sulfates (3S-HS) in neurons in AD vulnerable brain regions, such as the hippocampus. We have shown that the neuronal heparan sulfate 3-*O*-sulfotransferase 2 (HS3ST2) is associated with AD related tau pathology. However, the mechanisms underlying HS3ST2 gene expression regulation in neurons vulnerable to develop AD-related tau pathology remain unclear. Because the β-adrenergic pathway has been reported to be implicated in the regulation of HS3ST2 gene expression, we aim here to investigate whether regulation of this pathway can affect Hs3st2 gene expression in mouse hippocampus, which receives adrenergic afferences from the locus coeruleus (LC). Our aim is to decipher the involvement of the β-adrenergic pathway in the regulation of Hs3st2 gene expression in its relationship with the physiopathology of AD related tau pathology.
Methods: We analysed transcriptomic data from human and mouse brains and studied the β-adrenergic pathway by using agonists and antagonists of β-adrenergic receptors and related cell markers using *in vitro* and *in vivo* approaches in the rTg4510 model of tauopathy.
Results: We confirmed the presence of a specific set of β-adrenergic receptors in the hippocampus both in human and mouse and showed that modulating the β-adrenergic signalling pathway affects Hs3st2 gene expression *in vitro*. Then, we validated *in vivo* that the β-adrenergic pathway leads to a change in Hs3st2 expression, with effect in tau pathology.
Conclusions: Our results show that the β-adrenergic pathway can regulate Hs3st2 gene expression, allowing us to study the mechanisms leading to AD related tau pathology.

Aims: Arginine increases during course of Alzheimer's disease (AD) and in animal models of tauopathies. mTORC1 senses nutrients in eukaryotes and translocates to the lysosome during nutrient abundance to increase protein synthesis. During nutrient scarcity mTORC1 fails to translocate and autophagy is uninhibited. mTORC1 signaling can uncouple during neurodegenerative disease and precipitate proteinopathies. Arginine activates mTORC1 and signals through protein sensors such as GPRC6a, which also increases in AD brains and tauopathy models. We hypothesize that tau pathology promotes nutrient sensing dysfunction and hyper-mTORC1 activation. We posit that GPRC6a suppression activates autophagy, which rebalances proteostasis and hallmarks of tau pathology.
Methods: Tau transgenic mice (*PS19*) and non-transgenic littermates were bred to mice with GPRC6a hemizygous deletion to generate four genotypes: (*nTg, GPRC6a* $^{+/-}$*, PS19, PS19/GPRC6a* $^{+/-}$). Mice brains aged 7-9mo were harvested for western blot and bulk RNA-seq. Tau biochemistry, mTOR activation, lysosomal function, and autophagy were measured in detergent soluble or urea soluble fractions from anterior and posterior cortcies. Hippocampal tissue was used for bulk RNA seq Nanostring for transcriptome pathway analysis.
Results: Hemizygous deletion of GPRC6a (*PS19/GPRC6a* $^{+/-}$) decreased total tau and phospho-tau compared to *PS19* mice. GPRC6a suppression in PS19 mice significantly decreased mTORC1 activation compared to PS19 mice and increased autophagy and autophagosome formation. LC3-I and LC3-II increased in PS19/GPRC6a$^{+/-}$ mice compared to PS19 mice suggesting increased lysosomal biogenesis. PS19 mice showed increased transcripts associated with autophagy, neurogenesis, and proteotoxic stress compared to *nTg* littermates, and hemizygous deletion of GPRC6a (*PS19/GPRC6a*$^{+/-}$*)* normalized these signatures to control levels.
Conclusions: These data indicate that GPRC6a expression regulates proteostasis of tau and could serve as a therapeutic target in tauopathies. Additionally, our data suggests that GPRC6a impacts lysosomal function and mTORC1 activation state.

Aims: Lysosomal dysfunction and protein aggregation have been implicated in neurodegenerative disorders, including tauopathies. In a subset of tauopathies, rare mutations in the *MAPT* gene (which encodes the tau protein) are sufficient to cause disease; however, the exact mechanisms by which tau contributes to disease is unknown.
Methods: Here, we leveraged stem cell models to identify novel molecular mechanisms that influence the pathobiology of tauopathies and to identify therapeutics targeted to these mechanisms. Super resolution microscopy was used in human induced pluripotent stem cells (iPSC)-derived neurons expressing the FTD-associated *MAPT* p.R406W and isogenic controls (WT).
Results: In mutant neurons, the majority of lysosomes contained tau protein: pTau was enriched in the lysosomal membrane, while total Tau was enriched in the lysosomal lumen. Transcriptomic analyses revealed defects in genes enriched in pathways associated with lysosomal motility and maturation of autophagic vesicles. We observed several defects in retrograde transport that could impact lysosomal motility. Lysosomes were farther away from the perinuclear region, with slower motility and traveled shorter distances in mutant neurons. We found this may be due to dysregulation of JIP3, a dynein associated protein involved in retrograde transportation. Next, we evaluated maturation of autophagic vesicles. Mutant neurons exhibited an increase in autophagosomes (size and number), suggesting more autophagic flux. However, p62 and LC3-II were also increased, suggesting a defect autophagosome-lysosome fusion that may impact cargo degradation. Enhancing autophagy function was sufficient to rescue tau-specific defects in mutant neurons.
Conclusions: Together, our findings suggest that *MAPT* p.R406W may be sufficient to cause impaired autophagy and lysosomal function leading to disrupted tau degradation by lysosomes, which may contribute to the development of tau pathology.

Aims: Neurons with tau pathology are not only faced with the direct proteostatic challenge imposed by pathological tau accumulation, but also with tau-induced impairment of the proteostatic machinery, resulting in a toxic vicious cycle of disturbed proteostasis. Here we aimed to gain more insight in the molecular pathways that mediate neuronal resilience to tau-induced proteostatic disturbance. To this end we investigated the mechanism and functional implications of the formation of granulovacuolar degeneration bodies (GVBs), a neuron-specific lysosomal response to tau aggregation, that contain endo- and autolysosomal cargo.
Methods: We employed a spontaneously aggregating tau model in primary mouse neurons to study the effect of tau aggregation and GVB accumulation on proteostasis. Quantitative high-content automated microscopy was used to measure the effect of our (genetic and pharmacological) interventions on protein synthesis, GVB accumulation and/or cargo accumulation to the GVB. Since CK1δ specifically targets to GVBs, we studied the effect of inhibition of CK1δ on GVB accumulation. We also tested the effect of inhibition and stimulation of autophagy on GVB accumulation.
Results: While tau aggregation reduces protein synthesis, the presence of GVBs rescues this phenotype. Moreover, GVB-positive neurons elicit a stronger proteostatic response than GVB-negative neurons. Furthermore, inhibition of CK1δ decreases GVB formation. Similar results were obtained when autophagy was inhibited, while stimulation of autophagy did not affect GVB accumulation.
Conclusions: Our data show that GVB-positive neurons are resilient to tau-induced proteostatic impairment. Furthermore, CK1δ activity as well as autophagy are required for the formation of GVBs. We conclude that CK1δ is an essential upstream regulator for the formation of GVBs as a protective neuron-specific, proteostatic stress response to tau pathology.

Aims: Estrogens, such as estradiol (E2), are known to regulate cellular metabolism. They also have neuroprotective effects, and represent potential candidates for Alzheimer's disease (AD) prevention, especially as hormone replacement therapy (HRT) for post-menopausal women. However, these molecules are also associated with unwanted effects. Estetrol (E4), a natural estrogen exclusively produced by the human fetal liver during pregnancy, is currently under development as HRT and could be a safer therapeutic alternative. The aim of this study was to investigate the effect of E4 on cell viability and bioenergetic functions in control and AD cell models.
Methods: Cell viability and bioenergetic parameters were assessed in three cell lines: - Native SH-SY5Y neuroblastoma cells: control cells; - P301L mutant tau overexpressing SH-SY5Y cells: cellular model of AD-related tauopathy; - Amyloid precursor protein (APP) overexpressing SH-SY5Y cells: cellular model of amyloidopathy. Cells were treated with E4 or E2 (as control for comparison) for 48h. Cell viability tests and bioenergetic measurements, including adenosine triphosphate (ATP) level, mitochondrial membrane potential (MMP) and reactive oxygen species (ROS) level, were realized at the end of the treatment.
Results: Treatments with E4 and E2 improved cell survival and bioenergetic functions. ATP production and MMP were increased, while ROS production was decreased. The effects of E4 on cell metabolism slightly varied depending on the cell line.
Conclusions: The data indicate that E4 is able to modulate cellular bioenergetics with an overall similar or, for some parameters, better efficacy than E2. E4 and E2 treatment showed better efficacity in the cellular model of AD-related tauopathy than in the model of amyloidopathy. This statement must be verified with further experiments.

Aims: We established, here, experimental paradigms enabling the investigation of tau-related abnormalities (pathological phosphorylation, amyloid aggregation) in Alzheimer's disease (AD) and related tauopathies to evaluate the therapeutic potential of anti-tau molecules for these disorders. More specifically, we were interested in characterizing the effects of DDMC and DOT, two non-antibiotic tetracycline (TC) derivatives of demeclocycline and oxytetracycline, respectively.
Methods: To monitor pathological tau phosphorylation, we implemented cultures of mouse cortical neurons grown in astrocyte-conditioned medium (ACM) [Tourville et al, Antioxidants, 2023] and submitted them to sustained low-level insults generated by either catalytic iron or glutamate. Pathological tau was revealed with the AT8 antibody that identifies p-Ser202/p-Thr205 residues. We also adapted an ex vitro assay where amyloid aggregation of tau is achieved using heparin as a co-factor [Medina et al, Front Aging Neurosci, 2021].
Results: When exposed to iron (1.6 µM)-containing medium, p-tau accumulation culminated in neuronal somas 4 days after the change of culture medium, to decrease progressively thereafter when neurodegeneration had further advanced. When cultures maintained in ACM where challenged with glutamate, p-tau induction peaked earlier, i.e., 24h after initiating the excitotoxic insult. The use of two fluorogenic probes DHR-123 and TMRM revealed that p-tau accumulation correlated in both cases with an escalation of oxidative stress and a drop of mitochondrial membrane potential. Oxidative stress and p-tau build-up as well as ensuing neurodegenerative changes were efficiently prevented by either DDMC or DOT. Rescued neurons remained fully functional as they efficiently accumulated [^{3}H]-2-deoxyglucose. Interestingly, these two compounds also prevented heparin-activated tau aggregation, at low micromolar concentrations.
Conclusions: Based on present results, we suggest that the non-antibiotic TCs DDMC and DOT may have therapeutic value in preventing early tau-related abnormalities in AD and other tauopathies.

Aims: Alzheimer's disease (AD) is a prevalent neurodegenerative disorder, marked by neurofibrillary tangles (NFTs) and beta amyloid plaques in human brain, linked to cognitive decline and memory loss. Mitochondrial dysfunction contributes to AD progression, as mitochondria provide neurons with ATP, regulate calcium balance, and modulate apoptosis. Clinical data indicate mitochondrial malfunctions, energy metabolism deficits, and oxidative damage in AD. However, the direct impact of tau pathology on mitochondria remains unclear, necessitating further investigation. This study examines influence of AD-tau pathology on mitochondria using in-vitro and in-vivo AD models.
Methods: In-vitro experiments employed RD P301S tau FRET Biosensor cell model, expressing P301L mutant tau protein. While, in-vivo experiments used SHR72 transgenic rats with truncated human tau protein, at an early terminal stage. Flow cytometry and Immunohistochemistry were employed to validate the AD-tau aggregation in-vitro and tau pathology in-vivo in free floating sections. While confocal microscopy and western blotting were utilized to analyse the effect on mitochondria. Furtermore, the reactive oxygen species (ROS) production was quantified using standard protocol for flow cytometry.
Results: We confirmed the induction of Tau pathology in both in-vitro and in-vivo settings. Mito-tracker fluorescence intensity was significantly reduced in AD tau-infected cells, and confocal imaging revealed disrupted mitochondrial network configuration. Likewise, elevated amount of mitophagy markers (PARKIN and PINK 1) were noted in transgenic animal models. The production of reactive oxygen species were increased in the cells infected with AD-tau.
Conclusions: Our findings suggest that AD-tau pathology might trigger mitochondrial dysfunction in Alzheimer,s disease, however, it requires further investigation. **Acknowledgement:** This work is supported by APVV-20-0331, APVV-19-0585, APVV-20-0585, and VEGA 2/0127/22grant.

MOLECULAR AND CELLULAR DETERMINANTS OF LOCUS COERULEUS-SPECIFIC TAU PATHOLOGY

POSTERS: B01.G. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

Katharina Ochs[1,2], Theresa Niedermeier[1], Stephan Müller[3,4], Stefan Lichtenthaler[3,4], Jochen Herms[2,5,6], Lars Paeger[1]

Aims: The locus coeruleus (LC) is a small nucleus in the brainstem and the sole source of the neurotransmitter noradrenalin in the forebrain (1). In Alzheimer's disease, it is among the first regions affected by Tau pathology and early neurodegeneration (2). However, the spatiotemporal development of Tau pathology as well as the underlying reasons for the selective vulnerability of LC neurons is still unclear. Given the high-energy demand of their unmyelinated long-ranging axons, tau-mediated mitochondrial impairment has been proposed as one important driver for the development of this neuropathological phenotype. 1. Poe, G.R., Foote, S., Eschenko, O. et al. Locus coeruleus: a new look at the blue spot. Nat Rev Neurosci 21, 644–659 (2020). https://doi.org/10.1038/s41583-020-0360-9 2. Braak H, Thal DR, Ghebremedhin E, Del Tredici K. Stages of the pathologic process in Alzheimer disease: age categories from 1 to 100 years. J Neuropathol Exp Neurol. 2011 Nov;70(11):960-9. doi: 10.1097/NEN.0b013e318232a379. PMID: 22002422.
Methods: We performed stereotactic injections of Cre-dependent AAVs carrying either human Tau-P301S-mKate2 or mKate2 into the LC of mice expressing GFP in the outer mitochondrial membrane (OMM) specifically in LC neurons. We applied immunofluorescent analysis, 3D reconstructions as well as magnetic-activated cell sorting (MACS) of mitochondria for subsequent Mass Spectrometry analysis.
Results: Our findings reveal a stable transduction of LC neurons and hyperphosphorylated Tau, recapitulating human Tau pathology. Importantly, we observed the localization of Tau with mitochondria. Proteomic analysis of isolated LC-mitochondria in human Tau-expressing mice revealed multiple alterations.
Conclusions: Here, we provide insights into a new Tau model to better understand the earliest pathological defects. Our findings point towards a mitochondrial dysfunction and their crucial involvement in the intriguing vulnerability of LC neurons.

Aims: Mitochondria are essential organelles that play a predominant role in cellular bioenergetics, notably by providing the main source of cellular energy via adenosine triphosphate (ATP) generation. However, in tauopathies, abnormal tau proteins impair almost all mitochondrial functions, from respiration to mitophagy.
Spermidine (SPD) is a polyamine known to exert cardioprotective, neuroprotective and lifespan-promoting effects by triggering autophagy as its main mode of action. However, the effects of SPD on mitochondrial dysfunction induced by abnormal tau protein have not yet been investigated. Therefore, the present study aimed at evaluating the effects of SPD on mitochondrial function in a cellular model of tauopathy.
Methods: SH SY5Y cells expressing the mutant tau P301L (P301L cells) or the empty vector (vector cells) were treated with SPD at a concentration of 0,1µM for 48h. Then, bioenergetic parameters such as ATP production, mitochondrial membrane potential (MMP), cell respiration and cell metabolic activity were assessed. Effects of SPD on autophagy and mitophagy in vector and P301L cells were also investigated in this study.
Results: SPD improved mitochondrial bioenergetics, characterized by an increase of the mitochondrial membrane potential, mitochondrial respiration, and adenosine triphosphate (ATP) production, in both control and P301Ltau-expressing cells. In addition, SPD decreased the level of free radicals, increased autophagy, and restored P301Ltau-induced impairments in mitophagy.
Conclusions: This study suggests that SPD supplementation might represent an attractive therapeutic approach to prevent/counter-act tau-related mitochondrial impairments. This research was funded by a Natvantage grant from the Wilhelm Doerenkamp-Foundation.

IMPACT OF GINKGO BILOBA EXTRACT ON MITOPHAGY AND AUTOPHAGY IN TAU MUTANT CELLS

POSTERS: B01.G. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

Ina Vukalovic[1], Fairley Lauren[1], Amandine Grimm[2], Anne Eckert[1]
[1]University Psychiatry Clinics UPK Basel, Neurobiology Lab For Brain Aging And Mental Health, Basel, Switzerland, [2]University of Basel, Department Of Biomedicine, Basel, Switzerland

Aims: Mitochondrial impairment, including impaired mitophagy, has been identified as an early feature of tauopathies, leading to the accumulation of damaged or dysfunctional mitochondria. This study aimed to explore standardized Ginkgo biloba extract (GBE) potential as a therapeutic agent of tauopathies by investigating its effects on mitophagy, autophagy and associated protein expression in cells expressing the P301L mutant tau.
Methods: Human neuroblastoma cells SH-SY5Y, overexpressing the P301L mutant tau, were used. Cells were transiently transfected with DsRed-LC3 and then treated with either GBE (LI1370; 100µg/ml) or DMSO vehicle for a 24-hour period. Autophagic flux was assessed using bafilomycin A1 or DMSO, while mitophagy was assessed with FCCP. Mitochondria were visualized with a mitotracker. Autophagy and mitophagy were quantified by measuring fluorescence intensity and assessing colocalization. To analyze gene expression, total RNA was extracted from cells using the RNeasy Mini kit. RT-qPCR was employed for amplifying and quantifying mRNA expression levels.
Results: Under baseline condition, no impact of a GBE treatment on P301L mutant tau cells was observed. Following stimulation with FCCP, P301L mutant tau cells displayed reduced mitophagy compared to control cells. Baseline levels of LC3 were increased in P301L cells due to impaired autophagosome degradation. Treatment with GBE reduced LC3 levels in P301L cells, indicating improved autophagosome degradation, while it increased in control cells, suggesting enhanced autophagosome formation. Further, treatment with GBE led to changes in the gene expression of PARK2, PINK1 and P62.
Conclusions: Treatment with GBE was able to alleviate mitophagy deficits in P301L mutant tau expressing cells, improve autophagic flux and increase the expression of genes related to mitophagy and autophagy pathways.

VPS35 DOWNREGULATION IN MICROGLIA LEADS TO ENHANCED PATHOLOGICAL TAU ACCUMULATION AND ALTERED INFLAMMATORY STATE IN A MOUSE MODEL OF NEURODEGENERATION

POSTERS: B01.H.DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Yamini Mutreja[1], Domenico Pratico[2]
[1]Lewis Katz School of Medicine, Alzheimer's Center At Temple, Philadelphia, United States of America, [2]Temple University, Alzheimer's Center At Temple, Philadelphia, United States of America

Aims: Endosomal protein sorting is orchestrated by the multimeric protein complex called retromer complex. Dysfunction of this complex is associated with several neurodegenerative disorders including Alzheimer's disease. Vps35 is the core component of the retromer complex. Its relation to Aβ/APP functioning and pathophysiology has been demonstrated in recent years, however its relation to tau biology is less well established. Growing amount of evidence also incriminates microglial dysfunction as a contributing factor towards neurodegenerative pathology. Microglial dysfunction can lead to an aberrant neuroinflammatory response. Microglia are also involved in clearance of pathological tau as well as transcellular transport of tau. The current study aims to delineate the relation between microglial protein trafficking machinery particularly the retromer core protein Vps35, and pathophysiologic changes in a mouse model of neurodegeneration.
Methods: We utilized PS19 mice overexpressing P301S tau to generate a conditional knockout of Vps35 in microglial cells. We performed behavioral analysis to assess memory function, biochemical and histochemical analysis to assess accumulation of pathological tau, and whole brain cytokine analysis to understand neuroinflammatory alterations.
Results: We found that the loss of microglial Vps35 results in enhanced accumulation of tau and phospho epitopes of tau with aging although no major effect was observed on the memory function of these mice. Our data also indicates an altered inflammatory state possibly via dysregulated chemokine signaling.
Conclusions: Dysregulation of endosomal protein trafficking pathways within microglia are a contributing factor for tau accumulation in the brain. Retromer pathways within microglia could also be important for chemokine receptor recycling and a disruption of such signaling could lead to a miscommunication between various brain cell types leading to a dysregulated neuroinflammatory response.

STREM2 IS ASSOCIATED WITH ATTENUATED TAU AGGREGATES ACCUMULATION

POSTERS: B01.H.DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Fardin Nabizadeh
Iran University of Medical Science, Tehran, Iran, School Of Medicine, Tehran, Iran

Aims: Triggering Receptor Expressed on Myeloid Cell 2 (TREM2) plays a crucial role in the transition of microglia from a state of homeostasis to a state associated with the disease. Mutations in TREM2 are strongly linked with a higher risk of developing neurodegenerative diseases, including Alzheimer's disease (AD). There have been contradictory findings regarding the potential detrimental or protective effects of microglial activation and TREM2-related microglial responses in AD. Although previous studies reported increased CSF soluble TREM2 (sTREM2) in different clinical stages of AD, the exact association between AD hallmarks such as Aβ and tau pathology remains unclear. In the present study, I aimed to investigate the association between TREM2-related microglial responses and tau accumulation in the presence and absence of Aβ pathology in order to give a better view of the role of microglial activation in AD development.
Methods: Imaging data of 178 non-demented participants including 107 Aβ-negative participants, 71 Aβ-positive were recruited from ADNI. The CSF sTREM2 was used as an in vivo indicator of microglial responses associated with TREM2. Furthermore, I used longitudinal tau-PET and resting-state fMRI connectomes in order to investigate the association of TREM2-related microglial activation and tau spreading through functional connections.
Results: A higher level of sTREM2 was associated with slower tau aggregates accumulation in non-demented Aβ-positive. Furthermore, measuring the tau spreading through inter-connected regions using fMRI connectomes confirms that the TREM2-related microglial activity might be a protective factor against tau pathology in brain tissue.
Conclusions: These findings demonstrate that in individuals with initial Aβ abnormalities, TREM2-related microglial activation is linked to reduced regional accumulation of tau aggregates and also, spreading across interconnected brain regions, as evaluated through fMRI connectomes during the early stages of AD.

TAU PATHOLOGY ACCOMPANIED WITH IMPAIRED HIPPOCAMPAL-DEPENDENT SPATIAL NAVIGATION AND ANXIETY-LIKE BEHAVIORS IN DB/DB MICE

POSTERS: B01.K. DISEASE MECHANISMS, PATHOPHYSIOLOGY: METABOLISM, INSULIN

Aims: Type 2 diabetes mellitus (T2DM) has been associated with impaired cognitive behaviors. However, the impact of T2DM on specific hippocampal-associated cognitive domains and tau pathology has not been fully characterized. Here, we investigated the effects of T2DM on several cognitive and psychiatric domains and tau pathology using the leptin receptor-deficient db/db mouse model of T2DM.
Methods: To assess cognitive function, we tested db/db male mice and age-matched lean controls on the novel object task, the Morris Water Maze task, and the pariwise visual discrimination touchscreen task. We then assesed anxiety-like behaviors using the open field task. Tau pathology was assesed by protein expression in the cortex and hippocampus using antibodies targeting the phosphorylation sites: Ser202/Thr205, and Thr231. RNA-sequencing was then performed to determine the effects of insulin resistance on the forebrain of insulin resistant mice on tau-mediated gene expression. This was associated with the impact of insulin resistance on synaptic health.
Results: We found that db/db mice had significant impairments in both acquisition and reversal learning test in the touchscreen task. We also showed that db/db mice had impaired spatial navigation in the Morris Water Maze task, and the novel object recognition task. Severe anxiety-like patterns were observed in db/db mice in the open field test. Moreover, db/db mice showed significant age-related changes in tau pathology and synaptic health in both the cortex and the hippocampus. RNA-sequencing data showed differential gene expression in genes associated with neuronal health in db/db mice.
Conclusions: Our data provides direct evidence on the consequences of insulin resistance on specific cognitive and pyschiatric domains. Our findings also indicate a role for metabolic health in modulating central tau pathology and synaptic function.

Aims: Cellular senescence has been observed in both Alzheimer's disease (AD) patients and animal models. In this study, we investigated the effects of senolytic therapy in the PS19 mouse model by exploring human translatable MRI measures and mechanisms involved in senolytic therapy in the Tau model.
Methods: PS19 mice were treated with dasatinib plus quercetin (DQ) from 3 months of age for 6 months. T2 relaxation under spin tagging (TRUST) and phase contrast (PC) MRI was used to assess cerebral metabolic rate of oxygen (CMRO2), water extraction with phase-contrast arterial spin tagging (WEPCAST) MRI was employed to detect the blood-brain barrier (BBB) permeability longitudinally. Brain volumes were analyzed by diffusion tensor imaging (DTI) at the end of study. Cognitive function was evaluated by the tracing fear conditioning test along MRI measures.
Results: PS19 mice displayed significantly reduced cerebral CMRO2 and increased BBB permeability to water at 9 months of age. Meanwhile hippocampal atrophy and impaired cognitive function were evident in PS19 mice at the same age. DQ senolytic treatment dramatically mitigated cerebral hypometabolism, maintained BBB integrity, attenuated hippocampal atrophy, reduced tauopathy and improved cognitive function. Furthermore, the DQ treatment led to a shift of microglia from a disease-associated subtype to a homeostatic subtype.
Conclusions: These findings provide evidence for the potential therapeutic benefits of senolytic therapy and highlight the involvement of microglia in the underlying mechanisms. The use of human translatable biomarkers in the PS19 mouse model contributes to our understanding of the brain functional changes associated with tauopathy and the effects of senolytic therapy.

TAU LOSS OF FUNCTION, BY DELETION OR AGGREGATION, CONTRIBUTES TO PERIPHERAL INSULIN RESISTANCE

POSTERS: B01.K. DISEASE MECHANISMS, PATHOPHYSIOLOGY: METABOLISM, INSULIN

Rabab Al-Lahham, Nicolas Mendez
The University of Texas Health Science Center at Houston, Neurology, Houston, United States of America

Aims: Several epidemiological data revealed an association between Alzheimer's disease (AD) and type 2 diabetes, and impaired glucose metabolism and insulin signaling has been shown in AD patients and animal models of AD. Researchers concentrated on brain insulin resistance with little emphasis on the link between systemic insulin resistance and AD,even though the incidence of type 2 diabetes is higher in AD patients and that impairment in insulin signaling is a risk factor for AD. The goal of this study is to determine the role of systemic insulin resistance in the pathogenesis of Alzheimer's disease by evaluating the consequences of tau loss-of-function on peripheral insulin sensitivity.
Methods: Primary hepatocytes isolated from transgenic mouse models (Tau KO, P301 L) and wild type mice (C57BL/6) were evaluated for their insulin sensitivity using glucose uptake assays and biochemical analysis of insulin signaling markers. Wild type hepatocytes were treated with subtoxic concentrations of TauO to explore the effect of TauO on insulin signaling.
Results: Our data show that tau deletion or loss of function promotes peripheral insulin resistance as seen in primary hepatocytes isolated from Tau KO and P301 L mice, respectively. Furthermore, exposure of wild-type primary hepatocytes to sub-toxic concentrations of tau oligomers (TauO) results in a dose-dependent inhibition of glucose uptake, associated with downregulation of insulin signaling. TauO-induced inactivation of insulin signaling proteins was rescued by inhibition of p38 MAPK, suggesting the involvement of p38 MAPK.
Conclusions: This is the first study testing tau role in peripheral insulin resistance at the cellular level using multiple transgenic mouse models. Moreover, this study suggests that tau should be functional for insulin sensitivity, therefore, any loss of function by deletion or aggregation would result in insulin resistance.

NEURONAL AMPK REGULATES MICROGLIAL LIPID DROPLET ACCUMULATION IN TAUOPATHY BRAIN

POSTERS: B01.K. DISEASE MECHANISMS, PATHOPHYSIOLOGY: METABOLISM, INSULIN

Xu Chen[1], Yajuan Li[1], Yuhang Nie[1], Daniel Munoz-Mayorga[1], Ningxin Kang[1], Lingyan Shi[2]
[1]University of California, San Diego, Department Of Neurosciences, La Jolla, United States of America, [2]University of California, San Diego, Department Of Engineering, La Jolla, United States of America

Aims: Neurodegenerative diseases are commonly linked to impaired metabolism in the brain. In aging and Alzheimer's disease (AD), lipid droplets (LDs) accumulate in the brain. Yet, the cellular and molecular mechanism underlying this phenomenon is largely unknown. We aim to elucidate the LD phenotype in tauopathy brains and the mechanistic underpinings.
Methods: We used label-free stimulated Raman scattering (SRS) imaging technique to visualize *in situ* LD accumulation in mouse and fly models of tauopathy, and *in vitro* neuronal and glial cultures. Using heavy water (D_2O)-probed stimulated Raman scattering (DO-SRS) imaging, we assessed lipid turnover within LDs accumulated in tauopathy fly brains and in Tau^{V337M} neurons. In addition, we dissected the role of AMPK in regulating LD accumulation and inflammation.
Results: We found striking *in situ* LD accumulation in tauopathy mouse and fly brains primarily in microglia that correlated with neuronal loss and neuroinflammation. DO-SRS imaging revealed impaired lipid turnover within LDs accumulated in tauopathy fly brains. LDs also accumulated in induced pluripotent stem cell (iPSC)-derived human neurons bearing the Tau^{V337M} mutation, which transferred lipids to microglia through conditioned media, resulting in microglial LD accumulation, oxidative stress, impaired phagocytosis and a proinflammatory response. Activation of neuronal AMPK, a key regulator of lipid metabolism, alleviated lipid burden in neurons via inhibiting lipogenesis and promoting lipophagy, thereby decreasing lipid flux to microglia. Neuronal AMPK overexpression in tauopathy fly brain alleviated LD accumulation, while neuronal AMPK depletion in prodromal tauopathy mouse brain increased LD accumulation and exacerbated proinflammatory microgliosis.
Conclusions: Our results provide direct evidence of LD accumulation in tauopathy brains, new mechanistic insight into the anti-aging and neuroprotective effects of AMPK pathway, and highlight the metabolic crosstalk between neurons and glia in the setting of AD.

OBESITY, APOE4 AND METABOLIC MANIFESTATIONS OF PATHOLOGICAL TAU

POSTERS: B01.K. DISEASE MECHANISMS, PATHOPHYSIOLOGY: METABOLISM, INSULIN

Johanna Gentz[1,2], Gerda Mitteregger[2], Jochen Herms[1,2], Lars Paeger[1,2]
[1]German Center for Neurodegenerative Diseases, Translational Brain Research, Munich, Germany, [2]Center for Neuropathology and Prion Research, Ludwig-maximilians University Munich, Munich, Germany

Aims: Recent research has unveiled a complex interplay between neurodegenerative diseases and metabolic dysfunction. In turn, metabolic changes due dietary choices and genetic dispositions may critically influence disease severity. Here, we aim to investigate the pivotal role of metabolism in neurodegeneration, being both target and player in disease progression.
Methods: We use longitudinal high resolution metabolic and behavioural phenotyping in a mouse model of tauopathy (PS19) along with rectal and intraabdominal temperature measurements and immunohistochemical analysis from animals aged 3-9 month. Further, animals are subjected to either a high fat diet (HFD) or normal control diet (NCD) for specified durations with or without combination of a human ApoE4 knock-in (PS19 x APOE4-KI) to display bidirectional metabolic interactions with tauopathy.
Results: Reduced bodyweight correlated with decreased core temperature in PS19 mice compared to WT littermates and increased locomotor activity. In line, our histological findings reveal early elevated levels of phosphorylated tau and activated astrocytes in the hypothalamus, including the temperature- and sleep- regulating preoptic area. In turn, HFD-feeding induced obesity increased the amount of phosphorylated tau and activated astrocytes in the cortex, hippocampus, amygdala and hypothalamic regions of both PS19 and compared to NCD. Importantly, the presence of the ApoE4 knock-in appeared to intensify diet-induced obesity and pathological changes in PS19 animals.
Conclusions: Our results highlight the hypothalamus as an early affected region in tauopathy impacting metabolic processes assigning metabolic changes in early disease diagnosis. In turn, bad dietary choices may exacerbate existing pathology and inflammatory response. Thus, especially in the ApoE4 background, nutrition may be an important factor impacting neurodegenerative disease.

Ananda Devices Inc., Biochemistry, Laval, Canada

Aims: There is no cure and no efficient therapy for most neurological disorders, including Alzheimer's Disease (AD), a progressive type of dementia largely associated with the loss of synapses in the brain. It is estimated that 99.6% of the drugs targeting neurological diseases, such as AD, that pass animal tests fail on human trials. Animal experiments are currently the gold standard to test toxicity and efficacy of compounds. However, it is not feasible to test all compounds in the market with current guidelines due to high costs; long testing times, high number of animals required and low reproducibility. New, human based, more predictive models are required to accelerate the development of effective therapies. At Ananda Devices, we developed technology for rapid growth and precise organization of human neuronal networks, adapted to multi-well microplates (NeuroHTS™) and automated analysis of multiple parameters on neuronal morphology, neurite growth, synapse formation and network dynamics in 3000 individual neurons per plate.
Methods: In this study, we used the Ananda Devices microphysiological system to compare neuronal morphology, network dynamics, synapses and electrical function of neurons derived from iPSC cells from Healthy and Alzheimer's Disease donors.
Results: Using this high-definition analysis, we were able to identify key differences in axonal growth, axonal thickness, neuronal connections, synapse formation, synaptic maturity, tau distribution in cells derived from Alzheimer's Disease donors and Healthy donors. The results were validated using RNAseq analysis highlighting key signaling pathways involved in neurodegeneration.
Conclusions: The high sensitivity of the NeuroHTS™ platform enables rapid and automated compound screening directly on patient's derived cells. The main advantages of the technology are faster acquisition of neuronal data and generation of more predictive data of compounds' safety and efficacy prior to exposure to humans.

EXPLORING THE RELATIONSHIP BETWEEN INSULIN RESISTANCE AND ALZHEIMER'S DISEASE USING A NOVEL IN-VITRO MODEL

POSTERS: B01.K. DISEASE MECHANISMS, PATHOPHYSIOLOGY: METABOLISM, INSULIN

Rashi Kumar[1], Ritu Varshney[2], Sharad Gupta[2]
[1]Indian Institute of Technology, Gandhinagar, Department Of Cognitive Science, Gandhinagar, India, [2]Indian Institute of Technology Gandhinagar, Department Of Biological Science And Engineering, Gandhinagar, India

Aims: To investigate the relationship between Alzheimer's disease and insulin resistance with a particular emphasis on examining the role of glucose transporter 4 (GLUT4) by creating an in-vitro model using the SH-SY5Y neuroblastoma cell line. GLUT4 is an insulin-dependent transporter and is found in the hippocampus, amygdala, and cortex region of the brain. Our objective was to discern whether insulin resistance serves as a driver for the onset of Alzheimer's disease or if AD pathology, conversely, contributes to the development of insulin resistance.
Methods: To achieve our aim, we employed the following methods: 1. Transfection of SH-SY5Y cells with either a wild-type tau plasmid or a mutant tau plasmid to create the AD pathology. 2. Induction of insulin resistance in these cells using high glucose or dexamethasone. 3. Conducting a glucose uptake assay to measure glucose concentration. 4. Utilizing immunocytochemistry to assess the expression of insulin-dependent glucose transporter 4 (GLUT4), which is pivotal in the development of insulin resistance.
Results: 1. A significant increase in glucose concentration was observed in the AD condition. 2. There was a marked decrease in the expression of GLUT4 in the neuronal cells in the AD condition.
Conclusions: Our study provides evidence supporting the notion that insulin resistance is a contributing risk factor for the development of Alzheimer's pathology later in life. The presence of tau aggregates can increase the likelihood of developing insulin resistance by impairing the insulin signalling pathway, ultimately leading to Type 2 diabetes. The findings suggest that impaired insulin signalling in the brain may contribute to the pathogenesis of Alzheimer's, by decreased GLUT4 expression, hyperglycemia, cellular hypertrophy. The development of this model offers a tool for further understanding the GLUT4 expression, concentration and translocation in AD

MORPHOLOGICAL DIFFERENCES BETWEEN HUMAN IPSC-DERIVED NEURONS FROM ALZHEIMER'S S VERSUS PARKINSON'S DISEASE PATIENT

POSTERS: B01.L. DISEASE MECHANISMS, PATHOPHYSIOLOGY: NEURAL NETWORKS & PLASTICITY

Margaret Magdesian, Carolin Madwar, Victoria Kwok
Ananda Devices Inc., Biochemistry, Laval, Canada

Aims: There is no cure and no efficient therapy for most neurological disorders, including Alzheimer's Disease (AD), and Parkinson's Disease (PD). Today, 99.6% of the drugs targeting neurological diseases that pass animal tests fail on human trials and currently available animal models fail to reproduce the pathological complexities of AD or PD. For the successful development of new therapies, robust alternative approaches methods (NAMs) that specifically recapitulates the human neuronal signaling pathways are required to elucidate the mechanism of neurodegeneration in AD, PD and other neurological diseases. Ananda Devices developed a microphysiological system (MPS) for rapid growth and precise organization of human neuronal networks-on-a-chip, in scalable multi-well microplates, enabling automation of the analysis of multiple neuronal parameters in 3000 individual neurons per plate (NeuroHTS™ platform). In this study, the aims were to identify key morphological parameters in neurons derived from iPSC cells from patients to understand and measure AD and PD Disease progression.
Methods: In this study, we used the NeuroHTS™ platform to compare neuronal morphology, network dynamics, synapses, and electrical function of excitatory neurons derived from human induced pluripotent cells from healthy and AD donors as well as dopaminergic neurons derived from human induced pluripotent cells from healthy and PD donors.
Results: showed key differences in axonal growth, axonal thickness, neuronal connections, synapse formation, synaptic maturity, and tau distribution.
Conclusions: The data highlight how Ananda Devices' human based, in vitro, NeuroHTS™ platform enables rapid and automated compound screening directly on patient's derived cells.

IN VIVO CALCIUM AND VOLTAGE IMAGING TO STUDY CELL-TYPE SPECIFIC CONSEQUENCES OF PV NEURON TAUOPATHY

POSTERS: B01.L. DISEASE MECHANISMS, PATHOPHYSIOLOGY: NEURAL NETWORKS & PLASTICITY

Paul Feyen[1], Carsten Vos[1], Lars Paeger[1], Teodoro De Vecchi[2], Jochen Herms[1,2,3]
[1]German Center for Neurodegenerative Diseases, Translational Brain Research, Munich, Germany, [2]Ludwig-Maximilians-Universität München, Center For Neuropathology And Prion Research, Munich, Germany, [3]Munich Cluster for Systems Neurology, Synergy, Munich, Germany

Aims: Tauopathies feature pTau accumulation in cortical neurons and glia. Although neurons are heterogeneous, varying in molecular and morphological characteristics, the subtypes susceptible to tauopathy and their role in disease progression remain unidentified. Our study aimed to (1) assess pTau distribution in cortical neurons of Tauopathy patients, (2) create a cell-type-specific in vivo model for tauopathy of affected population, and (3) characterize morphological and neural activity changes of novel models utilizing chronic in vivo imaging.
Methods: Multiplexed IF staining of human Tauopathy cortical tissue and a deep learning pipeline was used to assess pTau accumulation in excitatory and inhibitory neuron subtypes. Guided by finding of abundant pTau+ Parvalbumin (PV) neurons, we generated a PV-specific tauopathy model using custom AAVs and cre-driver line. Awake in vivo Ca2+ and voltage imaging via AO-2P microscopy was used to study the response properties of PV neurons to multisensory stimulation, and to assess their integration in the cortical network. The model was further characterized via 6-month chronic in vivo 2-photon imaging.
Results: Ca2+ imaging uncovered poor fidelity of sensory representations in PV neurons of secondary motor cortex. First ever optical voltage recordings of neurons in neurodegenerative models, enable longitudinal imaging of the same neurons at a single action potential resolution in awake mice, offering unparalleled spatio-temporal resolution of the consequences of Tauopathy on neural activity. Chronic 6 month imaging revealed progressive axonal swellings and cell-loss.
Conclusions: We find Parvalbumin neurons present pTau accumulation in Tauopathy. Our observation of early deficits in sensory processing in PV-tauopathy model, indicates a role for PV in symptomatic landscape of CBD and PSP, potentially by loss of feedforward inhibition. Cell-type specific tauopathy models serve as effective platforms to isolate cell-autonomous disease processes.

EFFECT OF HEAVY ALCOHOL CONSUMPTION ON THE ONSET AND DEVELOPMENT OF ALZHEIMER'S DISEASE

POSTERS: B01.L. DISEASE MECHANISMS, PATHOPHYSIOLOGY: NEURAL NETWORKS & PLASTICITY

Marcos Uceta[1], Fernando Maestú[2], Alberto Muñóz[1]
[1]Universidad Complutense of Madrid, Faculty of Biology, Department Of Cellular Biology, Madrid, Spain, [2]Universidad Complutense de Madrid, Psicología Experimental, Procesos Cognitivos Y Logopedia, Pozuelo de Alarcón, Spain

Aims: In this study, we seek to ascertain the relationship between alcohol consumption during the early stages of neurodevelopment (characterized as Binge Drinking) and the onset and progression of Alzheimer's disease. Therefore, our fundamental objectives are to characterize the primary transformations identified both in the inhibitory neurons of the key areas associated with the disease and in the glial cells (astrocytes and microglia) linked to the characteristic neuroinflammatory state induced by such agents.
Methods: Using a murine model of P301S tauopathy, we will aim to administer alcohol (5 g/kg/d - 25% EtOH) or water at an equivalent volume to different experimental groups during a period of their life analogous to human adolescence (P20-P25), following a pattern associated with adolescent Binge Drinking (2-2, on-off). Subsequently, we will allow normal development of the animals until P200, at which point they will be euthanised for sample collection and immunohistological analysis of the primary neurons and target structures.
Results: We anticipate a significant increase in neurofibrillary tangles in those animals that have consumed alcohol. Additionally, we expect an increase in glial cell reactivity in these animals, along with an augmentation of distinct extracellular structures (PNNs) characteristic of the inhibitory neurons.
Conclusions: In this study, we expect to conclude that alcohol consumption during adolescence seemingly exerts effects not only in the short term but also in the long term, manifesting in an earlier and more aggressive onset of the tauopathy characteristic of Alzheimer's disease. Furthermore, the inhibitory connections and networks, typically distorted in the early stages of the disease, possess a barrier that is not only physiological but also physical in the form of proteoglycans and sugars, enhancing the rigidity of the network and reducing its flexibility and plasticity.

XBP-1S TRANSCRIPTIONAL TARGETS IN THE ENDOPLASMIC RETICULUM UNFOLDED PROTEIN RESPONSE AMELIORATE TAUOPATHY

POSTERS: B01.M. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TRANSCRIPTIONAL & TRANSLATIONAL REGULATION, MICRO RNAS

Brian Kraemer[1], Sarah Waldherr[2], Marina Han[2]
[1]SIBCR, Grecc, SEATTLE, United States of America, [2]VAPSHCS, Grecc, Seattle, United States of America

Aims: Protein homeostasis (proteostasis) mechanisms fail with aging and disease, promoting toxic protein accumulation. Neurons are particularly vulnerable to proteostatic disruption leading to aging related neurodegeneration. Abnormal activation of the endoplasmic reticulum unfolded protein response (UPR^{ER}) is implicated in tauopathies, a group of neurodegenerative diseases characterized by pathological accumulation of the microtubule-associated protein tau. Previous work showed neuronal overexpression of IRE1a branch UPR^{ER} transcription factor XBP-1s suppresses tauopathy in *C. elegans*.
Methods: We conducted RNA sequencing of mRNAs to analyze the transcriptome of xbp-1s and tau transgenic animals.
Results: Transcriptomic analysis of XBP-1s animals showed upregulation of the following genes with human homologs: *csp-1, F42G8.7, F41E7.6, Y19D10A.16, C01B4.6, dnj-28, hsp-4, ckb-2, mct-2, lipl-3,* and *eol-1*. Surprisingly, each one of these genes is required for *xbp-1s*-mediated suppression of tauopathy, suggesting that XBP-1s activates a broad and non-redundant network of cellular mechanisms to reduce tau pathology. Of these, we examined the critical UPR^{ER} regulator BiP/hsp-4, the ER resident HSP70 homolog. *Hsp-4* loss of function, but not loss of the cognate ER resident DNAJ protein *dnj-28*, eliminates *xbp-1s*-mediated suppression of tauopathy. While *hsp-4* loss of function exacerbates tau-induced behavioral deficits, tau protein level and phosphorylation are unaffected. High level overexpression of *hsp-4* exacerbates tau-induced behavioral deficits and protein accumulation, while moderated *hsp-4* overexpression ameliorates this phenotype. Furthermore, caspases also appear to play an important role downstream of XBP-1s: both the XBP-1s target *csp-1* and its non-XBP-1s target gene family member *ced-3* are required for *xbp-1s*-mediated suppression of tauopathy.
Conclusions: We present a dataset illuminating the mechanism of *xbp-1s*-mediated suppression of tauopathy involving a suite of diverse transcriptional targets.

A COMPARISON BETWEEN EARLY PRESENTATION OF ALZHEIMER'S DISEASE, PARKINSON'S DISEASE AND DEMENTIA WITH LEWY BODIES IN ROUTINE PRIMARY CARE AND UK BIOBANK DATA.

POSTERS: B01.O. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AGING

Thomas Nedelec
Paris Brain Institute, Aramis, Paris, France

Aims: Understanding the shared and specific clinical manifestations of neurodegenerative diseases in the prodromal phase is key to understanding their complexity and specific pathophysiologies.
Methods: Using the longitudinal THIN database in the UK, we contrasted clinical characteristics from individuals with a final diagnosis of Parkinson's disease (PD), Alzheimer's disease (AD), dementia with Lewy Bodies (DLB), and controls without neurodegenerative disorders. We tested the association (OR) of each neurodegenerative disorder for a selected list of symptoms including motor, autonomic, and neuropsychiatric features, as well as broad families of treatments (laxatives, antihypertensives, statins, benzodiazepines and neuroleptics). We subsequently tested whether the association were different between disorders, in recognition that the difference may indicate possible disease-specific effects. We replicated the main findings in the UK Biobank (UKB).
Results: We used 28,222 patients with PD, 20,214 with AD, 4,682 with DLB and 20,214 controls, from the THIN UK Database. Neurodegenerative disorders were significantely associated with the presence of multiple clinical characteristics before their diagnosis including memory problems, tremor, confusion, hallucinations, constipation, sleep disorders, anxiety, depression, falls, hypotension, urinary tract disorders and abnormal weight loss, and less frequent use of agents acting on the renin–angiotensin–aldosterone system and selective beta-2-adrenoreceptor agonists. Benzodiazepines and serotonin reuptake inhibitors consumption was more frequent in individuals who later developed all three diseases while antidiabetic medication consumption was lower in both future AD and PD patients.
Conclusions: In addition to a range of non-motor features, benzodiazepines and serotonin reuptake inhibitor use was increased in individuals at a pre-diagnosis stage of neurodegenerative diseases, while agents acting on the renin–angiotensin–aldosterone system and selective beta-2-adrenoreceptor agonists were less prescribed.

A UNIQUE SENESCENCE-ASSOCIATED SECRETORY PHENOTYPE OF HUMAN ASTROCYTES FOLLOWING CHRONIC INFLAMMATORY STIMULATION

POSTERS: B01.O. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AGING

Jong-Heon Kim[1], Jong Hyuk Yoon[2], Ho-Won Lee[3], Jun-Yeong Lee[4], Kyoungho Suk[5]
[1]Brain Science & Engineering Institute, Kyungpook National University, Daegu, Korea, Republic of, [2]Korea Brain Research Institute, Neurodegenerative Diseases Research Group, Daegu, Korea, Republic of, [3]Kyungpook National University Chilgok Hospital, Department Of Neurology, Daegu, Korea, Republic of, [4]Kyungpook National University, School Of Life Sciences, Bk21 Four Knu Creative Bioresearch Group, Daegu, Korea, Republic of, [5]School of Medicine, Kyungpook National University, Department Of Pharmacology, Daegu, Korea, Republic of

Aims: Senescent astrocytes are prominent in brain tissues from patients with neurodegenerative diseases, such as Alzheimer's disease. The accumulation of senescent astrocytes in the aging brain can contribute to Aβ accumulation, tau hyperphosphorylation, and the deposition of neurofibrillary tangles. These astrocytes exhibit impaired homeostatic function and secretion of senescence-associated secretory phenotype (SASP) factors exerting detrimental effects, such as persistence of neuroinflammation, impairment of synaptic plasticity, and blood–brain barrier dysfunction. Cultured astrocytes can enter a senescent-like state when exposed to various stimuli, including oxidative stress, oligomerized amyloid beta peptide, and SASP factors such as IL-1β. Importantly, SASP factors produced by senescent astrocytes can induce neighboring cells to undergo senescence, thereby amplifying both the population of senescent cells and these detrimental phenotypes. However, implications of SASP in neurodegenerative diseases remain to be fully understood. In this study, we conducted a combined analysis of human astrocyte secretome and profiling of transcription factor (TF) binding motifs.
Methods: We examined the secretome of human fetal astrocytes in culture following chronic stimulation with pro-inflammatory cytokine mixtures containing TNF-α, IL-1β, and IFN-γ. We also analyzed the occurrence of TF binding motifs at the promoter surrounding region of the genes encoding the astrocyte secretome.
Results: The combined analysis identified a unique profile of senescence-associated secretory phenotype proteins and their regulatory TFs in the long-term cytokine-treated astrocytes, which were distinct from acutely activated astrocytes.
Conclusions: Our study provides the resource for potential biomarkers and therapeutic targets, shedding light on the intricate relationship among chronic neuroinflammation, astrocyte senescence, and neurodegenerative diseases.

RECONSTITUTING THE FIRST STEPS OF AUTOPHAGY IN ALZHEIMER'S DISEASE

POSTERS: B01.N. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AUTOPHAGY, APOPTOSIS, CELL DEATH

Kryštof Knapp, Oliver Daumke
Max Delbrück Center, Ag Daumke, Berlin, Germany

Aims: To deal with protein aggregation and misfolding, living organisms have developed several mechanisms to recognize and recycle these targets: the protein quality control system. Autophagy is one of the modules of PQC that is capable of tackling larger targets, such as organelles or protein aggregates (aggrephagy).
Selective autophagy receptors are essential components of the autophagy machinery that recognize cellular material, and cargo, labeled for degradation. p62, also known as sequestome 1, is a member of this family responsible for the detection of ubiquitinated cargo and the recruitment of other components of the autophagy machinery. Although p62 is highly enriched in tau protein aggregates, which should trigger autophagy and tau recycling, this is not the case in the brains of patients with tauopathies.
Therefore, we aim to understand the initial steps of autophagy from a structural point of view.
Methods: To establish a working aggrephagy model, which can reconstitute the first steps of autophagy of tau aggregates one has to introduce ubiquitination into the system. To achieve that we use several non-canonical approaches including DNA origami, *in vitro* aggregation of ubiquitin-tau fusion constructs, and cellular models of tau aggregation.
The resulting biological assemblies of cargo with selective autophagy receptors are then studied using single-particle electron cryo-microscopy and electron cryo-tomography.
Results: To this end, we established a new approach for studying the initial stages of aggrephagy using DNA origami as the carrier of the ubiquitination signal which can trigger the initial steps of aggrephagy. This will allow us to better understand the architecture inside pathological condensates, highly enriched for selective autophagy receptors.
Conclusions: Reconstitution experiments in combination with cellular models can help us to better understand autophagy impairment in neurodegenerative diseases on a molecular level.

REPLICATIVE MICROGLIA SENESCENCE: A POTENTIAL MECHANISM UNDERLYING PATHOLOGICAL BRAIN AGEING.

POSTERS: B01.O. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AGING

Bangyan Liu
Weill Cornell Medical College, Neuroscience Program, New York, United States of America

Aims: Microglia, the resident immune cells of the central nervous system, play critical roles in the neuroinflammatory alterations indicated in the pathogenesis of age-dependent neurodegenerative diseases including Parkinson's and Alzheimer's disease. However, the connection between microglia dysfunctions and chronological aging remains unclear. In the current study, we investigated the effect of telomere shortening, a critical hallmark of aging, in the both an *in vitro* and an *in vivo* model.
Methods: By inhibiting the telomerase activity, we successfully shortened the telomeres of the microglia in the mouse brain and generated iPSC-derived human microglia with shorter telomeres. We analyzed the transcriptomic changes of the microglia and tested the functional impacts of telomere shortening via behavioral studies.
Results: We identified strong senescence signals in the microglia with shorter telomeres in both our *in vitro* and *in vivo* models. Meanwhile, we identied an unique senescence-associated-secretory-phenotype (SASP) signautre that has potential effects on both neurons and oligodendrocytes. Our behavioral studies also demonstrated a detrimental effect of telomere shortening on the congnitive abilibities of mice.
Conclusions: Overall, our current data lead to the conclusion that replicative microglia senescence caused by telomere attrition disrupts homeostatic microglia-neuron and microglia-oligodendrocyte interactions and can potentially contributes to the pathogenesis of age-related neurodegenerative diseases.

THE AGE-ASSOCIATED MITOCHONDRIAL DONOR SIGNATURE IS PERCEIVED IN THE IPSCS DERIVED NEURONS (IPSCSN) AND DIRECTLY CONVERTED NEURONS (INS)

POSTERS: B01.O. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AGING

Nimmy Varghese[1,2], Leonora Szabo[1,2], Amandine Grimm[1,2], Zameel Cader[3], Imane Lejri[1,2], Anne Eckert[1,2]
[1]University Psychiatric Clinics Basel, Neurobiology Lab For Brain Aging And Mental Health, Basel, Switzerland, [2]University of Basel, Research Cluster Molecular And Cognitive Neurosciences, Basel, Switzerland, [3]University of Oxford, Nuffield Department Of Clinical Neuroscience, Oxford, United Kingdom

Aims: For neurodegenerative disorders, including tau pathology, it is crucial to comprehend the human brain aging on the mitochondrial level, which serves as the neuronal powerhouse. However, finding suitable models to study human brain aging is challenging due to limitations and ethical constraints. Advanced human neuronal in vitro models like iPSCs-derived neurons and directly induced neurons are of interest. There remains uncertainty in these model systems surrounding the potential to undergo rejuvenation or maintain an aging-associated donor signature, especially for the iPSCsN. The study aimed to investigate the degree to which iPSCsN and iNs retain the aging donor signature focusing on bioenergetics.
Methods: The total ATP level, mitochondrial membrane potential (MMP), reactive oxygen species (ROS), mitochondrial respiration (OCR), mitochondrial mass, mitochondrial morphology, and glycolysis were compared between iPSCsN and iNs from the same young (n = 4, Agemean = 31 years) and aged (n = 4, Agemean = 69 years) donors.
Results: Our preliminary findings demonstrated that both the iNs and the iPSCsN could preserve an aging- associated phenotype compared to the equivalent young neurons. The aged neurons showed a decrease in ATP, MMP, and OCR and an increase in ROS, glycolysis, and mitochondrial mass. The mitochondrial dynamics were characterized by a more fragmented mitochondrial shape.
Conclusions: Our preliminary findings indicate that iNs and iPSCsN display an aging-associated at the mitochondrial level phenotype contrary to the belief that aged iPSCsN would fully rejuvenate. Further investigation is needed to determine the extent of this preservation. Overall, this work will help us better understand how accurately "aged" iNs and iPSCsN simulate human brain aging and contribute to the development of cutting-edge methods for discovering pharmacological targets to enhance human health during aging and in tau pathology.

Aims: In anti-IgLON5 disease, autoantibodies against the surface protein IgLON5 trigger Tau pathology and neurotoxicity. Understanding how these autoantibodies targeting surface proteins can trigger Tau changes and exert neurotoxicity would help to conceptually understand why Tau reacts in different diseases and to design therapeutic approaches for anti-IgLON5 and similar neurological diseases. We attempt to understand: 1) Whether patient-derived IgLON5 autoantibodies directly trigger pathological Tau changes, and 2) how they induce neurotoxicity?
Methods: We use IgLON5 autoantibodies (AABs) purified from the serum of a clinically verified IgLON5 patient and study their effect on Tau pathology (immunocytochemistry, biochemistry) and neuronal activity (Calcium imaging, electrophysiology in autaptic cultures) in wildtype primary hippocampal mouse neurons, as well as on neuroinflammation in mice (immunohistochemistry, bulk RNAseq). AAB application into mice is achieved through ventricular infusion of AABs for 2 weeks.
Results: Our findings show that intraventricular infusion of patient-derived IgLON5 AABs into wildtype mice leads to phospho-Tau (PHF-1) accumulation in mossy fiber projections, corpus collosum, and cells of the dentate gyrus granule layer. In addition, we observe a neuroinflammatory response in the brain of these animals. In cultured primary mouse neurons, Tau phosphorylation and somatodendritic re-sorting induced by IgLON5 AABs was time- and dose-dependent, and followed a period of acute neuronal hyperactivity.
Conclusions: Collectively, our results indicate that IgLON5 AABs trigger prolonged (days) Tau phosphorylation and resorting by acutely (minutes to hours) stimulating high neuronal activity, which in the brain is associated with glia cell activation.

SINGLE-CELL EXCITABILITY OF INHIBITORY AND EXCITATORY NEURONS UNDER EARLY TAU PATHOLOGY

POSTERS: B01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Emmie Banks, Annie Goettemoeller, Kelly South Pham, Matthew Rowan
Emory University, Department Of Cell Biology, Atlanta, United States of America

Aims: Circuit hyperexcitability is a phenotype in preclinical Alzheimer's disease (AD), yet the interaction between neuronal dysfunction and the emergence of classic AD pathology remains unclear. Here we investigate how the emergence of pathological tau impacts the biophysical properties and intrinsic excitability of both inhibitory and excitatory neurons in a murine model of AD.
Methods: We used an adult-onset, region-specific AAV approach to model pre-tangle tau pathology in preclinical sporadic AD. Thus, we stereotaxically injected the wild-type human *MAPT* gene (hMAPT) into the lateral entorhinal cortex (LEC) of adult wild-type mice. This short-term viral approach eliminates the effects of transgene expression during development and restricts transgene delivery to the first forebrain region to show pathological tau in human AD. We then performed immunohistochemistry to characterize the pathological tau species produced by viral hMAPT expression, as well as patch-clamp electrophysiology to measure intrinsic changes in excitability.
Results: We demonstrate that 2-3 weeks of hMAPT-AAV expression produces hyperphosphorylated tau and oligomeric tau in the somatic compartment of LEC neurons, which is exacerbated with co-expression of the human *APP* gene. We further show how this pathological tau in the LEC affects the intrinsic excitability and passive membrane properties of each excitatory neurons and parvalbumin-expressing interneurons. We also demonstrate the presence of axonal swelling in the perforant pathway, reminiscent of dystrophic neurites, potentially suggesting the beginnings of transynaptic pathological spread to the dentate gyrus.
Conclusions: These results give us insight into the potential effects of early tau pathology on network dysfunction in a highly vulnerable region in AD, at a timepoint when intervention may still be preventative.

ULTRASTRUCTURAL CHARACTERIZATION OF HUMAN BRAIN TISSUE VITRIFIED AT TIME OF AUTOPSY USING CRYO-ELECTRON TOMOGRAPHY WITH CRYO-PLASMA FOCUSED ION BEAM MILLING

POSTERS: B01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Benjamin Creekmore[1], Kathryn Kixmoeller[2], Ben Black[2], Yi-Wei Chang[2], Edward Lee[1]
[1]University of Pennsylvania, Translational Neuropathology Research Laboratory, Philadelphia, United States of America, [2]University of Pennsylvania, Biochemistry And Biophysics, Philadelphia, United States of America

Aims: We sought to develop a method to image unfixed never previously frozen human brain at high resolution by cryo-electron tomography (cryo-ET) to identify and describe phenomena not easily recapitulated by cellular or animal models.
Methods: We obtained human brain tissue at time of autopsy from several individuals diagnosed with neurodegenerative disease. This tissue was sectioned and plunge-frozen directly onto cryo-electron microscopy (cryo-EM) grids. We used xenon plasma focused ion beam (PFIB) milling at cryogenic temperatures to generate lamellae directly on cryo-EM grids, thereby avoiding cryo-sectioning and cryo-liftout. We imaged these lamellae by transmission EM, ultimately using cryo-ET to generate three-dimensional tomograms of targets of interest.
Results: We developed a method to freeze human brain tissue up to at least 180μm thick directly onto cryo-EM grids via plunge-freezing as opposed to high-pressure freezing that has been used before for thick samples. Using PFIB, we developed a method to efficiently generate lamellae suitable for cryogenic transmission EM. By using PFIB as opposed to gallium FIB, we were able to use ion beam currents never previously used on biological samples to ultimately make on-grid milling of large samples, like human brain tissue, feasible. From these lamellae we identified intact subcellular structures such as components of autophagy and potential Alzheimer's disease tau fibrils. Additionally, we identified intact compact myelin and other myelin components such as cytoplasmic channels, ultimately using our data to further describe how myelin basic protein (MBP) functions.
Conclusions: We developed a method whereby we can now generate lamellae suitable for high resolution, relatively artifact free cryo-ET imaging in unfixed, never previously frozen human brain samples to better study and understand phenomena, like neurodegenerative disease, that are not easily recapitulated in cell or animal models.

PROTECTIVE EFFECT OF SYNTAXIN-6 KNOCKOUT ON BEHAVIOURAL AND NEUROPATHOLOGICAL READOUTS IN A HUMANISED P301S TAUOPATHY MOUSE MODEL

POSTERS: B01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Elizabeth Hill, Michael Farmer, Jacqueline Linehan, Nicholas Kaye, Craig Fitzhugh, Sebastian Brandner, Silvia Purro, John Collinge, Thomas Cunningham, Simon Mead
UCL, Mrc Prion Unit, London, United Kingdom

Aims: Variants in and near to the syntaxin-6 (*STX6*) gene are genetic risk factors for progressive supranuclear palsy (PSP) and sporadic Creutzfeldt-Jakob disease (sCJD), with an increase in *STX6* expression being the likely genetic mechanism driving disease risk. Increased syntaxin-6 protein levels are causally associated with Alzheimer's disease (AD) further suggesting syntaxin-6 has pleiotropic risk effects in neurodegenerative diseases. This work aims to functionally validate a role of syntaxin-6 in tau pathogenesis *in vivo* by assessing the effect of syntaxin-6 knockout on behavioural, neuropathological and biochemical readouts in h*Tau*$^{P301S/P301S}$ mice.
Methods: We crossed *Stx6*$^{-/-}$ mice with h*Tau*$^{P301S/P301S}$ mice to generate cohorts of *Stx6*$^{-/-}$;h*Tau*$^{P301S/P301S}$, *Stx6*$^{+/+}$;h*Tau*$^{P301S/P301S}$, *Stx6*$^{-/-}$;m*Tau*$^{+/+}$ and *Stx6*$^{+/+}$;m*Tau*$^{+/+}$ mice (n=20/genotype). Rotarod was assessed monthly and gait assessed at 5.5 months. h*Tau*$^{P301S/P301S}$ mice were humanely culled at endpoint. A 3 and 5 month timed cull (n=10/genotype) was also conducted for biomarker, biochemical and pathological measurements.
Results: We found an early protective effect of syntaxin-6 knockout on rotarod performance in h*Tau*$^{P301S/P301S}$ mice. This partial phenotypic rescue coincided with reduced neuronal loss in the superficial cortex seen early in the disease course. h*Tau*$^{P301S/P301S}$ mice with syntaxin-6 knockout also had partial rescue of some gait parameters. These observations could not be explained by gross differences in levels of total tau. Later in the disease, no differences were seen between *Stx6*$^{-/-}$;h*Tau*$^{P301S/P301S}$ and *Stx6*$^{+/+}$;h*Tau*$^{P301S/P301S}$ mice. We present a range of additional pathological and biomarker endpoints in correlation with a modified early behavioural phenotype.
Conclusions: Syntaxin-6 knockout in h*Tau*$^{P301S/P301S}$ mice appears to have an early beneficial effect on disease progression providing complementary evidence for a role of syntaxin-6 in tau pathogenesis and experimental support that syntaxin-6 lowering could be employed as a potential therapeutic approach in tauopathies.

TAUOPATHY RESEARCH USING A NOVEL TRAUMATIC BRAIN INJURY MODEL

POSTERS: B01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Taeko Kimura[1], Masami Masuda-Suzukake[2], Masashi Hashimoto[2], Shin-Ichi Hisanaga[3], Taisuke Tomita[4], Masato Hasegawa[2]
[1]The University of Tokyo, Department of neuropathology and neuroscience Graduate school of pharmaceutical sciences, Tokyo, Japan, [2]Tokyo Metropolitan Institute of Medical Science, Department Of Brain And Neurosciences, Tokyo, Japan, [3]Tokyo Metropolitan University, Laboratory Of Molecular Neuroscience, Department Of Biological Sciences, Hachioji City,, Japan, [4]The University of Tokyo, Department Of Neuropathology And Neuroscience Graduate School Of Pharmaceutical Sciences, tokyo, Japan

Aims: Chronic traumatic encephalopathy (CTE) is a tauopathy caused by traumatic brain injury (TBI). Since the onset and cause of CTE are clear, it is possible to track the progression of the disease. In this study, we developed a CTE animal model using a new system called CHIMERA, which is quantitative and can reproduce human sports and traffic accident injuries.
Methods: Mild repetitive TBI was administered to wild-type and P301S tau transgenic (Tg) mice, and changes were observed 1and 2 months post-TBI. We also investigated the impact of TBI on tau propagation.
Results: After TBI was administered to wild-type and Tg mice, axonal damage in the optic tract and superior colliculus was observed up to two months later, and inflammation positive for Iba1 and GFAP was seen. However, pathological tau phosphorylation (AT8) was not observed. Subsequent analysis in the cerebral cortex, where pathology is seen in CTE patients, revealed no tau pathology in wild-type mice. In Tg mice, two months post-TBI, there was an increase in AT8-positive neurons in layers IV and V of the motor and sensory cortex. Phosphorylation of tau at these sites was analyzed by mass spectrometry, revealing elevated phosphorylation at S262, S235, and S416. Moreover, in mice inoculated with tau fibrils, there was a trend for increased propagation of tau pathology in the cerebral cortex due to TBI.
Conclusions: These results suggest the successful construction of a CTE mouse model. In the future, we will investigate the mechanism of pathology in layers IV and V neurons caused by TBI.

TAU DRIVES EARLY TRANSCRIPTOMIC CHANGES IN A C. ELEGANS MODEL OF TAU AND TDP-43 CO-PATHOLOGY

POSTERS: B01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Vaishnavi Jadhav[1], Randall Eck[1], Samuel Smukowski[1], Paul Valdmanis[1], Brian Kraemer[1,2], Nicole Liachko[1,2]
[1]University of Washington, Medicine, Seattle, United States of America, [2]VA Puget Sound Health Care System, Grecc, Seattle, United States of America

Aims: TDP-43-positive inclusions are present as a co-pathology in over half of patients with Alzheimer's disease (AD). AD patients with TDP-43 pathology have a faster disease course, more rapid cognitive decline, and increased neurodegeneration, but the molecular mechanisms underlying this are unknown. It is possible that synergies between pathological proteins drives worsened outcomes in these patients.
Methods: Using *C. elegans* models of mixed pathology in AD, we have previously shown that TDP-43 specifically synergizes with tau but not Aβ, resulting in enhanced neuronal dysfunction, selective neurodegeneration, and increased accumulation of pathological tau. However, cellular responses to co-morbid tau and TDP-43 preceding neurodegeneration have not been characterized. In this study, we evaluate transcriptomic changes at time-points preceding frank neuronal loss using a *C. elegans* model of tau and TDP-43 co-expression.
Results: We find significant differential expression and exon usage in genes enriched in multiple pathways including lipid metabolism and lysosomal degradation. We test loss-of-function mutations in a subset of tau and TDP-43 responsive genes, identifying new modifiers of neurotoxicity.
Conclusions: Characterizing early cellular responses to tau and TDP-43 co-pathology is critical for understanding protective and pathogenic responses to mixed proteinopathies, and an important step in developing therapeutic targets protecting against pathological tau and TDP-43 in AD.

SOMATIC MUTATIONS IN CHRONIC TRAUMATIC ENCEPHALOPATHY IDENTIFIED BY SINGLE-NEURON GENOME SEQUENCING

POSTERS: B01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Michael Miller[1], Chanthia Ma[1], Guanlan Dong[2], Samuel Naik[1], Gannon Mcdonough[1], Shulin Mao[2], Ann Mckee[3], August Huang[2], Alice Lee[2], Christopher Walsh[2]
[1]Brigham and Women's Hospital, Pathology, Boston, United States of America, [2]Boston Children's Hospital, Genetics And Genomics, Boston, United States of America, [3]Boston University / VA, Pathology, Boston, United States of America

Aims: Chronic Traumatic Encephalopathy (CTE) is a neurodegenerative tauopathy associated with repetitive head trauma. The pathogenesis of neuronal dysfunction and loss in CTE is poorly understood, highlighting a need to probe disease mechanisms from a broad lens. Neurons each harbor somatic single-nucleotide variants (sSNV) in their genomes, which we have found accumulate with age and increase in Alzheimer's disease (AD). Somatic mutational patterns provide fingerprints of cellular disease mechanisms, identified through signature analysis.
Methods: We performed single-cell whole-genome sequencing on neurons from CTE and age-matched controls, and analyzed the burden of somatic mutations and associated nucleotide change signatures for mutational patterns.
Results: We found that neurons in CTE harbor significantly increased sSNV, compared to non-diseased control neurons. Signature analysis showed specific disease-related patterns in the somatic mutations that accumulate in CTE. Somatic mutations in CTE neurons share certain signature features with AD, but also show distinct mutational signatures that suggest CTE-specific pathogenic mechanisms impacting the neuronal genome.
Conclusions: CTE, a neurodegenerative disease associated with repetitive head trauma, shows neuronal somatic mutation accumulation, a finding also seen in sporadic neurodegeneration in AD. The somatic mutational signatures of CTE illuminate divergent mechanisms from AD, but also point to common mutational features that may constitute broader hallmarks of neurodegeneration. The identification of somatic mutation in distinct neurodegenerative diseases will enable further dissection of pathogenesis cascades, to illuminate diagnostic and therapeutic targets.

BILE ACID PROFILE ASSOCIATED WITH CSF AND PET BIOMARKERS IN ALZHEIMER'S DISEASE

POSTERS: B01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Fardin Nabizadeh[1], Parya Valizadeh[2], Mohammad Sadegh Fallahi[2]

Aims: Recent studies have shown that gut microbiota can affect the development of Alzheimer's disease (AD) through various mechanisms. Bile acids (BAs), which are the final byproducts of cholesterol metabolism created through both the human body and gut microbiome, appear to be influenced by gut microbiota and may impact AD pathological characteristics such as the accumulation of tau and amyloid-β. We aimed to investigate the associations between various serum BAs and CSF biomarkers (including Aβ, total tau, and p-tau). Additionally, we sought to examine the longitudinal changes in brain Aβ and tau through PET imaging in relation to BAs profile.
Methods: The data of 828 subjects including 491 diagnosed with mild cognitive impairment (MCI), 119 patients diagnosed with AD, and 267 cognitively normal (CN) participants were obtained from ADNI. The baseline and longitudinal [^{18}F] florbetapir and [^{18}F] flortaucipir PET standard uptake value ratios (SUVR) measures were obtained to assess the accumulation of tau and Aβ. Moreover, baseline levels of serum BAs and CSF Aβ1-42, tau, and p-tau were used.
Results: After FDR correction we observed that five BAs level and relevant calculated ratios were associated with CSF p-tau and tau, three with CSF Aβ1-42. Furthermore, three BAs level and relevant calculated ratios were associated with the tau-PET rate of change, and two with the Aβ rate of change.
Conclusions: The findings from our study suggest a correlation between altered profiles of BAs and CSF and imaging biomarkers associated with AD. These results provide supporting evidence for the link between the gut microbiome and the pathological features of AD.

CELL TYPE-SPECIFIC HIPPOCAMPAL ALTERATIONS UNDERLIE MEMORY DEFICITS IN NOVEL APP/TAU MICE

POSTERS: B01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Arnaldo Parra-Damas[1,2], Angel Deprada[1,2], Maria Capilla-López[1,2], Carlos A. Saura[1,2]
[1]Universitat Autònoma de Barcelona, Institut De Neurociències, Department De Bioquímica I Biologia Molecular, Bellaterra, Spain, [2]Centro de Investigación Biomédica en Red (CIBER), Ciber Enfermedades Neurodegenerativas (ciberned), Madrid, Spain

Aims: Excitatory/inhibitory neurotransmission imbalance in memory neural circuits affected by amyloid-β and tau pathologies are thought to underlie memory deficits in Alzheimer's disease (AD). However, the specific cellular mechanisms by which these neuropathological hallmarks induce dysfunction of excitatory and inhibitory hippocampal neurons remain poorly understood. Here, we report differential deleterious effects of amyloid-β and tau on hippocampal-dependent memory and synaptic plasticity as well as cell type-specific pathology in novel APP/Tau transgenic mice expressing human familial AD-linked mutant amyloid precursor protein (APP) and microtubule-associated protein tau (MAPT) genes.
Methods: We combined behavioral, molecular, biochemical, as well as conventional and advanced histological and microscopy analyses, including tissue clearing and expansion microscopy, to assess the effect of Aβ and Tau accumulation on the hippocampus of APP/Tau mice, focusing on Pvalb-expressing interneurons. Furthermore, we applied cell type-specific RNA-seq analyses in hippocampal excitatory neurons (CaMKIIα+) and inhibitory interneurons (Pvalb+) of APP/Tau;RigoTag mice.
Results: Histopathological analyses reveal that Aβ and pTau are expressed in hippocampal CaMKIIα+ neurons but not Pvalb+ interneurons in 6 month-old APP/Tau mice. Accordingly, cell type-specific gene expression profiling using APP/Tau;CamK2α-Cre;RigoTag and APP/Tau;Pvalb-Cre;RiboTag mice show that APP and Tau gene expression is restricted to excitatory neurons. Importantly, 6 month-old Tau and APP/Tau mice show spatial learning and memory deficits, which are associated with reduced levels of synaptic proteins and synaptic Tau accumulation, as revealed by biochemical and expansion microscopy analyses. Moreover, APP/Tau mice show a selective reduction and altered morphology of hippocampal inhibitory Pvalb-expressing neurons, accompanied by age-dependent alterations in perineuronal nets (PNNs).
Conclusions: Altogether, APP/Tau mice reproduce AD pathological changes, showing cell type-specific alterations in excitatory and inhibitory neurons, making this model a useful tool for studying the molecular mechanisms underlying selective cellular vulnerability in AD.

Houston Methodist Academic Institute, T. T. & W. F. Chao Center For Brain, Houston, United States of America

Aims: Alzheimer's disease (AD) remains a challenging condition with no cure to halt its progression. Drug repositioning, an expedited drug development strategy, offers promise in the pursuit of effective AD therapeutics. This study presents a comprehensive investigation into the potential of ebselen, a knowledge drug, in targeting AD.
Methods: Utilizing a systematic Alzheimer's disease drug repositioning (SMART) framework, we conducted high throughput AD 3D cell culture systems, computational cellular analysis, and iterative procedures for effective drug repositioning. Our screening involving 4,600 known drugs and bioactive compounds and employed AD murine models for in *vivo* validation of promising hits, assessing the efficacy of ebselen in alleviating pathological features of AD.
Results: The study identified eight drug candidates capable of alleviating p-Tau accumulation and/or Aβ burden in a multi-well formatted 3D culture assay. Ebselen, an organoselenium compound, emerged as a top candidate, demonstrating significant potential both *in vitro* and *in vivo*. Acute and chronic treatments with ebselen exhibited substantial improvements in neurite abundance, intensity, and p-tau inhibition in the high-throughput 3D cell assay. Behavior assessments further demonstrated the cognition enhancement achieved with ebselen administration. Notably, biosafety evaluations indicated minimal adverse effects even with high dosage and long-term ebselen treatment, underscoring its potential as a safe therapeutic option for early onset of AD.
Conclusions: Ebselen shows a promising drug candidate for the treatment of early onset AD. This study not only demonstrated its efficacy in alleviating pathological markers of AD but also highlighted its favorable biosafety profile. The findings offer important implications for AD treatment and further clinical investigations are warranted to validate the potential of ebselen in human subjects, bringing us closer to a viable therapeutic solution to Alzheimer's disease.

ALZHEIMER'S DISEASE WITH ALPHA-SYNUCLEIN CO-PATHOLOGY: CO-LOCALIZATION OF PHOSPHODIESTERASE 1 AND MGLUR1 WITH ALPHA-SYNUCLEIN AND PHOSPHO-TAU IN THE FRONTAL CORTEX

POSTERS: B01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Doris Weissenbrunner[1,2], Mochen Cui[1,2], Paul Feyen[2], Antonia Neubauer[1], Felix Struebing[1,2], Jochen Herms[1,2,3]
[1]University of Munich, Center For Neuropathology And Prion Research, Munich, Germany, [2]German Center for Neurodegenerative Diseases (DZNE), Translational Brain Research, München, Germany, [3]Munich Cluster for Systems Neurology, Synergy, Munich, Germany

Aims: OBJECTIVES:
Alzheimer's disease (AD) is characterised pathologically by the aggregation of β-Amyloid plaques (Aβ) and hyperphosphorylated tau deposits. Additionally, up to 50% of AD cases exhibit the accumulation of α-synuclein (ASYN). Single nucleus RNA-sequencing (sn-RNA-seq) on frontal cortex tissue has identified differentially expressed genes in neuronal clusters of cases with AD and AD+ASYN. Interestingly, most of these genes were upregulated in AD+ASYN. Some of them encode proteins, such as Phosphodiesterase 1A (PDE1A) and mGluR1 (GRM1), which have previously been linked to neurodegenerative diseases in the literature. The primary aim of this study is to elucidate whether these proteins are colocalized with α-synuclein and phospho-Tau in human brain tissue in the frontal cortex.
Methods: METHODS:
We intend to conduct immunofluorescence co-staining using primary antibodies against PDE1A, GRM1, α-Synuclein and phospho-Tau on post-mortem human brain tissue obtained from four cases with AD, four cases with AD+ASYN and four control cases. Furthermore, the tissue will be stained with DAPI and Methoxy, to determine cellular localization of the antigens and their association with Aβ. Images will be acquired and statistically analysed exploring potential variations between AD, AD+ASYN and control cases.
Results: RESULTS:
The sn-RNA-seq analysis revealed a set of genes which were significantly upregulated in AD patients with α-synuclein co-pathology. Immunohistochemistry may demonstrate the co-localisation of some of the proteins coded by these upregulated genes with α-synuclein aggregates and phospho-Tau in the frontal cortex.
Conclusions: DISCUSSION:
The potential co-occurrence of PDE1A and GRM1 with the pathological hallmarks of AD+ASYN may indicate pathophysiological convergence, necessitating further research. These findings will contribute to our understanding of the mechanisms underlying this co-pathology and may have implications for the development of targeted therapies for AD patients with α-synuclein involvement.

Okinawa Institute of Science and Technology, Cellular And Molecular Synaptic Function Unit, Okinawa, Japan

Aims: Accumulation of soluble tau causes *synaptic* dysfunction leading to cognitive impairment in tauopathies including Alzheimer's disease (AD). Dynamin plays a key role in synaptic vesicle endocytosis and recycling in the presynaptic terminal, thereby supporting synaptic strength. Our previous studies at the calyx of Held in mouse brainstem slices suggest that soluble tau over-assembles microtubules (MTs). Since dynamin is a MT-binding protein, sequestration of free dynamin by MTs impairs vesicle endocytosis and synaptic transmission. A synthetic dodecapeptide, PHDP5, corresponding to amino acids 560–571 of the dynamin 1 pleckstrin-homology (PH) domain, can inhibit the MT-dynamin interaction and significantly rescue endocytic impairments, suggesting its potential value for AD treatment. In this study, we investigated whether PHDP5 can rescue memory deficits in the tauopathy model mice Tau609.
Methods: We conjugated PHDP5 to FITC and a cell-penetrating TAT peptide (CPP) as FITC-PHDP5-CPP. We also prepared PHDP5 scrambled control conjugated to FITC and CPP. In six-month old male Tau609 mice, we administered FITC-PHDP5-CPP intranasally for one month, and then tested their spatial learning and memory abilities in the Morris water maze.
Results: *In vitro,* FITC-PHDP5-CPP significantly inhibited MT-dynamin1 binding like unconjugated PHDP5. After intranasal administration of FITC-PHDP5-CPP in mice, FITC signal was found in the hippocampal CA1 region, indicating that the peptide crossed the blood brain barrier (BBB). In comparison to non-treated or scramble peptide controls, FITC-PHDP5-CPP-treated mice exhibited significant cognitive improvements including shorter latencies to the escape platform and increased time spent in the target quadrant of the water maze.
Conclusions: Intranasal administration of FITC-PHDP5-CPP can be an effective therapy for cognitive decline associated with AD.

Aims: Alzheimer's disease (AD) is the most common type of dementia, for which there is no effective treatment. AD is characterized by a robust immune response, the presence of extracellular amyloid-β (Aβ) plaques, and intraneuronal neurofibrillary tangles (NFTs) composed of hyperphosphorylated tau. We have recently shown that nicotinic acid activates the microglial receptor HCAR2 to induce a protective phenotype in an amyloid mouse model of AD, attenuating disease severity. However, the therapeutic potential of HCAR2 in tauopathy has not been assessed. We **aimed** to investigate whether the activation of HCAR2 with the FDA-approved agonist Niaspan® is a potential therapeutic approach to reduce tau pathology.
Methods: *Hcar2* expression was analyzed by qPCR and IHC in brain tissue of the tauopathy mouse model PS19. At 9 months of age, PS19 mice exhibited a severe pathological phenotype and were treated with Niaspan® daily by oral gavage (100 mg/kg) for 30 days. Treated mice were assessed for motor tasks and their brain tissue used for biochemical and imaging analysis.
Results: HCAR2 expression was significantly induced by microglia in 9-month-old PS19, particularly in the hippocampus. Niaspan® treatment rescued the motor coordination deficits, reduced tau hyperphosphorylation, and microgliosis.
Conclusions: Our results indicate that in 9-month-old PS19 mice, there was an increase in hippocampal HCAR2 expression. Moreover, treatment with Niaspan® improved motor coordination but did not affect the clasping reflex nor inflammatory markers. These results indicate that niacin may be acting via microglial HCAR2, attenuating disease severity. However, additional studies are necessary to determine the exact mechanisms of this process. Overall, this work could support the repurposing of marketed niacin-formulations a potential therapy for AD.

TORPOR INDUCES ROBUST AND REVERSIBLE TAU HYPERPHOSPHORYLATION IN HUMAN TAU EXPRESSING MICE

POSTERS: B02.A. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: TAU, PHOSPHORYLATION, TRUNCATION

Christina De Veij Mestdagh[1], Guus Smit[2], Ronald Van Kesteren[2], Rob Henning[3]
[1]Alzheimer Center Amsterdam, Vrije Universiteit Amsterdam, Amsterdam UMC location VUmc, Neurology, Amsterdam, Netherlands, [2]Vrije Universiteit, Molecular And Cellular Neurobiology, Amsterdam, Netherlands, [3]University Medical Center Groningen, Clinical Pharmacy And Pharmacology, Groningen, Netherlands

Aims: Tau protein hyperphosphorylation is a key pathological event in neurodegenerative tauopathies such as Alzheimer's disease. Interestingly, seasonal hibernators show extensive, yet completely reversible tau hyperphosphorylation during periods of hypothermia and hypometabolism followed by rapid rewarming and metabolic reactivation, so called torpor and arousal cycles. Using seasonal hibernators to unravel torpor-associated mechanisms that reverse and protect against pathological effects of tau hyperphosphorylation is challenging and focusses on native tau which might not model human tau properly. We therefore aimed to assess the effects of daily torpor on tau phosphorylation dynamics in human tau expressing mice.
Methods: We induced daily torpor in wildtype mice that express mouse tau (mtau), and uniquely in mice that lack mouse tau and instead express human tau (htau). AT8 immunoblotting and immunohistochemistry were used to assess tau (hyper)phosphorylation at two phosphorylation sites, Ser202 and Thr205, commonly used for Alzheimer's disease staging.
Results: Torpor robustly and reversibly increased the levels of phosphorylated tau in the hippocampus of both mtau and htau mice. Immunohistochemistry revealed four brain areas with prominent tau phosphorylation: the hippocampus, posterior parietal cortex, piriform cortex and cortical amygdala. Whereas wildtype mice primarily showed increased levels of phosphorylation of diffusely organized tau, htau mice had somato-dendritic accumulation of AT-8 reactivity resembling tau pre-tangles as observed in Alzheimer patient brain. Interestingly, this AT8 positive accumulation also disappeared upon arousal, and overall tau phosphorylation at 24h after arousal was even lower than observed at baseline in euthermia.
Conclusions: Daily torpor in htau mice offers a quick, controllable and standardized method to study tau (hyper)phosphorylation, accumulation and clearance in a model relevant for neurodegeneration. It therefore offers opportunities to discover new mechanisms underlying the clearance of hyperphosphorylated tau.

Aims: Hypothermia, a phenomenon observed in elderly patients with obesity and type 2 diabetes mellitus as well as in mouse models of obesity (e.g. leptin deficient ob/ob obese mice), was linked to development of Alzheimer's disease (AD), especially hyperphosphorylation of Tau protein. Currently, anorexigenic and antidiabetic substances, such as cocaine- and amphetamine-regulated transcript peptide (CARTp), are examined as possible neuroprotective agents.
Methods: We employed a mouse model of obesity with hypothermia, insulin resistance, and increased hippocampal Tau hyperphosphorylation, namely mice with monosodium glutamate (MSG)-induced obesity, to explore potential neuroprotective properties of natural CARTp, CART(61-102), administered intracerebroventricularly to the 3rd ventricle (ICV, 1 µg/day/mouse for 2 weeks) and its novel palmitoylated analog, palm-CART, administered subcutaneously (SC, once daily 10 mg/kg for 3 weeks); control lean or obese MSG mice were treated with saline. We examined peripheral and central insulin resistance and neuropathological changes in the hippocampus using the method of western blot.
Results: Compared to saline-treated MSG mice, MSG mice treated with CART(61-102) or palm-CART significantly decreased food intake and body weight, as well as increased the body temperature. MSG mice developed peripheral insulin resistance expressed by QUICKI (quantitative insulin sensitivity check index); the treatment with palm-CART tended to reverse it. In the hippocampi, we observed only insignificant reduction in activation of insulin signaling cascade, and no significant changes in its activation after the treatment with both peptides. However, we detected significantly increased Tau hyperphosphorylation at Thr212 or Ser404 in hippocampi of MSG mice, which was attenuated by the treatment with CARTp analogs.
Conclusions: Analogs of CARTp were able to reduce food intake and body weight, increased body temperature of obese MSG mice, and attenuated Tau hyperphosphorylation in hippocampi.

Aims: The tetracycline doxycycline (Dox) has been reported to have neuroprotective effects unrelated to its antibiotic activity. Our present aim was to determine whether Dox could prevent behavioral and biochemical phenotypes related to abnormal tau accumulation in a htau mouse model of tauopathy.
Methods: htau mice were analyzed in the open field, rotatord and novel object recognition test to determine time course of behavioral deficits. From 3 months-old mice were treated chronically with doxycycline in the diet during 6 months. Phenotypic rescue was analyzed by behavioral and biochemical studies. Phospho tau and insoluble tau contents were determined as well as autophagy markers.
Results: Htau mice display deficits in motor coordination and novel object recognition test which correlates with the presence of insoluble and hyperphosphorylation tau in the prefrontal cortex. Dox treatment precluded the onset of cognitive deficits at 6 and 12 months old. Moreover olfactory dysfunction and motor coordination impairments were also prevented.
Conclusions: Dox prevents tau pathology and cognitive deficits when administered at aearly stages of disease. These results highlight the potential of doxycycline treatment for therapeutic application in human tauopathies.

Aims: In Alzheimer's disease (AD) levels of aggregated tau protein correlate with neuronal dysfunction and cognitive decline. Therefore, clearing tau aggregates may modify disease progression in AD and primary tauopathies. The growing field of proximity induced modalities that enable targeted degradation of proteins of interest prompted us to explore these approaches for clearance of pathological, aggregated tau. Selective removal of pathological intracellular protein aggregates using a small molecule represents a novel approach towards the development of a future therapeutic.
Methods: We tested a set of published heterobifunctional tau degraders that utilize Cereblon E3 ligase in a human iPSC neurons overexpressing aggregation-prone tau, and in B35 rat neuroblastoma and CHO-K1 Tau P301L cell-lines with tau pathology induced by tauopathy mouse brain seeds. We performed global proteome profiling to explore putative off-targets of tau degraders.
Results: Using imaging and AlphaLISA assay we confirmed a decrease of tau aggregates with treatment of degraders in human iPSC tau model. However, global proteome profiling indicated degradation of GSPT1 protein, a translation termination factor and a reported thalidomide/CRBN off-target, with the treatment of putative tau degraders. Additionally, tested published tau degraders that did not reduce GSPT1 did not decrease tau levels without accompanying cytotoxicity. Hypothesizing that this lack of an effect and observed cytotoxicity could be specific to iPSC neurons, we tested putative tau degraders in additional tau pathology assays in rodent cells, B35 and CHO-K1. Again, we did not observe a decrease in tau levels without cytotoxicity.
Conclusions: Our efforts highlight the challenge in conclusively demonstrating reduction of tau pathology using proximity induced degradation and emphasize a need for in depth understanding and confirmation of the mechanisms of action that lead to observed tau decreases.

EFFICACY OF A NEW VACCINE TARGETING TAU IN MOUSE MODELS

POSTERS: B02.B. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: IMMUNOTHERAPY

Christopher Brown[1], Louise Kelly[1], Jeanne Brooks[2], Matthew Longo[2], Justin Boyd[2], Roxana Carare[1], Jean-Cosme Dodart[2]

Aims: A novel class of vaccines, based on a technology where a synthetic, promiscuous Th-cell epitope linked to functional antigenic peptides, are being developed by Vaxxinity to target tau in Alzheimer's disease (AD). These vaccines generate antibodies that have demonstrated binding to pathological tau *in vitro*, and efficacy in cell-based tau aggregation assays comparable to monoclonal antibodies. Here we report the ability of one such tau-targeting vaccine to prevent the progression of tau pathology *in vivo* using two distinct mouse models.
Methods: The onset of phenotypes associated with the progression of tau pathology in P301L mice, such as ataxia and premature death, were measured over 210 days. Saline-inoculated control mice were compared to mice inoculated with the tau-targeting vaccine, p5555kb. The efficacy of vaccines against tau seeding *in vivo* was assessed by injecting C57BL6 mice with tau fibrils purified from post-mortem human AD brain tissue via differential centrifugation of the sarkosyl-insoluble brain fraction. Mice were inoculated with p5555kb, and the extent of tau pathology compared to saline-inoculated controls was measured by immunohistochemistry after 9 months.
Results: P301L mice vaccinated with p5555kb showed greater survival rates at 210 days than saline-inoculated control mice. The onset of ataxia was also delayed in vaccinated mice compared to controls. Mice injected with purified human AD tau developed inclusions of phosphorylated tau in the contralateral hippocampus 9 months post-injection. Vaccination with p5555kb significantly reduced the amount of tau inclusions detected by immunohistochemistry, as compared to saline inoculation.
Conclusions: These studies demonstrate that the vaccine p5555kb tested is effective at preventing onset of adverse phenotypes associated with tau pathology *in vivo* and can prevent the transfer of tau pathology between neuroanatomically connected brain regions via tau seeding.

HIGH-AFFINITY ANTI-TAU IMMUNOTHERAPY TARGETING THE CORE EXHIBITS INHIBITION OF TAU PATHOLOGY IN A MOUSE MODEL OF TAUOPATHY

POSTERS: B02.B. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: IMMUNOTHERAPY

Lewis Penny[1], Mohammad Arastoo[1], Richard Lofthouse[1], Aya Abdallah[1], Peter Imoesi[1], Karima Schwab[1], Valeria Melis[1], Gernot Riedel[1], Andy Porter[1], Soumya Palliyil[1], Charlie Harrington[1,2], Claude Wischik[1,3]

Aims: Immunotherapy is an attractive proposition to prevent the spread of pathologic tau in Alzheimer's disease and other tauopathies. S1D12, a chimeric IgG2a isolated via phage display, targets the disease-causing core of tau. S1D12 recognises tau341-353 with high affinity (200 pM) and prevents tau aggregation and propagation in biochemical and cellular assays, respectively. The objective was to assess the potential of anti-tau immunotherapy targeting the core to prevent tau pathology in tau transgenic mice.
Methods: Four-weekly doses followed by four-fortnightly doses of S1D12 (30 mg/kg) or negative control (n=10 per group) were administered via intraperitoneal injection to tau transgenic mice (Line 66; Melis et al., 2015) that were sacrificed one week after their final dose. Dosing was performed on two cohorts of mice starting from 2 months and 4.5 months of age, respectively, with baseline animals sacrificed for reference. Endpoints included quantification of oligomeric tau and phosphorylated tau in brain homogenate and neurofilament light and core tau in plasma.
Results: In both cohorts of mice, S1D12 inhibited generation of oligomeric tau and phosphorylation at p202/p205 and p396. This was associated with a reduction in neurodegeneration and an increase in core tau in plasma. In the 4.5-month cohort, S1D12 did not remove already established tau pathology below baseline.
Conclusions: High-affinity anti-tau immunotherapy targeting the core offers great potential for inhibiting progression of tau pathology. Mechanism of action of core immunotherapy appears exclusive to inhibition rather than removal of established pathology.

COMPARATIVE ANALYSIS OF TAU N-TERMINAL ANTIBODIES IN VITRO AND IN A MOUSE MODEL OF TAUOPATHY

POSTERS: B02.B. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: IMMUNOTHERAPY

Esteban Cruz[1], Rebecca Nisbet[2], Pranesh Padmanabhan[1], Ashley Van Waardenberg[3], Mark Graham[4], Godfrey Nkajja[1], Phil Robinson[4], Jürgen Götz[1]

Aims: The microtubule-associated protein Tau has gained significance as a therapeutic target in Alzheimer's disease and various other tauopathies. To date, clinical development of antibodies targeting Tau's N-terminus has yielded disappointing outcomes. However, the observation that antibodies targeting the N-terminus can show drastically different binding profiles to aggregated pathological forms of Tau has been overlooked. Here, we aimed to assess how the reactivity against aggregated forms of Tau impacts the therapeutic efficacy of Tau N-terminal antibodies.
Methods: We generated a novel pan-Tau antibody, RNJ1, which binds to a region in Tau's N-terminus adjacent to the epitope of the clinically tested HJ8.5 (murine version of tilavonemab), which we used here as a benchmark for comparison of therapeutic efficacy. Given the proximity of their epitopes, we compared both antibodies' capacity to bind and neutralize aggregated Tau seeds in two independent Tau FRET biosensor cell lines. We then compared the therapeutic efficacy of both antibodies, alone or in combination, in a longitudinal passive immunization study in the K3 mouse model of tauopathy.
Results: Our findings show that despite the proximity to the HJ8.5 epitope, RNJ1 displays higher reactivity against aggregated Tau and neutralizes Tau seeds from various tissue sources with higher efficiency in our biosensor seeding assays. In our passive immunization study, RNJ1 treatment improved behavioral outcomes across the treatment duration, with no efficacy achieved in the HJ8.5 or combination arms. Furthermore, biochemical and histological examination of antibody-treated mice showed reductions in Tau pathology with RNJ1.
Conclusions: Our study presents RNJ1 as a promising Tau antibody with enhanced therapeutic potential and underscores the importance of exploring Tau's N-terminus in pathology and as a therapeutic target.

CLEARANCE OF INTRACELLULAR TAU PATHOLOGY AND ENHANCED COGNITIVE FUNCTIONS IN AGED TAUOPATHY MICE BY NASAL IMMUNOTHERAPY

POSTERS: B02.B. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: IMMUNOTHERAPY

Sagar Gaikward[1], Nicha Puangmalai[1], Minal Sonawane[2], Anamika Ray[1], Rakez Kayed[1]
[1]University of Texas Medical Branch, Department Of Neurology, Galveston, United States of America, [2]utmb galveston, Department Of Neurology, GALVESTON, United States of America

Aims: This study aimed to develop toxic tau conformation-specific monoclonal antibody-loaded micelles (TTCM2-ms) for the selective recognition and clearance of intracellular tau aggregates, targeting disease-relevant tau species. Additionally, the study aimed to investigate the mechanisms underlying the therapeutic effects of intranasally delivered TTCM2-ms on cognitive function in tauopathy mice.
Methods: We developed TTCM2-ms and characterized their selectivity for disease-relevant tau aggregates in brain tissues from patients with Alzheimer's disease, progressive supranuclear palsy, and dementia with Lewy bodies. We assessed the inhibitory effects of TTCM2-ms on tau-seeding activity, a crucial process in tauopathy progression. Intranasal delivery of TTCM2-ms was employed to investigate their ability to reach various regions and intracellular compartments in the brain of tauopathy mice. The therapeutic efficacy of a single intranasal dose of TTCM2-ms was evaluated by measuring the clearance of pathological tau, the increase in synaptic protein levels, and the improvement in cognitive functions in aged tauopathy mice. Mechanistic studies were conducted to elucidate the role of tripartite motif-containing 21 (TRIM21) in TTCM2-ms-mediated clearance of tau pathology.
Results: Our findings revealed that TTCM2-ms selectively recognized disease-relevant tau aggregates, effectively inhibited tau-seeding activity, and efficiently reached the brain when administered intranasally. A single intranasal dose of TTCM2-ms led to the clearance of pathological tau, increased synaptic protein levels, and improved cognitive function in tauopathy mice. Mechanistic studies demonstrated that TTCM2-ms cleared intracellular, synaptic, and seed-competent tau aggregates through the involvement of TRIM21, an intracellular antibody receptor, and E3-ubiquitin ligase.
Conclusions: These findings offer valuable mechanistic insights into the role of TRIM21 in reducing intracellular and synaptic tau pathology upon intranasal immunotherapy. This study provides a foundation for the development of fast and effective tau immunotherapy strategy.

COMPARATIVE EFFICACY AND SELECTIVITY OF PHARMACOLOGICAL INHIBITORS OF DYRK AND CLK PROTEIN KINASES

POSTERS: B02.C. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: KINASES, PHOSPHATASES, OTHER ENZYMES

Mattias Lindberg, Emmanuel Deau, Laurent Meijer
Perha Pharmaceuticals, Neurosciences, Roscoff, France

Aims: Dual specificity, tyrosine phosphorylation regulated kinases (**DYRKs**) and cdc2-like kinases (CLKs) play a large variety of cellular functions, regulating alternative splicing, DNA damage repair, chromatin transcription, cell cycle, apoptosis, neuronal cytoskeleton and axonal transport, synaptic plasticity, etc. There is thus growing interest in pharmacological inhibitors of as research reagents to evaluate the cellular functions of these Ser/Thr kinases. There is also growing interest in the development of drug candidates specifically targeting some of these kinases, especially in the context of Down syndrome, Alzheimer's disease and Parkinson's disease (DYRK1A), diabetes (DYRK1A, DYRK1B), viral infections (DYRKs, CLKs), etc.
Methods: In this study, we made an unbiased **comparative evaluation** of the kinase inhibitory activity of a **library of 56 reported DYRK/CLK inhibitors**.
Results: All inhibitors were compared, side-by-side, in a dose-dependent manner, for catalytic activity on a panel of 12 recombinant human kinases (CDK5/p25, CK1ε, CLK1-4, DYRK1A, 1B, 2-4, GSK3β), enzyme kinetics allowing the determination of residence time and Kd (DYRK1A, CLK1, GSK3β), in-cell inhibition of Thr-212-Tau phosphorylation (a DYRK1A specific site particularly relevant to Alzheimer's disease) and cytotoxicity. The 26 most active inhibitors were modelled in the crystal structure of DYRK1A. Results show a rather large diversity of potency and selectivity among the reported inhibitors, and emphasize the difficulties to avoid "off-targets" in this area of the kinome.
Conclusions: Strengths and weaknesses of each inhibitor are discussed. The use of a **panel of selected DYRKs/CLKs inhibitors** is suggested to analyze the functions of these kinases in cellular processes, especially in the CNS.

THE NEUROLEPTIC DRUG AMISULPRIDE AS A NOVEL THERAPEUTIC APPROACH FOR TAUOPATHIES

POSTERS: B02.D. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: NEUROTRANSMITTERS & RECEPTOR-BASED

Alina Brüge[1], Sungsu Lim[2], Enza Lacivita[3], Kim Yun[2], Leopoldo Marcello[3], Evgeni Ponimaskin[1], Josephine Labus[1]
[1]Hannover Medical School, Cellular Neurophysiology, Hannover, Germany, [2]Korea Institute of Science and Technology, Brain Research Institute, Seoul, Korea, Republic of, [3]University of Bari Aldo Moro, Department Of Pharmacy-drug Sciences, Bari, Italy

Aims: Tauopathies manifest as progressive neuronal cell loss and cognitive decline caused by the accumulation of hyperphosphorylated tau. Recently, we identified the serotonin receptor 7 (5-HT7R) as a novel target in the treatment of tauopathies. We demonstrated that the neuroleptic drug amisulpride efficiently blocks the 5-HT7R constitutive activity and demonstrated its therapeutic effects on various aspects of tau pathology, e.g., phosphorylation, aggregation and cognition (Jahreis et al., Alzheimer's & dementia, 2023). However, amisulpride treatment is associated with dopamine receptor-related extrapyramidal side effects. Here, we aim to improve the therapeutic potential of amisulpride while minimizing its adverse side effects. Since the (R)-enantiomer of amisulpride has a higher affinity for 5-HT7R than for dopamine receptors, we investigated its therapeutic potency compared to the (S)-enantiomer.
Methods: Therapeutic effects on tau pathology were investigated in different cellular models of tauopathy including neuroblastoma cells overexpressing the disease-associated mutant tau[R406W] and the tau aggregation cell line HEK tau-BiFC using biochemical and microscopic approaches. Furthermore, transgenic tau[P301L]-BiFC mice were intraperitoneally treated with the racemic amisulpride and its enantiomers. Effects on cognition and motor side effects were assessed with behavioral experiments followed by tissue analysis to examine tau pathology after treatment.
Results: The (R)-enantiomer of amisulpride ameliorates tau pathology *in vitro* to the same extent as amisulpride, whereas (S)-amisulpride shows no beneficial effects. In the transgenic mouse model, both, (R)- and (S)-amisulpride have a pro-cognitive effect. However, we observe different effects of the enantiomers on locomotor activity. While mice treated with amisulpride and (S)-amisulpride show reduced activity, (R)-amisulpride-treated animals exhibit fewer dopaminergic side effects.
Conclusions: (R)-amisulpride shows an improved safety profile, highlighting the potential for further chemical refinement to increase 5-HT7R affinity and thereby enhance drug efficacy.

Aims: The aim of our study was to prepare a series of compounds derived from the hit compound 7-FEOTA and investigate its biological properties rising from their dual action. After assessing in vitro affinities for all 30 compounds within the series, we applied a selection *in vitro/in vivo* process, where the most promising compounds was highlighted, in particular by favorable behavioral and neuroprotective effect *in vivo* using various models.
Methods: In vitro evaluation done by Ellman´s method and patch-clamp for block of acetylcholinesterase and NMDA receptors respectively. Rat wistar model was used to evaluate pharmacokinetics and acute toxicity. Behavioral effects was investigated using MK-801 in the open field test, Morris water maze and prepulse inhibition. Neuroprotection was evaluated using NMDA-induced model of hippocampal lession
Results: A series of 30 compounds derived from 7-phenoxytacrine was evaluated the inhibitory potency towards acetylcholinesterase and hGluN1/hGluN2B receptor. We have selected.**I-52, III-52 and III-56** as the most effective NMDA-blockers and **II-52** as the compound with dual effect. After evaluating BBB penetration and acute toxicity in vivo we further selected **I-52** and **II--52** and performed behavioral tasks. Applying open field assessment and PPI the results indicate that unlike MK-801, the compounds **I-52** and **II-52** at selected doses (2 and 5 mg/kg, respectively) possess low risk of serious behavioral side effects of NMDA receptor antagonists. Furthermore, **I-52** (2 mg/kg) but not **II-52** (5 mg/kg) mitigated the scopolamine-induced cognitive deficit. Finally, NMDA-induced session experiment showed the neuroprotective effect of **I-52** against the neurodegeneration.
Conclusions: We have developed a lead compounds **I-52** 7-(2-methoxyphenoxy)-1*H*,2*H*,3*H*-cyclopenta[*b*]quinoline-9-amine hydrochloride) showing neuroprotective effect and no side effect in vivo typical for the class of NMDA antagonists. The mechanism of action involves the interaction with NMDA receptors with uncertain contribution of AChE.

Ncardia, Discovery Technologies, Leiden, Netherlands

Aims: Proteinopathies are a group of diseases characterized by the accumulation of specific proteins within the brain. Among the most notable examples of proteinopathies are Alzheimer's disease, Parkinson's Disease (PD) and Amyotrophic lateral sclerosis (ALS). Ncardia has developed *in vitro* disease pathology models for synucleinopathies (e.g PD), Tauopathies (TAU aggregation) and ALS (TDP-43 aggregation) using iPSC-derived neuronal cell models. These robust *in vitro* assays, developed in physiologically relevant human models, are amenable to various therapeutic to support all stages of the drug discovery process (i.e. hit ID, hit-2-lead and lead optimization).
Methods: Ncardia used iPSC-derived cortical neurons (iPSC-CN) treated with SNCA and Tau recombinant pre-formed fibrils (PFFs) to model disease relevant phenotypes of synucleinopathies and Tauopathies. Using high content imaging, aggregate localization, size, counts and intensity as well as co-localization with phosphorylated forms (pS129 α-syn and pTau (AT8)) were calculated. To model ALS, Ncardia used TDP-43 mutant iPSC-derived motor neurons (iPSC-MN) to quantify mis-localization and aggregation of TDP-43, as well as the human specific mis-splicing of STMN2. Additionally, Ncardia determined the electrophysiological deficits of the iPSC-MN in healthy and disease conditions.
Results: Modulators of protein degradation, both inhibitors and activators, were able to significantly increase or decrease (respectively) the counts and size of SNCA and counts of pS129 α-syn in a concentration-dependent manner. Stressor-treated TDP-43 mutant and wild type iPSC-MN showed disease-specific mis-localization of TDP-43 to the cytoplasm, aggregation of TDP-43, reduction of STMN2 and appearance of the truncated variant.
Conclusions: Ncardia developed three custom assays for the aggregation of α-synuclein, Tau and TDP-43 using human iPSC-derived neuronal cell models, providing clinically relevant readouts to support drug developers at various stages of drug development while reducing the use of laboratory animals.

TAU CONFORMATION MONOCLONAL ANTIBODIES MODULATE TOXIC TAU OLIGOMERS IN VITRO AND EX VIVO

POSTERS: B02.F. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: PROTEIN AGGREGATION, NFT, MISFOLDING, CHAPERONES

Md. Anzarul Haque, Nemil Bhatt, Rakez Kayed
University of Texas Medical Branch Galveston, Department Of Neurology, Galveston, United States of America

Aims: Aims: The pathological aggregation and accumulation of toxic tau is a common feature various neurodegenerative diseases that are collectively known as tauopathies. Tau oligomers are thought to be the major neurotoxic species in AD, but there is currently a gap in knowledge concerning standardized methods for isolating and biochemical characterization of tau oligomers.
Methods: Methods: Biochemical and biophysical techniques were used to characterize recombinant tau oligomers and brain-derived tau oligomers from Alzheimer's disease in the presence and absence of antibodies tau oligomer specific antibody (TOMA1) and toxic tau conformational monoclonal antibody (TTCM1), Montalbano, M. at. Al. 2023 and Carranza, D. L at. al. 2015. I used Isothermal calorimetry for affinity characterization between tau oligomers and antibodies. Propagation and toxicity of tau oligomers were performed using cell-based antibody neutralization assays in cell models.
Results: Results: TOMA 1 and TTCM1 have strong affinity with tau oligomers and modulate its aggregation state resulting in the formation of tau structures with decreased toxicity and seeding behavior in human neuroblastoma SH-SY5Y cell line and primary cortical neuron cultures.
Conclusions: Conclusion: These results provide novel insights into tau confirmational and toxicity, which can be modulated using high affinity conformational antibodies. Using conformational antibodies could be a powerful therapeutic strategy that advances the diagnostic field for the detection of toxic tau oligomers and early diagnosis for tauopathies.

TAU LIQUID-LIQUID PHASE SEPARATION IS REGULATED BY THE CALCIUM-BINDING S100B CHAPERONE

POSTERS: B02.F. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: PROTEIN AGGREGATION, NFT, MISFOLDING, CHAPERONES

Guilherme Moreira, Cláudio Gomes
Faculdade de Ciências da Universidade de Lisboa, Bioisi - Biosystems & Integrative Sciences Institute, Lisboa, Portugal

Aims: The phenomenon of liquid-liquid phase separation (LLPS) involving tau is increasingly acknowledged as a contributory process in the onset of tau aggregation and the generation of pathogenic conformers within Alzheimer's disease (AD). Neuroinflammation accompanies tau pathology, with late-stage astrocyte-released alarmin exacerbating the condition, while early inflammatory responses encompass protective functions. This applies to the Ca^{2+}-binding protein S100B, which we recently implicated as a proteostasis-regulator that inhibits amyloid-β (Cristóvão et al. 2018 Sci Adv) and tau aggregation/seeding (Moreira et al. 2021 Nat Commun). These findings suggest a broad holdase-type chaperone function for S100B in counteracting the malformation of protein structures. Our study aims to elucidate S100B's role in tau LLPS.
Methods: PEG-induced tau LLPS was followed by spectroscopy measurements of light absorbance (400nm) and tau fluorescently labelled. Co-localization of S100B within tau droplets was achieved using fluorescence-labelled proteins and FLIM-FRET. Evaluation of droplet fluidic characteristics encompassed fluorescence recovery after photobleaching (FRAP) and observation of fusion events.
Results: Phase diagrams indicate significant suppression of tau droplet formation by Ca^{2+}-S100B, preserving droplet liquid properties. The introduction of Ca^{2+} to PEG-induced LLPS with apo-S100B promptly reduces tau droplet levels, highlighting the dynamic, calcium-triggered nature of Ca^{2+}-S100B's action. Likewise, S100B effectively halts PEG-free Zn^{2+}-induced tau LLPS due to its combined Zn^{2+}-buffering and tau-interaction capabilities.
Conclusions: Our results establish S100B as a calcium-dependent suppressor of tau LLPS. Collectively, these findings suggest that S100B, functioning as a chaperone, regulates the formation of various pathological conformers and phase-separated systems, strengthening its pivotal role as a proteostasis regulator in early neurodegeneration. RNAI KNOCKDOWN OF MICROTUBULE-ASSOCIATED PROTEIN TAU AS A THERAPEUTIC STRATEGY FOR TAUOPATHIES

POSTERS: B02.G. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: GENE AND RNAI THERAPY

Jeffery Haines[1], Jon Farley[2], Sean Gannon[1], Kara Crowley[1], Mark Schlegel[2], Adam Castoreno[2], Anna Bisbe[2], Ivan Zlatev[2], Jeff Rollins[2], Diana Cha[2], Bret Bostwick[2], Andreja Avbersek[1], Kirk Brown[2], Lynn Macdonald[1], Min Gao[1], Matthew Anderson[1]
[1]Regeneron Pharmaceuticals Inc, Neuroscience, Tarrytown, United States of America, [2]Alnylam Pharmaceuticals, Biology, Cambridge, United States of America

Aims: The hyperphosphorylation and subsequent aggregation of the microtubule-associated protein Tau (encoded by the *MAPT* gene) is one of the major histopathological hallmarks of numerous tauopathies, including Alzheimer's disease and progressive supranuclear palsy. The intracellular accumulation of aggregated Tau is associated with neuronal loss and disease progression in tauopathies. There is a high-unmet need to identify strategies to target the intracellular accumulation of Tau aggregates with the aim of slowing tauopathy progression.
Methods: Using Alnylam's lipophilic C16-conjugated siRNA for CNS delivery, we identified potent molecules targeting the *MAPT* gene both in vitro and in mice carrying multiple copies of a transgene with a prion promoter driving human *MAPT* with human tauopathy-inducing mutation P301S.
Results: P301S mice treated with a single intracerebroventricular injection of Tau siRNA at eight months of age, had a sustainable decrease in *MAPT* mRNA and soluble Tau protein for three months following siRNA treatment (reduced ~83% and ~59%, respectively). siRNA treatment also prevented the progressive decrease in body weight and abrogated axonal damage, evidenced by decreased neurofilament light (NFL) chain in plasma and cerebrospinal fluid of eleven-month-old mice. Importantly, immunohistochemical analysis of misfolded Tau *in vivo* and HEK293-4RD-CFP/YFP Tau aggregate biosensor assay testing *in vitro* revealed a ~97% decrease of Tau aggregates in the eleven-month-old mice, suggesting there exists a yet-to-be identified mechanism of Tau fibril clearance. Furthermore, in a 16-week non-human primate study, we observed robust target engagement resulting in sustained reduction of *MAPT* transcript and Tau protein in brain tissue and cerebrospinal fluid.
Conclusions: Together, these results suggest an RNAi therapeutics approach targeting of *MAPT* mRNA may be sufficient to improve multiple parameters of tauopathy disease progression and a provide a compelling rationale for further development of Tau-lowering strategies.

Aims: Alzheimer's disease (AD) is a neurodegenerative disorder characterized by the World Health Organization as a public health priority. The pathology is characterized by the aggregation of amyloid-β (Aβ) and Tau protein into amyloid-β plaques and neurofibrillary tangles, respectively. Neuroinflammation is also implicated in AD and is responsible for the secretion of alarmins, which include the S100B protein. S100B is highly studied in the context of AD, and it's known for its dual function as a detrimental pro-inflammatory mediator and a beneficial anti-aggregation chaperone over Aβ and tau, making it an amenable drug target. Since there is still no cure for AD and is highly attractive to target chaperones with an already reported anti-aggregation activity, a library of single-domain antibodies (or nanobodies) targeting S100B was developed to potentiate S100B chaperone activity and modulate tau aggregation.
Methods: Here, we employed ThT-monitored kinetics of heparin-induced K18 aggregation to study the effect of nanobodies alone and in combination with S100B on K18 aggregation. Moreover, we performed mechanistic analysis to determine which step of the aggregation reaction are targeted by the nanobodies.
Results: Several nanobodies potentiated S100B inhibitory effect over K18 (Tau244-372), possibly by harnessing S100B in a more competent conformation to bind K18. Surprisingly, control experiments revealed that some nanobodies alone significantly inhibit K18 aggregation even at sub-stoichiometric ratios. This striking observation is discussed in the context of possible heterotypic interactions between the nanobody CDR3 region and Tau/K18. Further, mechanistic analysis demonstrates that different nanobodies target multiple steps of K18 fibrillation.
Conclusions: These findings uncover the therapeutic potential of anti-S100B nanobodies, which can be used as modulators of K18 aggregation or as activators of S100B chaperone activity. Funded by EU-TWIN2PIPSA/GA101079147 and FCT-Portugal BD/11023/2022 (MCS)/UID/MULTI/04046/2020 (BioISI).

SCREENING OF NOVEL ASOS AGAINST TAU PROTEIN

POSTERS: B02.G. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: GENE AND RNAI THERAPY

Carlos Campos-Marques[1], Bruno Mdc Godinho[2], Jonathan K Watts[2], Nuno Sousa[3], Ioannis Sotiropoulos[4], Joana Silva[3]
[1]Life and Health Sciences Research Institute, School Of Medicina, University Of Minho, Braga, Portugal, [2]University of Massachusetts Medical School, Rna Therapeutics Institute, Worcester, United States of America, [3]Life and Health Sciences Research Institute, School Of Medicine, University Of Minho, Braga, Portugal, [4]NCSR Demokritos, Institute Of Biosciences And Applications, Athens, Greece

Aims: Considering recent evidence from Alzheimer's disease (AD) field about the essential role of Tau in AD brain pathology, we aimed to screen novel antisense oligonucleotides (ASOs) designed for lowering total Tau or 4R-Tau levels, addressing these objectives: i.Design, generate and test *in vitro* novel ASOs against mouse or human Tau, using cell lines; ii. Select and test the most efficient ASOs in primary neurons; and iii.Test the efficiency of the selected ASOs in mouse brain.
Methods: This project tested several ASOs with different chemical modifications against Tau protein in cell lines and primary neurons, identifying novel ASOs with high efficiency reducing Tau levels or 4R-Tau, measured by qRT-PCR, Western blot and immunofluorescence. After selecting the most potent ASOs from *in vitro* studies, we performed a pilot study to assess the efficiency of ASOs *in vivo*.
Results: Firstly, mouse-Tau ASOs and human-Tau ASOs were tested on mouse and human neuroblastoma cells, respectively. After qRT-PCR analysis, 13 of each were re-tested for protein level assessment, through Western blot. Next, the 4 most efficient mouse-Tau and human-Tau ASOs were tested in primary neurons. Their efficiency on reducing Tau levels was confirmed, and we evaluated their impact on neuronal morphology, revealing significant alterations in complexity. Finally, mouse-Tau ASOs were tested in a pilot in vivo study using wild-type mice, whereas human Tau-ASOs were tested in THY-Tau22 mice, revealing significant reductions in both mRNA and protein levels of Tau.
Conclusions: Altogether, these data provide the first *in vitro* and *in vivo* confirmation of the efficiency of novel ASOs against Tau, that can further support future studies focusing on ASOs as an innovative RNA-based therapeutic approach against AD, Down Syndrome, and other Tau-related brain pathologies.

INTRAVENOUS ADMINISTRATION OF BBB-PENETRANT AAV CONTAINING PRIMARY ARTIFICIAL MICRORNA TARGETING TAU REDUCES TAU BROADLY AND ROBUSTLY IN HTAU MOUSE BRAIN

POSTERS: B02.G. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: GENE AND RNAI THERAPY

Wencheng Liu[1], Hechen Bao[1], Shiron Lee[1], Cansu Colpan[2], Elisabeth Knoll[2], Ching Lien Fang[1], Barbara Bueno[1], Gretchen Rivera[2], Maneesha Paranjpe[1], Brian Ezell[2], Kyle Grant[3], Dinah Sah[1], Todd Carter[1]

Aims: Progression and spread of tau pathology in the brain correlates very well with cognitive decline in Alzheimer's disease (AD). Reduction of tau is being pursued as a promising therapeutic approach. Lowering tau with anti-sense oligonucleotides (ASOs) has been shown to reduce tau and tau pathology in preclinical and clinical studies; however, this approach requires repeated administration of the ASO either intra-ventricularly or intrathecally. To evaluate the potential of intravenous (IV) administration of AAV to provide therapeutically relevant levels of tau knockdown broadly through the brain with one-time administration, we have evaluated the use of a blood-brain barrier (BBB)-penetrant capsid containing a primary artificial microRNA (pri-amiRNA) specifically targeting tau mRNA.
Methods: 1. Candidate siRNA sequences were screened in silico and in vitro in multiple cell lines to identify siRNAs that lower tau mRNA for subsequent AAV vectorization into proprietary pri-amiRNA backbones. 2. A pri-amiRNA targeting tau mRNA, vectorized with a BBB-penetrant capsid (9P39) was tested using IV administration in hTau transgenic mice, with subsequent quantitation of vector genome and tau mRNA levels.
Results: At 4 weeks post-dosing with this AAV9P39.tau pri-amiRNA in hTau mice, we observed a dose-dependent increase in vector genome levels, concomitant with a dose-dependent decrease in tau mRNA levels, in multiple brain regions. Tau mRNA reductions ranged from 70% to 90% relative to the vehicle control group.
Conclusions: These studies demonstrate that robust lowering of tau in hTau mice was achieved by treatment of mice with an AAV.pri-amiRNA specifically targeting tau mRNA. These encouraging results suggest that the combination of a potent pri-amiRNA targeting tau mRNA together with IV dosing of a BBB-penetrant capsid could be a useful one-time treatment for AD and other tauopathies.

[1]University of California, San Francisco, Institute For Neurodegenerative Diseases, Department Of Neurology, Ucsf Weill Institute For Neurosciences, San Francisco, United States of America, [2]University of Colorado Anschutz Medical Campus, University Of Colorado Alzheimer's And Cognition Center, Linda Crnic Institute For Down Syndrome Research, Department Of Neurology, Aurora, United States of America, [3]Fudan University, Department Of Rehabilitation Medicine, Huashan Hospital, State Key Laboratory Of Medical Neurobiology, Institute For Translational Brain Research, Moe Frontiers Center For Brain Science, Shanghai, China, [4]Daiichi Sankyo Co., Ltd., Cns Drug Development, Tokyo, Japan

Aims: Microglia are central to pathogenesis in many neurological conditions and their depletion is one therapeutic strategy. However, drugs targeting colony-stimulating factor-1 receptor (CSF1R) to block microglial proliferation in preclinical disease models have shown mixed outcomes, thus the therapeutic potential of this approach remains unclear. Given the dynamic nature and complexity of microglial activation, the timing of CSF1R inhibition in tauopathy and its translational relevance is still an open question. Thus, the goal of our study was to define a therapeutic window that not only reduced pathological markers, but also led to functional improvement.
Methods: Transgenic B6-Tg(Thy1-MAPT*P301S)2541 mice express the 0N4R isoform of human tau with the P301S mutation. To deplete microglia, mice were dosed with CSF1R inhibitors PLX3397 or PLX5622 in three different dosing paradigms: acute (2−4 months old), chronic (2−7 months old), and terminal (2 months old until death).
Results: CSF1R inhibitors given by multiple dosing paradigms caused a sex-independent reduction in pathogenic tau and reversion of non-microglial gene expression patterns toward a normal wild type signature. Despite greater drug exposure in male mice, only female mice had functional rescue and extended survival. A dose-dependent upregulation of immediate early genes and neurotransmitter dysregulation were observed in the brains of male mice only, indicating that excitotoxicity may preclude functional benefits. Drug-resilient microglia in male mice exhibited morphological and gene expression patterns consistent with increased neuroinflammatory signaling, suggesting a mechanistic basis for sex-specific excitotoxicity.
Conclusions: Complete microglial ablation is neither required nor desirable for neuroprotection and therapeutics targeting microglia must consider sex-dependent effects. Therapeutic modulation of microglial activation by CSF1R inhibitors is a potential approach to treating human tauopathies.

Aims: Alzheimer's disease (AD) and related tauopathies are characterized by the aberrant accumulation of tau protein aggregates within the brain, resulting in neurodegeneration. Recent research has highlighted the prion-like propagation of disease-associated tau, where pathological forms of tau corrupt normal tau proteins, instigating their misfolding and integration into amyloid fibrils. With no cure currently available, inhibiting tau aggregation offers a promising therapeutic approach.
Methods: The experimental conditions to obtain a highly reproducible and specific tau seed amplification assay (Tau-SAA) were optimized using brain homogenate (BH) from patients affected by AD and other tauopathies. Dilutions of BH between 10^{-4} and 10^{-9} for an average of 10 specimens per group. Tau-SAA signal was read using thioflavinT fluorescence in the presence or absence of known inhibitors of tau aggregation.
Results: Tau-SAA demonstrates remarkable sensitivity, capable of detecting seeding activity at dilutions as extreme as 100 million-fold from AD-afflicted brain samples and displays no seeding activity when exposed to healthy human control brain tissue or specimens from other neurological conditions. We tested a range of established anti-aggregation compounds, distinguishing those with the ability to impede tau aggregation induced by AD brain. Further, we explored the possibility of repurposing drugs by screening a commercially available drug library and identify compounds with the capacity to counteract tau aggregation.
Conclusions: Tau-SAA is a robust and versatile method for the detection of tau aggregates. Additionally, it serves as an effective screening platform for the discovery of small molecules that can inhibit tau seeding when challenged with biologically relevant tau seeds sourced from AD-affected brains. Our findings suggest that Tau-PMCA is a robust technique for both detection of tau aggregates in biological samples and for identification of small molecules able to inhibit tau seeding.

Aims: Alzheimer's disease (AD) presents a dysfunction in the U1 small nuclear ribonucleoprotein (snRNP) along with RNA splicing deficiency and mislocalization, which causes cell cycle re-entry and neuronal death. Considering that this dysfunction may precede protein aggregation and enhance spliceosome dysfunction, we aimed to analyze the effects of APT20TTMG, a synthetic single stranded cDNA, in human induced pluripotent stem cells (hiPSCs) derived neurons from healthy (HDC) and AD (ADC) donors and in the senescence-accelerated mouse prone 8 (SAMP8) model.
Methods: Binding of APT20TTMG to U1 snRNP complex and pre-mRNAs was analyzed through protein and qRT-PCR immunoprecipitation, in SK-N-SH neuroblastoma cells. Following treatment with five concentrations of APT20TTMG, mitochondrial activity, glutamate release, apoptosis, morphology, Tau levels, and enrichment analysis of differentially expressed genes (DEGs) were evaluated in hiPSC-derived neurons. Immunofluorescence for amyloid-β (Aβ), total Tau, pTau, and U1-70K was analyzed in cortex and hippocampus of SAMP8 mice, following a 42-day treatment with one concentration of APT20TTMG, via i.c.v.
Results: APT20TTMG selectively bound to U1-70K and U1-C proteins of the U1 complex, U1 snRNA, and Tau and GAPDH pre-mRNAs. Treatment with APT20TTMG did not change mitochondrial activity, glutamate release, or apoptosis in both HDC and ADC neurons. However, it rescued the morphology of ADC neurons, with fiber breadth and branching levels similar to HDC neurons. It also specifically decreased Tau levels in ADC neurons and led to an enrichment of DEGs related to neurogenesis and neuron differentiation. In the SAMP8 model, treatment decreased Aβ in cortex, insoluble pTau in hippocampus, and U1-70K in both cortex and hippocampus.
Conclusions: APT20TTMG is safe to neurons, with significant effects in preventing neurodegeneration and improving axonal functions, suggesting a novel therapeutic approach for AD.

ND523: A NOVEL PROTEIN-PROTEIN NRF2 INDUCER WITH ANTI-NEUROINFLAMMATORY EFFECTS

POSTERS: B02.I. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Manuela G. Lopez[1], Eric Del Sastre[1], Cristina Fernández-Mendívil[1], Lucia Viqueira[1], Rafael Leon[2], Maria Isabel Rodriguez Franco[2]
[1]Universidad Autonoma de Madrid, Pharmacology, Madrid, Spain, [2]Consejo Superior de Investigaciones Cientificas, Instituto De Química Médica, Madrid, Spain

Aims: Nuclear factor erythroid derived 2-like 2 (NRF2) is a transcription factor that is being proposed as a target for neurodegenerative diseases as it regulates a wide array of genes implicated in regulating cellular redox status and inflammation. Electrophilic NRF2 inducers are highly reactive molecules that can cause off-target effects. Therefore, NRF2-KEAP1 protein-protein inhibitors (PPI) could be a safer alternative. After a drug discovery program, we have identified ND525 as lead compound. Here we studied its mechanism of action and its anti-neuroinflammatory effects.
Methods: The NRF2 inducing mechanism has been evaluated in AREc32 cells, by superficial plasmon resonance, GSH conjugation and lC-IT-MS analysis, and by using WT and NRF2-KO MEFs. The potential anti-neuroinflammatory effect has been evaluated using LPS *in vitro* (BV2 cells and primary glial cultures) and *in vivo*. Sickness behaviour in vivo and cytokines levels were measured by qPCR and multiplex ELISA . Primary cortial neurons transfected with AAV-hTauP301L were used as an *in vitro* tauopathy model.
Results: ND523 is a non-electrophilic compound that induces NRF2 by inhibiting NRF2/KEAP1 interaction. It showed a good anti-neuroinflammatory profile in a microglial murine cell line and in rat primary glial cell cultures; these effects were lost in NRF2 KO cells. The anti-neuroinflammatory effects were corroborated *in vivo* as shown by a reduction of cytokines 4 and 24 h post LPS-injection, reduction in brain microgliosis and improvements in locomotion and cognitive decline. Peliminary data show that ND523 can reduce tauopathy *in vitro* evaluated as a redcution of AT8 staining.
Conclusions: ND523 is a first in class protein-protein inhibitor of NRF2/KEAP1 with potential therapeutic interest in neurodegenerative diseases with neuroinflammation.

Aims: Our aim is to develop "theranostic" molecules usable in the Alzheimer's disease and Tauopathies. These molecules will i) inhibit Tau fibrillation targeting its nucleation process and ii) be used as a vector coupled to a PET radionuclide in order to perform positron emission tomography (PET) imaging for an early detection of amyloid deposits in brain.
Methods: Chosen molecules are peptides composed of natural "L" amino acids that have the same composition than Tau PHF6 peptide. These peptides have been designed and selected for their therapeutic potential. These peptides have been tested on pathologic hTau.P301S mouse strain and on brain cellular models. Their structures will be modified for optimizing their bioavailability and their potential therapeutic effect.
Results: About fifty peptides have been classified in three groups that are i) amyloid, ii) aggregative and iii) neither amyloid nor aggregative. Peptides belonging to the latter group have been pre-selected and their inhibitory activity was tested on PHF6 *in vitro* self-assembly model. Most of them led to inhibition of the fibrillation rate ranging between 20 and 90%. Peptides exhibiting the highest inhibition were then called "leaders" and were further evaluated. Notably, we demonstrated that selected "leaders" had no effects on SH-SY5Y neuroblastoma cell line growth. Among the leaders, two were chosen for being evaluated as molecular probes for PET imaging. Probes tested on SH-SY5Y cell line had no effects on SH-SY5Y neuroblastoma cell line growth. They will be further tested on our animal model hTau.P301S.
Conclusions: The most promising peptides (patent WO 2023/099560) and probes exhibit the required qualities to become "theranostic" molecules for Alzheimer's disease and Tauopathies therapy and diagnostic.

FRATERNIN-LIKE PEPTIDES AND THEIR NEUROTOCITY EFFECTS IN PARKINSON'S DISEASE

POSTERS: B02.I. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Leticia Germino Veras[1], Andréia Mayer[2], Henrique Amaral[2], Danilo De Oliveira[2], Gabriel Campos[2], Adolfo Carlos De Souza[2], Anamélia Bocca[2], Solange Rego[2], Raffael De Castro[2], Márcia Renata Mortari[2]
[1]Universidade de Brasília, Intitite Of Biological Sciences Of Unb, Brasilia, Brazil, [2]University of Brasilia, Institute of Biological Sciences, Department Of Physiological Sciences, Laboratory Of Neuropharmacology, Asa Norte, Brasília, Brazil

Aims: Parkinson's disease (PD) is a neurodegenerative condition characterized by the progressive degeneration of dopaminergic neurons in the Substantia Nigra. With the absence of a specific PD treatment, research into novel therapeutic approaches has gained momentum. One emerging avenue of exploration involves the study of animal venoms, which have demonstrated intriguing interactions with the cardiovascular and nervous systems, opening up new possibilities for treatment development. A candidate in this quest is the natural peptide known as fraternin, sourced from the wasp venom from *Parachatergis fraternus*. To better understand its potential, three analogues—fra-24, fra-14, and fra-10—were synthesized and assessed for their neurotoxic effects using a 6-hydroxydopamine mouse model of PD. To ensure accuracy, all peptides underwent rigorous purity verification exceeding 99%.
Methods: The investigation delved into potential adverse effects, without inducing the 6-OHDA lesion, and encompassed intracerebral ventricular administration at varying doses: 10, 5, and 1 µg/animal for fra-1 and fra-14, and 20, 10, and 5 µg/animal for fra-24. Motor coordination was assessed through behavioral tests, including latency to fall on the rotarod apparatus during treatment and post-treatment temporal evaluations on the rotarod.
Results: revealed that fra-24, administered at 20 µg/animal, exhibited neuromuscular toxicity compared to the SHAM group on the rotarod, potentially impairing motor function. Fra-14, at a dose of 10 µg/animal, induced motor incoordination, while fra-10, administered at all three doses, displayed neuromuscular toxicity, as evidenced by reduced time spent on the rotarod compared to the SHAM group.
Conclusions: Notably, neither fra-14 nor fra-10 demonstrated therapeutic effects, with only minor improvements in motor behavior observed in lesioned groups. Fra-24, at a dose of 20 µg/animal, did not significantly impact animals' motor coordination but displayed toxicity potential, warranting further investigation into its safety and efficacy.

NON-INVASIVE PHOTO-OXYGENATION REDUCES INTRACELLULAR TAU AMYLOID IN THE BRAIN OF TAU MODEL MICE

POSTERS: B02.I. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Yukiko Hori[1], Takanobu Suzuki[1], Taka Sawazaki[2], Makoto Higuchi[3], Youhei Sohma[2], Motomu Kanai[4], Taisuke Tomita[1]
[1]Graduate School of Pharmaceutical Sciences, The University of Tokyo, Laboratory Of Neuropathology And Neuroscience, Tokyo, Japan, [2]School of Pharmaceutical Sciences, Wakayama Medical University, Department Of Medicinal Chemistry, Wakayama, Japan, [3]National Institutes for Quantum Science and Technology, Department Of Functional Brain Imaging, Chiba, Japan, [4]Graduate School of Pharmaceutical Sciences, The University of Tokyo, Laboratory Of Synthetic Organic Chemistry, Tokyo, Japan

Aims: Tauopathies, including Frontotemporal dementia and Corticobasal degeneration, are a group of neurodegenerative diseases characterized by the intracellular deposition of tau amyloid. Since tau amyloid is associated with the onset, the efficient clearance of tau amyloid is one of the therapeutic strategies for tauopathies. We have previously developed the amyloid selective *in vivo* photo-oxygenation technology for Aβ, that forms amyloid like tau, using a membrane-impermeable photocatalyst. Moreover, we showed successfully that photo-oxygenated Aβ was cleared from the brain efficiently (Ozawa *et al*., Brain, 2021), suggesting that this technology has potential as therapy. This catalyst was also capable of photo-oxygenating tau, but the effect of photo-oxygenation on intracellular tau amyloid was still unknown due to photocatalyst's membrane-impermeability.
Methods: To access the intracellular tau amyloid, we have developed a novel photocatalyst, CatO, which is permeable to blood brain barrier and cell membranes. The CatO was administered intravenously to 9 months-old tau transgenic mice, and non-invasive *in vivo* photo-oxygenation was performed by light irradiation from outside the skull.
Results: After photo-oxygenation reaction for 10 days, we found in immunohistochemistry and biological analysis that the amount of intracellular tau amyloid was significantly reduced by photo-oxygenation. Furthermore, neuronal cell death in brain was also significantly inhibited, indicating that the photo-oxygenation was able to ameliorate toxicity associated with tau accumulation.
Conclusions: In this study, we have succeeded in non-invasive *in vivo* photo-oxygenation of intracellular tau amyloid using a newly developed cell membrane-permeable photocatalyst, CatO. And we revealed the possibility that photo-oxygenation enhances the degradation of tau amyloid in brain. Clarification of its mechanisms and potential for the therapy against tauopathies are underway.

EFFECTS OF STANDARDIZED GINKGO BILOBA EXTRACT ON BIOENERGETICS IN HUMAN IPSCS

POSTERS: B02.I. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Imane Lejri[1,2], Anne Eckert[1,2]
[1]Neurobiology Lab for Brain Aging and Mental Health, Research Cluster, Molecular & Cognitive Neuroscience, Basel, Switzerland, [2]Universitäre Psychiatrische Kliniken, University Of Basel, Basel, Switzerland

Aims: Protective effects of standardized Ginkgo biloba extract (GBE, LI1370) has been demonstrated on energy metabolism defects in an *in vitro* Alzheimer's disease (AD) model. In this study, we investigated the effect of GBE (OM Pharma support) on bioenergetics in human IPSCs from aged donors.
Methods: First, to characterize the bioenergetics in human iPSCs from aged donors, ATP production (ATP), mitochondrial membrane potential (MMP) and reactive oxygen species (ROS) levels were measured in iPSCs from young and aged donors. Then, the effect of GBE on ATP production, MMP, ROS and mitochondrial respiration were investigated after 24h of treatment in human IPSCs from aged donors.
Results: Our findings demonstrated that in the iPSCs from aged donors, ATP and MMP levels were significantly decreased and mitochondrial ROS (DHR) and mitochondrial superoxide anion (MITOSOX) levels were significantly increased compared to those of the iPSCs from young donors. Low OCR and ECAR levels were reported in the iPSCs from aged donors compared to those from the young donors. GBE treatment (100 ug/ml) exerted significant improvement of ATP production and MMP levels, reduction of the ROS and an amelioration of the mitochondrial respiration.
Conclusions: These findings indicate that GBE seems to be able to improve significantly the age related decline in bioenergetics of the human IPSC from aged donors, through the increase of the ATP production and the improvement of the mitochondrial membrane potential, as well as the reduction of the ROS levels and the amelioration of the mitochondrial respiration.

MILD COGNITIVE IMPAIRMENT (MCI) IN PEOPLE WITH PARKINSON'S DISEASE (PD): THE NEED TO CONSIDER THE INDIVIDUAL PROFILE

POSTERS: B02.I. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Sara Rosenblum[1], Sharon Hassin-Baer[2]
[1]University of Haifa, Occupational Therapy, Haifa, Israel, [2]Sheba Medical Centre and Tel Aviv University, Neurology, Ramat Gan, Israel

Aims: In a series of five studies focused on identifying mild cognitive impairment in Parkinson's disease (PD-MCI), we found that subjective self-report standardized questionnaires add important information about patient's daily functional cognitive abilities. Such information was not always in line with their objective global cognitive and the neuropsychological tests results. This presentation illustrates the inter- and intraindividual differences between four people with PD (PwP) suspected for PD-MCI, encompassing objective and subjective self-report tests and questionnaire scores.
Methods: our individuals, all with a Montreal Cognitive Assessment (MoCA) score of 24, were analyzed. Neuropsychological test results and subjective reports about their cognitive abilities, as reflected in real-world daily functioning, were collected. The Movement Disorder Society-Unified Parkinson's Disease Rating Scale cognitive functional score, PD Cognitive Functional Rating Scale (PD-CFRS), Daily Living Questionnaire (DLQ) , Time Organization and Participation (TOPS), and Behavior Rating Inventory of Executive Function-Adult (BRIEF-A) version were also administered and scored. Additionally, their handwriting performance was captured by a computerized system. Each individual's profile was created and will be presented.
Results: All four individuals' global cognitive abilities were similar when measured by the MoCA scores. However, these abilities were completely different as reflected through the neuropsychological battery, the various self-reported daily functional cognitive ability questionnaires, and their handwriting performance. Their individual profiles clearly reflect their personal daily functional challenges.
Conclusions: Characterization of personal profiles of PwP suspected for MCI is essential for providing personalized intervention programs to maintain their cognitive functioning along with their physical state and well-being.

Aims: Autonomy, an ongoing, phase 2, global, multicenter, double-blind, placebo-controlled, randomized, parallel-group study assesses whether the anti-phosphorylated tau monoclonal antibody posdinemab (mid-domain epitope, amino acid 212 and 217) will slow clinical decline in participants with early symptomatic (prodromal/mild dementia) Alzheimer's disease (early AD). The screening period contained several unique features to identify and enroll appropriate participants.
Methods: Adults (55-80) with early AD defined as gradual/progressive subjective decline in cognition over at least 6 months, Clinical Dementia Rating-Global Score (CDR-GS) of 0.5 and memory box score greater or equal to 0.5 at screening and Repeatable Battery for the Assessment of Neuropsychological Status (RBANS) delayed memory index score <85. Eligible participants also had plasma p217+tau prescreening for tau PET eligibility and were required to have intermediate levels of tau burden on tau PET (18FMK6240). Participants receive posdinemab (low or high dose) or placebo IV, every 4 weeks. The primary outcome is change from baseline in integrated Alzheimer's Disease Rating Scale (iADRS) Total Score at Week 104. The iADRS composite includes the complete Alzheimer's Disease Assessment Scale Cognitive subscale 13-item (ADAS Cog13) and Alzheimer's Disease Cooperative Study Activities of Daily Living for Mild Cognitive Impairment (ADCS-ADL MCI). Secondary outcomes include change from baseline on ADAS Cog13, RBANS, ADCS-ADL MCI, CDR-SB and tau PET.
Results: Screening began Jan2021 with last participant randomized Aug2023. 522 of 523 participants randomized received at least one dose of blinded treatment. Preliminary baseline characteristics and demographics will be presented.
Conclusions: Autonomy screening period experience is informative for the field, including implementing novel strategies to mitigate cognitive scale learning effects and experience implementing the first trial to use plasma biomarkers as a prescreen for tau PET imaging to enroll the target patient population.

OCCUPANCY OF BIIB113, AN INHIBITOR OF THE ENZYME O-GLCNACASE (OGA) IN THE HUMAN BRAIN.

POSTERS: B03.B. DRUG DEVELOPMENT, CLINICAL TRIALS: TAU CLEARANCE

Maciej Kaliszczak[1], Sangram Nag[2], Heike Hering[1], Ben Suttle[3], Flavia C Nery[1], Lori Jones[4], Esin Yesilalan[1], Jaren Landen[1], Lars Farde[2], Per Stenkrona[2], Martin Bolin[2], Anton Forsberg Moren[2], Christer Halldin[2], Laurent Martarello[1]
[1]Biogen, Medical Affairs, Cambridge, United States of America, [2]Karolinska Institutet, Department Of Clinical Neuroscience, Center For Psychiatry Research, Stockholm, Sweden, [3]qPharmetra, Pharmacokinetics, Raleigh, United States of America, [4]Biogen, Medical Affairs, Durham, United States of America

Aims: BIIB113 is an inhibitor of the enzyme O-GlcNAcase (OGA) and developed for the treatment of Alzheimer's disease. OGA inhibition is proposed to increase tau O-GlcNAcylation, resulting in reduced formation of tau. The aim of the present Positron Emission Tomography (PET) study was to describe the relationship between BIIB113 exposure and target engagement in the human brain.
Methods: Single and multiple oral dose studies were conducted in healthy volunteers (HV). 3 to 4 subjects were included per cohort and dosed with BIIB113. Target occupancy (TO) was measured with [^{11}C]BIO-1819578, a PET tracer that binds specifically to OGA. TO was assessed at up to 72 hours (h) post dose. The volumes of distribution (V_T) were estimated using Ichise's Multilinear Analysis (MA1) model with arterial input function. Plasma PK was assessed up to 72 h after BIIB113 administration.
Results: A total of 10 HV participated in the study. A single dose of BIIB113 was able to maintain >90 % TO up to 48 h post treatment. Lowering the dose was needed to obtain lower TO and thereby derive an EC_{50} after a single dose. However, 14 days of treatment with the lower dose of BIIB113 was sufficient to maintain >90% TO up to 48 h post last dose. PK/PD modelling was applied to the totality of data and suggested that the relationship between plasma BIIB113 concentrations and TO was described with an Emax model.
Conclusions: We have demonstrated a high-level of brain TO (>90%) following single and multiple doses of BIIB113 in HV. These results support continued clinical development of BIIB113 in Phase 2 studies and will support the selection of dose regimens.

PHARMACOKINETICS AND TOLERABILITY OF VY-TAU01, AN ANTI-TAU ANTIBODY FOR THE TREATMENT OF ALZHEIMER'S DISEASE, IN P301S MOUSE AND NONHUMAN PRIMATE

POSTERS: B03.A. DRUG DEVELOPMENT, CLINICAL TRIALS: IMMUNOTHERAPY

Wencheng Liu[1], Joydip Kundu[2], Maury Emery[1], Daniel Epling[3], Jeff Thompson[2], Ishan Shah[1], Maneesha Paranjpe[1], Shiron Lee[1], Alison Walsh[4], Matteo Placidi[4], Krishanu Mathur[4], Nancy Everds,[1], Ruth Lightfoot-Dunn[1], John Mondick[3], Sunny Chapel[3], Todd Carter[1], Johnny Yao[2], Chanchal Sadhu[2], Dinah Sah[1]
[1]Voyager Therapeutics, Neuroscience, Cambridge, United States of America, [2]Voyager Therapeutics, Translational Research, Cambridge, United States of America, [3]A2-Ai LLC, Research, Ann Arbor, United States of America, [4]Voyager Therapeutics, Tech Ops, Cambridge, United States of America

Aims: VY-TAU01 is a recombinant humanized IgG4 monoclonal antibody (mAb) directed against pathological tau that is intended to be administered via intravenous (IV) infusion to patients with mild dementia or mild cognitive impairment due to Alzheimer's disease (AD). VY-TAU01 specifically targets an epitope in the C-terminus of tau and is derived from the mouse IgG1 mAb Ab-01. VY-TAU01 binds to pathological tau with high affinity and selectivity over wild-type tau, blocks paired helical filaments seed-induced tau aggregates in vitro, and selectively stains tau tangles in AD and P301S mouse (C57/B6J-Tg[Thy1-MAPT*P301S]2541Godt) brain. Nonclinical studies to support the initiation of the first-in-human study are being conducted in P301S mice and nonhuman primates (NHP). Here we describe the pharmacokinetics (PK) and tolerability of Ab-01 in P301S mice and VY-TAU01 in NHP.
Methods: 1. Characterizing the PK and tolerability of Ab-01 in the P301S mouse after 5 weekly IV doses at 30, 80 or 120 mg/kg. 2. Characterizing the PK and tolerability of VY-TAU01 in NHP after a single IV dose at a high or mid dose level.
Results: No adverse effects were observed in P301S mice or NHP following Ab-01 or VY-TAU01 administration, respectively. The serum PK of 80 mg/kg Ab-01 in the P301S mouse exhibited a profile expected from a mouse IgG1 antibody with a half-life of approximately 12.6 days. Model based PK parameter estimates yielded a clearance rate (C_L) of 0.166 mL/day, and central and peripheral volumes of distribution were 0.839 mL and 1.87 mL, respectively. Additional serum and cerebrospinal fluid PK results will also be presented.
Conclusions: Initial studies demonstrated that Ab-01 and VY-TAU01 are well-tolerated in P301S mice and NHP, respectively, and that the serum PK profile is as expected.

HIGH CONTENT SCREENING FOR MODIFIERS OF ENDOGENOUS WILD-TYPE/MUTANT TAU

POSTERS: B03.B. DRUG DEVELOPMENT, CLINICAL TRIALS: TAU CLEARANCE

Maika Itsuno, Sumihiro Maeda, Hideyuki Okano
Keio University, School of Medicine, Physiology, Tokyo, Japan

Aims: To identify human Tau modifiers at multiple levels, such as transcription, translation, and protein degradation, we developed a high-content screening (HCS) assay using human induced pluripotent stem cell (hiPSC)-derived neurons. We fluorescently labeled the endogenous wild-type (WT) tau. In addition, we introduced the hTau A152T mutation or knocked out tau by replacing tau with the fluorescent gene. The hTau A152T mutation is associated with an increased risk of Alzheimer's disease (AD) and frontotemporal dementia spectrum diseases. We aimed to identify modifiers of WT and/or mutant tau by screening existing drug compound libraries.
Methods: First, we fused TagGFP2 to the N-terminus of Tau to monitor endogenous tau in hiPSC-derived neurons, then introduced hTau A152T mutations or replaced Tau with TagGFP2 (KO). We then differentiated the iPSCs into neurons by overexpressing neuron-enriched miRNA 9/9*/124 and a transcription factor, Neurogenin 2. The A152T mutation increased neuronal activity, as measured by Ca^{2+} imaging, mimicking the epileptic phenotype in the hTau-A152T transgenic mouse model. After exposing the hiPSC-derived neurons to small compounds for 10 days, we quantified the TagGFP2 fluorescence intensity using an automated confocal microscope.
Results: We confirmed that the Z', an indicator of assay robustness, was high enough to perform the screens (Z'>0.5). In the initial screen of 1405 compounds, 15 compounds effectively suppressed tau protein levels. While some of these compounds were equally effective in reducing WT and A152T Tau, others were more effective in reducing A152T Tau.
Conclusions: We have developed HCS for Tau modifiers and identified candidate compounds. Interestingly, some compounds have been reported to reduce the risk of neurodegenerative diseases in clinical settings. One of them may do so by reducing oxidative stress by blocking the xanthine dehydrogenase/oxidase pathway.

LEVOSIMENDAN INHIBITS DISULFIDE TAU OLIGOMERIZATION AND AMELIORATES TAU PATHOLOGY IN TAUP301L-BIFC MICE.

POSTERS: B03.C. DRUG DEVELOPMENT, CLINICAL TRIALS: AGGREGATION INHIBITORS

Sungsu Lim, Yun Kyung Kim, Ae Nim Pae
Korea Institute of Science and Technology, Brain Research Institute, Seoul, Korea, Republic of

Aims: Accumulation of abnormal tau aggregates is a pathological hallmark of multiple neurodegenerative disorders, collectively called tauopathies. Soluble tau aggregates play a key role in tau pathology as neurotoxic species causing neuronal cell death and also act as prion-like seeds transmitting the disease in the brain. Accordingly, prevention of tau oligomerization or elimination of tau oligomer species became an important therapeutic strategy to halt the disease progression. Here we assessed the potential therapeutic effect of levosimendan as an anti-tau oligomer agent.
Methods: Toward tau-targeted drug discovery, our group has established a tau-BiFC platform to monitor and quantify tau oligomerization in living cells and the mouse brain. By utilizing the tau-BiFC cells, we screened the FDA-approved and passed PhaseI drug library and identified levosimendan as a potent anti-tau agent inhibiting tau oligomerization. By using tau-BiFC mice, we could evaluate the anti-tau oligomerization effects of levosimendan.
Results: Under pathological conditions, most tau exists as a form of disulfide-linked tau oligomers and the treatment of levosimendan prevents the formation of disulfide-linked oligomers by covalently modifying tau cysteines(IC_{50}=2.6±0.1mM). In addition, levosimendan was able to disassemble tau oligomers into monomers, rescuing cells from aggregation states. In comparison, LMTM, the leading tau-targeted drug candidate that is currently on a clinical trial, failed to rescue cells from aggregation states, generating high-molecular-weight tau oligomers instead. Levosimendan displayed robust potency against tau oligomerization and rescued tauopathy-induced cognitive declines in the Tau^{P301L}-BiFC mouse model.
Conclusions: Our data present the potential of levosimendan as a disease-modifying drug for tauopathies.

THERAPEUTIC APPROACHES TARGETING 3R/4R TAUOPATHIES FOR THE TREATMENTS OF AD AND PSP

POSTERS: B03.C. DRUG DEVELOPMENT, CLINICAL TRIALS: AGGREGATION INHIBITORS

Ae Nim Pae, Sungsu Lim, Yun Kyung Kim
Korea Institute of Science and Technology, Brain Science Institute, Seoul, Korea, Republic of

Aims: Tauopathies are neurodegenerative disorders characterized by accumulation of tau in neurons or glial cells. Several neuropathologic phenotypes are distinguished based on the distinct anatomic areas and specific isoforms of tau (3R/4R) in pathologic deposits. As tauopathies are strongly linked with neurodegenerative disease, there have been a growing interest in tau-targeted drug discovery. Therefore, we studied and developed novel tau-targeted therapeutic drug candidates for the treatment of AD and PSP by inhibition of tau oligomerization in early stage.
Methods: We performed high-contents screening based on Tau Bi-FC cell-based assay platform and identified novel tau-aggregation inhibitors. Lead optimization was subsequently performed to improve potency and ADME/Tox properties, resulting in the production of lead compounds. *In vivo* efficacy of the lead compound was validated by demonstration of restoring memory impairment and motor dysfunction in transgenic animal models of P301L Tau-BiFC.
Results: The lead compound, **DTC2423** exhibited excellent 4R tau aggregation inhibitory activities (cell-based IC_{50}, 88 nM, in vitro IC_{50}, 40 nM) with good cell viability (MTS IC_{50}, 105 uM). **DTC2423** reduced tau oligomerization and protected neuronal cell death. It restored memory impairment and motor dysfunction in P301L Tau-BiFC Tg mouse models (NOR, Y-maze, Barnes-Maze test, Balance beam and Rotarod test) with reduction of tau pathology. The mode of action of **DTC2423** was confirmed by MALDI-TOF Mass Spectrometric Analysis and TR-2 competition study to show reversible covalent inhibition of disulfide dependent oligomer formation.
Conclusions: Highly potent lead compound was identified having selective inhibition of 4R tau aggregation by using 3R and 4R Tau-BiFC, disease-specific cell-based assay platform and in vivo Tau-BiFC P301L Tg mice model that improved significantly cognitive and motor dysfunction, and reduced tau pathology with good pharmacological properties.

A PHASE 2A STUDY OF TPN-101, A NUCLEOSIDE REVERSE TRANSCRIPTASE INHIBITOR, IN PATIENTS WITH PROGRESSIVE SUPRANUCLEAR PALSY

POSTERS: B03.E. DRUG DEVELOPMENT, CLINICAL TRIALS: COMBINATION THERAPY, SEX/RACE, PERSONALIZED MEDICINES, AI, OTHER

Andrew Satlin[1], Michael Cordingley[1], Debbie Liebert[1], Walter Bee[1], Ethan Geier[1], John Sedivy[1], Jay Soto[1], Eckard Weber[1], Adam Boxer[2]
[1]Transposon Therapeutics, Medical, San Diego, United States of America, [2]UCSF Weill Institute of Neurosciences, Memory And Aging Center, San Francisco, United States of America

Aims: To assess the safety, tolerability, pharmacokinetics in plasma and CSF, effect on biomarkers of neuroinflammation and neurodegeneration, and clinical effects of TPN-101, a nucleoside reverse transcriptase inhibitor, in patients with progressive supranuclear palsy (PSP).
Methods: 42 patients with probable PSP meeting Richardson criteria who were symptomatic for less than 5 years were randomly assigned to double-blind treatment with TPN-101 100 mg, 200 mg, 400 mg, or placebo once daily for 24 weeks. Patients who completed the double-blind period of the study were eligible to receive once-daily TPN-101 400 mg in a 24-week open-label treatment period. Patients were assessed for safety, biomarkers, and clinical effects at regular intervals. Lumbar punctures were done at baseline, Week 24, and Week 48 for CSF assessment of PK and biomarkers. The prespecified biomarker of interest was CSF neurofilament light (NfL) at Week 24.
Results: TPN-101 was well-tolerated, with only 2 withdrawals due to adverse events in the TPN-101 treatment groups. Plasma pharmacokinetics were in line with predicted and CSF concentrations exceeded target levels. Compared with baseline values, NfL_{CSF} decreased in the TPN-101 400 mg group and increased in placebo-treated patients (18.4% difference; p=0.158). Interleukin-6 (IL-6), a measure of neuroinflammation that correlates with PSP disease severity, also increased in the CSF in placebo-treated patients and decreased in patients treated with TPN-101. No differences among treatment groups were observed during the 24-week double-blind treatment period on the Progressive Supranuclear Palsy Rating Scale.
Conclusions: All doses of TPN-101 were well-tolerated in patients with PSP. Numerical trends toward reductions in NfL and IL-6 support the potential for a positive effect on neuroinflammation and neurodegeneration. Clinical improvements were not expected due to the size and duration of the study.

Aims: To investigate the relationship between body mass index (BMI) and Alzheimer's disease (AD) markers as well as cognition in the elderly with cognitively normal (CN) and cognitive impairment (CI), respectively.
Methods: Participants' data were collected from the Alzheimer's Disease Neuroimaging Initiative (ADNI) database. Participants with cognitively normal (CN) were included in the CN group. Participants with mild cognitive impairment and mild dementia were included in the cognitive impairment (CI) group. Linear and logistic regression were used to assess the association between BMI and AD markers as well as cognition.
Results: A total of 330 participants with CI and 84 participants with CN were included in this study. Linear regression showed that BMI was positively associated with baseline hippocampal volume (HV, β=0.04, P<0.001) and negatively associated with p-tau181 (β=-0.005, P=0.044) in participants with CI, whereas in participants with CN, BMI was positively associated with p-tau181 (β=0.012, P=0.013) and not with HV. In the CI group, the interaction effect between APOE ε4 status (or amyloid β positive status) and BMI demonstrated a significant impact on the 2-year Mini-Mental State Examination (MMSE) score, baseline HV, and 2-year HV. Mediation analysis showed that in the CI group, the effect of BMI on HV was partially mediated by diastolic blood pressure (DBP). In the CN group, BMI had a vicious effect on the MMSE score, while the mediating effect of DBP was insignificant.
Conclusions: In the CI participants, BMI may affect HV and cognition via influencing DBP, particularly prominent in APOE ε4 carriers and Aβ positive individuals. Therefore, in clinical practice, we should prioritize the appropriate maintenance of BMI in the elderly with AD patients.

MULTIMODAL BRAIN MRI CHARACTERIZATION OF A MOUSE MODEL OF DOWN SYNDROME AND EVALUATION OF A PHARMACOLOGICAL TREATMENT

POSTERS: B04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Julien Caillette[1], Laetitia Degiorgis[1], Marion Sourty[1], Helin Atas-Ozcan[2], Laurent Meijer[3], Yann Herault[2], Laura-Adela Harsan[4]

Aims: DYRK1A overexpression is a key player in cognitive impairments observed in Down syndrome (DS) patients and in animal models. Inhibition of this kinase rescues cognitive deficits in the Dp1Yey mouse model of DS. Our aims were to characterize, by multimodal MRI, the brain changes (morphology, microstructure, functional connectivity (FC)) underlying cognitive deficits in the Dp1Yey DS model, and to investigate, via resting state functional MRI (rsfMRI), how brain functional network patterns are remodeled by the Leucettinib-92 DYRK1A inhibitor.
Methods: Dp1Yey mice and wildtype (wt) control mice received either Leucettinib-92 or vehicle. Brain MRI data was acquired on day 11 of the treatment. Anatomical, diffusion and rsfMRI images were preprocessed. Anatomical images were analyzed by Voxel Based Morphometry (VBM). Parametric maps were extracted from the DTI images and parametric diffusion values were compared. RsfMRI data was processed to extract the BOLD time-course from each ROI, and correlation matrices were created. Graph theory was applied to map FC features for each group.
Results: VBM analysis revealed significant brain-wide cortical and subcortical volume alterations in Dp1Yey, involving frontal and sensory cortices and striatal, hippocampic and thalamic regions. Comparison of parametric diffusion maps showed significant changes, suggesting microstructural alterations in Dp1Yey model brain. Graph theory was applied to identify the regions with the most changed functional connections, showing hyperconnectivity in Dp1Yey. Comparing the treated and untreated animals showed that hyperconnectivity to be rescued by Leucettinib-92 treatment in several brain circuitries. The spatio-temporal dynamics of the functional connectivity is also altered in the Dp1Yey model and appears to be partially restored by Leucettinib-92 treatment.
Conclusions: RsfMRI should be further evaluated as a non-invasive tool as a biomarker during clinical trials of DYRK1A inhibitors in DS patients.

CLASSIFYING NEUROPATHOLOGICALLY CONFIRMED ALZHEIMER'S DISEASE AND LEWY BODY DEMENTIA ON CLINICAL NEUROIMAGING WITH DEEP LEARNING

POSTERS: B04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Frank Provenzano[1], David Park[2]
[1]Columbia University, Neurology, New York, United States of America, [2]Columbia University, Biomedical Engineering, Manhattan, United States of America

Aims: AD and DLB co-occur frequently, but post-mortem pathology reveals limited ante-mortem accuracy in the clinical diagnosis of AD comorbid with DLB (AD/DLB) against AD alone. We tested whether a single T1-weighted (T1) MRI scan may differentiate AD/DLB and AD using heterogeneously acquired (both research and clinically acquired) neuroimaging, to maximize the amount of pathology-confirmed in-vivo MRIs.
Methods: Datasets consist of mostly clinically-acquired scans from National Alzheimer's Coordinating Center (NACC) and purely research scans from Alzheimer's Disease Neuroimaging Initiative (ADNI). T1 MRI scans are limited to those participants with neuropathology. We examine two groups, an AD with and without LBD pathology. A five-fold cross validation is performed using NACC, while ADNI scans are added in the training dataset. Slice-level 2D Convolutional neural networks (CNN) are trained to differentiate the two groups. From each scan, gray matter is segmented, normalized, smoothed and thresholded and used as input.
Results: On the subject-level, CNN records a classification accuracy of 82% and f1 score of 0.79. Prediction accuracy was higher when the scan date is closer to DOD, with a 100% accuracy recorded within a year from the date-of-death. A Grad-CAM attribution map reveals distinctive cortical patterns for AD and AD/DLB groups.
Conclusions: This study demonstrates how machine learning approaches can help harmonize neuroimaging data from clinical sources to better understand disease diagnosis and progression using a true gold-standard of neuropathological confirmation. The frameworks utilized here can be extended to other diseases that are frequently co-occurring and feasibly extend to single scan diagnostic clinical utility of scans already being acquired.

TOWARDS ROBUST QUANTIFICATION OF LONGITUDINAL [18F]MK-6240 TAU-PET SUVR CHANGES IN CLINICAL STUDIES

POSTERS: B04.B. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - TAU

Yuchuan Wang[1], Michal Tomaszewski[1], Richard Baumgartner[2], William Herring[3], Wenping Li[1], Eric Hostetler[1]
[1]Merck Sharp & Dohme, Translational Imaging, Rahway, United States of America, [2]Merck Sharp & Dohme, Biostatistics, Rahway, United States of America, [3]Merck Sharp & Dohme, Clinical Research, Rahway, United States of America

Aims: Longitudinal [18F]MK-6240 tau-PET is increasingly used clinically for monitoring AD progression and/or assessing therapeutic responses. Quantifying standardized uptake value ratio (SUVR) changes in predefined brain regions-of-interests (ROIs) requires analysis-pipeline implementations that often employ distinct methods, leading to differing robustness of study data readouts and statistical power. Our aim is to improve pipeline implementations to achieve more robust longitudinal quantification and to reduce the risk of reporting artificial SUVR-reduction.
Methods: Several historical [18F]MK-6240 tau-PET datasets were investigated using an in-house longitudinal SUVR analysis-pipeline, allowing comparisons of different implementations. Three methods for reference-region SUV estimation were assessed: (1) SUVmean of whole-cerebellar-grey, (2) SUVmean of eroded-cerebellar-grey, and (3) SUVmax-probability of whole-cerebellar-grey. Both (2) and (3) are capable of reference-region decontamination, using empirical erosions and probability-density-functions (PDFs), respectively. Two approaches of ROI-handling were compared: (a) use of “stationary” baseline ROIs to quantify both baseline and follow-up PET, and (b) use of “time-point-matched” ROIs, where quantification of follow-up PET use ROIs generated from follow-up MRI.
Results: Among three methods of quantifying reference-region, method #1 exacerbated artificial SUVR-reductions in target ROIs, especially early Braak regions, due to spill-in contaminations. Both methods #2 and #3 were effective for decontamination, with #3 allowing replicable implementations for all datasets. Between two approaches of ROI-handling, “stationary” approach exacerbated artificial SUVR-reductions when compared to “time-point-matched” approach, especially notable among subjects with higher baseline SUVR. Combining reference-region decontamination and “time-point-matched” ROI-handling enhanced statistical power in detecting longitudinal changes for historical datasets, beneficially impacting sample-size calculations.
Conclusions: Tau-PET quantification robustness is improved by reference-region decontamination and “time-point-matched” ROI-handling. PDF-based decontamination is more consistent/replicable across pipelines/studies. Effective use of longitudinal MRI for PET quantification may be important for future clinical studies.

DOES VASCULAR RISK EXPLAIN ACCELERATED TAU ACCUMULATION IN WOMEN COMPARED WITH MEN?

POSTERS: B04.B. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - TAU

Melanie Dratva[1], Kenneth Rostowsky[2], Qian Shen[1], Xin Wang[1], Jazmin Diaz[3], Michael Thomas[3], Erin Sundermann[4], Sarah Banks[5]
[1]UCSD, Neurosciences, La Jolla, United States of America, [2]University of Chicago, Neurology, Chicago, United States of America, [3]Colorado State University, Neurosciences, Fort Collins, United States of America, [4]University of California, San Diego, Psychiatry, La Jolla, United States of America, [5]University of California, San Diego, Neurosciences, La Jolla, United States of America

Aims: Across the Alzheimer's Disease spectrum, women have higher rates of tau accumulation compared to men, particularly at the mild cognitive impairment (MCI) stage. Women have been found to have stronger associations between vascular risk and tau than men at single time points. In our earlier work, the Framingham Risk Score (FRS), was found to predict tau PET levels in cognitively normal women but not men. Here, we asked if vascular risk scores explain some of the sex differences seen in tau accumulation in MCI.
Methods: 53 amyloid positive subjects (21 women) with clinical diagnoses of MCI, tau-Positron Emission Tomography (PET) data, and cardiovascular component data from the Alzheimer's Disease Neuroimaging Initiative (ADNI) database were included in this analysis, which controlled for age, *APOE* status, and education. FRS scores were calculated based on cardiovascular disease points derived from age, sex, total cholesterol, high-density lipoprotein cholesterol, systolic blood pressure, hypertension treatment status, smoking status, and diabetic status. Models were fitted to the data to test (1) whether sex moderated the relationship between FRS and tau accumulation and (2) whether FRS fully mediated the associating between sex and tau accumulation.
Results: Women had lower FRS and accumulated more tau over the 1-2 year period examined in comparison to men in the regions of interest (which spanned Braak regions 3,4, 5 and 6). While FRS was a predictor of higher tau accumulation, it was independent of sex (i.e., not moderated by sex). Moreover, sex predicted higher tau accumulation independent of FRS scores.
Conclusions: While prior research pointed to vascular risk predicting early tau accumulation in women with normal cognition, sex differences in the accumulation of tau during MCI are not explained by vascular risk.

VENOUS ABNORMALITIES AND BRAIN CLEARANCE

POSTERS: B04.B. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - TAU

Lidia Glodzik, Yi Li, Xiuyuan Hugh Wang, Emily Tanzi, Liangdong Zhou, Silky Pahlajani, Tracy Butler, Gloria Chiang, Adrienne Biskaduros, Thomas Maloney, Mony De Leon
Weill Cornell Medicine, Radiology, New York, United States of America

Aims: The concept of glymphatic system proposes that cerebrospinal fluid (CSF) enters the brain parenchyma through spaces surrounding arterioles, passes through interstitial spaces mixing with interstitial fluid and exits the brain through perivenous spaces, facilitating the clearance of metabolic waste. While much attention has been paid to the arterial part of the vascular tree, the role of venous abnormalities remains relatively unexplored. Using our in-house developed PET based method to assess ventricular efflux we examined whether this clearance measure is related to venous density as assessed by deep medullary veins count.
Methods: Data was collected from cognitively impaired and unimpaired research participants enrolled in studies between 2020 and 2023 at the Brain Health Imaging Institute at Weill Cornell Medicine. All participants had their medical history and cognition assessed through standardized clinical interviews. Imaging consisted of 3T MRI scans and 18F-MK6240 PET/CT to estimate brain clearance and tau deposition. The number of DMVs was assessed by visual inspection of minimal intensity projection images (SWI) for veins traversing perpendicularly to the lateral ventricle and defined as the total count of both hemispheres.
Results: We included 32 cognitively impaired subjects (66.1± 12.3 years old, 15 women) and 72 normal individuals (69.8± 7.0, 37 women). Age and sex did not differ between groups. Among subjects with cognitive impairment, but not in normal volunteers, the number of DMVs was positively related to the measure of CSF ventricular efflux (rho=0.43, p=0.01) and inversely associated with tau accumulation in Alzheimer Disease-related composite region (rho=-0.37, p=0.04). The correlation between clearance measure and tau deposition did not reach statistical threshold (rho= -0.28, p=0.10).
Conclusions: Our findings support the notion that healthy venous system plays a role in brain clearance.

Aims: Progressive supranuclear palsy (PSP) is characterized pathologically by abnormal tau protein depositions and clinically by motor impairments, including vertical oculomotor deficits. This study aimed to identify regional tau accumulations associated with discrete domains of PSP symptoms using PET with [^{18}F]PM-PBB3/florzolotau(18F), a radioligand capable of capturing tau aggregates in primary tauopathies.
Methods: Data were obtained consecutively from February 2018 to August 2021 and included 48 PSP subjects. We performed neurological examinations, including an evaluation of the PSP rating scale, which was sorted into six domains consisting of 'history', 'mentation', 'bulbar', 'ocular motor', 'limb motor', and 'gait and midline' subsections. Correlations of these domain scores with tau accumulations and local atrophy in the brain were evaluated using standard brain-transformed tau PET and T1-weighted MRI images, respectively.
Results: 'Ocular motor' scores were significantly correlated (unc. <0.001) with tau accumulations in the midbrain tegmentum and globus pallidus. By contrast, 'limb motor' and 'gait and midline' scores were significantly correlated (unc. <0.001) with tau depositions in the precentral to supplementary motor cortex and the caudate nucleus, respectively. Volumes of the midbrain tegmentum and globus pallidus were significantly correlated (unc. <0.001) with 'ocular motor' scores, and precuneus volumes were correlated with 'gait and midline' scores.
Conclusions: The present findings have revealed that tau pathologies in distinct brain areas are differentially implicated in individual symptomatic domains in PSP. Tau depositions and local atrophy in the midbrain were associated with oculomotor impairments, indicating that tau-induced, on-site neurotoxicity provokes disrupted eye movements as focal symptoms. Meanwhile, gait and midline deficits may arise from caudate tau accumulations leading to the deterioration of a network involving the precuneus.

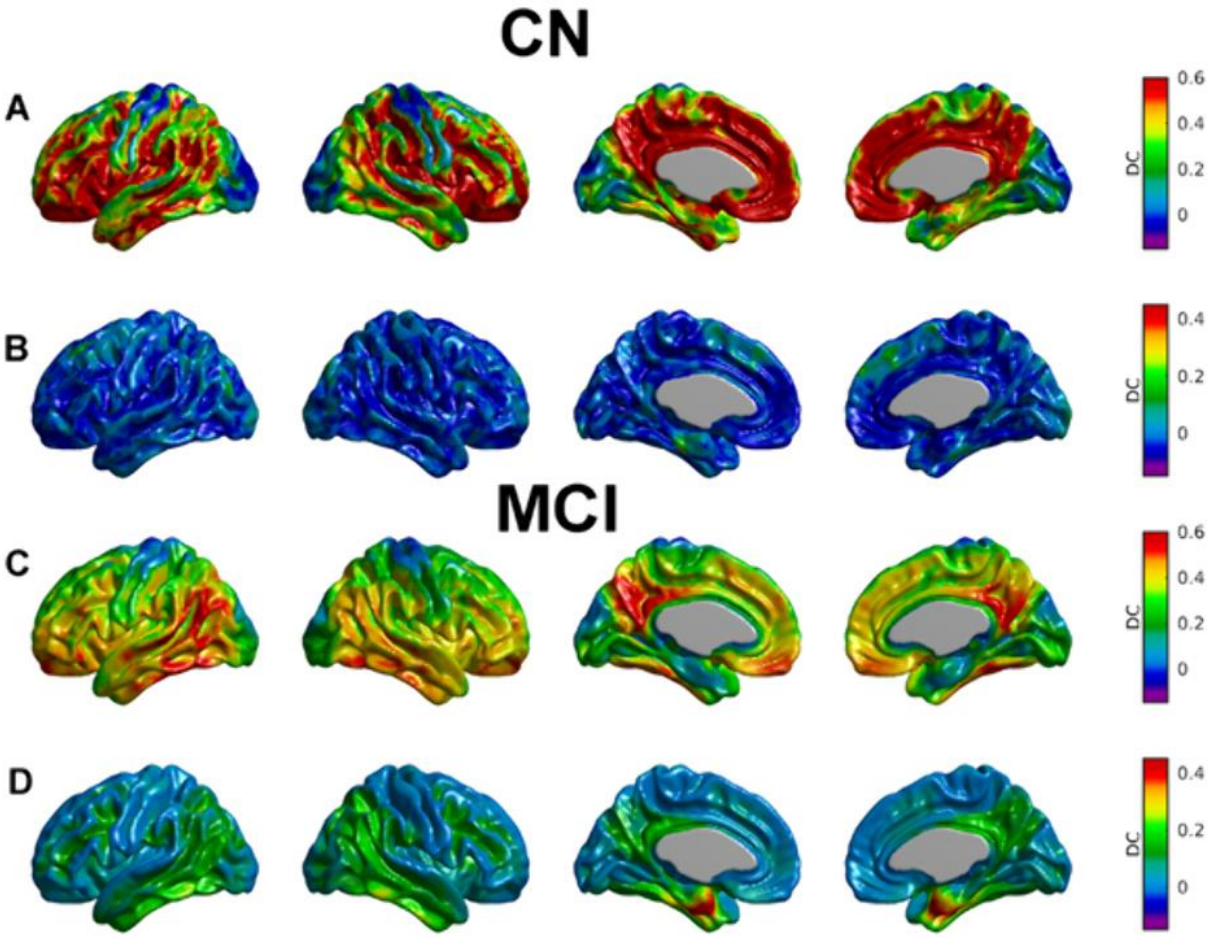
SPATIAL ASSOCIATION BETWEEN DISTRIBUTED B-AMYLOID AND TAU VARIES WITH COGNITION

POSTERS: B04.B. IMAGING, BIOMARKERS, DIAGNOSTICS: PET - TAU

Felix Carbonell[1], Carolann Mcnicoll[1], Alex Zijdenbos[2], Barry Bedell[3]
[1]Biospective Inc., Clinical, Montreal, Canada, [2]Biospective Inc., Technology, Montreal, Canada, [3]Biospective Inc., Preclinical, Montreal, Canada

Aims: Most studies exploring the synergistic effect between β-amyloid and tau at early stages of Alzheimer's disease (AD) have only focused on their linear relationship at the local spatial scale. We hypothesize that patterns of spatial association between β-amyloid and tau may be more thoroughly interrogated using alternative association metrics that account for linear as well as more complex, possibly nonlinear, dependencies.
Methods: Our cross-sectional analysis was applied to Tau and Amyloid PET images from cognitively normal (CN) and mild cognitive impairment (MCI) subjects from the ADNI study. We propose a new Canonical Distance-Correlation (CDC) Analysis to uncover spatial patterns in the association between Tau and Amyloid images. Based on the concept of distance-correlation, the CDC approach produces statistically independent components in the distributed-to-distributed organization of the nonlinear association between the two modalities.
Results: The CDC analysis led to scores that were maximally cross-distance-correlated, a sign of an underlying (nonlinear) dependency. The strength and spatial extent of the distance-correlation between the first β-amyloid scores and tau images were stronger in CN than in MCI subjects (Figures 1A, 1C). In contrast, the tau cross-eigenimage carried stronger loads in MCI than in CN subjects, particularly within the entorhinal cortex (Figures 1B, 1D). This pattern of distributed β-amyloid–focal tau dependency could represent an initial indication of cognitive
deterioration.



Conclusions: The CDC analysis can reveal complex patterns in the spatial association between the β-amyloid and tau. Our results suggest that β-amyloid and tau act in a spatially coordinated manner that depends on the cognitive stage. Thus, the CDC analysis may be more accurate than the amyloid or tau SUVR for the enrollment in clinical trials of those individuals on the path of cognitive deterioration.

Aims: Iron accumulation is observed in brain regions affected by progressive supranuclear palsy (PSP), a rare tauopathy among the parkinsonism disorders. The influence of iron on amyloid aggregation is well-documented, however, the aetiology of tau aggregation and the role of metals in tauopathies has received less attention. The objective of this work was to facilitate, through a multimodal microscopy approach, a method incorporating synchrotron x-ray fluorescence (SXRF), to investigate the underlying relationship between tau aggregation and iron accumulation. This required a protocol to preserve the metallomics properties of the samples while allowing for cellular-level correlation with neuropathology in the same sections.
Methods: Brain tissue from two age-matched individuals (PSP and control) was prepared and cryo-sectioned with a sapphire blade using a metal-contamination-free protocol. Sections were mounted onto quartz slides etched with finder grids. Regions of interest (ROIs) of 1x1 mm were defined using optical microscopy, and SXRF mapping of elemental distributions in each ROI was performed at Beamline I18 at Diamond Light Source synchrotron. This beamline is distinguished by its microfocus capabilities, with two micron mapping resolution, unambiguous chemical element specificity, and sensitivity to parts-per-million concentrations.
Results: The SXRF chemical element mapping was performed with this label-free technique, and the unique quartz finder grid enabled direct correlation with the light microscope images. PyMCA software was used to derive maps of chemical concentration distribution, by performing spectral fitting to accurately identify elemental peaks and integrate the area beneath each peak.
Conclusions: This method development study has made it possible to correctly identify and evaluate cells and other features in both chemical element and optical microscopy images, creating new scope for direct correlation between iron and tau pathology when the sections are immunostained after SXRF analysis.

[1]Tanz Centre for Research in Neurodegenerative Diseases, University Of Toronto, Toronto, Canada, [2]Canadian Concussion Centre, Toronto Western Hospital, Toronto, Canada, [3]University of Toronto, Tanz Centre For Research In Neurodegenerative Diseases, Toronto, Canada, [4]University of Gothenburg, Department Of Psychiatry And Neurochemistry, Molndal, Sweden

Aims: To determine whether biomarker evidence of neurodegeneration in former contact sports athletes (ExPros) with a history of repeated concussion is associated with changes in specific brain structures and functional connectivity networks.
Methods: 41 male former professional athletes with a history of multiple concussions were recruited. The sample was divided into neurodegenerative biomarker positive (N+, n = 16) and negative (N-, n = 25) groups. Classification was based on the positivity in at least one of these biomarkers: plasma and cerebrospinal fluid (CSF) neurofilament light, CSF total tau and plasma phospho-tau181. Ten healthy controls (negative for neurodegenerative biomarkers) were also included. Cognitive and mood/behavior composite scores, whole-brain grey matter volume and functional connectivity (default mode [DMN], salience [SN] and frontoparietal [FPN] networks) were compared across groups. Statistical threshold was set at $p < 0.001$, FWE correction at cluster level ($p < 0.05$). Spearman's rank correlations were performed between network functional connectivity and the number of concussions.
Results: Normal-range mean performance was found in executive function, memory and mood/behavior tests across groups. We found no differences in grey matter volume. The DMN in the N (+) group showed lower connectivity compared to N (-) and healthy controls. No differences were obtained for the SN and FPN. Lower DMN connectivity correlated with a higher number of concussions in the N (+) group ($r = -0.66$, $p = 0.005$), but not in the N (-) group ($r = -0.10$, $p = 0.60$).
Conclusions: DMN functional connectivity may provide sensitive tools to detect asymptomatic ExPros with positive biomarkers of neurodegeneration. Follow-up studies are needed to show whether this alteration is associated with a higher risk of developing dementia after repetitive concussions.

PERFORMANCE OF A METHOD FOR QUANTIFYING PROGRANULIN AS A TARGET ENGAGEMENT BIOMARKER FOR AZP2006 IN PROGRESSIVE SUPRANUCLEAR PALSY

POSTERS: B04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Cécilia Estrella[1], Aurélien Blondel[1], Philippe Verwaerde[1], Noëlle Callizot[1], Renaud Jasnowski[2], Audrey Pabiou[2], Aurélie Chene[2], Cendrine Josson[2], Christine Bain[2]
[1]Alzprotect, Clinical Research, Loos, France, [2]Active Biomarkers - Kcas, Bioanalytics, LYON, France

Aims: Progranulin (PGRN) is a neurotrophic factor that plays a key role in the development, survival and maintenance of neurons and microglia. Strategies aiming at restoring PGRN levels in patients with Progressive Supranuclear Palsy (PSP) are investigated as potential therapeutic approaches. In the context of a Phase IIa clinical trial conducted by Alzprotect, evaluating AZP2006 in PSP, Active Biomarkers as the bioanalytical laboratory, quantified PGRN as a target engagement biomarker together with other biomarkers, in plasma and cerebrospinal fluid (CSF) of PSP patients.
Methods: Biotechne and Adipogen PGRN ELISA kits were evaluated in plasma and CSF samples for parallelism and selectivity. Performance of the selected method, including working range and long-term stability at -80°C for up to 52 weeks, was evaluated.
Results: Both PGRN kits were equivalent in terms of selectivity in plasma and CSF and parallelism in plasma. However, Biotechne kit was not sufficiently sensitive to quantify PGRN in CSF. PGRN was then measured both in plasma and CSF by Adipogen kit. Quantification of endogenous PGRN paralleled calibration curve with the recombinant protein. After having determined the minimal required dilution, clinical sample analysis showed that upon AZP2006 treatment, PGRN levels at the end of the treatment were increased in plasma when compared to the baseline. AZP2006 treatment was able to prevent the PGRN decrease observed in CSF of the placebo group. These data were further consolidated by demonstrating acceptable precision of the method across all analytical runs and analysts, and PGRN stability in in-study samples for at least 52 weeks at -80°C.
Conclusions: Quantification of PGRN by a method, qualified according to its context-of-use, generates robust results establishing PGRN as a target engagement biomarker for AZP2006 in PSP.

MAPPING SIX BRAIN CELL TYPES TO ALZHEIMER'S DISEASE PATHOLOGY.

POSTERS: B04.D. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Min Su Kang[1,2], Julie Ottoy[1,2], Jean-Paul Soucy[3], Gassan Massarweh[3], Sandra Black[2,4], Pedro Rosa-Neto[5,6], Maged Goubran[1]
[1]Sunnybrook Research Institute, The Physical Sciences, Toronto, Canada, [2]Sunnybrook Research Institute, Hurvitz Brain Sciences Program, Toronto, Canada, [3]Montreal Neurological Insitute, Neurology, Montreal, Canada, [4]University of Toronto, Department Of Medicine (neurology), Toronto, Canada, [5]Translational Neuroimaging Laboratory, Mcgill University Research Centre For Studies In Aging, Alzheimer's Disease Research Unit, Douglas Research Institute, Montréal, Canada, [6]McGill Research Centre for Studies in Aging, Translational Neuroimaging Laboratory, Montreal, Canada

Aims: The abnormal amyloid-beta (Aβ) and tau aggregates can be quantified and studied using PET biomarkers. However, the spatial profile of different brain cell types associated with AD pathology at a large-scale imaging level is still unknown.
Methods: A total of 100 participants (67 A-T-, 26 A+T-/+) from the TRIAD cohort underwent T1, ^{18}F-AZD4694, and ^{18}F-MK6240 PET. All T1 and PET images were processed using Freesurfer and PETsurfer, respectively. The DKT atlas was uniformly divided into a high-resolution atlas at 1631 regions. We conducted a group comparison between A- and A+ groups on Aβ or tau PET with age, sex, APOE€4 and education as covariates. The t-statistics from the group contrast were correlated with the six brain cell-type (endothelial, neuron, astrocyte, microglia, oligodendrocyte, oligodendrocyte precursor (OP) cells) spatial proportions maps estimated from cell deconvolution of the Allen Human Brain Atlas in the DKT atlas. The bonferroni correction was applied for the multiple comparisons test.
Results: We showed a significantly greater Aβ or tau PET in the A+ compared to the A- group. Such differences in the Aβ or tau PET were significantly correlated with all six brain cell types (fig1). The proportion of the neuronal cell type was positively correlated with Aβ or tau PET while the other cell types were negatively correlated. The neuronal, endothelial, and OP cell types showed the highest R2 whereas the astrocyte cell type had the lowest R2 with the Aβ or tau PET t-statistics

Conclusions: This study highlights a significant spatial relationship between the Aβ or tau deposition in AD and the proportion of the six different brain cell-type maps. Notably, the regions with a larger proportion of neuronal cell type were more associated with greater Aβ or tau deposition in AD.

Aims: Extracellular vesicles (EVs) exhibit great potential for the theragnostics of brain disorders, representing a valuable tool for precision medicine which demands high-quality human biospecimens to unravel individual clinical profiles within pathologically heterogeneous disorders and develop precise patient-tailored treatments. Thus, the collection and characterization of physiologically relevant sEVs are of the utmost importance. However, standard brain EV isolation approaches rely on tissue dissociation, which can contaminate EV fractions. Therefore, we aim to develop a protocol that enriches spontaneously released vesicles and assess their contribution to stress-driven Alzheimer’s disease and depression pathology.
Methods: Based on multiscale analyses (e.g., cryo-EM, label-free proteomics, advanced flow cytometry, ExoView), we characterized the EV fraction isolated with this novel method. Moreover, EV biogenesis was pharmacologically manipulated to assess the validity of the method, while the injection of labelled-EVs into the mouse brain further supported the integrity of the isolated vesicles and their contribution to pathology.
Results: We hereby present an efficient purification method for sEV-enriched population spontaneously released by mouse and human brain tissue. In addition, we tested the significance of the protocol with manipulation of sEVs biogenesis, and under exposure to chronic stress, a clinically relevant precipitant of depression and Alzheimer's disease. Our findings show that the released method monitors the drug-evoked inhibition or enhancement of sEVs secretion while chronic stress induces the secretion of Tau-bearing exosomes accompanied by memory loss and mood deficits suggesting a potential role of sEVs in the brain response to stress and related stress-driven brain pathology.
Conclusions: Overall, the release method offers an isolation method for physiologically-relevant EVs and an ex vivo platform for manipulation of EV biogenesis, which will contribute to the characterization sEVs in brain function and pathology.

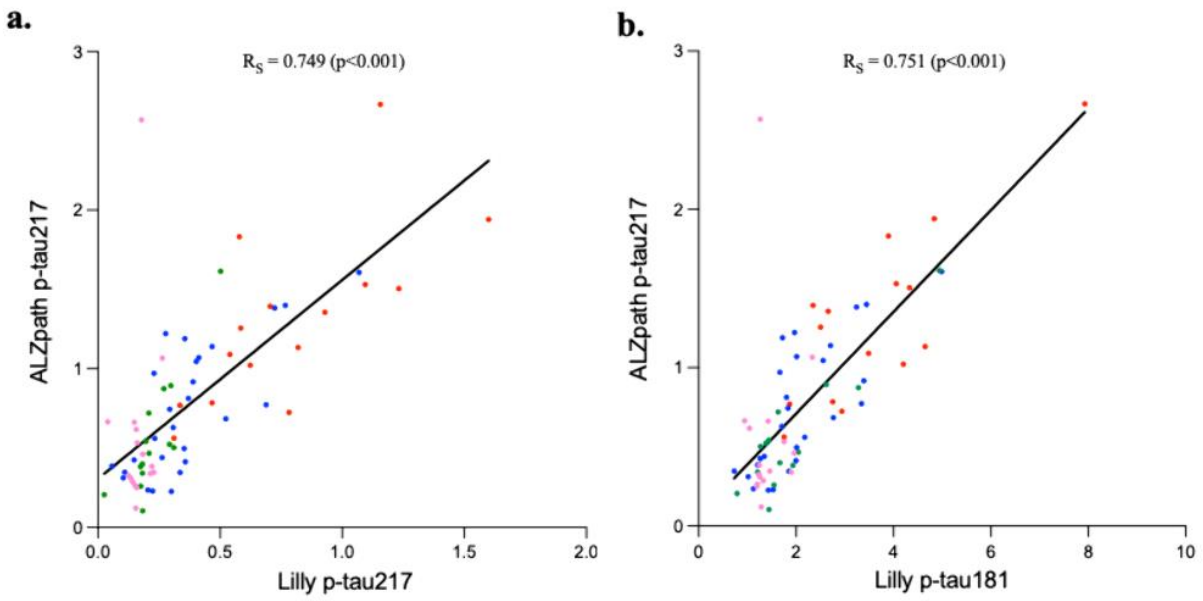
COMPARISON OF PLASMA ALZPATH P-TAU217 WITH LILLY P-TAU217 AND P-TAU181

POSTERS: B04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Divya Bali[1], Shorena Janelidze[1], Gemma Salvadó[1], Geidy Serrano[2], Thomas Beach[2], Andreas Jeromin[3], Oskar Hansson[1]
[1]Lund University, Clinical Memory Research Unit, Lund, Sweden, [2]Banner Sun Health Research Institute, Brain And Body Donation Program, Sun City, United States of America, [3]ALZPath, Inc, Alzpath, Inc, Carlsbad, United States of America

Aims: There is an urgent need for accurate and validated methods to measure plasma phosphorylated tau (p-Tau) biomarkers in Alzheimer´s disease (AD). Here we compare the performance of newly developed plasma ALZpath p-Tau217 assay to other established p-Tau assays such as Lilly p-Tau217 and Lilly p-Tau181.
Methods: We included 72 participants from the Arizona Study of Aging and Neurodegenerative Disorders (AZSAND) cohort, where we analysed antemortem collected plasma samples with ALZpath p-Tau217 as well as Lilly p-Tau217 and p-Tau181. The plasma biomarkers were compared with relevant post-mortem neuropathological measures.
Results: We found that ALZpath p-Tau217 correlated significantly with Lilly p-Tau217 and Lilly p-Tau181 (Figure1). ALZpath p-Tau217, Lilly p-Tau217 and Lilly p-Tau181 were found to be significantly associated with plaque load (ρ=0.53, ρ=0.73 and 0.59 $p<0.001$), when adjusting for tangle load (Table1). However, only Lilly p-Tau217 was significantly associated with tau tangle load (ρ=0.32, p=0.007), when adjusting for plaques. The correlations of ALZpath p-Tau217 and Lilly p-Tau181 with plaque load were comparable but Lilly p-Tau217 exhibited significantly higher correlations with plaques (ρ_{diff} =0.20; p=0.015) and tangles (ρ_{diff} =0.29; p=0.003) than ALZpath p-Tau217. ALZpath p-Tau217 and Lilly p-Tau181 predicted the elevated levels of ADNC, tangle, and amyloid pathology with similar accuracy (AUCrange, 0.74-0.79) but the AUC´s of Lilly p-Tau217 were significantly higher in comparison to ALZpath p-Tau217 (ADNC, AUC_{diff}=0.12, p_{diff}=0.021; Braak, AUC_{diff}=0.08, p_{diff}=0.021; CERAD, AUC_{diff}=0.11, p_{diff}=0.024) (Figure5) (Figure 2-4).

Figure 1



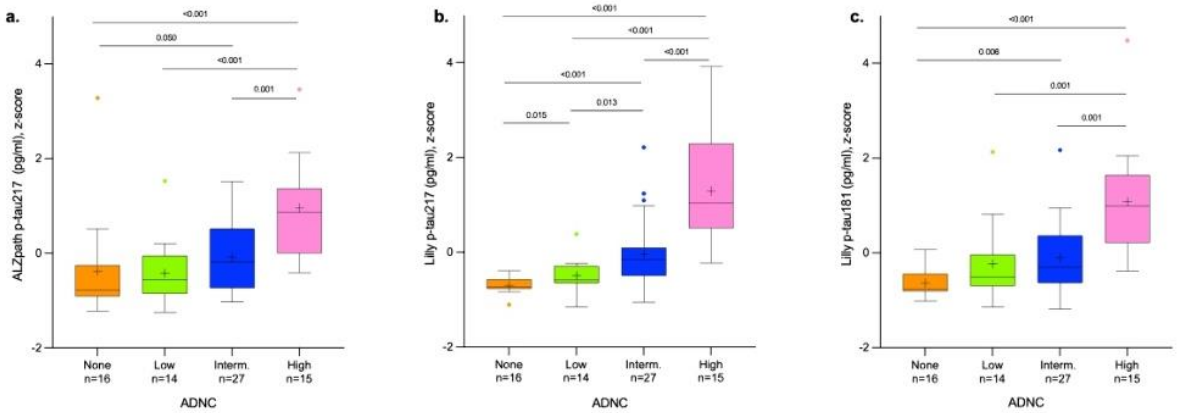
Correlation analysis between different plasma biomarkers
Spearman correlation analysis was used to assess the association between a) ALZpath p-tau217 and Lilly p-tau217 b) Alzpath p-tau217 and Lilly p-tau181.

Table1: Association between ALZpath p-tau217and Lilly p-tau181 or Lilly p-tau217 with amyloid or tangle load

Adjusted for covariates (age, sex and PMI) and pathology (tangles or plaques)			
	ρ	**p-value**	**p-value comp.**
Tangles			
ALZpath p-tau217	0.03	0.82	Ref.
Lilly p-tau181	0.15	0.21	0.29
Lilly p-tau217	0.32	0.007	0.003
Plaques			
ALZpath p-tau217	0.53	**<0.001**	Ref.
Lilly p-tau181	0.59	**<0.001**	0.491
Lilly p-tau217	0.73	**<0.001**	0.015

Partial correlation analysis was used to assess the association of ALZpath p-tau217 and Lilly p-tau181 or Lilly p-tau217 with amyloid or tangle load, adjusting for covariates such as age, sex and time between blood drawn and death (PMI) as well as other pathology (i.e., when looking at tangles adjusting for plaques and conversely). Bootstrapping was used to measure the significant differences between the correlation coefficients. Abbreviations: p-tau, phosphorylated tau.

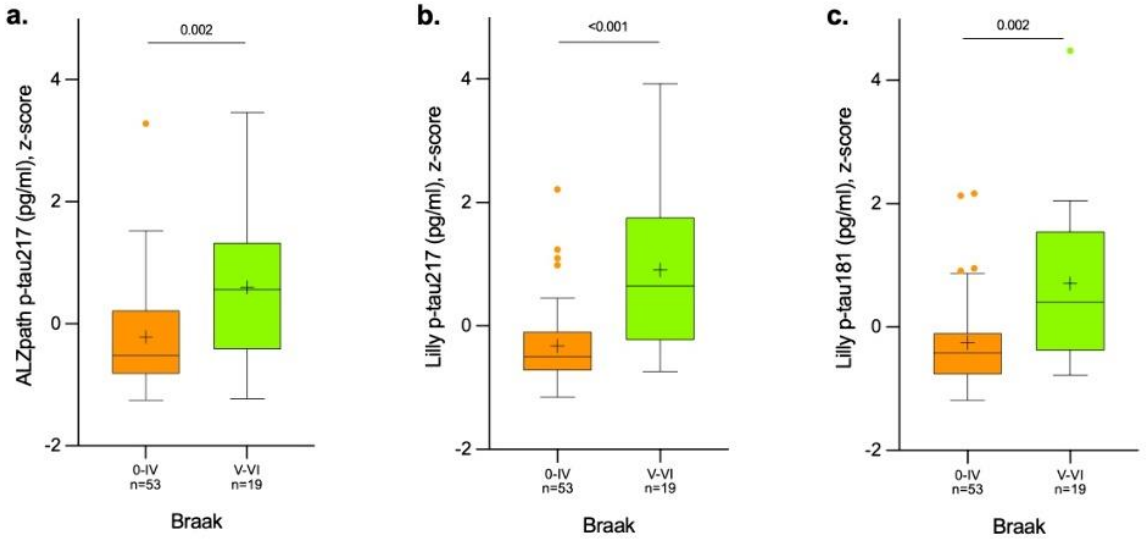
Figure 2



Levels of plasma biomarkers by ADNC classification

Plasma levels of a) ALZpath p-tau217 b) Lilly p-tau217 c) Lilly p-tau181 by ADNC classification. Overall group differences were assessed using Kruskal Wallis test and within group differences were measured using Mann-U-Whitney test (p-value). Boxes show interquartile range, the horizontal lines are the medians, and the whiskers are plotted using Tukey method. Abbreviations: ADNC, Alzheimer´s disease neuropathologic change; p-tau, phosphorylated tau.

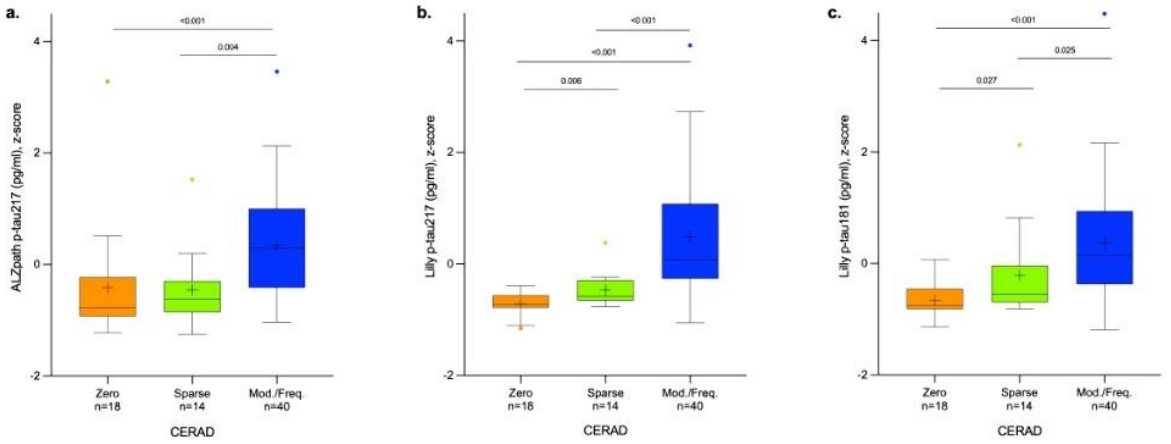
Figure 3



Levels of plasma biomarkers by Braak Staging

Plasma levels of a) ALZpath p-tau217 b) Lilly p-tau217 c) Lilly p-tau181 by Braak Staging. Overall group differences were assessed using Kruskal Wallis test and within group differences were measured using Mann-U-Whitney test (p-value). Boxes show interquartile range, the horizontal lines are the medians, and the whiskers are plotted using Tukey method. Abbreviations: p-tau, phosphorylated tau.

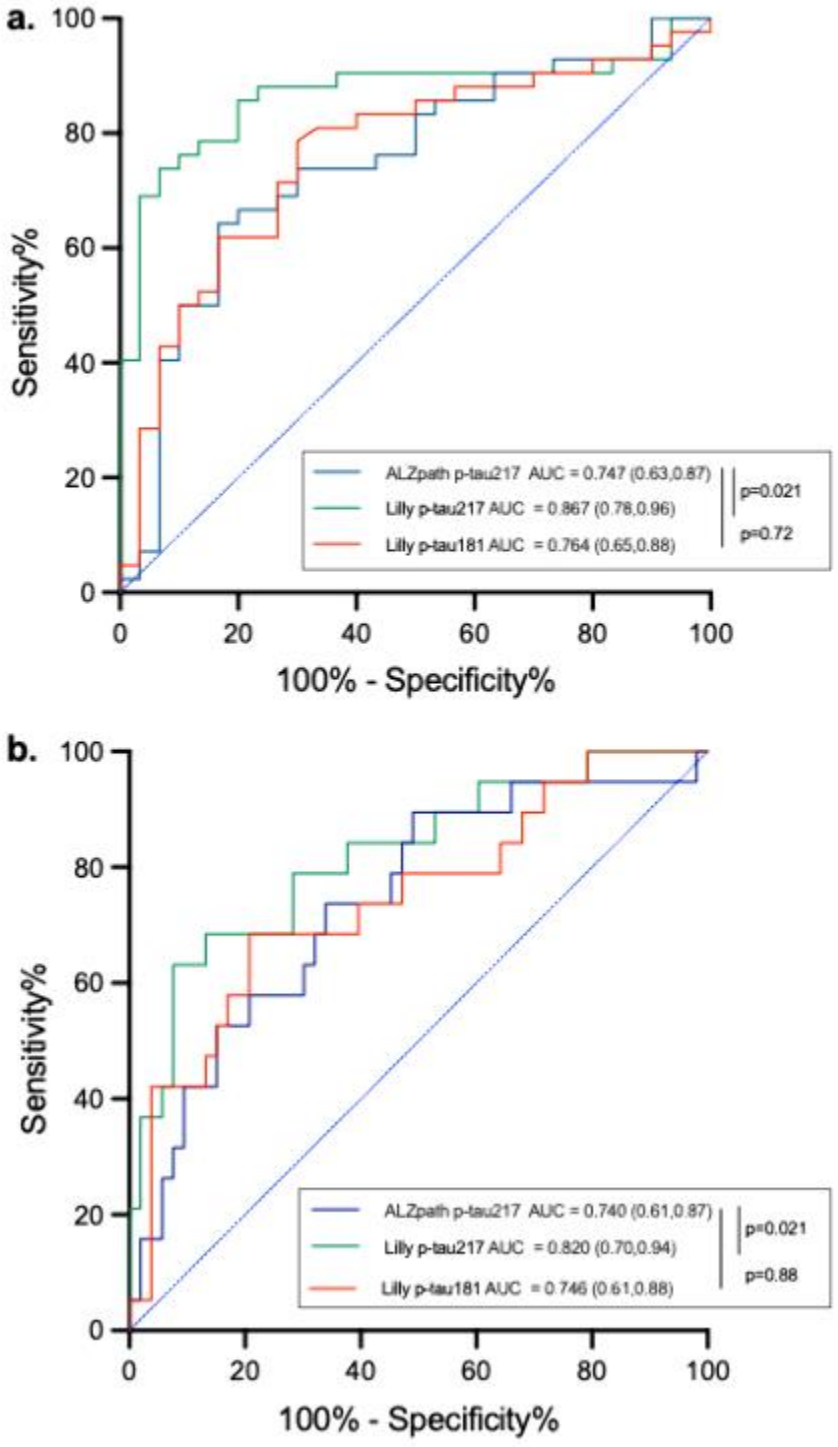
Figure 4



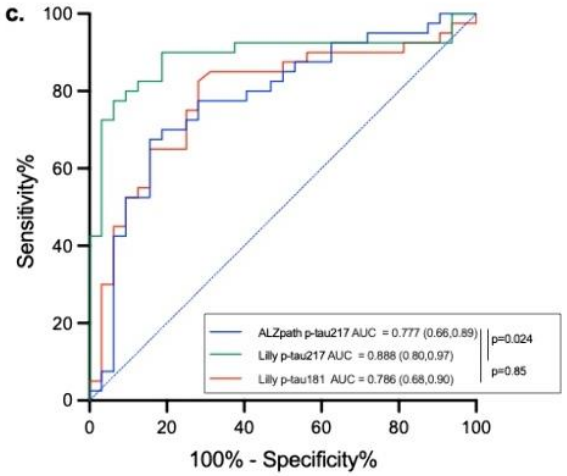
Levels of plasma biomarkers by CERAD classification

Plasma levels of a) ALZpath p-tau217 b) Lilly p-tau217 c) Lilly p-tau181 by CERAD classification. Overall group differences were assessed using Kruskal Wallis test and within group differences were measured using Mann-U-Whitney test (p-value). Boxes show interquartile range, the horizontal lines are the medians, and the whiskers are plotted using Tukey method. Abbreviations: CERAD, Consortium to Establish a Registry for Alzheimer´s Disease; p-tau, phosphorylated tau.

Figure 5



a.
Sensitivity%
100% - Specificity%
ALZpath p-tau217 AUC = 0.747 (0.63,0.87)
Lilly p-tau217 AUC = 0.867 (0.78,0.96)
Lilly p-tau181 AUC = 0.764 (0.65,0.88)
p=0.021
p=0.72
b.
Sensitivity%
100% - Specificity%
ALZpath p-tau217 AUC = 0.740 (0.61,0.87)
Lilly p-tau217 AUC = 0.820 (0.70,0.94)
Lilly p-tau181 AUC = 0.746 (0.61,0.88)
p=0.021
p=0.88



Predicting neuropathological scales classification

ROC curves analysis for predicting a) ADNC b) Braak c) CERAD classification. ADNC was dichotomized as negative (none/low) or positive (intermediate/high), CERAD was dichotomized as negative (low/sparse) or positive (moderate/frequent) and Braak stages were also dichotomized as negative (0-IV) or positive (V-VI). The DeLong test was used to determine whether the area under the curve (AUC) of two ROC curves was statistically different. Abbreviations: ADNC, Alzheimer´s disease neuropathologic change; AUC, Area under the curve; CI, confidence interval; CERAD, Consortium to Establish a Registry for Alzheimer´s Disease; p-tau, phosphorylated tau; ROC, receiver-operating characteristic.

Conclusions: ALZpath p-Tau217 exhibited similar performance as Lilly p-Tau181, but in this cohort associations between ALZpath p-Tau217 and the core measures of AD pathology were significantly lower in comparison with Lilly p-Tau217. These findings will need to be replicated in larger independent cohorts.

Aims: Dementia is one of the leading causes of impaired ability in elderly people, affecting approximately 50 million people worldwide. Alzheimer's disease (AD) is the most common form of dementia representing almost 70% of cases, followed by frontotemporal dementia (FTD). The main goal of the current study is the identification of a suitable combination of biomarkers in cerebrospinal fluid (CSF) allowing differential diagnosis of AD from FTD patients and from healthy controls.
Methods: A multiplex panel of four biomarker candidates, namely glial fibrillary acidic protein (GFAP), neurofilament light chain (NfL), total tau (TAU) and ubiquitin carboxyl-terminal hydrolase L1 (UCH-L1) have been analyzed using the ultrasensitive single-molecule array (SIMOA) assay. To identify biomarker differences between CSF samples from a cohort of 43 AD, 33 FTD and 60 Control patients, Principal of sparse Partial Least Squares – Discriminant Analysis (sPLS-DA) was used.
Results: We observed that in CSF samples all four biomarkers were significantly elevated in AD patients compared to control samples. Receiver operating characteristic (ROC) curve analysis resulted in a very good diagnostic accuracy as indicated by the area under the curve (AUC) values of 0.71-0.94 & $p \leq 0.0003$. We also observed that CSF-NfL, CSF-TAU & CSF-UCH-L1 were significantly elevated in FTD patients compared to controls, with an AUC of 0.72-0.91 & $p \leq 0.0006$. Finally, we also noticed an increase on CSF-GFAP and CSF-TAU in AD compared to FTD patients, with an AUC of 0.7- 0.8 and $p \leq 0.004$.
Conclusions: Our study suggests that NfL, TAU and UCH-L1 could evolve into useful biomarkers to discriminate between AD or FTD and healthy individuals, while GFAP and TAU could be used for differential diagnosis between AD and FTD patients.

PLASMA PHOSPHORYLATED TAU 217 AS AN EARLY BIOMARKER FOR ALZHEIMER'S DISEASE

POSTERS: B04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Maciej Dulewicz[1], Fernando Gonzalez-Ortiz[1], Przemyslaw Kac[1], Agnieszka Kulczńska-Przybik[2], Barbara Mroczko[2], Thomas Karikari[1], Michael Turton[3], Peter Harrison[3], Johannes Kornhuber[4], Jörg Hanrieder[1], Henrik Zetterberg[1], Kaj Blennow[1], Piotr Lewczuk[4]

Aims: The primary goal of this study is to investigate the diagnostic utility of measuring plasma and cerebrospinal fluid (CSF) pTau217 levels in identifying possible AD cases. This study intends to evaluate how effectively the concentrations of pTau217 in the blood and CSF can differentiate individuals with possible AD in comparison to the control group.
Methods: Plasma and CSF concentrations of pTau217 were measured by an in-house single molecule array (Simoa) developed at the University of Gothenburg (UGOT pTau217). The quantitative assessment of classical biomarkers (Aβ-42, Aβ-42/Aβ-40, Tau, and pTau181) in the CSF of patients with possible AD according to the Erlangen Score algorithm (ER 2 and 3) and controls (ER 0) were performed by Lumipulse.
Results: Significantly higher CSF and plasma concentrations of pTau217 were noticed in possible AD patients compared to controls. The levels of CSF pTau217 correlated positively with pTau217 in plasma and pTau181 and negatively with CSF Aβ1-42 and Aβ ratio. Similar results were observed for plasma levels of pTau217.
Conclusions: As new anti-Aβ therapies become available for AD, blood biomarker could be used to screen patients for treatment eligibility and monitoring. The results of the present study indicate that plasma pTau217 could be potentially a valuable blood biomarker for detecting early AD pathology.

MALDI-MS METHOD DEVELOPMENT TO DETECT PHOSPHORYLATED TAU FRAGMENTS IN CEREBROSPINAL FLUID

POSTERS: B04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Yusaku Hioki, Rie Yamamoto, Sadanori Sekiya, Shinichi Iwamoto, Koichi Tanaka
Shimadzu Corporation, Koichi Tanaka Mass Spectrometry Research Laboratory, Kyoto, Japan

Aims: Tau pathology in brain and increased total and phosphorylated tau concentrations in CSF are hallmarks of Alzheimer's disease (AD). In recent years, analytical methods that utilize mass spectrometry, which can measure multiple regions or phosphorylation site occupancies in tau, have been developed, and their performance as biomarker for AD has been reported. This study aims to develop a simple, robust, and reliable analytical method for tau and p-tau in CSF, taking advantage of the features of MALDI-MS.
Methods: Immunoprecipitation was carried out using monoclonal antibody HT7 or a combination of HT7 and BT2 to capture the mid-region of tau. Isolated and enriched tau fragments were then analyzed by MALDI-MS under matrix conditions that facilitate the detection of a hydrophilic group of peptides in the mid-domain.
Results: More than a dozen tau fragments were detected in 0.5 mL of CSF, including fragment that appeared to be multi-phosphorylated. In the case of additional trypsin digestion, MS/MS analysis of a possibly phosphorylated fragment showed a -98 peak, suggesting that it was phosphorylated. Further evaluation, including identification of fragments, is warranted.
Conclusions: Our simple analytical workflow combining immunoprecipitation with high recovery and MALDI-MS could be applicable to the analysis of tau fragments including phosphorylation in CSF.

NEW SITE-SPECIFIC PHOSPHO-TAU BIOMARKERS FOR ALZHEIMER'S EARLY DETECTION

POSTERS: B04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Bin Xu[1], Shih-Hsiu Wang[2], Ling Wu[2], Nailya Gilyazova[1], John Ervin[3]
[1]BRITE Research Institute of North Carolina Central University, Pharmaceutical Sciences, Durham, United States of America, [2]Duke University Medical Center, Pathology, Durham, United States of America, [3]Duke University Medical Center, Neurology, Durham, United States of America

Aims: Currently reliable biomarkers are lacking for detecting mild cognitive impairment (MCI), an early stage of Alzheimer's disease.
Methods: We developed a site-specific phospho-tau (p-tau) antibody screening approach that targets high-molecular-weight misfolded p-tau aggregates in brain. We screened a comprehensive set of p-tau epitopes targeting all major phosphorylation sites with high AD patient frequencies.
Results: Using postmortem AD dementia, MCI, and normal controls brains, we identified multiple new phospho-tau epitopes including p-tau396 and p-tau422 as new epitopes for differential detection of AD dementia and MCI. From quantitative ELISA, p-tau396 and p-tau422 were not only able to differentiate subjects with AD dementia from controls (AUC=0.983, $p<0.0001$ for p-tau396; AUC=1.000, $p<0.001$ for p-tau422), but was also able to differentiate subjects with MCI from controls with diagnostic performance (AUC=0.83, $p<0.05$ for p-tau396; AUC=0.91, $p<0.01$ for p-tau422) that are more sensitive/selective than comparison biomarkers p-tau181 (AUC=0.72, $p<0.05$), p-tau217 (AUC=0.75, $p<0.01$) and p-tau231 (AUC=0.58, $p=0.26$) in our study. We further validated our findigns with immunohistochemical staining of postmortem brain tissues with p-tau396 and p-tau422 antibodies. Both epitopes showed increased neurofibrillary tangle pathology in the hippocampus and temporal cortex of subjects with MCI. Image analysis using machine-learning algorithms reliably detected more severe tau burden in MCI brains versus cognitively normal controls, even among subjects with the same Braak stages.
Conclusions: Brain p-tau396 and p-tau422 levels strongly correlate with cognitive status in early AD. Our findings provide potential targets for MCI neuropathological staging and for developing novel fluid-based biomarker tests for early AD diagnosis.

BRAIN-DERIVED TAU OLIGOMERS IN PLASMA BRAIN-DERIVED EXTRACELLULAR VESICLES AS A POTENTIAL PREDICTIVE BIOMARKER FOR ALZHEIMER'S DISEASE.

POSTERS: B04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Michela Marcatti, Wen-Ru Zang, Rakez Kayed, Giulio Taglialatela
University of Texas Medical Branch, Neurology, Galveston, United States of America

Aims: Alzheimer's disease (AD) represents a pressing global healthcare issue; therefore, it is necessary to establish reliable predictive biomarkers to identify individuals at a high risk of developing AD, enabling the potential initiation of treatments during the preclinical stage. Our aim is to address this imperative by investigating plasma brain-derived extracellular vesicles (pl-BDEVs) and brain-derived tau oligomers (BDTOs) as potential biomarkers for early AD detection.
Methods: In this study, we employed plasma samples longitudinally collected from participants enrolled in the Texas Alzheimer's Research and Care Consortium (TARCC), who were initially cognitively normal or displayed mild cognitive impairment (MCI), and later either progressed to AD (termed "converters") or remained cognitively normal/MCI (termed "non-converters"). We enriched pl-BDEVs from central nervous system (CNS) cell types, including neurons, microglia, astrocytes, and oligodendrocytes. These isolated pl-BDEVs were subject to comprehensive analyses, such as nanoparticle tracking analysis for size, number, and distribution assessments, and western blotting to evaluate the expression of extracellular vesicles markers (CD63, CD9, CD81) and CNS cell type markers (L1CAM, TMEM119). Western blotting was also employed to detect the presence of BDTOs in pl-BDEVs.
Results: We successfully detected BDTOs in pl-BDEVs derived from MCI plasma samples and identified differences between converters (individuals who progressed to AD) and non-convertrs (individuals who remained cognitively stable).
Conclusions: Our study highlights BDTOs as potential indicators of AD pathology in plasma samples, underscoring their significance as a novel class of biomarkers. By exploring previously uncharted BDTO conformers in pl-BDEVs, we contribute to the quest for predictive AD biomarkers. Discovering distinct BDTOs conformers in peripheral BDEVs holds promise for enhancing preclinical forecasting and advancing early-stage AD treatments.

DEVELOPMENT OF NULISA™ CNS DISEASE PANEL FOR COMPREHENSIVE PROTEOMIC PROFILING OF NEURODEGENERATIVE DISEASES

POSTERS: B04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Xiao-Jun Ma, Shweta Iyengar, Shalaka Deshmukh, Sean Kim, Xiaomei Xu, Wei Feng, Xiaolei Qiu, Bingqing Zhang, Yuling Luo
Alamar Biosciences, LLC, Research And Development, Fremont, United States of America

Aims: Objectives: The pursuit of blood biomarkers for neurodegenerative diseases (NDDs) has been hampered by the lack of a proteomic tool with the required sensitivity to detect exceedingly low levels of brain-derived proteins in blood. We recently developed a novel proteomic technology called NULISA™ with attomolar sensitivity and high multiplexing in a fully automated system. In this study, we developed the NULISA CNS disease panel, a highly multiplexed assay designed to characterize key hallmarks of NDDs in blood and cerebrospinal fluid (CSF). We evaluated the performance of this panel in plasma and CSF samples from NDD patients and healthy controls.
Methods: Methods: A 120-plex NULISA including known disease markers such as neurofilament light, synuclein A and phosphorylated Tau (p-Tau181, p-Tau217, and p-Tau231) was developed and used to analyze plasma (n=38) and CSF (n=29) samples from NDD patients and age-matched controls. Target detectability and assay precision were assessed, and linear regression analysis was performed for each target for differential abundance between disease and controls.
Results: Results: We developed a CNS disease panel of 120 targets implicated in various pathways and processes characteristic of NDDs. Using 10 mL plasma or CSF, NULISA demonstrated high sensitivity detecting ~95% of the targets in plasma and ~80% in CSF and high precision with a median CV of ~6.0%. Linear regression analysis identified both known and novel proteins with significant differences in abundance between disease and age-matched controls.
Conclusions: Conclusion: We developed a comprehensive CNS disease-targeted panel for the NULISA platform to address the growing demand for blood-based biomarker discovery and validation. This study demonstrated the potential of the NULISA CNS disease panel to advance research in blood-based biomarkers for early neurodegenerative disease detection and monitoring and eventually therapeutic intervention.

STRATIFICATION OF PARKINSON SYNDROMES BY EXOSOME TAU PROTEIN PROFILING

POSTERS: B04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Mojtaba Nemati, Günter Höglinger, Franziska Hopfner
LMU hospital, Department Of Neurology, München, Germany

Aims: We aimed to explore the molecular profile of neuronal exosomes from different Parkinson's syndromes regarding their Tau protein profile.
Methods: Exosomes of neuronal origin were enriched through immunoprecipitation using the cell surface marker L1CAM. The Tau protein contents of the purified exosomes were then examined using ultrasensitive SIngle MOlecule Array (SIMOA) assays.
Results: The exosomes captured using L1CAM were confirmed to be positive for the neuronal markers.
The total Tau protein and Phosphorylated Tau protein contents of each exosome population were then compared to generate molecular profiles for the different Parkinson's syndromes.
Conclusions: Here we characterize the Tau protein and phosphorylated Tau protein contents of blood-derived exosomes from neuronal exosomes providing molecular profiles of different Parkinson's syndromes.

ALZHEIMER'S DISEASE BIOLOGICAL AND CLINICAL STAGES CORRELATION IN A REAL-WORLD MEMORY CLINIC POPULATION

POSTERS: B04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Marina Scop Medeiros[1], Pamela Lukasewicz Ferreira[2], Bruna Bellaver[2], Hussein Zalzale[2], Guilherme Povala[2], Guilherme Negrini[2], Francieli Rohden[2], Markley Silva Oliveira Junior[3], Sarah Abbas[4], Firoza Lussier[5], Helmet Karim[2], Chang Hyung Hong[6], Hyun Rho[6], Sang Son[6], Tharick A Pascoal[7]
[1]University of Pittsburgh, Psychiatry, Pittsburgh, Brazil, [2]University of Pittsburgh, Psychiatry, PITTSBURGH, United States of America, [3]University of Pittsburgh, Department Of Psychiatry, Pittsburgh, United States of America, [4]3501 Forbes Avenue, Psychiatry, Pittsburgh, United States of America, [5]University of Pittsburgh, Psychiatry, Pittsburgh, United States of America, [6]Ajou University School of Medicine, Psychiatry, Suwon, Korea, Republic of, [7]Department of Neurology and Psychiatry, University Of Pittsburgh School Of Medicine, Pittsburgh, United States of America

Aims: To investigate whether a 4-level biological staging system involving amyloid-beta (AB) PET, plasma GFAP, plasma p-tau217 and plasma NfL correlates with clinical stages as measured by Global Deterioration Scale (GDS) in patients with Alzheimer's Disease (AD) from South Korean memory clinics.
Methods: We assessed data from BICWALTZS, a cohort composed of multiple memory clinics. Biological stages were defined as exclusively AB PET positive (stage 1), additional presence of elevated plasma GFAP (stage 2), additional elevated plasma p-tau-217 (stage 3) and additional elevated plasma NfL (stage 4). Classification and cut-off points are shown in Table1. For clinical staging, we used the GDS, ranging from 1 (Preclinical) to 7 (very severe cognitive decline), as described in Table2.

Biological Stages	1	2	3	4
Biomarker	Aβ PET only	Additional Plasma GFAP	Additional Plasma P-tau217	Additional NFL
Cut-off	Visual interpretation	192.68pg/mL *	0.23pg/mL*	36pg/mL *

Table1. Classification criteria for biological stages. * Cut-off points were determined as two standard deviations (SD) above the mean of cognitively unimpaired AB-negative individuals.

1	2	3	4	5	6	7
No cognitive decline	Very mild cognitive decline	Mild cognitive decline	Moderate cognitive decline	Moderately severe cognitive decline	Severe cognitive decline	Very severe cognitive decline

Table2. Classification criteria for clinical stages according to Global Deterioration Scale (GDS).

Results: Of the total clinical population (N=1359), 230 patients were AB-PET positive and clinically diagnosed with subjective memory decline or MCI (n=109) or AD (n=121). The distribution of clinical cases across biological stages is represented in Figure 1. The figure demonstrates an increase in later clinical stages (mainly stages 4 and 5) in later biological stages. Biological stages were able to predict clinical stages, even controlling for age, sex, APOE status and years of education (R=0.2486, P=< 2e-16).

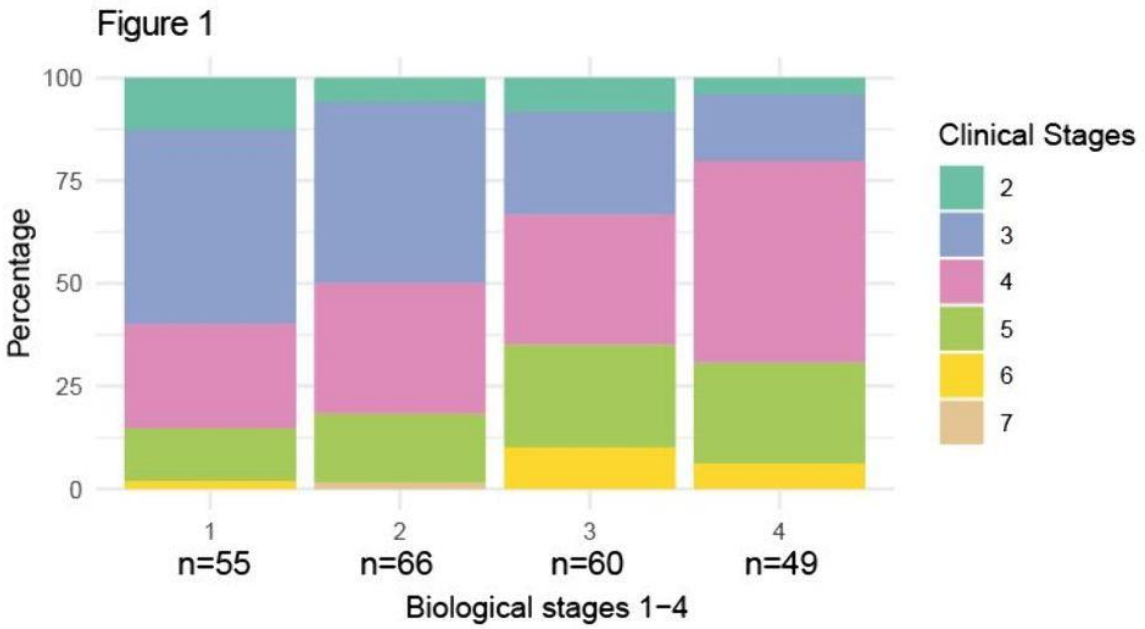

Figure1. Distribution in percentages of clinical stages across biological stages in the BICWALTZS memory clinic cohort. Biological and clinical stages are described in Table1 and Table2.

Conclusions: Fluid biomarkers may serve as proxy of higher clinical burden of AD pathology, even in the absence of Tau PET for biological staging, which is less accessible although required in the latest NIA-AA criteria (as of July 2023 – draft). Importantly, we demonstrated that creating a biological staging system based on fluid biomarkers may better characterize the disease in real-world large populations. More studies are needed to assess the prognostic value of these fluid biomarkers.

A PERIPHERAL CANDIDATE MICRORNA PROFILE FOR EARLY DIAGNOSIS OF SPORADIC ALZHEIMER'S DISEASE

POSTERS: B04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Maria Tsamou[1], Faidra Kalligerou[2], Eva Ntanasi[2], Nikolaos Scarmeas[2], Susanna Skalicky[3], Matthias Hackl[3], Erwin Roggen[1]

Aims: Late-onset or sporadic Alzheimer's disease (sAD) is a progressive, neurodegenerative, and age-related disease, leading to irreversible brain damage along with cognitive impairment and memory loss. The underlying pathological changes take place several years prior to the appearance of the first clinical symptoms, however, due to the disease's complexity, the diagnosis of sAD at the preclinical stage remains poor and inaccurate. The aim was to identify changes in circulating microRNA (miR) expression to detect early biomarkers of underlying sAD pathology.
Methods: A set of candidate miRs, earlier detected in biofluids from subjects at early stage of sAD compared to cognitively healthy controls, was retrieved from available publicly data, and was linked to processes described by the recently proposed Tau-driven adverse outcome pathway (AOP) for memory loss. Quantitative RT-PCR was used to measure the relative expression of the selected miRs in serum samples of 12 cases (mild cognitive impairment (MCI)) and 29 healthy controls (HC), recruited within the ongoing Aiginition Longitudinal Biomarker Investigation Of Neurodegeneration (ALBION) cohort study. Data on the protein levels of amyloid-β ($A\beta_{42}$), total and phosphorylated Tau (t-tau and p-tau), in cerebrospinal fluid (CSF) as well as the cognitive z-scores of the participants were also retrieved.
Results: Each doubling in the relative expression of 13 miRs in serum was associated with changes in the odds of having MCI (vs HC) or having pathological proteins ($A\beta_{42}$, t-tau and p-tau) in their CSF, or with the global composite z-score.
Conclusions: These candidate human circulating miRs may be of great importance in early diagnosis of sAD. There is an urgent need for confirming these proposed early predictive biomarkers for sAD, which can further contribute not only to societal but also to economic benefits.

Aims: Alzheimer's disease (AD) is the most common irreversible neurodegenerative disorder of the elderly. Its clinical diagnosis can be confirmed with expensive and invasive laboratory exams. Thus, new biomarkers and diagnostic tools to facilitate the proper management of patients are required. With the aim to identify new biomarkers for AD, we characterized the expression of multiple plasmatic Extracellular Vesicles (EVs) surface markers, related to immune response and inflammation. Indeed, emerging evidence suggests a central role of inflammation in the development and pathogenesis of AD.
Methods: Thirty confirmed AD patients, among which 7 with mild cognitive impairment (MCI) and 23 with moderate-severe dementia, and 20 healthy controls (HC) were enrolled. Patients underwent clinical evaluation, cerebrospinal fluid Aβ and Tau analysis, and magnetic resonance imaging (MRI). All subjects underwent blood collection. Plasma-derived EVs were analyzed by flow cytometry to measure the expression of 37 EV surface markers.
Results: AD-derived EVs showed higher CD62P and lower CD2 expression compared to those from HC. CD62P was associated with AD diagnosis, displaying good diagnostic performance, correlating with cognitive impairment, and showing higher expression in AD patients with pathological levels of Aβ42 in the CSF. These results were re-confirmed considering the moderate-severe patients only. In addition, CD41b was found increased in MCI subjects compared to both HC and severe AD showing reliable diagnostic performance for the MCI group.
Conclusions: Plasmatic EV surface markers characterization reinforces the role of EVs as promising biomarkers for AD, opening the possibility of developing non-invasive diagnostic tools.

Aims: Confirming amyloid pathology in the brain is necessary for determining the eligibility for Alzheimer's disease treatment with disease-modifying therapeutics. Blood-based biomarkers have attracted attention for invasiveness and accessibility, including the plasma β-amyloid1-40, 1-42 ratio (Aβ42/40) and phosphorylated tau (p-tau). We have previously shown that plasma Aβ42/40 measured by an Automated Immunoassay System HISCL™-5000 / HISCL-800 can predict amyloid pathology with high accuracy. In this study, clinical performance was evaluated in combination with prototype p-tau181 assay to investigate the additional potential of blood biomarkers in predicting amyloid pathology.
Methods: Plasma Aβ42/40 and p-tau181 were measured in 25 samples collected at Tokyo Metropolitan Geriatric Hospital and Institute of gerontology to assess their ability to predict amyloid pathology. Amyloid pathology in the brain was determined by amyloid PET scans as assessed by visual read method. The distribution of each biomarker level in the PET-positive and PET-negative groups was compared by Mann-Whitney U test. The predictive performance of amyloid pathology was evaluated by ROC analysis.
Results: The samples were classified into 8 amyloid PET positive and 17 negative groups. Both Aβ42/40 and p-tau181 showed significant differences between two groups ($p<0.005$, $p<0.05$, respectively). Furthermore, ROC analysis showed that the area under the curve (AUC) value was increased when combining p-tau181 with Aβ42/40 (AUC: 0.890) compared to Aβ42/40 alone (AUC: 0.857).
Conclusions: Our study has demonstrated that the plasma p-tau181 assay increased the predictive accuracy of plasma Aβ42/40 for amyloid PET status. In the future, we would increase the number of clinical samples to confirm the reliability of this specific combination. Through the expanding of our research, our goal is to contribute to the advancement of AD diagnosis using blood-based biomarkers.

HIGH BURDENS OF PHOSPHORYLATED TAU PROTEIN AND DISTINCT PRECUNEUS ATROPHY IN SPORADIC EARLY-ONSET ALZHEIMER'S DISEASE

POSTERS: B04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Xinyi Lv[1], Yong Shen[1], Jiong Shi[2]
[1]The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, Department Of Neurology, Hefei, China, [2]The FirsAffiliated Hospital of USTC, Department Of Neurology, HeiFei, China

Aims: Early onset Alzheimer's disease (EOAD) is a rare but devastating sub-classification of AD. We selected patients who had an age of onset younger than 65 years. Most of these patients did not have a family history of dementia.The objective of this study was to gather additional evidence regarding the clinical characteristics and potential underlying mechanisms of sEOAD within the population.
Methods: sEOAD (n=110), late onset AD (LOAD, n=89), young controls (YC, n= 50), and old controls (OC, n=25). Fluid biomarkers were measured with single molecule array, including cerebrospinal fluid (CSF) and plasma Aβ42, Aβ40, P-tau181, T-tau, serum NfL, and GFAP.
Results: We found sEOAD patients exhibited more severe executive function impairment and bilateral precuneus atrophy (p< 0.05, FWE corrected) compared with LOAD patients. sEOAD patients showed elevated CSF and plasma P-tau181 levels (153 ±81.2 pg/ml, p= 0.002; 6.08± 2.26 pg/ml, p= 0.046 respectively). Furthermore, a significant correlation was observed between precuneus atrophy and serum GFAP levels in the sEOAD group (p< 0.001). Serum GFAP levels (AUC= 96.0%, cutoff value= 154.3 pg/ml) showed excellent diagnostic value in distinguishing sEOAD patients from the control group. These preliminary findings highlighted the crucial role of tau protein phosphorylation in the pathogenesis and progression of sEOAD.
Conclusions: Our cohort study found that while sEOAD patients did not exhibit specific risk factors compared to LOAD patients, they did present with more severe executive function deficits, higher tau burden, and more severe precuneus atrophy. Given the age of onset, greater caution may be necessary in the design and selection of tau-targeted treatment trials.Moreover, it is also worth mentioning that brain function treatments targeting the precuneus and addressing tau pathology may hold promise for

improving outcomes in sEOAD patients.

Aims: One characteristic hallmark observed in the brain during aging and Parkinson's disease (PD) is the neuronal accumulation of iron and other toxic metals in substantia nigra (SN) and locus coeruleus (LC), e.g., in the Neuromelanin (NM) organelle (having melanin, lipid and protein-based partitions of less than 100 nm). However, few studies attempted high lateral resolution subcellular (re)distribution analyses of these metals. Therefore, this work aims to study metal distributions in NM of LC using novel analytical approaches based on secondary ion mass spectrometry (SIMS) and to correlate the changes with the onset of PD.
Methods: Epon-embedded or fresh frozen human LC from elderly and PD patients were investigated by light, fluorescence and electron microscopy for high resolution imaging and immunohistochemistry, and the chemical analysis was performed by analytical electron microscopy and mass spectrometric imaging (MSI).
Results: We present first results for the chemical identification of sub-organellar NM metal storage sites in LC. The semi-quantitative SIMS data shows higher accumulation of iron in NM in comparison to the cytoplasmic and other cellular compartments, without accumulation of copper or zinc in LC as compared to previous analysis on SN NM. Additional immunohistochemistry shows the molecular profiling of LC NM with a comparison between PD and non-PD patients.
Conclusions: We analysed the sub-cellular localization of metals in elderly patients using novel high-resolution chemical and structural imaging techniques in addition to the molecular profiling. Continued work will be done on fresh frozen samples of PD specimen for a better close to native analysis of PD pathophysiology also including molecular MSI.

Aims: Mild cognitive impairment (MCI) is a potential therapeutic window in the prevention of dementia; however, automated detection of early cognitive deterioration is an unresolved issue. The aim of our study was to compare various classification approaches to differentiate MCI patients from healthy controls, based on rs-fMRI data, using machine learning algorithms.
Methods: A local database was used from two independent institutions. Three fMRI parameters were used in five feature selection algorithms: Local Correlation, Intrinsic Connectivity, and Fractional Amplitude of Low Frequency Fluctuations. Support Vector Machine (SVM) and Random Forrest (RF) methods were applied for classification. Intracalcarine cortex, Superior Parietal lobule, Superior Frontal gyrus, Supracalcarine Cortex, Inferior Temporal gyrus and Precentral Gyrus were identified via feature selection algorithms as the most relevant features.
Results: We achieved a relatively wide range of 78-87% accuracy for the various feature selection methods with SVM combining the three rs-fMRI parameters. RF provided a more harmonized result among the feature selection algorithms with 80-84% accuracy.
Conclusions: Our results suggest that the combination of various fMRI parameters is needed for precise automated detection of MCI. Since feature selection algorithms can highly influence the final accuracy of the detection algorithm, RF classification method seems to be superior. Our results highlight the potential of ML- based fMRI applications for automated diagnostic techniques to distinguish MCI patients from healthy subjects.

Aims: Alzheimer's disease (AD) is a neurodegenerative disease characterized by the progressive impairment of behavioral and cognitive functions. Neurofibrillary tangles (NFTs), composed of hyperphosphorylated tau protein, are established hall-marks of the pathology and Alzheimer's disease progression. Developing a therapeutic strategy based on the selective detection of NFTs in the retina is a promising diagnostic tool for early detection of AD. In this study we describe development of highly specific tau fluorophores, such as BT-1, for selective detection of pathological forms of tau protein and the use of cell permeant peptides (CPP) nanocage to deliver BT-1 to hiPSC-derived retinal neurons and in and postmortem samples of AD patients' retina.
Methods: BT-1 fluorophore (Soloperto et al., 2021) is a BODIPY-based fluorescent probe developed to bind hyperphorylated and oligomeric tau. The fluorescent probe BT-1 was delivered to retinal cells and in retinal tissues using CCP, natural nanocages capable of encapsulating small molecules.
Results: The results showed the effective internalization of the Nanocage-BT-1 complex into living retinal neurons, exhibited low toxicity. Moreover, has been shown the ability of NC-BT-1 complex to bind hyperphosphorylated and oligomeric tau in iPSC derived retinal cells as well as in postmortem retina of AD patients.
Conclusions: We demonstrated the ability of CPP nanocages loaded with the fluorescent probe BT-1 to detect NFTs in hiPSC derived retinal cells and AD retinal slices, developed a promising method for the early diagnosis of AD.

MOVEMENT DISORDER (MD) IN FRONTOTEMPORAL LOBAR DEGENERATION (FTLD) DUE TO TAUOPATHY

POSTERS: B04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC & BEHAVIORAL TESTS, DIGITAL ENDPOINTS, REMOTE TESTING

Manisha Narasimhan[1], David Foxe[1,2], Rebekah Ahmed[1,3], Olivier Piguet[1,2]

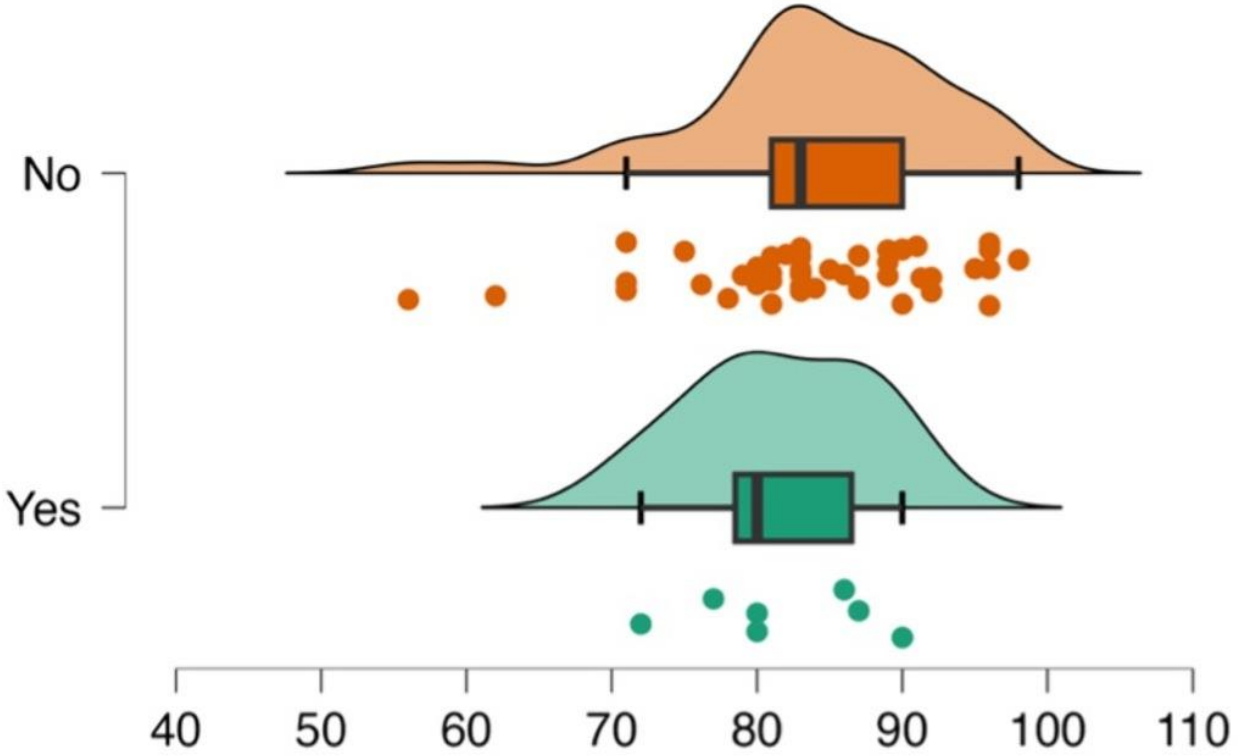
Aims: Frontotemporal Lobar Degenerations (FTLDs) are clinically, pathologically and genetically heterogenous disorders involving frontal and temporal lobes and causing a wide range of clinical disease. Movement disorder (MD) phenomenology in FTLD due to Tauopathy is reported but not well understood. We studied the prevalence and neuropsychological profile of MD on initial presentation of behavioural-variant Frontotemporal Dementia (bvFTD), Progressive Supranuclear Palsy (PSP), Corticobasal Syndrome (CBS) and Progressive Non-Fluent Aphasia (PNFA).
Methods: A total of 273 patients were included from the FRONTIER Research Clinic database between 2008 and 2020. Patients underwent comprehensive neurological and neuropsychological assessment. Presence of MD was recorded on initial presentation. Patients were assessed on the Addenbrooke's Cognitive Examination (ACE) and seven cognitive domains of attention, verbal memory, visual memory, language, visuospatial function, executive function and social cognition. Composite measures were developed.
Results: Of 273 patients, 78 (29%) had MD on initial presentation. Movement disorder was noted in 15/150 (10%) of bvFTD, 7/45 (15.56%) of PNFA, 16/25 (64%) of PSP, 36/41 (87.8%) of CBS and 4/12 (33.33%) of CBS-PNFA patients. Total ACE scores were higher in the group without MD *(p=0.05)* as depicted in **Figure 1**. Patients with MD had lower scores across all cognitive domains, significantly for attention *(p=0.02)* and visuospatial function *(p=0.02*). **Figure 1 Total ACE scores in FTLD-MD vs FTLD-noMD**



Conclusions: This study demonstrates overlap between cognitive, language and motor FTLD-phenotypes. On initial presentation, patients with behavioural and language syndromes had MD, seen in 10% of bvFTD and 15.6% of PNFA. Conversely 36% of PSP and 12.2% of CBS patients did not present with MD. Identification of MD may be important in early disease identification and predicting prognosis. Neuropsychological testing may provide an effective way of profiling clinical FTLD subtypes.

A NOVEL DIAGNOSTIC METHOD FOR ALZHEIMER TAU PATHOLOGY BASED ON SEEDED AMPLIFICATION AND ULTRA-SENSITIVE QUANTIFICATION OF IN VIVO AGGREGATES.

POSTERS: B04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Md Tohidul Islam, Thomas Karikari, Kaj Blennow
University of Gothenburg, Psychiatry And Neurochemistry, Göteborg, Sweden

Aims: Aggregated tau is a crucial pathophysiological indicator in various neurodegenerative diseases, but accurately quantifying tau aggregates remains challenging due to low abundance. Our research aims to pioneer a novel approach for the amplification and quantification of minute amounts of aggregated human tau protein, focusing on a specific domain crucial for disease pathology.
Methods: Our innovation incorporates cutting-edge methodologies and customized reagents to selectively amplify aggregated tau protein, specifically targeting the pathological domain. The amplification step covers generating recombinant tau aggregates using monomeric recombinant tau proteins, which enhances the detection sensitivity of tau aggregates, allowing for their precise quantification. Following amplification, we employ Single Molecule Array (Simoa)assay, an immunoassay employing high-affinity antibodies to quantify tau aggregates in CSF samples, ensuring accuracy and reliability. The immunoassay is designed to be adaptable for the evaluation of blood plasma and serum, thus broadening its clinical utility.
Results: Our initial findings are exceptionally promising, demonstrating the successful amplification of minute amounts of aggregated tau protein. This has led to a substantial enhancement in the detectability of tau aggregates, offering enhanced sensitivity compared to existing techniques. Moreover, the immunoassay has demonstrated exceptional precision and specificity in quantifying tau aggregates in CSF samples. These preliminary findings verify the potential of our approach as a revolutionary tool for early neurodegenerative disease diagnosis and monitoring. In the current application, we propose to perform further analytical and clinical validation of the assay towards establishing its context of use.
Conclusions: The proposed method offers clinical significance by pioneering a novel approach to sensitively amplify and quantify aggregated human tau protein, targeting a critical disease-related domain. This approach holds immense value for clinical studies and clinical trials, allowing for the precise monitoring of treatment responses.

IMPAIRED MELANOPSIN ACTIVITY IN PARKINSON'S VS. ALZHEIMER'S DISEASE

POSTERS: B04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Oliver Steiner[1], Jan De Zeeuw[2]
[1]Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Campus Benjamin Franklin (CBF), 3. motor And Cognition Group, Department Of Neurology, Berlin, Germany, [2]Charité –Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Sleep Research & Clinical Chronobiology, Institute Of Physiology, Berlin, Germany

Aims: The eye, as an extension of the brain, provides a window into neurodegenerative processes. Yet, neurodegenerative diseases exhibit shared retinal abnormalities, for example, in the retinal ganglion cells (RGCs). Chromatic pupillometry enables in vivo evaluation of the functional integrity of melanopsin-expressing RGCs. This meta-analysis examines chromatic pupillometry data from Alzheimer's disease (AD) and Parkinson's disease (PD) to assess the functional state of mRGCs across neurodegeneration.
Methods: We conducted a literature search on PubMed and Scopus spanning 1991 to August 2023. We analyzed chromatic pupillometry parameters including baseline pupil size (BPS), transient peak amplitude (showcasing rods and cones' activity), and post-illumination pupil response (PIPR) from red and blue light stimuli—with blue PIPR denoting melanopsin function. Using fixed and random effects models, these parameters were compared across AD patients (n = 42; 2 studies), PD (n = 66; 3 studies), and healthy controls (n = 91).
Results: Relative to controls, PD patients demonstrated a marked decrease in melanopsin-mediated blue PIPR (weighted mean difference (WMD) = -9.14, 95% CI: -14.19 to -4.08, $p < 0.001$). For both blue and red light stimuli, no significant differences were observed in BPS or transient peak amplitude in PD patients ($p>0.05$). For AD patients, neither the PIPR nor transient peak amplitude for blue or red light revealed significant deviations when compared to controls.
Conclusions: The results delineate disease-specific photoreceptor dysfunctions in neurodegeneration: While the rods and cones system seem intact in both conditions, the integrity of the melanopsin system might be in specific relation to PD pathology. Thus, functional analysis is a promising strategy to increase the discriminative validity of structural retinal modeling and might help to tailor interventional strategies targeting the melanopsin system.

Aims: Free-water diffusion (FWD), a diffusion MRI metric, is a non-specific marker of neuroinflammation. Given previous research implicating neuroinflammation in the pathogenesis of neurodegenerative diseases (NDs), we examined the relationship between FWD and biofluid markers for neuroinflammation and neurodegeneration across NDs.
Methods: We generated FWD maps in 367 subjects (108 AD/MCI, 37 ALS, 42 FTD, 122 PD, 58 VCI) using diffusion and structural MRI data from the ONDRI cohort. Plasma glial fibrillary acidic protein (GFAP) and neurofilament light (NfL) concentrations were measured using Simoa Human N4PE assay. Recursive Feature Elimination (RFE) was implemented on regional FWD to identify which ROIs are the most important features in relation to GFAP or NfL, and utilized a deep learning model to determine if selected features better predict GFAP or NfL.
Results: Across NDs, FWD is correlated with GFAP (Left Cortical-GM; R=0.2, p=0.0001, Right Cortical-GM; R=0.18, p=0.0002) but not NfL. RFE revealed that the middle frontal, superior temporal and parahippocampal gyri, temporal pole, and lateral occipital cortex are the most important features to predict GFAP, whereas the frontal pole, superior parietal lobule, and left cerebral white matter are the most important features to predict NfL. A deep learning model was used to predict GFAP or NfL concentration using selected features along with group, plasma-pTau^{181}, age, sex, and ethnicity. A data split of 80% for training and 20% for testing were employed to develop/evaluate our model. The selected features predict GFAP (R_{train}=0.89, R_{test}=0.83) more strongly that NfL (R_{train}=0.72, R_{test}=0.42).
Conclusions: FWD is more related to astrogliosis than neuro-axonal damage. RFE allowed for the generation of a model including regional FWD, demographic and AD biomarkers, that predicted GFAP better than NfL. FWD may be a useful neuroinflammatory marker in NDs.

DEVELOPMENT OF A "REAL-TIME QUAKING-INDUCED CONVERSION" (RT-QUIC) ASSAY FOR DETECTION OF MISFOLDED TAU PROTEIN AFTER IMMUNOPRECIPITATION-ENRICHMENT FROM PATIENT PLASMA

POSTERS: B04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Samuel Uhlig[1], Max Holzer[2], Isabel Hilbrich[2], Jens Stieler[2], Ingolf Lachmann[3], Thomas Arendt[2], Katharina Waniek[3], Jakob Hasler[1]

Aims: Alzheimer's disease and related tauopathies are characterized by the presence of abnormal tau protein aggregates in the central nervous system. Detecting misfolded tau protein before symptomatic onset is crucial for effective intervention. Currently, diagnosis relies on PET-Scan or invasive procedures like cerebrospinal fluid analysis, which are only feasible when cognitive symptoms are manifest. Our research aims to adapt the "real-time quaking-induced conversion" (RT-QuIC) assay, initially designed for brain and cerebrospinal fluid samples, to detect tau aggregates in blood plasma.
Methods: In our study, we determined the influence of various buffer ions following the Hofmeister series to enhance RT-QuIC sensitivity. Furthermore, different Tau fragments were assessed for their suitability as seeding agents.
Immunoprecipitation (IP) was employed to enrich tau protein in patient sera and to eliminate matrix effects from blood proteins. Two IP elution methods, boiling and pH adjustment, were tested for efficient recovery of tau fragments, addressing the challenge of low picogram per milliliter (pg/ml) tau content in blood.
Results: Standardized conditions were developed to enhance assay sensitivity and reliability for the early detection of tau aggregates such as sodium citrate buffer and dextran sulfate. Currently, we are using the recombinant tau protein fragment K12CFh for RT-QuIC assay, offering more sensitivity than the dGAE tau fragment. Preliminary results show a significant inverse correlation between lag time of seeded aggregation using plasma samples and the corresponding CSF tau concentration.
Conclusions: In summary, our work focused on refining the RT-QuIC assay for the early detection of tau aggregates in blood plasma. Through standardization and the use of recombinant tau protein fragment K12CFh, our goal is to enable a less invasive means of diagnosing tauopathies prior to symptomatic presentation.

ACOUSTIC AND OTHER CORRELATES OF REDUCED WORDS PER BREATH GROUP IN PRIMARY PROGRESSIVE APRAXIA OF SPEECH

POSTERS: B04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Rene Utianski, Joseph Duffy, Gabriela Meade, Heather Clark, Kennedy Josephs, Hugo Botha, Jennifer Whitwell, Keith Josephs
Mayo Clinic, Neurology, Rochester, United States of America

Aims: Primary Progressive Apraxia of Speech (PPAOS) is a neurodegenerative syndrome that manifests as disruptions of motor speech planning/programming. In connected speech, some patients produce fewer syllables per breath than might be expected from their observed respiratory support. To date, no investigations have explored the relationship between this subjectively identified feature and acoustic measurements of syllables per breath group, which is the goal of this study.
Methods: Data were collected from 46 patients with PPAOS. As a part of the speech evaluation, alternating motion rates (AMRs) were recorded to evaluate the ability to perform rapid and accurate repetitions of sounds ("puh," "tuh," and "kuh") on a single breath. The Apraxia of Speech Rating Scale (ASRS-3), which indexes the presence and severity of speech characteristics, including articulatory (sound distortions, distorted sound additions and substitutions) and prosodic (sound prolongations, between and within word segmentation, and slow rate) disruptions, was also scored. Spearman correlations, with adjusted values, were calculated between a subjective ratings of syllables per breath group (where 0=8+ and 4=1-2) and 1) other ASRS features and 2) the mean number of syllables produced in one breath across the AMR tasks.
Results: Reduced words per breath group ratings were inversely associated with the mean number of syllables produced in the AMR task (-0.61) and positively with the overall severity of ASRS (.55), with a trend for the prosodic speech features.
Conclusions: These results suggest subjective judgments of reduced words per breath group in conversation track with acoustic measurements of this feature in AMRs, either of which may serve as a biomarker of PPAOS and facilitate earlier identification. Future studies will explore data-driven analysis of this feature and the sensitivity and specificity of subjective versus objective measures.

MAPT EXPRESSION IS MEDIATED BY LONG-RANGE INTERACTIONS WITH CIS-REGULATORY ELEMENTS

POSTERS: B05.I. GENETICS, EPIDEMIOLOGY: OTHER

Brianne Rogers[1], Ashlyn Anderson[2], Shelby Lauzon[1], Natalie Davis[2], Rebecca Hauser[1], Sydney Roberts[1], Ivan Rodriguez-Nunez[2], Katie Trausch-Lowther[2], Erin Barinaga[1], Paige Hall[2], Jared Taylor[1], Mark Mackiewicz[2], Brian Roberts[2], Sara Cooper[3], Lindsay Rizzardi[2], Richard Myers[2], J. Nicholas Cochran[1]

Aims: *MAPT* expression is absent in neural progenitor cells (NPCs) and increases during differentiation. This temporally dynamic expression pattern suggests that *MAPT* expression is controlled by transcription factors and *cis*-regulatory elements specific to differentiated cell types. Given the relevance of *MAPT* expression to neurodegeneration pathogenesis, identification of such elements is relevant to understanding disease risk and pathogenesis.
Methods: We performed HiC, chromatin conformation capture (Capture-C), single-nucleus multiomics (RNA-seq+ATAC-seq), bulk ATAC-seq, and ChIP-seq for H3K27Ac and CTCF in NPCs and neurons differentiated from human iPSC cultures. We nominated candidate *cis*-regulatory elements (cCREs) for *MAPT* in human NPCs, differentiated neurons, and pure cultures of inhibitory and excitatory neurons. We then assayed these cCREs using luciferase assays and CRISPR interference (CRISPRi) experiments to measure their effects on *MAPT* expression. Finally, we integrated cCRE annotations into an analysis of genetic variation in AD cases and controls.
Results: We nominated 94 cCREs for *MAPT*, including the identification of cCREs specifically active in differentiated neurons. Eleven regions enhanced reporter gene transcription in luciferase assays. Using CRISPRi, 5 of the 94 regions tested were identified as necessary for *MAPT* expression. Rare and predicted damaging genetic variation in both nominated and confirmed CREs was depleted in AD cases relative to controls, consistent with the hypothesis that variants that disrupt *MAPT* enhancer activity, and thereby reduce *MAPT* expression, may be protective against neurodegenerative disease.
Conclusions: We identified both proximal and distal regulatory elements for *MAPT* and confirmed the regulatory function for several regions, including three regions centromeric to *MAPT* beyond the well-described H1/H2 haplotype inversion breakpoint. This study provides compelling evidence for pursuing detailed knowledge of CREs for genes of interest to permit better understanding of disease risk.

Aims: Increasing evidence indicates that physical activity may delay or prevent the onset of Alzheimer's disease (AD). *KLOTHO* KL-VS heterozygosity (KL-VS$_{HET}$) has also been associated with resilience against AD pathology. We examine whether there is a potential for synergy between the functionally advantageous KL-VS$_{HET}$ variant and aerobic fitness (measured via VO_2 max) on core cerebrospinal fluid (CSF) biomarkers for AD in a cognitively unimpaired, adult cohort enriched for AD risk.
Methods: Middle-aged and older adults (N=131; Mean$_{AGE}$=63) from the Wisconsin Registry for Alzheimer's Prevention and Wisconsin Alzheimer's Disease Research Center who were genotyped for *KLOTHO* and *APOE*, underwent CSF sampling, and had available VO_2 max data were included in analyses. General linear models, covarying for sex, age, parental history of AD, and *APOE*, examined whether *KLOTHO* modified the relationship between VO_2 max and core CSF biomarker levels (pTau, tTau, $A\beta_{42}/A\beta_{40}$, pTau/$A\beta_{42}$).
Results: For KL-VS non-carriers (KL-VS$_{NC}$) (N=89), CSF biomarker levels were similar across the range of VO_2 max values (p's>0.54). For KL-VS$_{HET}$ (N=42) however, those with higher VO_2 max had significantly lower levels of CSF tTau (p=0.03) and pTau (p=0.04) but not $A\beta_{42}/A\beta_{40}$ or pTau/$A\beta_{42}$ (p's>0.13).
Conclusions: Our present results suggest a synergistic benefit of being aerobically fit and heterozygous for KL-VS in relation to tau accumulation, suggesting potentially shared underlying biological mechanisms that need to be further investigated and elucidated.

[1]VIB Center for Molecular Neurology, Complex Genetics Of Alzheimer's Disease Group, Wilrijk, Belgium, [2]University of Antwerp, Department Of Biomedical Sciences, Wilrijk, Belgium, [3]KU Leuven, Laboratory For Neuropathology, Department Of Imaging And Pathology, And Leuven Brain Institute, Leuven, Belgium, [4]Martin-Luther-University Halle-Wittenberg, Department Of Neurology, Halle (Saale), Germany, [5]University Medical Center Göttingen, Devision Of Geriatrics, Göttingen, Germany, [6]VIB-KU Leuven, Laboratory For Neurobiology, Leuven, Belgium, [7]UZ Leuven, Department Of Neurology, Leuven, Belgium, [8]KU Leuven, Experimentele Neurologie, Leuven, Belgium, [9]University Hospital Leuven, Department Of Pathology, Leuven, Belgium

Aims: Alzheimer's disease is the leading cause of dementia worldwide. Besides neurofibrillary tangles and amyloid beta plaques, a wide range of co-morbid neuropathological features can be observed. Since AD has a very strong genetic background and displays a wide phenotypic heterogeneity, this study aims at investigating the genetic underpinnings of co-morbid and hallmark neuropathological lesions.
Methods: DNA was extracted from fresh frozen brain material of 351 individuals aged 55 or older. Genotyping data was collected for 49 single nucleotide polymorphisms (SNPs) known to be associated with AD using an in-house designed long read sequencing multiplex assay (Oxford Nanopore Technologies). Variants were tested for association with Braak NFT stage, TDP-LATE stage, Thal amyloid phase, CAA severity, Granulovacuolar degeneration stage, CERAD, NIA-AA score and Braak PD stage. Association testing was done using PLINK linear regression. Replication of significant associations was performed in the ROSMAP cohort for overlapping neuropathological phenotypes.
Results: Association testing revealed several nominally significant associations, but besides *APOE*, a SNP in exon 1 of *APH1B* was strongly associated with Braak NFT stages ($p=3.15*10^{-7}$), GVD stage ($p=0.0003$), CERAD score ($p=0.0002$), Thal amyloid phase ($p=0.0002$) and NIA-AA score ($p=1.48*10^{-5}$), all passing Bonferroni multiple testing correction. The SNP was also nominally associated with CAA severity ($p=0.005$). Association signals were corrected for age and sex and were independent of *APOE* genotype. These results were independently replicated in the ROSMAP cohort (n=1141) for Braak NFT score ($p=0.02$) and CERAD score ($p=0.004$).
Conclusions: Our results highlight the role of *APH1B* in several neuropathological phenotypes observed in AD. *APH1B* encodes a subunit of gamma-secretase, making it especially interesting that we find strong association with tangle-related pathologies. Future perspectives include functional validation to further unravel the downstream effects of the mutation.

EFFECTS OF THE AIS PROTEINS ANKYRIN G AND TRIM46 ON TAU SORTING

POSTERS: B06.A. CELL, MOLECULAR AND SYSTEMS BIOLOGY: TAU, TAU ISOFORMS

Daniel Adam[1], Michael Bell-Simons[1,2], Helen Breuer[1], Hans Zempel[1]
[1]Institute of Human Genetics, University Hospital Cologne, Center For Molecular Medicine Cologne (cmmc), Cologne, Germany, [2]Max-Planck-Gesellschaft, Max-planck-institute For Biology Of Ageing, Cologne, Germany

Aims: The somatodendritic, pathophysiological missorting of the axonal, microtubule-associated protein TAUau is one of the main hallmarks of Alzheimer's Disease. However, the main mechanism behind physiological, axonal sorting of TAUau remains elusive. The axon initial segment (AIS) and two of its major components, i.e., Ankyrin G (ANKG) and Tripartite motif-containing protein 46 (TRIM46) have been postulated as constituents of a physiological Tau diffusion barrier (TDB) located at the AIS in rodent *in-vitro* cell models, but human neurons is elusive.
Methods: Here we investigated the development of the AIS in human iPSC-derived neurons (iNs) and *MAPT*-KO iNs using western blot, qPCR and immunofluorescence. We established the knockdown of ANKG and TRIM46 in iNs using lentiviral transduction, expressed dendra2-tagged Tau in *MAPT*-KO iNs for pulse-chase life-tracking of TAU trafficking, and expressed BirA-fused to several deletion constructs of TAU to identify AIS-based interactors via mass-spectrometry.
Results: Our time course revealed accumulation of ANKG and TRIM46 to occur between days 5 and 21 after neuronal differentiation, serving as a baseline for knockdown to study TAU localization. We visualised Tau diffusion using photoconvertible dendra2, albeit poorly due to low brightness. Our BirA-Tau fusion proteins sort correctly, and biotinylation was demonstrated via WB and IF, pending proteomic analysis.
Conclusions: Our system allows tracking the TAU-diffusion, in future, we will employ mEosEM as photoconvertible tag. Knockdown of ANKG and TRIM46 will reveal if these proteins impact Tau sorting human neurons. The establishment of our BirA-Tau constructs will reveal new Tau interaction partners within the AIS when coupled with laser microdissection-assisted proteomic analysis of the AIS.

DEVELOPMENT OF A HUMAN IPSC-BASED FTD MODEL SHOWING ADVANCED TAUOPATHY PHENOTYPES

POSTERS: B06.A. CELL, MOLECULAR AND SYSTEMS BIOLOGY: TAU, TAU ISOFORMS

Angelika Dannert[1,2], Lea Knez[2], Martina Fetting[3,4], Dominik Paquet[2,4]
[1]LMU Munich, Graduate School For Systemic Neurosciences, Planegg-Martinsried, Germany, [2]University Hospital LMU Munich, Institute For Stroke And Dementia Research, Munich, Germany, [3]German Center for Neurodegenerative Diseases, Dzne Munich, Munich, Germany, [4]Munich Cluster for Systems Neurology, Synergy, Munich, Germany

Aims: Malfunction of the protein Tau is a hallmark of neurodegenerative Tauopathies such as Alzheimer's disease and Frontotemporal Dementia (FTD). In the healthy human brain, Tau expression and splicing are highly regulated and dys-regulation of the ratio between 3-repeat (3R) and 4R splice isoforms leads to FTD. To understand the relevance of Tau isoforms for disease, we aimed to create one of the first models that reproduces the adult human 1:1 splice ratio of 3R and 4R Tau and use it to recreate endogenous development of molecular Tauopathy hallmarks.
Methods: For this purpose, we developed a novel iPSC-based cortical neuron model that, as a default, expresses 3R and 4R Tau in the 1:1 ratio found in adult human neurons using a multi-step CRISPR/Cas9 genome editing strategy that alters endogenous Tau isoform expression from the genomic MAPT locus. To create a disease model, we further included disease-causing Tau mutations.
Results: 4R Tau expression in these cortical neurons was required to elicit strong and robust formation of late-stage Tau pathology in the presence of Tau mutations. In particular, these neurons endogenously accumulated seeding-competent, misfolded, fibrillar Tau in tangle-like structures inside the somata of affected neurons. Exclusive expression of mutant 4R Tau in the absence of 3R Tau disproportionately intensified pathology, resulting in abundant Tau misfolding and aggregation.
Conclusions: The generated human iPSC-derived neuronal model recapitulates the adult human 3R/4R Tau ratio and develops endogenous late-stage Tau pathology. We further demonstrated modulability of the phenotypes in a proof-of-principle drug screen. The presented model will thus provide a valuable experimental platform to study mechanistic disease processes and to complement drug screening efforts.

INTRON RETENTION AS A PRODUCTIVE MECHANISM IN HUMAN MAPT: RNA SPECIES GENERATED BY RETENTION OF INTRON 3

POSTERS: B06.A. CELL, MOLECULAR AND SYSTEMS BIOLOGY: TAU, TAU ISOFORMS

Vega García-Escudero[1], Daniel Ruiz-Gabarre[2], Laura Vallés Saiz[2], Almudena Carnero-Espejo[1], Isidro Ferrer[3], Félix Hernández[4], Ramón García-Escudero[5], Jesús Ávila[4]
[1]Universidad Autónoma de Madrid, Anatomy, Histology And Neuroscience, Madrid, Spain, [2]CBM Severo Ochoa, Molecular Neuropahtology, Madrid, Spain, [3]University of Barcelona, Department Of Pathology And Experimental Therapeutics, Barcelona, Spain, [4]Centro de Biología Molecular Severo Ochoa, Molecular Neuropathology, Madrid, Spain, [5]CIEMAT, Biomedical Oncology Unit, Madrid, Spain

Aims: Tau is a microtubule-binding protein encoded by the *MAPT* gen. Tau is essential for several physiological functions and associated with pathological processes, including Alzheimer's disease. Six tau isoforms are typically described in the central nervous system, but current research paints a more diverse landscape and a more nuanced balance between isoforms. Recent work has described tau isoforms generated by intron 11 and intron 12 retention. This work adds to that evidence, proving the existence of *MAPT* transcripts retaining intron 3. Our aim is to demonstrate the existence of mature *MAPT* RNA species that retain intron 3 in human brain samples and to study its correlation with Alzheimer's disease across different regions.
Methods: First evidence of intron-3-retaining *MAPT* species come from analysis of RNA-seq databases. We further demonstrate the existence of these mature RNA species in human neuroepithelioma cells and human brain samples by qPCR. We also use digital droplet PCR to demonstrate the existence of RNA species that retain either intron 3, intron 12 or both introns.
Results: Intron-3-retaining species are even more prominently present that intron-12-retaining ones. We show the presence of *MAPT* transcripts that retain both introns 3 and 12. Relative abundance of intron-3- or intron-12-retaining MAPT species are increased with respect to double-retaining species in patients with Alzheimer's disease, especially in hippocampal samples. Moreover, we find a significant increase in intron-3- or intron-12-retaining species and its relative abundance with respect to double-retaining *MAPT* species in cerebellum in contrast to frontal lateral cortex and hippocampus in individuals with no signs of dementia.
Conclusions: Intron retention constitutes a potential mechanism to generate Tau isoforms whose mature RNA expression levels correlate with Alzheimer's pathology showing its potential as a biomarker associated to the disease.

NUCLEAR LAMINA ALTERATIONS IN NEURONS AND GLIAL CELLS IN ALZHEIMER'S DISEASE

POSTERS: B06.A. CELL, MOLECULAR AND SYSTEMS BIOLOGY: TAU, TAU ISOFORMS

Mauro Montalbano[1], Zachary Walton[2], Rakez Kayed[1]
[1]The University Of Texas Medical Branch, Neurology, Galveston, United States of America, [2]The University Of Texas Medical Branch, School Of Medicine, Galveston, United States of America

Aims: The nuclear lamina (NL) is a structural determinant of the nuclear envelope. The NL is a meshwork of four Lamin proteins (Lamins A, B1, B2, and C) along the nuclear margin of eucaryotic cells that provides nuclear structural support and regulates chromatin organization. Cytoplasmic aggregation of misfolded tau is associated with Alzheimer's Disease (AD). With emerging evidence indicating that tau protein aggregation profoundly impacts nuclear structure and function, we hypothesize that tau aggregates induce maladaptive nuclear lamina structure and affects chromatin organization.
Methods: Using cell fractioning, biochemical assays, co-immunofluorescence, high-resolution airyscan microscopy and comprehensive high-throughput image analysis, we identified and quantified structural lamin alterations (tickness and integrity) in neurons and glia cells of aged-matched non-demented and AD brains.
Results: We found that tau, particularly in its oligomeric form, triggers NL maladaptive structures and deep reorganization of chromatin. Additionally, our in vivo observations revealed that the pathogenic P301S mutant tau exacerbates age-related NL alterations, specifically impacting Lamin A cellular localization and protein levels.
Conclusions: Our data suggest that in AD brains, the NL is morphologically and structurally altered as characterized by defective lamins expression and cellular mislocalization. Addittionally, tau aggregates drive NL structural impairments, which determine a deep re-organization of chromatin suggesting additional molecular insights of tau-induced toxicity in AD.

RT-QUIC IN THE DETECTION OF 4R TAU SEEDS ACROSS NEURODEGENERATIVE DISEASES AND BRAIN REGIONS

POSTERS: B06.A. CELL, MOLECULAR AND SYSTEMS BIOLOGY: TAU, TAU ISOFORMS

Heidi Standke[1], David Coughlin[2], Matteo Manca[1], Mikayla Huntley[1], Olivia Thomas[1], Caitlin Swanberg[1], Yongya Kim[2], Thea Andreasson[2], Varun Rachakonda[3], Douglas Galasko[4], Annie Hiniker[4], Allison Kraus[1]
[1]Case Western Reserve University School of Medicine, Department Of Pathology, Cleveland, United States of America, [2]University of California, San Diego, Department Of Neurosciences, San Diego, United States of America, [3]Nova Southeastern University, Kiran C. Patel College Of Allopathic Medicine, Fort Lauderdale, United States of America, [4]University of California, San Diego, Department Of Neurology, San Diego, United States of America

Aims: It is unknown how self-replicating misfolded proteins, or protein seeds, co-occur in other neurodegenerative diseases. Here, we utilize the ultrasensitive real-time quaking induced conversion (RT-QuIC) assay to selectively detect 3R/4R and 4R tau protein seeds across neurodegenerative diseases and brain regions to examine tau seeding activity as it relates to neuropathological characteristics and varies across brain regions.
Methods: The 4R RT-QuIC assay was used to evaluate neuropathologically characterized brain tissue samples (n=67) to explore 4R tau seeding in frontal cortex samples across a variety of neurodegenerative diseases including PSP and CBD. We further examined the topographic differences of 3R/4R and 4R tau seeds through the analysis of 3R/4R and 4R RT-QuIC seeding activity from hippocampus, frontal cortex, and basal ganglia samples in a subset of cases with AD (n=11), PSP (n =13), mixed AD and PSP pathology (n=7), and control cases (n=4).
Results: 4R RT-QuIC identified all 4R tauopathy cases, with 4R seeding activities being 10,000-fold higher than age-comparable controls. 4R tau seeds were detected, albeit in lower quantities, in other neurodegenerative diseases. Additionally, the 4R RT-QuIC assay could discriminate PSP and CBD with differing characteristic 4R tau amyloid structures based on ThT amplitude readout, with electron microscopy indicating distinct ultrastructures of disease-specific seeded amyloids. The 3R/4R RT-QuIC assay was also neuroanatomically selective in tau seeding in cases of AD, PSP, and mixed tau pathologies.
Conclusions: 4R tau seeds are a prevalent co-occurrence across neurodegenerative diseases. RT-QuIC assays can determine the neuroanatomic distribution of tau seeds, even in cases of mixed tau pathology, and can be used to infer amyloid core structural differences.

STUDY THE CELLULAR EFFECT OF NEW TAU ISOFORMS OVER EXPRESSION GENERATED BY INTRON RETENTION.

POSTERS: B06.A. CELL, MOLECULAR AND SYSTEMS BIOLOGY: TAU, TAU ISOFORMS

Francisco Vallejo-Bedia[1], Daniel Ruiz-Gabarre[2], Anastasia Stoliarov-Radushinskaya[1], Mar Pérez-Martínez[3], Félix Hernández[4], Jesús Ávila[4], Vega García-Escudero[3]
[1]CBM Severo Ochoa, Molecular Neuropathology, Madrid, Spain, [2]CBM Severo Ochoa, Molecular Neuropahtology, Madrid, Spain, [3]Universidad Autónoma de Madrid, Anatomy, Histology And Neuroscience, Madrid, Spain, [4]Centro de Biología Molecular Severo Ochoa, Molecular Neuropathology, Madrid, Spain

Aims: Truncated by intron retention CW-Tau isoform could have protective Alzheimer's disease functions on a cellular level. To prove this, will be studying its subcellular localization compared to other canonical Tau isoforms, analyzing its role in mitochondrial morphology and microtubule function, and characterizing its effect on vesicle trafficking, with special emphasis on the autophagic flux and vesicles exportation.
Methods: SH-SY5Y cells were infected with pWPI lentiviral vectors containing T30 canonic tau, TIR-30 CW-Tau and GFP as control before carrying out immunoflourencent assays againts mitochondria, microtubules and vesicles involved in the autophagic flux. In addition, cells were subcellular fragmented to analyze the nuclear presence of CW-Tau. Concurrently, HEK293T cells were transfected with psG5 eucaryotic expression plasmids with different Tau isoforms and were treated with cccp and Bafilomicine A1 to analyze in detail the autophagic flux and the vesicle exportation in different tau conditions.
Results: We first validated the specifity of a new antiody against CW-Tau performing immunofluorescence. Once the specifitiy of the transduction was confirmed, we saw that CW-Tau shows homogeneous localization throughout the cell, with high nuclear representation, comparing with canonic Tau isoforms, with a lack of presence on the nucleous. We further demonstrated that CW-Tau overexpression does not affect the microtubule net area, and neither affect the mitochondrial morphological conditions. Finally, CW-Tau overexpression showed an increased endocytosis EEA1 clusters, a mainteined autophagic flux with LC3 and p62 synthesis and degradation ratios, differing on the overexpression of canonic tau isoforms, which had unbalanced synthesis and degradation ratios.
Conclusions: The results obtained point out that CW-Tau could ameliorate or at least mantain cell funcion in Alzheimer's disease, and could be proposed as a therapeutic target and genic therapy strategy against this dementia and other tauopathies.

LINKING SINGLE-NUCLEUS-ATAC/RNA-SEQ WITH NEUROPATHOLOGICAL TRAITS IN PRIMARY TAUOPATHIES

POSTERS: B06.C. CELL, MOLECULAR AND SYSTEMS BIOLOGY: NETWORK BIOLOGY, CONNECTOME, PROTEIN-PROTEIN INTERATIONS

Nils Briel[1,2], Viktoria Ruf[2], Paul Feyen[3], Felix Stübing[2,3], Günter Höglinger[4,5], Jochen Herms[2,3,5]
[1]University Hospital Zurich, Neurology, Zurich, Switzerland, [2]University of Munich, Center For Neuropathology And Prion Research, Faculty Of Medicine, Munich, Germany, [3]German Center for Neurodegenerative Diseases, Translational Brain Research, Munich, Germany, [4]LMU hospital, Department Of Neurology, München, Germany, [5]Munich Cluster for Systems Neurology, Synergy, Munich, Germany

Aims: Our previous work [1] highlighted distinct astrocyte signatures in progressive supranuclear palsy (PSP) and corticobasal degeneration (CBD). In this study, we aimed to investigate network-based gene-expression/gene-activity patterns and their molecular function in these diseases. We also aimed to link network activity with neuropathological (NP) traits.
Methods: We performed unpaired single-nucleus ATAC/RNA-seq on postmortem frontal cortex samples from N=8 PSP, N=8 CBD, and N=8 control cases. After preprocessing and QC, we recovered more than 93,000 (ATAC) and 112,000 (RNA) high-quality nuclei. Using *Seurat&hdWGCNA* we determined cell type identity, constructed weighted gene co-expression networks on meta cells, and assessed gene ontologies. Associations between networks and manually quantified NP traits (ie, tufted astrocytes, TA; FFPE, contralateral cortex) were tested with *glm* (adjusted for age and postmortem-interval).
Results: In PSP, our analysis revealed dysregulated gene activity modules in astrocytes. Specifically, we found a gene network “turquoise” enriched with synaptic terms downregulated in PSP astrocytes. Another network “blue” reminiscent of tangle-positive cells was upregulated in PSP astrocytes and associated with TA counts. Network “blue” core regulators were involved in mRNA processing, astrocyte, and B cell differentiation.
In CBD, the gene expression module "yellow" with its core regulator *PPARGC1A* was enriched with neuroinflammatory terms and downregulated in Parvalbumin+ inhibitory neurons.
Conclusions: Our analysis demonstrates a) cell type-resolved dysregulated gene-networks in primary Tauopathien, b) specific hub genes (eg, *C1orf61*, astrocytic DEG in AD [2]; *PPARGC1A*, implicated in inhibitory neurons in AD [3]), and c) a possible systems biology approach to identify therapeutic targets. Further studies are needed to validate outlined alterations and their role in tangle-bearing cells themselves or their microenvironment. References:

Columbia University Irving Medical Center, Center For Translational And Computational Neuroimmunology, Department Of Neurology And Taub Institute For Research On Alzheimer's Disease And The Aging Brain, New York, United States of America

Aims: We defined 92 neocortical (glial, neuronal, endothelial,..) cell subtypes in 1.6 million transcriptomes from the prefrontal cortex of 424 participants in the ROSMAP cohorts. Here, we attempted to recover these cell subtypes in spatial transcriptomic data generated from the same 4 tissue blocks profiled using 4 different platforms and to map their topological relationships. This is part of the NIH-funded Brain-MAAP project.
Methods: After careful evaluation, we selected 4 participants with prefrontal cortex frozen samples with RIN>7; 2 participants who do not fulfill a pathologic diagnosis of Alzheimer disease (AD) and have minimal amyloid and Tau proteinopathies, as well as 2 participants who fulfil a pathologic diagnosis of AD. For each participant, a section of the frozen tissue was cut and profiled with the visium platform from 10X Genomics. A sister section was profiled with a targeted 500 gene panel using the Vizgene Merscope platform. The next section was profiled the Xenium platform from 10x Genomics, and a fourth section is being profiled using Stereoseq from STOmics. Following data preprocessing, data will be made available through the AD Knowledge Portal, and results will be uploaded as well.
Results: Data quality for the first three platforms tested were excellent; Stereoseq data is being generated currently. We are currently analyzing these data and will present final results at the conference, along with a comparison of the platforms. Preliminary results using the Merscope data suggest that we were able to recover 9 of our 12 subtypes of microglia in these ST data.
Conclusions: Our results will help to guide platform selection by the community by presenting data collected from sister sections from same 4 brain samples using 4 distinct platforms representing both RNA capture and targeted multiplexed FISH.

BEYOND THE ROLE OF PLCG2 IN MICROGLIA IN ALZHEIMER'S DISEASE

POSTERS: B06.D. CELL, MOLECULAR AND SYSTEMS BIOLOGY: METABOLOMICS, TRANSCRIPTOMICS, LIPIDOMICS, PROTEOMICS

Hongjun (Harry) Fu[1], Tae Yeon Kim[1], Diana Acosta[1], Nicholas Sweeney[1], Qi Guo[2], Yuzhou Chang[1], Shuo Chen[1], Geidy Serrano[3], Douglas Scharre[1], Qin Ma[2], Thomas Beach[3]
[1]The Ohio State University Wexner Medical Center, Neuroscience, Columbus, United States of America, [2]The Ohio State University Wexner Medical Center, Biomedical Informatics, Columbus, United States of America, [3]Banner Sun Health Research Institute, Brain And Body Donation Program, Sun City, United States of America

Aims: Recent Genome Wide Association Studies have identified novel rare coding variants in immune genes associated with late onset Alzheimer's disease (LOAD) including the gene encoding the enzyme phospholipase-C-γ2 (PLCG2), which is associated with both reduced (P522R variant) and increased (M28L variant) risk of AD. The role of PLCG2 in AD has been largely investigated in microglia and responses to amyloid β (Aβ) pathology. We aim to investigate the cell autonomous role of PLCG2 in neurons in AD.
Methods: 10x Genomics single nucleus RNA-seq, ATAC-Seq, and Visium spatial transcriptomics were employed to characterize the cell-type-specific and region-specific changes of PLCG2 in the middle temporal gyrus of human AD compared to the control. The immunostaining and WB assay were used to measure the localization and protein levels of PLCG2, p-tau, and p62 in human AD and PS19 tau mice. The PLCG2 and FUW-mCherry-GFP-LC3 were utilized to measure the change of autophagy dynamics induced by PLCG2.
Results: Here we report that PLCG2 mRNA is significantly increased in AD not only in microglia, but also in neurons and astrocytes of human AD compared to the control. The protein level of PLCG2 is also significantly increased in tau transgenic mice and human AD compared to controls. It should be noted that the expression of PLCG2 protein is significantly lower in neurons with tau pathology than those cells without tau pathology. The effect of PLCG2 on autophagy dynamics is under investigation.
Conclusions: These results suggest that repression or dysfunction of PLCG2 may contribute to tau pathology in neurons in AD, probably via the regulation of autophagy pathway. Our findings provide a novel role of PLCG2 in neurons, beyond microglia, in AD.

ANALYSIS OF THE LOCUS COERULEUS CIRCADIAN TRANSCRIPTOME IN P301S TAU TRANSGENIC MICE

POSTERS: B06.D. CELL, MOLECULAR AND SYSTEMS BIOLOGY: METABOLOMICS, TRANSCRIPTOMICS, LIPIDOMICS, PROTEOMICS

Eun Young Kim[1], Eui-Beom Jeong[1], Do-Yun Koo[2], Jae Hyung Lee[2]
[1]Ajou University, School of Medicine, Department Of Biomedical Sciences, Suwon, Korea, Republic of, [2]School of Dentistry, Kyung Hee University, Department Of Oral Microbiology, Seoul, Korea, Republic of

Aims: Circadian clock system regulates the physiology and behavior of organisms to manifest about 24hr rhythm. Disruptions in circadian rhythms and sleep disturbance frequently occur in neurodegenerative diseases including Alzheimer's disease, Parkinson's disease etc. Furthermore, circadian rhythm disruption is a potential risk factor that may accelerate pathological processes of neurodegenerative diseases. However, the mechanistic link between circadian clock and neurodegeneration remains incompletely understood. The Locus coeruleus (LC) is the norepinephrine (NE)-containing nucleus in the brainstem and innervates into widespread brain regions including the cerebral cortex, hippocampus, and hypothalamus. The LC-NE system plays an important role in a variety of brain functions, including attention, emotion, cognition, and the sleep-wake cycle. Intriguingly, the LC is an initial site of neurofibrillary tangles (NFTs), a neuropathological hallmark of Alzheimer's disease. In this study, we aimed to understand how circadian clock might influence tauopathy pathology in the LC. Specifically, we sought to identify daily rhythmic oscillating genes in cell-type specific manner.
Methods: Briefly, 3-month-old B6C3F1(wild-type) and P301S Tau transgenic male mice were entrained under 12:12 light:dark (LD) cycle for 2 weeks and transferred to constant dark (DD) condition. Mice were scarified at every 4hrs during 2 days of DD and locus coeruleus containing brain region were processed for RNA sequencing.
Results: We identified total 638 oscillating genes in wild-type mice and total 376 oscillating genes in P301S Tau transgenic mice. The rhythmic genes were not completely overlapped and the phase distribution of rhythmic genes were delayed in P301S Tau transgenic mice.
Conclusions: We are currently analyzing the characteristics of circadian rhythmic oscillating genes in LC and will discuss the potential significance of those genes in the pathogenesis of P301S Tau transgenic mice.

CELL TYPE-SPECIFIC ASSOCIATIONS WITH ALZHEIMER'S NEUROPATHOLOGY AND COGNITIVE IMPAIRMENT CONSERVED ACROSS RACIAL AND ETHNIC GROUPS

POSTERS: B06.D. CELL, MOLECULAR AND SYSTEMS BIOLOGY: METABOLOMICS, TRANSCRIPTOMICS, LIPIDOMICS, PROTEOMICS

Vilas Menon[1], Tain Luquez[1], Rebecca Chiu[1], Jonathan Algoo[1], Jason Mares[1], Lin Wang[1], Archana Yadav[1], Matti Lam[1], Ivy Kosater[1], Pallavi Gaur[1], Philip De Jager[2], David Marquez[3,4], Lisa Barnes[4], Ya Zhang[1], David Bennett[4]
[1]Columbia University Irving Medical Center, Center For Translational And Computational Neuroimmunology, Department Of Neurology, New York, United States of America, [2]Columbia University Irving Medical Center, Center For Translational And Computational Neuroimmunology, Department Of Neurology And Taub Institute For Research On Alzheimer's Disease And The Aging Brain, New York, United States of America, [3]University of Illinois at Chicago, Kinesiology & Nutrition, Chicago, United States of America, [4]Rush University Medical Center, Rush Alzheimer's Disease Center, Chicago, United States of America

Aims: Objectives: To identify cell type-specific transcriptomic and epigenetic changes in brain tissue associated with clinical and pathological hallmarks of Alzheimer's Disease (AD). We focus on those found consistently across individuals of different races and ethnicities, to ensure that proposed cell type target signatures are broadly applicable to wider sections of the population.
Methods: We generated joint single-nucleus RNA/ATAC-seq data (Multiome) on post-mortem brain tissue from 3 regions – dorsolateral prefrontal cortex, superior temporal gyrus, and anterior caudate – from 160 individuals from one of five cohort studies (ROSMAP, MARS, AACore and LATC) from the Rush Alzheimer's Disease Center. Roughly one-third of these individuals self-identified as non-Latino White, one-third as non-Latino African American, and one-third as Latino. With median ~4000 nuclei post-QC from each decedent in each brain region, we investigated associations of cell type signatures – clusters, gene expression modules, and open chromatin regions – with Braak stage, CERAD score, and dementia status.
Results: Our three sets of analyses revealed consistent signatures across all three racial and ethnic groups. These included a higher frequency of GPNB+ microglia in cortical regions but not in the anterior caudate in individuals with greater pathology and dementia. In astrocytes, levels of SERPINH1 expression showed associations with pathology and dementia in multiple brain regions. Among cortical neurons, we find lower proportions of one SST+ subtype and higher proportions of two RORB+ subtypes in decedents at later Braak stages and in those with dementia.
Conclusions: We identify a set of cell types, genes, and open chromatin regions that show differences across AD pathology and clinical diagnosis. Importantly for selecting targets with broadest possible applicability, we highlight patterns that are found consistently in three different racial and ethnic groups.

FTD-MAPT HUMAN BRAIN PROTEOMICS: EXTENSIVE DYSREGULATION OF METABOLIC PATHWAYS

POSTERS: B06.D. CELL, MOLECULAR AND SYSTEMS BIOLOGY: METABOLOMICS, TRANSCRIPTOMICS, LIPIDOMICS, PROTEOMICS

Suzanne Miedema, Leon Balthaus, Remco Klaassen, Berna Özer, Guus Smit
Vrije Universiteit Amsterdam, Molecular & Cellular Neurobiology, Amsterdam, Netherlands

Aims: Frontotemporal dementia (FTD) is a major cause of lethal early-onset dementia. FTD is hereditary in 30% of cases, mainly induced by mutations in the C9orf72 (FTD-C9), progranulin (FTD-GRN), and microtubule-associated protein tau (FTD-MAPT) genes. The remaining 70% (sporadic FTD) can be conceived as a complex trait disorder. Our research aims to determine key cell types and disease mechanisms for hereditary FTD and to construct a disease framework to enable molecular profiling of sporadic cases.
Methods: We re-investigated our FTD-MAPT cohort using a state-of-the-art mass spectrometry-based quantitative approach. Laser-dissected temporal cortex tissues from FTD-MAPT (n=15) and non-demented controls (n=7) were analysed by LC-MS/MS using the timsTOF Pro2 running in dia-PASEF mode. Raw peptide data was analysed with DIA-NN followed by processing in the MS-DAP pipeline. Biological interpretation was inferred with Gene Ontology and cell type enrichment analyses (EWCE).
Results: We were able to deeply measure the FTD-MAPT proteome, detecting 38,489 peptides in 6,306 proteins with reliable quality. Differential abundance analysis (q<0.01) revealed major protein regulation in FTD-MAPT (n=1,011). We observed extensive involvement of metabolic pathways, related to e.g. RNA and amino acids (previously identified), fatty acid oxidation, and glutathione synthesis. In addition, specialized cell-ECM interactions, such as focal adhesion and integrin-mediated signalling, were strongly enriched. Cell type analysis this time showed additional enrichment for microglia, indicating we improved the detection of proteins of this cell type.
Conclusions: Our results demonstrate a heavy involvement of dysregulated metabolic processes in the FTD-MAPT subtype. Proteomic profiling of sporadic FTD cases is currently ongoing. With our efforts, we aim to build a resource that can be used to explore potential mechanisms of disease and to pave the way for the development of disease subtype-specific treatment.

CHARACTERIZATION OF TAU LEVELS, INCLUDING PTHR217 IN THE PS19 ALZHEIMER´S DISEASE MOUSE MODEL

POSTERS: B07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Benedikt Kien, Roland Rabl, Livia Breznik, Magdalena Daurer, Tina Loeffler, Stefanie Flunkert, Manuela Prokesch
QPS Austria GmbH, Neuropharmacology, Grambach, Austria

Aims: The microtubule-associated protein tau is a primary component of neurofibrillary tangles – one of the major pathological hallmarks of Alzheimer´s disease. PS19 transgenic mice overexpressing the disease-associated P301S tau mutation, are reported to present a strong tauopathy-related brain pathology. However, not all relevant phosphorylation sites were already evaluated in these mice. Recent studies highlight phosphorylated tau at residue threonine 217 (pThr217) as a new promising plasma biomarker for pathological changes implicated in Alzheimer's disease (AD) and it therefore gained attention as possible target in AD therapeutics. Here, we thus performed a detailed biochemical characterization of the soluble and insoluble brain fraction of PS19 mice at different ages, analyzing levels of total tau and different ptau species, including pThr231 and pThr217.
Methods: PS19 mice were sacrificed at the age of 2, 4, 6, and 8 months and cortical and hippocampal soluble and insoluble protein fractions were generated. Those fractions were analyzed for total tau and different ptau species, including pThr231 and pSer217, using different immunosorbent assays and automated western blotting.
Results: Analyses are still in progress, but results will provide an extensive characterization of PS19 mice across different ages including the new emerging marker tau pThr217.
Conclusions: Together with already published data, our results will further support the value of PS19 mice as a valid animal model to investigate the deleterious effects of increased mutant tau and to test novel drug agents.

Aims: Progressive supranuclear palsy (PSP) is the most common primary tauopathy characterized by a constellation of neuropathologic features including 4R-tau positive neurofibrillary tangles and glial tau inclusions. Most PSP cases are sporadic and associated with common structural variation in the 17q21.31 *MAPT* locus as well as other risk loci, including *EIF2AK3* which is critical for the unfolded protein response (UPR). Despite these known genetic risk associations, mechanisms underlying disease pathogenesis and selective vulnerability of different cell types are unclear.
Methods: To investigate transcriptomic changes in vulnerable cell populations, we performed single-nucleus RNA sequencing (snRNA-seq) in the subthalamic nucleus and adjacent regions from human post-mortem PSP brains with variable disease severity compared to clinically normal controls. Transcriptional differences were validated by immunohistochemistry on brain regions either selectively vulnerable or protected in PSP using antibodies for activated EIF2α (pEIF2α), phosphorylated tau (p-tau, AT8), and other cell-type specific markers.
Results: Differential gene expression and pathway analysis identified EIF2 signaling, a target of the UPR, as the top activated pathway in vulnerable cell types. Histological validation showed pEIF2α+ cells in 100% of PSP cases and no pEIF2α+ cells in controls. Vulnerable brain regions had the highest frequency of pEIF2α+ cells, while none were detected in protected regions. The number of pEIF2α+ cells positively correlated with tau burden, and pEIF2α+ granules localized to p-tau$^+$ neurons and astrocytes.
Conclusions: These data show EIF2 activation positively associates with tau burden in vulnerable brain regions and cell types in PSP, providing a potential mechanistic link with *EIF2AK3* genetic risk and the UPR.

CHARACTERIZATION OF A TRANSGENIC MOUSE MODEL OF TAUOPATHY USING QUANTITATIVE EEG: DO TAU-INDUCED DEFICITS LEAD TO DISRUPTED EEG SPECTRA

POSTERS: B07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Venceslas Duveau[1], Frank Menniti[2], Alexis Evrard[3], Betty Mandé-Niedergang[3], Corinne Roucard[1], Yann Roche[1], Katie Dunton[2]
[1]SYNAPCELL SAS, Sales, Saint-Ismier, France, [2]MindImmune Therapeutics, Pharmacology, Kingston, United States of America, [3]SYNAPCELL SAS, Operations, Saint-Ismier, France

Aims: Alzheimer's disease (AD), the most common form of dementia, is associated with two pathological hallmarks: beta amyloid deposition and neurofibrillary tau tangles. However, lack of understanding of how these primary pathologies result in cognitive deficits remains a hurdle to the development of meaningful therapeutics. We studied changes in electroencephalography (EEG) characteristics with age in the P301L tauopathy mouse model. P301L mice overexpress the 4R/2N isoform of human tau under control of the CaMKIIα promoter on a C57BL/6 background. In this experiment, C57BL/6 will be used as controls and their EEG profile will be compared to the transgenic P301L to evidence a potential EEG biomarker related to the P301L mutation, or the lack thereof.
Methods: In P301L mice and WT controls, monopolar electrodes were implanted bilaterally over the frontal cortex and over parietal cortex on one side. A depth electrode was also implanted in the hippocampus, with a reference electrode over the cerebellum. A Fast Fourier Transform (FFT) was performed on EEG signal from each electrode for frequencies ranging from 1 to 140Hz.
Results: In P301L mice up to 9 months of age, we observed a decrease of power in all classical frequency bands (from Delta to Epsilon) in the hippocampus as compared to WT. There was a persistent trend for an increase in high Delta in frontal cortex, and for a decrease in Theta in parietal cortex. Interestingly, this general pattern of change was evident from 4 months of age.
Conclusions: This study highlights the utility of EEG to identify subtle and persistent changes in brain function in response to AD-relevant tau pathology. Further characterization of the model, including study of the potential pharmaco-sensitivity of the phenotype to therapeutic intervention is ongoing.

OPTIMIZATION OF TAU EXTRACTION FROM HUMAN POST-MORTEM PROGRESSIVE SUPRANUCLEAR PALSY BRAIN FOR MODELLING TAU PATHOLOGY IN VIVO

POSTERS: B07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Hania Qamar[1], Rodylyn Ferry[1], Alison Mao[1], Ivan Martinez-Valbuena[1], Naomi Visanji[1,2,3]
[1]University of Toronto, Tanz Centre For Research In Neurodegenerative Diseases, Toronto, Canada, [2]University of Toronto, Department Of Laboratory Medicine And Pathobiology, Toronto, Canada, [3]Toronto Western Hosptial, Krembil Brain Institute, Toronto, Canada

Aims: To develop an animal model that replicates the anatomical and cytopathologic hallmarks, spatiotemporal spread of pathology and progressive neurodegeneration that characterize Progressive Supranuclear Palsy (PSP) using human brain derived tau. Here we compare the effects of five different tau extraction methods from human PSP brain inoculated in mice that express all six isoforms of human tau.
Methods: Whole brain extracts, PBS soluble extracts as well as 0.1%, 1% and 2% sarkosyl insoluble (SI) tau extracts were prepared from human PSP brain. The tau yield from each preparation was analyzed using ELISA. 6hTau mice were each inoculated in three key nuclei implicated in early stages of PSP (substantia nigra, globus pallidus and caudate putamen). Locomotor behaviour was assessed and tau cytopathologies were examined at 3- and 6-months post inoculation (mpi) using immunohistochemistry (IHC) for phosphorylated tau (AT8).
Results: The PSP whole brain extract yielded the greatest amount of total tau, followed by the PBS soluble extract, 0.1% SI, 1% SI and 2% SI extract, which had the lowest total tau yield. The brains of PBS soluble tau inoculated animals were negative for AT8 IHC at 3 and 6 mpi. 2% SI tau inoculation resulted in AT8 positive neurons and neurites at 3 mpi. Analysis of additional timepoints and extract preparations are ongoing.
Conclusions: Although PBS soluble tau extraction yielded the highest amount of total tau, inoculation in animals did not result in pathology. Conversely, inoculation with 2% SI tau, which had the lowest yield, induced abnormal neuronal tau deposition reminiscent of early pathology in PSP. These data demonstrate the importance of determining the optimal tau extraction method from human brain as a first step in developing an animal model of PSP pathology.

IMPACT ON LONGEVITY AND REDUCTION OF A-SYNUCLEIN AGGREGATION IN THE NL5901 STRAIN OF CAENORHABDITIS ELEGANS TREATED WITH CANNABIDIOL.

POSTERS: C01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: A-SYNUCLEIN AGGREGATION

Ruth Melida Sanchez Mora[1], Alejandra Mantilla Galindo[2], Rodrigo Gonzalez Reyes[2]
[1]Universidad Colegio Mayor de Cundinamarca, Bogota, Bogotá, D.C., Colombia, [2]Universidad del Rosario, Bogota, Bogotá, D.C., Colombia

Aims: Aims: To assess the impact of CBD on the NL5901 strain of Caenorhabditis elegans.
Methods: Materials and Methods: Nematodes were placed on Petri dishes, where the effect of CBD at various doses on lifespan and alpha-synuclein aggregation in the NL5901 strain was evaluated. The N2 strain was used as a control. They were fed with E. coli.
Results: : CBD treatment increased the lifespan in the N2 strain with a median of 32 days, 95% CI (0.2189 - 1.6) vs. CBD 3 µM with a median of 53 days, 95% CI (0.6 - 4.5), vs. CBD 30 µM with a median of 53 days, 95% CI (0.5 - 4.7). Similarly, in the NL5901 strain, the median lifespan was 23 days (0.1 - 1.1), vs. CBD 0.3 µM with a mean of 58 days, CI (0.8 - 7.5), vs. CBD 3 µM with a mean of 40 days, CI (0.6 - 5.2), vs. CBD 30 µM with a mean of 50 days, CI (0.8 - 5.8). CBD treatment also reduced alpha-synuclein aggregates compared to the control group (mean fluorescence intensity (IF) 88.84 ± 38.46) vs. 0.3 µM CBD (IF 32.56 ± 12.25), vs. 3 µM CBD (IF 36.32 ± 11.36), vs. 30 µM CBD (IF 24.89 ± 6.6).
Conclusions: Conclusion: CBD treatment in NL5901 nematodes demonstrated an increase in lifespan and a decrease in alpha-synuclein aggregation in vivo.

SRCD AND SAXS ANALYSIS OF (PYROGLUTAMATE) ALPHA-SYNUCLEIN – DIMERIC STATE AS A SIGNIFICANT INTERMEDIATE IN OLIGOMERISATION?

POSTERS: C01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: A-SYNUCLEIN AGGREGATION

Alexandra Bluhm[1], Anja Schulze[2], Wei Xiang[3], Maike Hartlage-Rübsamen[1], Stephan Schilling[2], Philippe Bénas[4], Aurélien Thureau[5], Frank Wien[6], Steffen Roßner[1], Claude Sauter[4]
[1]University of Leipzig, Paul Flechsig Institute For Brain Research, Leipzig, Germany, [2]Fraunhofer Institute for Cell Therapy and Immunology, Department Of Molecular Drug Design And Target Validation, Halle, Germany, [3]University Hospital Erlangen, Molecular Neurology, Erlangen, Germany, [4]University of Strasbourg, Molecular And Cellular Biology Institute, Strasbourg, France, [5]Synchrotron SOLEIL, Swing, Gif-sur-Yvette, France, [6]Synchrotron SOLEIL, Disco, Gif-sur-Yvette, France

Aims: Alpha-synuclein (aSyn) aggregation represents a key event in the neurodegenerative cascade of synucleinopathies. Here, we present new insights into structural characteristics of aggregated full-length (FL-) aSyn and, for the first time, of recently discovered pathological pyroglutamate (pGlu-) aSyn variants of different lengths. The generation of pGlu-aSyn post-translational modification (PTM) requires two enzymatic activities for: (i) N-terminal truncation of aSyn and (ii) the subsequent cyclisation of the resultant N-terminal glutamine to pGlu by glutaminyl cyclase (QC).
Methods: To initiate aggregation, recombinant FL- and pGlu-aSyn variants were agitated with 900 rpm, at 37°C for 5 h. To gain insights into structural properties of monomeric and oligomeric states, synchrotron radiation circular dichroism (SRCD) and size exclusion chromatography coupled small angle X-ray scattering (SEC-SAXS) were performed at SOLEIL synchrotron (France).
Results: SRCD analyses showed that soluble pGlu-aSyn variants are intrinsically disordered proteins, consistent with the known intrinsically disordered nature of FL-aSyn. In order to emulate a lipid environment, SDS micelles were added and the chameleon-like properties of aSyn became evident as the proteins adopted an alpha-helical fold, depending on the length of the pGlu-aSyn variants. An amyloid pore, which was described for the FL-aSyn, could be detected using SEC-SAXS data analyses. Furthermore, shapes of oligomeric pGlu-aSyn variants were bioinformatically modeled. Surprisingly, data suggest the formation of a dimeric state for all proteins studied.
Conclusions: Understanding the complexity and the influence of PTMs on protein aggregation is important for developing disease-modifying interventions. We here investigated the 3D-shape of the dimeric state as a key intermediate in the aggregation/oligomerisation process. Additionally, our results suggest a role of QC as aSyn-modifying enzyme and highlight it as a potential target for treatment of synucleinopathies.

FROM LOCAL TO GLOBAL: INDUCING PARKINSON'S DISEASE-LIKE PATHOLOGY FROM LOCUS COERULEUS TO OTHER BRAIN REGIONS

POSTERS: C01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: A-SYNUCLEIN AGGREGATION

Weilin Chen, Carolin Klaus, Pan Gao, Paul Feyen, Thomas Köglsperger, Lars Paeger, Jochen Herms
Deutsches Zentrum für Neurodegenerative Erkrankungen, Translational Brain Research, München, Germany

Aims: Parkinson's Disease (PD) is pathologically characterized by misfolded and abnormally aggregated α-synuclein (α-Syn) in neurons, called Lewy body. Current diagnostic criteria based on PD motor symptoms are not practical enough to distinguish early PD, so it is significant to understand the mechanisms and development of prodromal PD non-motor syndromes. Interestingly, locus coeruleus (LC), is also related with non-motor syndromes like hyposmia, sleep disorder, dementia and depression. Thus, we speculate that there may be potential relationships between LC and PD prodromal syndromes. To investigate that, we start from seeding the α-Syn preformed fibrils (PFFs) in LC of mouse, as animal model to simulate the premotor syndromes and development of prodromal PD.
Methods: C57BL/6J mice were injected with α -synuclein pre-formed fibrils (PFF) in locus coeruleus unilaterally. Mice were sacrificed at the time period of 1, 3 and 6 months after injection, and the propagation of phosphate-129 α -synuclein (Ps129), as well as the density of noradrenergic fibres in LC and other brain region were examined by immunofluorescence staining.
Results: Ps129 pathology appeared early in 1 month after injection, and mainly propagated to median prefrontal cortex, hypothalamus, amygdala and periaqueductal grey, which are also main input areas of LC. In 3 months and 6 months after injection, Ps129 keep aggregating morphologically. Degeneration of noradrenergic fibers were observed in amygdala after 3 months of injection.
Conclusions: Our data indicate that α-Syn pathology could be induced by PFF injection in LC and appeared in areas that innervate LC, hints that propagation of pathology may obey a retrograde neuroanatomical way. Furthermore, we assume that under α-Syn pathological status, brain regions like amygdala may suffer from noradrenergic degenerations, which may be one of the mechanisms of prodromal PD syndromes.

CHARACTERISING ALPHA SYNUCLEIN AGGREGATES FROM MOUSE MODELS AND HUMAN BRAIN SAMPLES USING DNA-PAINT

POSTERS: C01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: A-SYNUCLEIN AGGREGATION

Emre Fertan, John Danial, Jeff Lam, David Klenerman
University of Cambridge, Yusuf Hamied Department Of Chemistry, Cambridge, United Kingdom

Aims: Alpha synuclein (aSyn) is a major component of the Lewy bodies found in the brains of Parkinson's disease (PD) patients. However, the toxicity mechanisms of aSyn and the relationship between the morphological and geometric structure of the aggregates and the damage they cause has not been well understood. Moreover, while mouse models expressing human aSyn are often used to study PD, the aSyn aggregates produced by the mice has not been well characterised and compared with the aggregates from human brain samples. Lastly, the impact of the extraction method used to harvest the aggregates on the specific types of aggregates acquired is not well understood.
Methods: We first soaked and homogenised the brains of Line 61 mice as well as post-mortem brain samples from PD patients. Then the homogenised samples were further extracted with sarkosyl and triton-x. We characterised the aSyn aggregates in these samples using single-molecule pulldown (SiMPull) and DNA-PAINT using the epitope-specific 4B12 antibody.
Results: Our results show clear size and shape differences, as well as their numbers, between the mice at different ages, human PD samples and controls, and human and mouse PD samples. Moreover, the method of extraction also provides aggregates with statistically different sizes and shapes.
Conclusions: Since the geometric and structural characteristics of aggregates correlate with heir toxicity and involvement in different disease mechanisms, understanding how the method used to harvest these aggregates effects these properties is crucial. Here we provide a super-resolution characterisation of aSyn aggregates from a well validated mouse model as well as human samples, and show how using different methods of harvesting and imaging these aggregates can provide different results.

SUBCELLULAR AND BIOCHEMICAL CHARACTERIZATION OF THE NOVEL A30G A-SYNUCLEIN MUTANT IN PARKINSON'S DISEASE

POSTERS: C01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: A-SYNUCLEIN AGGREGATION

Vasilina Zafeira Gavra[1,2], Ronald Melki[3], Christina Kyrousi[4], Leonidas Stefanis[1,4], Marina Pantazopoulou[1,2]
[1]Biomedical Research Foundation, Academy of Athens, Clinical- Experimental Surgery & Translational Research, Athens, Greece, [2]National and Kapodistrian University of Athens, School Of Medicine, Athens, Greece, [3]Institut Francois Jacob (MIRCen), Cea And Laboratory Of Neurodegenerative Diseases, Fontenay-Aux-Roses cedex, France, [4]National and Kapodistrian University of Athens, School Of Medicine, athens, Greece

Aims: A30G is a novel heterozygous mutation of the SNCA gene, recently identified in five affected individuals of three non-related Greek families. This mutation is responsible for a PD phenotype, including prominent non-motor symptoms. Biochemical analysis in isolated systems revealed that the A30G SNCA mutation altered the alpha-helical structure of the protein, perturbed membrane binding and promoted fibril formation. However, the effects of this mutation in a cellular context have not been assessed. Our main aim is to unravel the biochemical properties of the A30G mutant in a cellular context, deciphering the mechanisms governing toxicity, seeding and aggregation, leading to a better understanding of PD pathogenesis.
Methods: Using WT α-synuclein recombinant fibrils (PFFs) in neuronally differentiated SH-SY5Y neuroblastoma cells with stable overexpression of mutant A30G α-synuclein, we examined the seeding and aggregation of endogenous α-synuclein by immunofluorescence and immunoblotting assays.
Results: SH-SY5Y neuroblastoma cell lines with stable overexpression of A30G α-synuclein were constructed and different clones with robust protein expression were selected. The overexpression of the A30G mutant protein resulted in the accumulation of insoluble α-synuclein species, partially phosphorylated at pS129, as well as in axonal retraction by 6 days and later neuronal death. Immunofluorescence and immunoblotting experiments showed that upon PFF addition, seeding and aggregation of endogenous A30G α-synuclein occurred within 4 days of PFF incubation.
Conclusions: The overexpression of A30G α-synuclein results in the accumulation of insoluble α-synuclein species and consequently in cell death in a neuronal cell system, while PFF-induced seeding and aggregation of endogenous A30G α-synuclein also occur at an accelerate pace compared to that previously reported for the WT protein. These results highlight the increased aggregation and toxicity propensity of the mutant A30G α-synuclein in a cellular context.

LYSINE-BASED CHARGE NEUTRALIZING PTMS MODULATE AGGREGATION PROPENSITY OF ALPHA-SYNUCLEIN

POSTERS: C01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: A-SYNUCLEIN AGGREGATION

Sharad Gupta[1], Joshna Gadhavi[2], Sumedha Shah[1]
[1]Indian Institute of Technology, Gandhinagar, Department Of Biological Science And Engineering, Gandhinagar, India, [2]Emory University, Department Of Biochemistry, Atlanta, United States of America

Aims: α-Synuclein (α-syn) is one of the major components of Lewy bodies and Lewy neurites, which are pathological hallmarks of Parkison's Disease (PD). α-Syn has been observed to be heavily post-translationally modified in samples derived from postmortem brain tissues of PD patients. Charge neutralizing PTMs such as Acetylation and leser known carbamylation which is an non-enzymatic age-dependent PTM could modulate amyloid formation of α-syn, tau, TDP-43 and other relevant proteins. Our aim was to understand this aggregation modulation by using short peptides from lysine rich region including KTKEGV repeats as model systems and extend our findings to the full-length α-syn.
Methods: We have monitored the aggregation propensity of KTKEGV repeats and amyloidogenic sequences (wild-type, carbamylated and acetylated) present in α-syn by various biophysical techniques including ThT fluorescence kinetic assay, SEM and Bio-AFM. Similarly, chemically modified α-syn was characterized by western blot and MALDI-TOF and it's aggregation was followed using biophysical techniques. We have further investigated the seeding propensity, a hallmark of amyloid structures.
Results: While none of the seven repeats aggregates on their own, we identified four regions that rapidly formed amyloid fibrils when carbamylated. Similarly, while 43-50 peptide WT sequence didn't aggregate even after carbamylation, disease-relevant mutated versions formed amyloid readily. At low concentrations, full length carbamylated α-syn protein aggregation indicated the formation of aggregates with many-fold higher amyloidogenic content than WT α-syn. Finally, we demonstrated that these aggregates of carbamylated α-syn can readily seed aggregation in WT monomeric α-syn preparations. This points to the strong amyloidogenic nature of carbamylated α-syn. Similar alteration in aggregation propensity were observed in acetylated α-syn repeat peptides.
Conclusions: Our studies indicate that carbamylation which is chemically similar to acetylation can significantly alter the physicochemical characteristics as well as aggregation propensity.

NEUROINFLAMMATION POTENTIATES ALPHA-SYNUCLEIN PATHOLOGY IN A MOUSE MODEL OF PARKINSON'S DISEASE.

POSTERS: C01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: A-SYNUCLEIN AGGREGATION

Hideki Hayakawa[1], Kousuke Baba[1], Hiroshi Sakiyama[1], Chi-Jing Choong[1], Yasuyoshi Kimura[1], Kensuke Ikenaka[1], Cesar Aguirre[1], Tatsusada Okuno[1], Seiichi Nagano[1], Yoshitaka Nagai[2], Hideki Mochizuki[1]
[1]Osaka University Graduate School of Medicine, Department Of Neurology, Osaka, Japan, [2]Kindai University, Department Of Neurology, Osaka, Japan

Aims: Alpha-synuclein (αsyn) is a major component of Lewy bodies, a pathognomonic feature of Parkinson's disease (PD), and its genetic mutations cause familial PD. In neurodegenerative diseases such as PD, the neuroinflammatory role of activated microglia have long been considered important, but the exact role of immune responses in disease progression is unclear. In this study, we analyzed the molecular mechanisms of αsyn propagation and aggregation mediated by neuroinflammation and microglial activation by performing osmotic minipump administration of Lipopolysaccharide (LPS) in αsyn fibril-injected mice.
Methods: αsyn fibrils were injected into the substantia nigra of wild-type and ASC (apoptosis-associated speck-like protein containing caspase recruitment domain) KO mice, and then LPS was introduced intraperitoneally using an osmotic minipump. ASC forms a complex called NLRP3 inflammasome, which induces the maturation and production of inflammatory cytokines IL-1β and IL-18 via the protease caspase-1 (Misawa T, et al. Nat Immunol. 2013). Therefore, in ASC KO mice, microglial activation and induction of inflammatory cytokine production are suppressed. αsyn fibril-injected wild-type mice and ASC KO mice were treated with LPS to induce microglial activation, which could lead to loss of nigrostriatal dopamine cells and formation of αsyn aggregates. The pathophysiology of microglial status and distribution was analyzed.
Results: Introduction of αsyn fibrils and LPS into wild-type mice showed an increase in phosphorylated αsyn aggregates and degeneration of dopamine cells. However, ASC KO mice showed no change in the aggregates of phosphorylated αsyn and degeneration of dopamine cells following LPS treatment.
Conclusions: These results suggest that neuroinflammation is involved in the formation of αsyn aggregates and the loss of dopamine cells and plays an important role in the progression of synucleinopathy.

Aims: Here, we report a novel rodent model of movement disability (Bradykinesia and Postural instability) based on the induction of alpha-Syn (aSyn) aggregation within the gigantocellular nuclei (GRN) in brainstem.
Methods: As proof-of-concept (PoC), we performed stereotactic delivery of fibrillar aSyn (termed PFF) into the GRN of young (3-4 months) homozygous M83$^{+/+}$ mice (overexpressing the human mutant A53T aSyn) or wild type littermates (n=3/cohort). The mice were then subjected to a battery of motor performance tests every 2 weeks (Challenging Beam Traversal, Rotarod, Open Field, Grip Strength, Hindlimb Clasping).
Results: In the PoC M83$^{+/+}$ study, we have observed a unique phenotype of movement disability, which becomes conspicuous 3-4 weeks of PFF injection (in GRN): *i) challenging beam*: difficulty in movement initiation, slow movement, hindlimb slips and impaired posture maintenance (visible around 4 weeks post-PFF injection, more pronounced on the narrow 8mm beam) *ii) Rotarod*: abnormal motor coordination, such that the mice continue passive movement on the rotating rod and paradoxically 'outperform' the control mice *iii) Open field*: reduced spontaneous activity, increasing freezing episodes, difficulty in turning, overall slow movement As follow-up, we have initiated a larger study in cohorts of heterozygous M83$^{+/-}$ mice (n=8/cohort) with additional controls (PBS vehicle injection, Monomeric aSyn injection), and we expect to present relevant findings at the conference.
Conclusions: This novel rodent model of progressive movement disability based on aSyn aggregation in GRN (a region affected in PD brain)- especially capturing clinically relevant phenotypes of bradykinesia and postural instability- will be a highly valuable tool for: i) dissecting the neural substrate of movement disability in PD and ii) potentially testing the therapeutic relevance of novel disease modifying interventions in PD. TAUOPATHY PROMOTES SPINAL CORD-DEPENDENT PRODUCTION OF TOXIC AMYLOID-BETA IN TRANSGENIC MONKEYS

POSTERS: B07.B. ANIMAL MODELS: PRIMATES, NATURALLY OCCURING MODELS AND BRAIN ORGANOIDS

Zhuchi Tu, Sen Yan, Bofeng Han, Shihua Li, Xiao-Jiang Li
Jinan University, Guangdong-hongkong-macau Institute Of Cns Regeneration, Guangzhou, China

Aims: Tauopathy, characterized by the hyperphosphorylation and accumulation of the microtubule-associated protein tau, and the accumulation of Aβ oligomers, constitute the major pathological hallmarks of Alzheimer's disease. However, the relationship and causal roles of these two pathological changes in neurodegeneration remain to be defined, even though they occur together or independently in several neurodegenerative diseases associated with cognitive and movement impairment. While it is widely accepted that Aβ accumulation leads to tauopathy in the late stages of the disease, it is still unknown whether tauopathy influences the formation of toxic Aβ oligomers.
Methods: To address this, we generated transgenic cynomolgus monkey models expressing Tau (P301L) through lentiviral infection of monkey embryos. These monkeys developed age-dependent neurodegeneration and motor dysfunction. Additionally, we performed a stereotaxic injection of adult monkey and mouse brains to express Tau (P301L) via AAV9 infection.
Results: We found that tauopathy resulting from embryonic transgenic Tau expression or stereotaxic brain injection of AAV-Tau selectively promoted the generation of Aβ oligomers in the monkey spinal cord. These Aβ oligomers were recognized by several antibodies to Aβ1–42 and contributed to neurodegeneration. However, the generation of Aβ oligomers was not observed in other brain regions of Tau transgenic monkeys or in the brains of mice injected with AAV9-Tau (P301L), suggesting that the generation of Aβ oligomers is species- and brain region-dependent.
Conclusions: Our findings demonstrate for the first time that tauopathy can trigger Aβ pathology in the primate spinal cord and provide new insight into the pathogenesis and treatment of tauopathy.

MOLECULAR DIVERSITY OF ALPHA-SYNUCLEIN IN PARKINSON'S DISEASE

POSTERS: C01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: A-SYNUCLEIN AGGREGATION

Zeynep Kaya, Melina Lim, Danilyn Amerna, Michael Deture, Alexandra Soto-Beasley, Owen Ross, Dennis Dickson, Pam Mclean
Mayo Clinic, Department Of Neuroscience, Jacksonville, United States of America

Aims: Parkinson's disease (PD) is a progressive neurodegenerative disorder characterized neuropathologically by the accumulation and aggregation of alpha-synuclein in the form of Lewy bodies. The disease can manifest with different clinical symptoms among subgroups, depending on the age of onset or the pace of symptom progression. However, the reasons for this clinical heterogeneity are not entirely clear. We hypothesize that the molecular diversity of alpha-synuclein impacts its seeding potential and pathology spread, contributing to clinical heterogeneity. To test this hypothesis, we characterized the levels of total alpha-synuclein and phosphorylated alpha-synuclein at serine 129 (pSer129-α-syn) in post-mortem brain extracts and conducted seeding assays to detect differences among the study groups.
Methods: Study groups were designated as fast-progressing (diseased duration <5 years), and slow-progressing (disease duration >10 years). A FRET biosensor cell line was used to perform FRET flow cytometry assay to characterize alpha-synuclein seeding activity. RT-QuIC was performed as an additional measure of seeding bioactivity. High-content imaging was performed to assess the brain homogenates' ability to support seeding and promote macroscopic aggregation. Total alpha-synuclein and pSer129-α-syn levels were measured by AlphaLISA assay and correlated to imaging and FRET assay outcomes.
Results: No significant difference was detected in total alpha-syn levels between groups. However, significantly higher phosphorylated synuclein levels were observed in the slow-progressing group when compared to the fast-progressing group. Interestingly, increased levels of pSer129-α-syn appear to correlate with increased aggregation as observed by imaging, and increased seeding activity as measured by Flow-FRET.
Conclusions: Our results demonstrate a putative connection between pSer129-a-syn levels and aggregation and seeding bioactivity. These results can enhance understanding the molecular pathophysiology of PD.

Aims: Early and accurate Parkinson's disease (PD) diagnosis can be difficult and remains a clinical challenge. The current gold standard is post-mortem histopathological confirmation. Alpha-synuclein (a-syn) seed amplification assay (SAA) is a novel method to detect aggregatable a-syn, the pathological hallmark of PD, with the potential for early detection of PD but needs to be validated against the current gold standard. Here we used a-syn SAA to detect a-syn aggregation in CSF samples taken at the time of initial diagnosis of PD from patients with histopathologically confirmed PD diagnosis after death.
Methods: Our in-house a-syn SAA utilizes novel assay chemistry and gives a result after 48 hours. CSF samples were derived from the Norwegian ParkWest study and taken at the time of diagnosis. All patients were followed prospectively. The included samples (n=27) represent a subset of patients whose PD diagnosis was histopathologically confirmed upon death.
Results: 24 of 27 PD patients had a positive SAA result at the time of diagnosis, corresponding to a sensitivity of 88.9%. On average, SAA detected PD 10.2 years (range 5.4 – 13.2) prior to the gold standard diagnosis. All patients were Braak stage VI at autopsy. The three SAA-negative PD patients had a disease duration between 8.0 and 12.7 years.
Conclusions: Our a-syn SAA was able to detect PD pathology with high sensitivity already at the time of diagnosis with reference to the current gold standard post-mortem diagnosis. A-syn SAA has the potential to increase diagnostic accuracy at the very early clinical stages of PD.

Aims: Small alpha-synuclein (αSyn) aggregates in solution are proposed to be the true drivers of neurotoxicity in Parkinson's disease (PD). However, small soluble aggregates are elusive research targets due to their variable structures and low abundance, obstructing efforts to fully understand their structures, interactions, and bioactivity in a physiologically-relevant context. The present study aims to characterise small αSyn aggregates from post-mortem human brain tissue using single-molecule techniques and super-resolution microscopy, thereby representing the heterogeneity of aggregates on the nanometer scale. This work will expand on previous limited results from our group in a larger cohort and across different brain regions.
Methods: Post-mortem human brain tissue from n= 14 PD and n=5 age-matched controls across six brain regions was acquired from the Cambridge Brain Bank and the soluble fraction was extracted for analysis. We use the single-molecule pull-down (SiMPull) assay to capture protein aggregates on a novel specialised surface using an antibody-sandwich approach. Total internal reflection fluorescence microscopy is used to visualise proteins on the surface, and super-resolution imaging enables us to characterize aggregate sizes and shapes down to 20 nm.
Results: We established a SiMPull assay for investigating αSyn aggregates from post-mortem human brain tissue, and paired with super-resolution microscopy, we found that aggregates were on average smaller and more fibrillar in PD compared to healthy controls. We extended this assay to investigate other pathological protein aggregates including tau and amyloid-beta, and compared the results with Lewy Body burden throughout the brain regions.
Conclusions: We have established a robust assay to investigate small soluble αSyn aggregates from human brain tissue at the single-molecule level and uncovered significant differences in aggregate size and morphology in PD compared to controls.

PATHOLOGICAL A-SYNUCLEIN PROFILING IN NASAL SPECIMENS OF PATIENTS WITH PARKINSON'S DISEASE

POSTERS: C01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: A-SYNUCLEIN AGGREGATION

Mary Xylaki[1], Michael Bartl[1], Sandrina Weber[1], Luis Concha-Marabio[2], Brit Mollenhauer[1]

Aims: Parkinson's disease (PD) is a neurodegenerative disorder whose diagnosis is based on clinical criteria that can be difficult to interpret and distinguish from other parkinsonian syndromes. Biomarkers such as pathological alpha-synuclein (aSyn) detection are established in cerebrospinal fluid (CSF) which is collected by an invasive outpatient procedure. Typical PD is thought to start in the olfactory bulb which is connected to the nose, rendering easily accessible nasal samples potent for biomarker development. We sought to identify whether asyn seed amplification assay (SAA) developed to detect pathological asyn in CSF could detect pathological asyn in nasal lavage samples (NLS) and olfactory mucosa (OM). In addition we assessed the olfactory epithelium to identify the cellular subtype contributing to pathology.
Methods: In this study, OM and NLS were collected from PD patients recruited at the Paracelsus-Elena-Klinik, Kassel, Germany (DeNoPa Cohort) and from controls free of neurological disease. Samples were analysed using SAA and their seeding ability was compared to that of CSF samples. Further analyses were performed to assess the presence of aggregated forms of aSyn in the olfactory epithelium.
Results: SAA activity in OM and NLS from PD patients compared to controls indicated the specificity and sensitivity of these samples. In addition, accuracy among results of asyn SAA activity for CSF, OM and NLS from the same patient was estimated.
Conclusions: Our results suggest that asyn SAA analysis of nasal samples alone or combined with CSF testing are useful for increasing the diagnostic accuracy of PD. Finally, more research is necessary to establish the use of the assay in peripheral samples as a biomarker to detect the disease earlier and monitor progression and response to disease modifying approaches.

SYNPHILIN-1 AS A MODULATOR OF ALPHA-SYNUCLEIN ASSEMBLY

POSTERS: C01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: A-SYNUCLEIN AGGREGATION

Diana Lázaro[1], Triana Amen[2], Ellen Gerhardt[3], Patricia Santos[3], Dragomir Milovanovic[4], Günter Höglinger[5], Tiago Outeiro[3]
[1]Perelman School of Medicine at the University of Pennsylvania, Pathology And Laboratory Medicine, Philadelphia, United States of America, [2]École Polytechnique Fédérale de Lausanne, Global Health Institute, Lausanne, Switzerland, [3]University Medical Center Gottingen, Department Of Experimental Neurodegeneration, Göttingen, Germany, [4]German Center for Neurodegenerative Diseases, Laboratory Of Molecular Neuroscience, Berlin, Germany, [5]LMU hospital, Department Of Neurology, München, Germany

Aims: In this study, we investigate the relationship between alpha-synuclein (aSyn), an intrinsically disordered protein, and synphilin-1 (Sph1).
Methods: Our new cell-based model allows real-time monitoring of aSyn-Sph1 assemblies, reflecting biologically-relevant protein-protein interactions. We identify striking morphological differences between aSyn-aSyn and Sph1-aSyn assemblies, characterized by distinct antibody recognition patterns, resistance to Proteinase K treatment, and protein mobility. We show that the Sph1-aSyn interaction can be genetically manipulated, influencing inclusion size and quantity. Additionally, protein interactions proved to be pivotal for inclusion localization and formation, with protein expression levels altering inclusion phenotypes.
Results: We show that the Sph1-aSyn interaction can be genetically manipulated, influencing inclusion size and quantity. Additionally, protein interactions proved to be pivotal for inclusion localization and formation, with protein expression levels altering inclusion phenotypes. Our study highlights the potential significance of membrane binding in inclusion formation, further emphasized by the presence of lysosomes and AP-1 vesicles within these inclusions. Our findings suggest that Sph1 expression, or lack thereof, is a critical factor in aSyn aggregation as the coiled-coil domain of Sph1 plays an essential role in its interaction/aggregation with aSyn. Furthermore, our study hints at the broader implications of Sph1 in proteostasis and neurodegenerative diseases, suggesting it may act as a sentinel protein, promoting protein clearance or compartmentalizing harmful proteins.
Conclusions: In conclusion, this study offers novel insights into the interplay between Sph1-aSyn, shedding light on potential therapeutic strategies that extend beyond conventional targets. Sph1 emerges as a key player in the modulation of protein aggregation and homeostasis, paving the way for innovative approaches to tackle synucleinopathies and related neurodegenerative disorders. Further investigations are necessary to explore the clinical relevance of Sph1 expression levels in disease contexts.

UNCOVERING FACTORS IN BACTERIA THAT INHIBIT PROTEIN AGGREGATION OF A-SYNUCLEIN

POSTERS: C01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: A-SYNUCLEIN AGGREGATION

Changhan Lee
Ajou University, Department Of Biological Sciences, Suwon, Korea, Republic of

Aims: Protein have their own structure and it is associated with its function and mechanism. Proteins can be denatured by various stresses such as heat, but certain proteins are naturally prone to be aggregated. Of note, the aggregation of proteins is related to the diseases in human, for example the aggregation of a-synuclein is associated with Parkinson's disease. In this study, we tried to discover known anti-protein aggregation factors in Escherichia coli.
Methods: In this study, tripartite protein folding sensors fused with a-synuclein were utilized, and transposon sequencing (Tn-seq) methodology was employed.
Results: Through the screening process. we were able to discover that the OPE1 protein exhibits potent anti-aggregation activity towards a-synuclein. In addition, we confirmed that OPE1 protein significantly contributes to the inhibition of a-synuclein aggregation. This discovery highlights OPE1 as one of the known protein aggregation inhibitors for a-synuclein.
Conclusions: This study provides important insights into the relationship between protein aggregation and diseases, with OPE1 protein being identified as an effective inhibitor of a-synuclein aggregation. These research results are expected to offer valuable information for disease-related protein aggregation studies and the potential development of therapeutic approaches.

EFFECTS OF ALPHA-SYNUCLEIN IN THE EXPRESSION OF PEROXISOMAL GENES AND THE DISLOCATION OF CATALASE

POSTERS: C01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: A-SYNUCLEIN AGGREGATION

He-Jin Lee[1], Ye-Seul Yoon[1], Soojin Shin[2], Woo Jung Ahn[3], Seung-Jae Lee[2,4]
[1]Konkuk University, Anatomy, Seoul, Korea, Republic of, [2]Seoul National University, Biomedical Sciences, Seoul, Korea, Republic of, [3]Konkuk University, Ibst, Seoul, Korea, Republic of, [4]Neuramedy, Research And Development, Seoul, Korea, Republic of

Aims: Peroxisomes are small, membrane-bound organelles that contain enzymes involved in various metabolic reactions, such as lipid metabolism and the processing of reactive oxygen species. Peroxisomes in the brain also maintain cellular membrane and myelin sheath in neuron and glial cells. Peroxisomal defects result in severe neurological dysfunctions in myelination, oxidative stress, inflammation, neuronal migration, etc., but little is known about the roles of peroxisomes in neurodegenerative diseases.
Methods: This study shows that a-synuclein overexpression decreased mRNA and protein expression of some peroxisome biogenesis factor proteins.
Results: We identified that these reductions result in abnormality of catalase import into the peroxisome lumen, causing dislocation of catalase outside the peroxisomes. Interestingly, these dislocated catalase proteins co-localized with a-synuclein aggregates in the cell cytoplasm.
Conclusions: These results suggest that a-synuclein overexpression may cause peroxisome dysfunction by regulating the expression of peroxisomal proteins that are important for the transport of catalase into the peroxisomes. The resulting accumulation of ROS species and increased oxidative stress may be critically unfavorable for the progression of neurodegenerative diseases.

Aims: The brain renin-angiotensin system (RAS) has been related to dopaminergic degeneration, and high expression of the angiotensin II (AngII) type-1 receptor (AT1) gene is a marker of the most vulnerable neurons in humans. However, it is unknown whether AngII/AT1 overactivation affects α-synuclein aggregation and transmission. As such, our main AIM is to determine the effects of AngII/AT1 overactivation on α-synuclein aggregation and transmission
Methods: To answer this question, we used in vitro (α-synuclein-T/V5-synphilin-1 and a modified version of bimolecular fluorescence complementation in HMC3 and BV2 microglial, C6 astroglial and N27 neuron cell lines) and in vivo (subacute MPTP PD mouse) models to study possible effects of AngII on α-synuclein aggregation and transmission in dopaminergic neurons, and astroglial and microglial cells.
Results: In vitro, AngII/AT1 activation increased α-synuclein aggregation in dopaminergic neurons and microglial cells, which was related to AngII-induced NADPH-oxidase activation and intracellular calcium raising. In mice, AngII/AT1 activation was involved in MPTP-induced increase in α-synuclein expression and aggregation, as they significantly decreased in mice treated with the AT1 blocker telmisartan and AT1 knockout mice. Cell co-cultures (transwells) revealed strong transmission of α-synuclein from dopaminergic neurons to astrocytes and microglia. AngII induced a higher α-synuclein uptake by microglial cells, and an increase in transfer α-synuclein among astroglial cells. However, AngII did not increase the release of α-synuclein by neurons. The results further support brain RAS dysregulation as a major mechanism for progression of Parkinson's disease, and AT1 inhibition and RAS modulation as a therapeutic target.
Conclusions: AngII/AT1 overactivity and brain RAS dysregulation appears involved in major processes related to PD progression such as oxidative stress, neuroinflammation, and α-synuclein expression, aggregation, and cell-to-cell transmission, as revealed for the first time in the present study.

HERPES SIMPLEX VIRUS TYPE 1 TRIGGERS THE PRODUCTION OF A-SYNUCLEIN IN BOTH HUMAN AND MOUSE CNS NEURONS IN VITRO.

POSTERS: C01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: A-SYNUCLEIN AGGREGATION

Ahmad Mahmoudikouhi, Ya Gao, Febe Lippens, Kathlyn Laval
Ghent university, Department Of Translational Physiology, Infectiology And Public Health, Merelbeke, Belgium

Aims: Alzheimer's disease (AD) and Parkinson's disease (PD) are progressive neurodegenerative disorders affecting millions of people worldwide. Although these two diseases have different clinical features, they share common mechanisms such as the accumulation of α-synuclein (a-syn) protein in CNS neurons, leading to neuroinflammation and neuronal death. There are currently no cures for AD and PD. The lack of etiology is the most important barrier to finding a cure. Accumulating evidence suggests that viruses, such as Herpes simplex virus type 1 (HSV1), may play a role in the pathogenesis of these diseases. Here we hypothesize that HSV1 infection directly contributes to the initiation of AD and PD by inducing the production and subsequent accumulation of a-syn in neurons.
Methods: We characterized and compared the replication kinetics of HSV1 in both mouse (N2A) and human (SH-SY5Y) CNS neuronal cells. We correlated these data with the kinetics of a-syn protein production by means of immunofluorescence staining techniques.
Results: We demonstrated that HSV1 induces the production of a-syn protein in both cell types starting from 6 hours post-inoculation (hpi). No a-syn protein was expressed in mock-infected cells. The production of a-syn significantly increased over time, as the infection progressed. This production was also found to be viral strain-dependent. Inoculation with HSV-1 virulent F strain resulted in a higher percentage of α-syn positive cells compared to inoculation with clinical isolate.
Conclusions: Overall, our data demonstrate that HSV1 specifically triggers a-syn protein expression in both mouse and human CNS cells. These results provide new direct evidence on the potential role of HSV1 in the pathogenesis of AD and PD.

METAL ION INDUCED ALPHA-SYNUCLEIN OLIGOMERS DISRUPT MEMBRANE INTEGRITY OF NEUTRALLY CHARGED LARGE UNILAMELLAR VESICLES

POSTERS: C01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: A-SYNUCLEIN AGGREGATION

Georg Nuebling[1], Frits Kamp[2], Felix Schmidt[3], Armin Giese[3], Johannes Levin[4,5,6]
[1]Ludwig-Maximilians University Munich, Department Of Neurology, Munich, Germany, [2]Ludwig-Maximilians University Munich, Division Of Metabolic Biochemistry, Faculty Of Medicine, Biomedical Center (bmc), Munich, Germany, [3]MODAG GmbH, N/a, Wendelsheim, Germany, [4]German Center for Neurodegenerative Diseases (DZNE), Site Munich, Munich, Germany, [5]Munich Cluster for Systems Neurology (SyNergy), N/a, Munich, Germany, [6]Ludwig-Maxmilians-University, Department Of Neurology, Munich, Germany

Aims: It was shown that trivalent metal ions promote the formation of alpha-synuclein (asyn) oligomers even at low nanomolar protein concentrations, and that these oligomers exhibit a pathological gain of function in binding to neutral lipid surfaces. The aim of the current study was to determine whether asyn oligomers formed in presence of ferric iron interfere with the integrity of lipid membranes upon membrane binding.
Methods: Human recombinant alpha-synuclein monomers and Fe^{3+}-induced oligomers were coincubated with large unilamellar vesicles (LUV) derived from 1-palmitoyl-2-oleoyl-sn-glycero-3-phosphocholine (POPC) at final protein concentrations of 10-20 nM. POPC-LUV contained the Ca^{2+} sensitive dye Fluo4. After baseline measurements, Ca^{2+} was added to the solution (final concentration 0.2mM). Applying single-particle fluorescence techniques (fluorescence correlation spectroscopy, FCS, and Scanning for Intensely Fluorescent Targets, SIFT) and fluorescence spectrometry, protein-membrane interactions were observed at nanomolar and micromolar protein concentrations at the single particle level. For FCS/SIFT experiments, asyn was labeled with the fluorescent dye Alexa-647-O-succiminidylester.
Results: As demonstrated previously, Fe^{3+} induced asyn oligomers, but not monomers, exhibited binding to POPC-LUV. Upon addition of Ca^{2+}, POPC-LUV with bound asyn oligomers showed a fluorescence intensity shift indicating the intrusion of Ca^{2+} ions into the vesicles and activation of the Ca^{2+} sensitive dye. This effect could be reversed upon addition of the Ca^{2+}-binding agent EDTA. Similarly, an increase in fluorescence was observed in fluorescence spectroscopy experiments upon coincubating POPC-LUV and asyn oligomers, but not monomers.
Conclusions: In conclusion, the results presented here demonstrate a pathological gain of function of metal ion induced asyn oligomers in disrupting lipid membranes. These findings have implications for the pathological role of asyn oligomers both concerning the disruption of intracellular organelles and intercellular spreading of pathological asyn oligomer species.

EFFECTS OF SPLICE VARIANTS ON THE PATHOGENIC AGGREGATION OF ALPHA-SYNUCLEIN

POSTERS: C01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: A-SYNUCLEIN AGGREGATION

Alexander Röntgen, Zenon Toprakcioglu, Samuel Dada, Owen Morris, Michele Vendruscolo
University of Cambridge, Yusuf Hamied Department Of Chemistry, Cambridge, United Kingdom

Aims: The aberrant aggregation of alpha-synuclein has long been associated with Parkinson's disease (PD) and related synucleinopathies. The predominant isoform of alpha-synuclein is expressed as a 140-amino acid protein (aSyn-140). However, alpha-synuclein does not exist as a single molecular species in cellular environments but as a variety of proteoforms, generated by variations in splicing, with increasing evidence suggesting that such variants are involved in the overall aggregation process and in the progression of the disease. We therefore investigate the role of splice variants in aggregation and cytotoxicity, as well as their aggregation in mixtures.
Methods: We employed computational solubility predictors, fluorescence-based aggregation assays, kinetic analysis and modelling, as well as electron microscopy to elucidate the mechanism of alpha-synuclein aggregation. In parallel, we used cell viability assays to determine the cytotoxicity of the formed aggregates on SH-SY5Y neuroblastoma cells.
Results: Variations in splicing led to marked differences in the aggregation kinetics and mechanisms, as well as morphological and cytotoxic properties of the proteoform aggregates. Moreover, we determined that the aggregation of aSyn-140 was influenced and modulated by the presence of splice variants.
Conclusions: Our findings imply that the mechanisms leading to the production of diverse proteoforms of alpha-synuclein may be involved in the pathogenesis of synucleinopathies. These results may open the possibility to further understand the role of alpha-synuclein splice variants in the pathological aggregation of this protein and therefore the development of synucleinopathies.

KAJO NEUROTECHNOLOGIES: HUMAN ALPHA-SYNUCLEIN AGGREGATION MODELS FOR DRUG DISCOVERY

POSTERS: C01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: A-SYNUCLEIN AGGREGATION

Vassilis Stratoulias[1,2], Amanda Sandelin[1,2], Irena Hlushchuk[1], Safak Er[1], Simas Janutenas[1,2], Jenni Montonen[1,2], Joel Noutere[1,2], Mikko Airavaara[1,2]
[1]University of Helsinki, Faculty Of Pharmacy, Helsinki, Finland, [2]University of Helsinki, Neuroscience Center, Helsinki, Finland

Aims: Developing drugs is a highly risky venture, with only a 0.1% success rate for preclinical candidates gaining approval. The current models employed in drug discovery and development, including in vivo and in vitro rodent models and human cell lines, do not completely replicate human neurodegenerative disorders. Our objective is to create a high-throughput in vitro human model using human cells that mimics pathological features of Parkinson's disease.
Methods: We produce dopaminergic neurons from human stem cells and validate their functionality through assessments of dopamine expression, electrophysiology, biochemical analysis, and transcriptomic profiling. Additionally, we have implemented innovative techniques to induce the formation of Lewy body-like alpha-synuclein aggregates within these dopaminergic neurons derived from human stem cells.
Results: We can induce the formation of alpha-synuclein aggregates within dopaminergic neurons derived from human stem cells. These aggregates can be analyzed using an unbiased high-throughput manner.
Conclusions: Our model, which utilizes alpha-synuclein aggregation in human stem cell-derived dopaminergic neurons, holds promise for drug screening purposes in the context of Parkinson's disease.

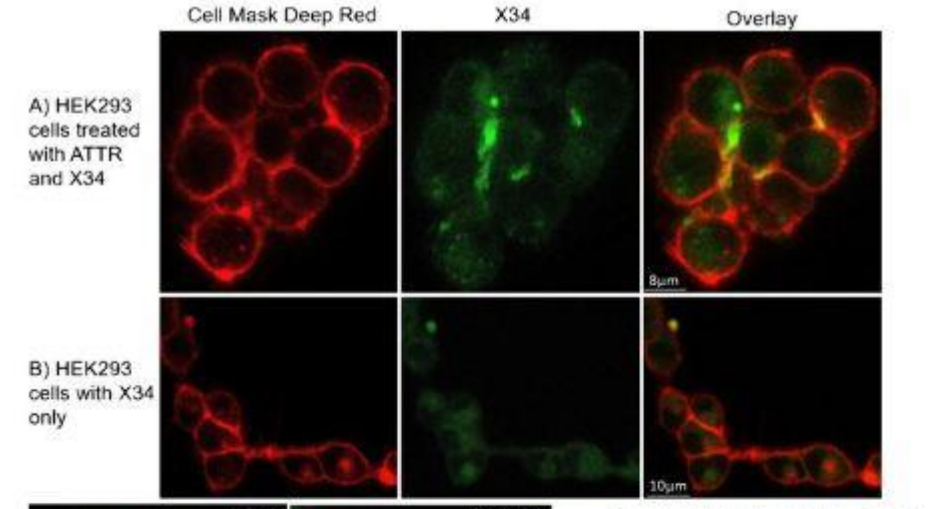
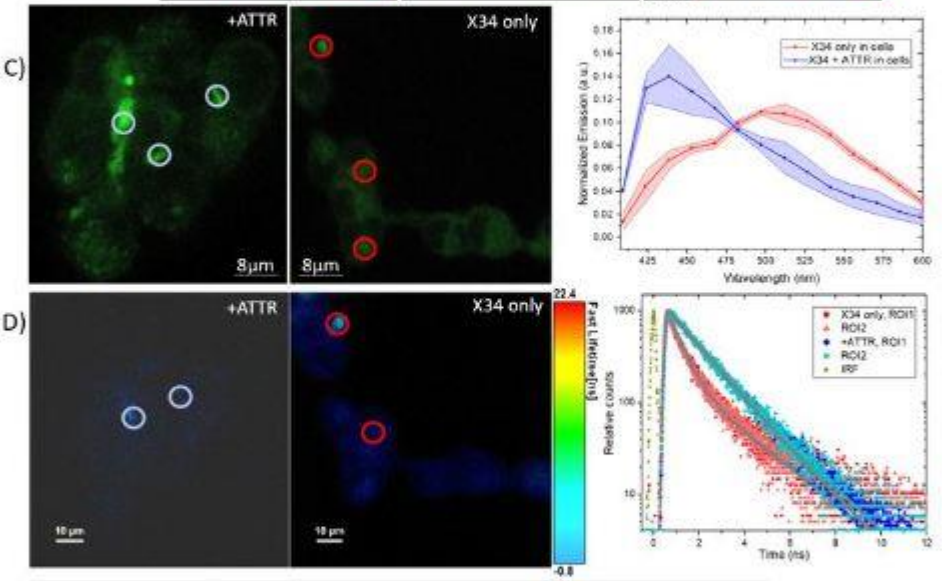
HYPERSPECTRAL IMAGING OF AMYLOID TRANSTHYRETIN (ATTR) AND ASYNUCLEIN IN CELL-MODELS USING NOVEL AMYLOID SPECIFIC FLUORESCENT LIGANDS

POSTERS: C01.A. DISEASE MECHANISMS, PATHOPHYSIOLOGY: A-SYNUCLEIN AGGREGATION

Priyanka Swaminathan[1], Marikken Sundnes[1], Mikael Lindgren[1], Odrun Gederaas[2], Ebba Hellstrand[3], Per Hammarström[3], Sofie Nyström[3], Therése Klingstedt[3], Peter Nilsson[4], Nathalie Van Den Berge[5]
[1]Norwegian University of Science and Technology, Department Of Physics, Trondheim, Norway, [2]University of Agder, Department Of Natural Sciences, Kristiansand, Norway, [3]Linköping University, Department Of Physics, Chemistry And Biology, Linköping, Sweden, [4]Linköping University, Dpt. Of Physics, Chemistry & Biology, Linköping, Sweden, [5]Aarhus University, Department Of Clinical Medicine, Aarhus N, Denmark

Aims: Pathological accumulation and misfolding of certain proteins into insoluble protein aggregates, known as amyloids, is typical to many neurodegenerative disorders. Furthermore, adding to the structural complexity, the cellular environment in which the amyloid protein tends to form aggregates, is also known to influence its molecular conformation. Therefore, we aim to use *in-vitro* cell-models to understand the conformation-specific amyloid pathology in cellular milieu. Here, we present the preliminary results of the hyperspectral imaging of amyloid Transthyretin (ATTR) filaments in Human Embryonic Kidney (HEK)293 cells in order to understand whether the cellular environment influences the spectral features of ATTR in these cells. This study also lays groundwork for detecting and study various polymorphic amyloid protein aggregates including, asynuclein and tau in future.
Methods: HEK293 cells were exposed to ATTR filaments in a serum-free growth medium. 48 hours post protein exposition, the cells were stained with a novel amyloid-specific fluorescent ligand, X34 and subsequently, they were incubated for 2 hours before imaging. The cells were then washed with PBS, followed by staining with a marker for cell membrane, Cell Mask Deep Red. They were then imaged using Confocal Laser Scanning Microscope (CLSM). Fluorescence lifetime imaging microscopy (FLIM) was measured using the PicoQuant's single photon counting feature of the CLSM.





E)

Samples	τ_1 ns (a_1)	τ_2 ns (a_2)	τ_{avg} (ns)
+ATTR	2.3 ± 0.2 (0.24)	1.2 ± 0.1 (0.76)	1.62 ± 0.02
X34 only	2.7 ± 0.07 (0.15)	0.6 ± 0.01 (0.85)	1.56 ± 0.03

Figure 1: Hyperspectral imaging to decipher the spectral characteristics of ATTR in HEK293 cells. **A)** HEK293 cells exposed to 7µM ATTR along with 1µM X34 (bright green) which is excited using 405 nm laser. Fluorescence intensity of X34 increased when it bound to ATTR within cells. **B)** HEK 293 cells exclusively exposed to 1µM X34.**C)** Emission spectrum of X34 is constructed using different Regions of interest (ROIs) within cells. The emission spectrum of X34 when it is bound to ATTR is considerably blue shifted in relation to emission spectrum of X34 when it is alone in cells. **D)** Color-coded images of X34 excited using 405 nm laser, acquired when it is exclusively exposed to HEK 293 cells or when it is bound to ATTR in cells. The color bars represent lifetimes ranging from -0.8 ns to 22.4 ns. The lifetime plots of X34 (red, orange) and when it is bound to ATTR (turquoise blue, dark blue), are constructed by selecting different ROIs within the cells and fitting the FLIM data to a double exponential function. **E)** The average lifetime of X34 when it is bound to ATTR in cells is significantly longer in comparison to the average lifetime of X34, when it is alone in cells.

Results: The spectral features of ATTR when it binds X34 in HEK293 cells is considerably blue shifted in relation to X34 when they are alone in cells .The ensuing fluorescence decay upon ATTR- X34 interaction exhibits longer lifetime.

Conclusions: The spectral feature of ATTR when it is bound to X34 in cells is significantly blue-shifted and exhibits longer lifetime which suggests that the structural morphology of ATTR might by influenced by hydrophobic interactions within the cellular environment .

INVESTIGATION OF THE RELATIONSHIP BETWEEN LRRK2 AND ALPHA-SYNUCLEIN IN PARKINSON'S DISEASE

POSTERS: C01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LRKK2, PARKIN, PINK1, DJ-1

Giuseppe Madaro[1], Laura Volpicelli-Daley[2], Kurt De Vos[1]
[1]University of Sheffield, Neuroscience, Sheffield, United Kingdom, [2]University of Alabama at Birmingham, Neurology, Birmingham, United States of America

Aims: LRRK2 mutations are the most common monogenic cause of Parkinson's disease (LRRK2-PD). LRRK2-PD is characterized by intraneuronal inclusions, prion-like spreading of aggregated alpha-synuclein, and dopaminergic neuron degeneration. LRRK2 is a protein with GTPase and kinase activity that regulates several biological functions, including autophagy and subcellular trafficking. We have previously shown that LRRK2 interacts with histone deacetylase 6 (HDAC6), a cytoplasmic deacetylase that regulates inflammation, axonal trafficking, and clearance of ubiquitinated protein aggregates via aggrephagy. Preliminary data indicate that LRRK2 may regulate HDAC6 by phosphorylation and that the kinase hyperactive LRRK2 mutant G2019S disrupts ubiquitin-dependent aggresome formation in PD. HDAC6 and LRRK2 have been independently linked to clearance and propagation of aggregated alpha-synuclein. However, how LRRK2 mutations cause alpha-synuclein pathology remains elusive.
Methods: Using *in cellulo* assays, we characterized the interaction between LRRK2 and HDAC6 and investigated the role of LRRK2 and HDAC6 in alpha-synuclein metabolism.
Results: We observed that LRRK2 kinase activity influences its binding to HDAC6, but does not regulate ubiquitin-dependent aggresome formation, NLRP3 inflammasome activation, or microtubule acetylation. We did not find evidence that PFF-induced alpha-synuclein aggregates are targeted to the aggresome via HDAC6. However, HDAC6 inhibition led to accumulation of both soluble and PFF-induced alpha-synuclein aggregates, indicating a role of HDAC6 in alpha-synuclein homeostasis under physiological and pathological conditions. Additionally, LRRK2 kinase inhibitors increased α-synuclein expression levels but had no impact on seeded alpha-synuclein aggregation. No changes were detected in basal alpha-synuclein secretion and subcellular localization upon either LRRK2 or HDAC6 inhibition.
Conclusions: Our data indicate that both LRRK2 and HDAC6 may be involved in alpha-synuclein homeostasis by influencing its clearance and aggregation. Future research will elucidate how LRRK2 regulates HDAC6 functions and how these intersect with alpha-synuclein dyshomeostasis.

DISCOVERY OF PINK1/PARKIN SMALL MOLECULE MODULATORS AS TREATMENTS FOR PARKINSON'S DISEASE

POSTERS: C01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LRKK2, PARKIN, PINK1, DJ-1

Arwa Alghamdi, Azeza Fdel, Youcef Mehellou

Aims: Loss of function mutations in the serine/threonine protein kinase PINK1 have been associated with the development of Parkinson's disease (PD) in humans. These mutations lead to impairment in mitophagy, a cellular process that removes damaged or depolarized mitochondria, consequently protecting cells from oxidative stress and eventually neuronal cell death. Upon mitochondrial depolarization, PINK1 gets stabilized on the outer mitochondrial membrane (OMM) and phosphorylates ubiquitin and the E3 Ubiquitin ligase, parkin, ultimately triggering mitophagy. Hence, PINK1 activation has been highlighted as a potential therapeutic approach for PD by promoting neuroprotection through the activation of mitophagy. Our aim of this work is to design and synthesize a series of small molecule PINK1 activators as potential treatments for PD.
Methods: We used chemical synthesis to generate a series of small molecules, and Western blotting/ELISA to probe their ability for activating PINK1 in cells and neurons. Also, we used *mito*-QC assay to assess the ability of these molecules to induce PINK1-dependent mitophagy in mouse embryonic fibroblasts (MEFs).
Results: Our compounds were able to activate PINK1 in cells as judged by the phosphorylation of parkin, a PINK1 physiological substrate. Intriguingly, such compounds were able to protect the cells from the formation of elevated phosphoubiquitin levels caused by mitochondrial damaging agents such as CCCP and niclosamide in cells and in neurons, a hallmark of PD. Subsequently, the compounds were found to trigger mitophagy in a PINK1-dependent manner in MEFs.
Conclusions: We have discovered a series of PINK1 activators that can trigger physiologically relevant PINK1-dependent mitophagy that is capable of suppressing the accumulation of phosphoubiquitin. Given the promise of such compounds, they warrant further development and investigation as potential PD treatment.

EXPLORING LRRK2-CLUSTERIN PATHWAY IN ASTROCYTES: IMPLICATIONS FOR ALPHA-SYNUCLEIN CLEARANCE AND SPREADING

POSTERS: C01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LRKK2, PARKIN, PINK1, DJ-1

Alice Filippini[1], Giulia Carini[1], Veronica Mutti[2], Massimo Gennarelli[1,2], Isabella Russo[1,2]
[1]University of Brescia, Molecular And Translational Medicine, Brescia, Italy, [2]IRCCS-Istituto Centro San Giovanni di Dio Fatebenefratelli, Unit Of Genetics, Brescia, Italy

Aims: Accumulating evidence highlights that dysfunction of astrocytes biology might contribute to Parkinson's disease (PD) onset and progression. To this regard, we recently showed that extracellular clusterin binds to and limits the uptake of alpha-synuclein fibrils by astrocytes, suggesting that its modulation might control alpha-synuclein spreading. Of relevance, we observed that Leucine-rich repeat kinase 2 (*LRRK2*), a gene linked to genetic and familial PD, regulates clusterin levels. Thus, in this study we explore LRRK2-Clusterin pathway in astrocytes to understand whether dysfunctions of this process might contribute to the spreading of alpha-synuclein species between neurons.
Methods: To this aim, we used primary astrocytes cultures and ex-vivo brain tissues from wild type (WT), LRRK2 knock-out (KO) and G2019S knock-in (KI) mice.
Results: Our results show that brain lysates and primary astrocytes from LRRK2 G2019S KI mice exhibit increased clusterin levels compared to their respective WT. Accordingly, we found an opposite effect in brain lysates and in primary astrocytes from LRRK2 KO mice in comparison to their WT. To gain insights in the molecular mechanism underlying LRRK2-dependent clusterin modulation, we found that LRRK2 controls clusterin at the translation level through the regulation of miR-22-5p. We are now validating miR-22-5p as a miRNA clusterin target. Moreover, in relation to PD pathology, we found that astrocytic LRRK2-clusterin pathway affects the spreading of alpha-synuclein aggregates between neurons.
Conclusions: Future studies will allow us to understand whether the modulation of this process through LRRK2 kinase inhibition might improve the ability of astrocytes to clear alpha-synuclein and thus to attenuate neuronal spreading of alpha-synuclein pathology.

REBALANCE OF MITOPHAGY BY INHIBITING LRRK2 IMPROVES PARKINSON'S DISEASE-RELATED COLON DYSFUNCTIONS

POSTERS: C01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LRKK2, PARKIN, PINK1, DJ-1

Alerssia Filippone, Deborah Mannino, Giovanna Casili, Marika Lanza, Laura Cucinotta, Irene Paterniti, Emanuela Esposito
University of Messina, Chemical, Biological, Pharmaceutical And Environmental Sciences, Messina, Italy

Aims: Mutations in the leucine-rich repeat kinase 2 (LRRK2) gene are the most common genetic causes of Parkinson's disease (PD). Mutations of LRRK2 cause dopaminergic neuron death, impaired neurotransmission, and inflammatory response. Also, approximately 80% of PD patients suffer from gastrointestinal dysfunction so the treatment of gut symptoms has been recognized as an important part of the management of PD. Recent studies have demonstrated that mutations of LRRK2 contribute to an increase of intestinal disorders, revealing that variants in LRRK2 genetically link dysfunctions to PD. We aimed to evaluate whether the selective inhibitor of LRRK2, PF-06447475 (PF-475), attenuates the PD induced by 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) in CNS and in the gastrointestinal system.
Methods: Animals received 4 injections of MPTP (20 mg/kg) at two hours intervals in one day. After 24 hours PF-475 was administered (2.5, 5 and 10 mg/kg) for seven days.
Results: LRRK2 targeting reduced brain α-Synuclein accumulation and modulated mitochondrial autophagic processes. Furthermore, PF-475 administration reduced pro-inflammatory markers like iNOS and COX-2 and α-Synuclein aggregates in colonic tissues PD-mice through the modulation of mitoautophagy proteins like p62, optineurin and LAMP2. LRRK2 inhibition suppressed MPTP-induced enteric dopaminergic neuronal injury through modulation of product 9·5 (PGP9.5) and neuron-specific enolase (NSE) and protected tight junction like ZO-1 and occludin disrupted by MPTP in the colon tissue.
Conclusions: We indicated that selective inhibition of LRRK2 restores disruption of colonic integrity and enteric dopaminergic neurons in an MPTP-injected mouse PD model via the mitoautophagy pathway, suggesting that PF-475 may attenuate gastrointestinal dysfunction associated with PD.

SYNAPTOJANIN 2-MEDIATED TRANSPORT OF MRNA MAINTAINS MITOPHAGY AND MITOCHONDRIAL FUNCTION IN AXONS AND SYNAPSES

POSTERS: C01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LRKK2, PARKIN, PINK1, DJ-1

Whitney Gibbs, Thomas Schwarz
Boston Children's Hospital, Neurobiology, Boston, United States of America

Aims: A unique problem for neurons is providing sufficient energy and protein synthesis to support distant axons and dendrites. Proteins that have short half-lives will not make it to the distal neuron, as it can take weeks for proteins to travel from the soma. Our work uncovered that the RNA recognition motif (RRM) of Synaptojanin 2(SYNJ2) tethers transcripts of PINK1, a short-lived protein mutated in a hereditary form of Parkinson's disease, to motile mitochondria for local protein synthesis. This novel work is the first to explore the unappreciated SYNJ2 RRM with respect to its RNA binding function as a mediator of mitochondrial and neuronal health.
Methods: Three alanine point mutations in SYNJ2 RRM ($SYNJ2^{AAA}$) prevented its RNA binding capacity. These mutations were endogenously expressed in SYNJ2 of mice and human iPSCs using CRISPR/Cas9 technology. iPSCs were differentiated into iNeurons.In situ hybridization allowed for the visualization of PINK1 mRNA in axons. To determine if mitophagy was impacted, we monitored phospho-ubiquitin staining under stress conditions. Mitochondrial respiratory capacity and metabolomic profile were determined using isolated synaptosomes. Electron microscopy was utilized to assess mitochondrial morphological changes.
Results: Axonal PINK1 mRNA and protein stabilization are absent in $SYNJ2^{AAA}$ axons. Antimycin-A increased levels of PINK1 protein and pUb in control, but was attenuated in $SYNJ2^{AAA}$ neurons, indicating decreased mitophagy. $SYNJ2^{AAA}$ synaptosomes exhibited decreased maximal respiration and spare capacity. Key mediators of the glycolytic pathway are upregulated in $SYNJ2^{AAA}$ synaptosomes, potential compensation for impaired mitochondrial respiration. Sciatic nerve mitochondria from aged $SYNJ2^{AAA}$ mice have irregular cristae area and regions with no discernible cristae.
Conclusions: Our work provides fresh insights into a newly discovered mechanism of how mRNA transport and local translation are required to keep the distal axon functioning properly.

Aims: Parkinson's disease (PD) represents a significant neurodegenerative disorder, and its occurrence is on the rise within our aging population. The loss of dopamine-producing neurons, which is at the core of PD, has long been associated with compromised energy production within the mitochondria. Meanwhile, ongoing research suggests that irregularities in DNA metabolism and the recycling of cellular components (autophagy) also play crucial roles in the development of this disease. Recent investigations have revealed deviations in mitochondrial function and nucleotide metabolism linked to PD in human neurons. Mitochondria, housing DNA (mtDNA) vital for energy production and overseeing autophagy, form a functional loop that we propose includes defects in mitochondrial DNA maintenance. Any alterations in these pathways, particularly in highly susceptible cell types, can potentially lead to neuronal cell death and the onset of PD. Our project aims to explore the relevance of Parkinson's disease-causing mutations, specifically LRRK2 mutations, in relation to mitochondrial function, autophagy, and DNA metabolism.
Methods: We use fibroblasts extracted from skin biopsies of PD patients carrying LRRK2 mutations, as well as idiopathic PD patients and *Drosophila melanogaster* models to develop different molecular and functional assays.
Results: In our study, we demonstrate that hyperactivation of LRRK2 within our Parkinson's disease (PD) models not only results in impaired lysosomal function but also disrupts mitochondrial function and compromises the maintenance of mitochondrial DNA (mtDNA).
Conclusions: Through the analysis of functional and molecular outcomes derived from our models, we demonstrate that hyperactivation of LRRK2, causing alterations in autophagy, results in mitochondrial dyfunction and mtDNA metabolism defects, ultimately affecting neuronal survival and locomotor function.These findings could shed light on their potential contribution to the pathogenesis of PD.

Aims: Hyposmia and accumulation of insoluble αSynuclein aggregates in the olfactory bulbs are associated with early, pre-motor stages of typical Parkinson disease (PD). In this study we investigated αSynuclein pathology in the human olfactory epithelium and whether it reflects pathology inside the nervous system and responds to environmental triggers such as viral infections.
Methods: We resected the nasal cavity at autopsy from >45 adults with PD, dementia with Lewy bodies, other neurodegenerative diseases, COVID-19 and controls. Nasal bone structures were decalcified and processed for immunohistological and immunofluorescence-based microscopy to screen for and localize aggregated αSynuclein within olfactory and respiratory epithelia.
Results: Select regions of nasal epithelia contained αSynuclein aggregates with four typical staining patterns observed. These were present most often in olfactory neurons, including in their apical dendrites, and in cells of the Bowmann glands in the form of small punctae. Large aggregates were seen in synucleinopathy cases at a rate of 50% and in subjects that died of COVID-19 at ~65%. αSynuclein aggregates were also detected to a lesser extent in control cases (at ~20%). In general, we found poor correlation between these aggregates in nasal epithelia and Lewy-type inclusions in the olfactory bulb and tract from the same subjects.
Conclusions: Our findings indicate that αSynuclein can physiologically form aggregates in the nasal cavity. These may represent the earliest Parkinson's-linked misfolding events described to date. Our results also suggest that environmental triggers, such as a nasal RNA virus infection, could play a role in the formation of such aggregates. The correlation of αSynuclein aggregate formation in relation to inflammation and epithelial turnover remains under investigation.

INVESTIGATING THE INTERACTIONS BETWEEN LRRK2 AND GBA1 IN MOUSE AND HUMAN IPSC-DERIVED ASTROCYTES IN PARKINSON DISEASE

POSTERS: C01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LRKK2, PARKIN, PINK1, DJ-1

Chiao-Yin Lee[1,2], Matthew Gegg[1,2], Anthony Schapira[1,2]
[1]University College London, Department Of Clinical And Movement Neurosciences, London, United Kingdom, [2]Collaborative Research Network, Aligning Science Across Parkinson's (asap), Chevy Chase, United States of America

Aims: Variants in the genes for leucine rich repeat kinase 2 (LRRK2) and glucocerebrosidase 1 (GBA1) are risk factors for Parkinson disease. An observational study reported that the gain-of-function G2019S-LRRK2 mutation has a protective effect in patients carrying a loss-of-function GBA1 mutation, but the biochemical basis of this interaction remains unclear. This project aims to identify the mechanisms by which LRRK2 influences GBA1 protein expression and activity via the lysosomal pathway, Rab8A and Rab10, as well as to determine if GBA1 exerts an effect on LRRK2.
Methods: Mouse and hiPSC-derived astrocytes carrying the G2019S-LRRK2 and/or N370S-GBA1 mutations were treated with the LRRK2 kinase inhibitor MLi-2 for 24 hours or the lysomotropic drug chloroquine for 5 hours, which has been shown to enhance LRRK2-dependent phosphorylation of Rab8A/10. Immunofluorescence, Western blot, lysosomal activity assays and LysoID are used to investigate how LRRK2 kinase activity impacts alpha-synuclein, GBA1 protein expression and activity and the lysosome, and if reduced GBA1 activity affects LRRK2 activity.
Results: As expected, phosphorylation of Rab8A and Rab10 in mouse and human iPSC-derived astrocytes were decreased or increased by MLi2 and chloroquine, respectively. Preliminary results suggest that in human astrocytes carrying both G2019S and N370S, G2019S rescues the loss of GBA1 protein, and partially rescues reduced lysosomal GBA1 activity, possibly through increasing overall lysosomal content. N370S also appears to slightly increase LRRK2 kinase activity in both mouse and human astrocytes.
Conclusions: Understanding the mechanisms of which GBA and LRRK2 interact within the lysosomal pathway will increase our knowledge of how the two genes cause disease as well as help identify possible drug targets for GBA1- or LRRK2- associated Parkinson disease.

EXPLORING OLIGODENDROCYTES AS A NEW PLAYER IN THE PATHOGENESIS OF PARKINSON'S DISEASE

POSTERS: C01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LRKK2, PARKIN, PINK1, DJ-1

Isabella Russo[1,2], Valentina Mazziotti[2], Elena Cannone[1], Alice Filippini[3], Giulia Carini[1], Veronica Mutti[2], Massimo Gennarelli[2,3], Marco Schiavone[1]
[1]University of Brescia, Department Of Molecular And Translational Medicine, Brescia, Italy, [2]IRCCS-Istituto Centro San Giovanni di Dio Fatebenefratelli, Unit Of Genetics, Brescia, Italy, [3]University of Brescia, Molecular And Translational Medicine, Brescia, Italy

Aims: Parkinson's disease (PD) is a neurodegenerative disorder pathologically characterized by progressive neuron loss in many brain regions, with a predominant effect in the *substantia nigra*. The mechanism on onset and progression of PD is currently unknown. Emerging evidence highlights that oligodendrocytes (OLGs) could play a causal role in the pathology, providing a new clue into PD etiology. *Via* their densely packed myelin sheaths, OLG intimately communicate with axons providing neurotrophic/metabolic support and maintaining their integrity/functionality. Intriguingly, recent literature reports OLGs pathophysiology in PD and a striking association of OLGs with PD-related *Leucine-rich repeat kinase 2* (*LRRK2*) gene, thus proposing OLGs as a new player in the PD pathogenesis. In this this study, we explore the role of LRRK2 in OLGs, to understand whether OLGs defects might lead to axonal and neuron degeneration observed in PD.
Methods: To this aim, we used murine primary OLGs, *ex-vivo* brain tissues from LRRK2 wild-type (WT) and knock-out (KO) mice and zebrafish model with LRRK2 morpholine.
Results: We observed that LRRK2 KO OLGs display 1) less branched cellular processes, 2) an increased number of OLG precursor cells (OPCs) and 3) a strong reduction of mature OLGs compared to LRRK2 WT cells, indicating defects in the transition of OPCs into OLGs. Consistently, we found a reduction of myelin basic protein (MBP) signal (a marker of mature OLGs) in the striasomes of LRRK2 KO mice and in the MBP:RFP transgenic zebrafishes injected with LRRK2 morpholine compared to control animals.
Conclusions: Overall, these findings indicate a crucial role of LRRK2 in OLGs maturation. Future investigations will allow us to understand if LRRK2 KO OLGs display defects in the functionality and if OLGs dysfunctions might lead to axonal and neuron degeneration.

LRRK2 ACTIVATION AND RECRUITMENT TO LYSOSOMES PARTIALLY PROTECTS AGAINST LYSOSOMAL STRESS IN PRIMARY ASTROCYTE CULTURE WITH PARKINSON'S-LINKED D620N VPS35 MUTATION

POSTERS: C01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LRKK2, PARKIN, PINK1, DJ-1

Dorian Sargent[1], P. Otero[2], Vanessa Howland[1], Darren Moore[1]
[1]Van Andel Institute, Department Of Neurodegenerative Science, Grand Rapids, United States of America, [2]Ohio State University, Department Of Neurological Surgery, Columbus, United States of America

Aims: Mutations in the *leucine-rich repeat kinase 2* (*LRRK2*) and *vacuolar protein sorting ortholog 35* (*VPS35*) genes cause late-onset, autosomal dominant familial Parkinson's disease (PD). It is widely accepted that LRRK2 mutations enhance LRRK2 kinase activity, which induces multiple cellular defects including an impairment of the endolysosomal pathway. Interestingly, the PD-linked *D620N VPS35* mutation has been reported to increase LRRK2 substrate phosphorylation in both a *D620N VPS35* knockin (KI) mouse model and in PD subjects bearing a *D620N* mutation. Our aim is to identify which cell type exhibit LRRK2 hyperactivation in the brain of *D620N VPS35* KI mouse and evaluate the potential impact on the endolysosomal pathway.
Methods: We detected LRRK2 substrates phosphorylation in the brain and in primary culture from *D620N VPS35* KI mice and evaluated the impact of LRRK2 hyperactivation on endolysosomal function using a LRRK2 kinase inhibitor.
Results: In the brain of D620N VPS35 KI mice, we find that Rab12 phosphorylation is robustly increased relative to Rab10. In primary culture, our data suggests that LRRK2 kinase hyperactivation is prominent in cortical astrocytes but not cortical neurons and that LRRK2 is partially recruited to lysosomes in D620N VPS35 KI astrocytes. The basal levels of endolysosomal pathway components, autophagic flux or lysosomal protease activity are not significantly altered in D620N VPS35 KI astrocytes, suggesting that the impact of LRRK2 hyperactivation on lysosomal function is limited. Interestingly, upon lysosomal stress using lysosomotropic agents, VPS35 KI astrocytes exhibit reduced lysosomal enlargement compared to wild-type cells that is reversed by LRRK2 kinase inhibitor treatment.
Conclusions: Altogether, our study suggests that LRRK2 is recruited to lysosomes and becomes activated in astrocytes from *D620N VPS35* KI mice where it plays a role in lysosomal homeostasis upon stress.

MECHANISM OF PARKIN UBIQUITIN LIGASE ACTIVATION BY SMALL-MOLECULE ALLOSTERIC MODULATORS

POSTERS: C01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LRKK2, PARKIN, PINK1, DJ-1

Veronique Sauve[1,2], Thomas Goiran[3,4], Nathalie Croteau[2,5], Eric Stephan[6], Simone Sciabola[6], Laura Silvian[6], Warren Hirst[6], Addy Hadzipasic[6], Jing Fang[6], Edward Fon[3,4], Kalle Gehring[1,2], Jean-Francois Trempe[2,5]
[1]McGill University, Biochemistry, Montreal, Canada, [2]McGill University, Centre De Recherche En Biologie Structurale, Montreal, Canada, [3]McGill University, Mcgill Parkinson Program, Montreal Neurological Institute, Montreal, Canada, [4]McGill University, Montreal Neurological Institute And Hospital, Montreal, Canada, [5]McGill University, Pharmacology & Therapeutics, Montreal, Canada, [6]Biogen, Physical Biochemistry, Biotherapeutics And Medicinal Sciences, Cambridge, United States of America

Aims: Mutations in parkin and PINK1 cause early-onset Parkinson's disease (EOPD). The ubiquitin ligase parkin is recruited to damaged mitochondria and activated by PINK1, a kinase that phosphorylates ubiquitin and the ubiquitin-like (Ubl) domain of parkin. Activated phospho-parkin then ubiquitinates mitochondrial proteins to target the damaged organelle for degradation. Last year, Biogen reported a new class of small-molecule allosteric modulators that enhance parkin activity in the presence of phospho-ubiquitin (pUb) (Shlevkov, *et al*, 2022, *iScience*). We aim to elucidate the mechanism of activation of the most potent modulator (BIO-2007817, EC_{50} = 150 nM), and characterize its ability to rescue pathogenic parkin mutants.
Methods: Ubiquitination assays and isothermal titration calorimetry were performed with parkin variants to identify the pUb binding site required for activation by BIO-2007817. X-ray crystallography was used to solve the structure of parkin bound to pUb and a BIO-2007817 derivative. The binding site was confirmed by nuclear magnetic resonance. Structure-activity relationships were established using in silico docking. In-organello and cell-based mitophagy assays were performed with pathogenic parkin mutants.
Results: BIO-2007817 binds to the RING0 domain with high affinity (K_d = 10 nM) and extends to the pUb moiety bound to RING0, at the same position as the phospho-Ubl domain. This bridging enhances the affinity for pUb, forcing parkin to adopt a conformation similar to phospho-parkin. The modulators thus mimic the parkin activation element and stimulates its activity by displacing the catalytic RING2 domain. Consistent with our model, BIO-2007817 rescues the activity of the parkin EOPD mutants R42P and V56E in the Ubl, as well as R275W.
Conclusions: The structure of parkin bound to allosteric modulators will serve as a scaffold for the design of parkin activators, a potential therapeutic treatment for EOPD.

METABOLIC ALTERATIONS IN LRRK2 G2019S MICROGLIA DERIVING FROM STEM CELLS OF PD PATIENTS

POSTERS: C01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LRKK2, PARKIN, PINK1, DJ-1

Maria Tziortziou[1], Katja Badanjak[1], Zied Landoulsi[1], Patrick May[1], Philip Seibler[2], Sandro Cardoso Pereira[1], Anne Grünewald[1]
[1]University of Luxembourg, Luxembourg Centre For Systems Biomedicine, Esch-sur-Alzette, Luxembourg, [2]University of Lübeck, Institute Of Neurogenetics, Lübeck, Germany

Aims: The G2019S mutation in the *leucine-rich repeat kinase 2* (*LRRK2)* gene is the most common genetic cause of PD and is inherited with reduced penetrance. Growing evidence supports an inflammatory component in PD and highlights microglia as key players in the etiology of this condition. Therefore, the aim of this study is to investigate alterations in metabolic pathways within microglia carrying the G2019S mutation in the *LRRK2* gene and assess their contribution to LRRK2-PD penetrance.
Methods: iPSC-derived microglia were generated from PD manifesting and non-manifesting G2019S mutation carriers and healthy individuals, following established protocols. Isogenic lines were also included. The expression of microglial markers was verified by immunocytochemistry and qPCR. The phagocytic ability was assessed by uptake of Zymosan particles. Cells were treated with interferon gamma (IFN-γ) and the kinase inhibitor MLi-2, and Western Blotting was performed for the evaluation of LRRK2 kinase activity. We are further exploring the metabolic profile of these cells assessing the mitochondrial function through Seahorse and microscopy methods. Intra- and extra-cellular metabolites will be examined by LC- and GC-MS analyses. Finally, these results will be combined with existing RNA-seq data.
Results: The presence of TMEM119 and P2RY12 verify the microglial identity. Furthermore, the LRRK2 G2019S mutation does not seem to interfere with the capacity of the cells to differentiate or phagocytose Zymosan particles. Additionally, the results indicate that upon IFN-γ treatment, there is a LRRK2 genotype-specific upregulation in the S1292 phosphorylation, a read-out of LRRK2 kinase activity, which was reversed after MLi-2 treatment.
Conclusions: With microglia being the immune cells of the brain, we hope that this study will provide invaluable insights into their role in PD and shed more light in the underlying mechanisms of LRRK2-PD penetrance.

PROTEIN PURIFICATION AND CHARACTERISATION OF EIF2AK1 AND ITS MUTANTS

POSTERS: C01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LRKK2, PARKIN, PINK1, DJ-1

Muzuki Ueda
Newcastle University, School Of Medicine, Newcastle upon Tyne, United Kingdom

Aims: Parkinson's disease is associated with impaired mitophagy, a process of selective removal and degradation of damaged mitochondria. Singh et al., screened all (n=428) known human Serine/Threonine kinases and found that Eukaryotic Translation Initiation Factor 2 Alpha Kinase 1 (EIF2AK1) acts as a negative regulator of PINK1 protein activity, thereby downregulating mitophagy. This study aims to characterise purified EIF2AK1 and its mutants.
Methods: GST-tagged plasmids, including Wild Type (WT), Serine 41 to Alanine mutation (S41A), Kinase Dead mutation (KD), and S41A+KD were transformed into BL21 E. coli cells. Cells were cultured in 1 litre growth medium and protein expression was induced with IPTG. Cells were lysed using sonication. EIF2AK1 proteins were purified using column chromatography.
Results: Western blotting and Coomassie staining were used to analyse purified EIF2AK1 proteins. EIF2AK1 antibody was detected in the western blot, suggesting that the target protein has been eluted. The most prominent band in the Coomassie staining of EIF2AK1 appeared slightly below 75 kD, aligning with the expected molecular weight of EIF2AK1, which is 71 kD. Both Coomassie stains and western blots revealed faint bands above the darkest bands for WT and S41A, while KD and KD+S41A did not exhibit such bands. This suggests that the faint band indicates phosphorylated EIF2AK1, which is absent in KD and KD+S41A due to the absence of kinase activity.
Conclusions: The results indicate that Serine 41 is not the sole kinase domain of EIF2AK1. To further investigate, a kinase assay will be conducted to explore the time and concentration-dependent kinetics of EIF2AK1 and its mutants. Furthermore, EIF2AK1 and PINK1 will be incubated together in a kinase assay to study whether EIF2AK1 directly influences PINK1 phosphorylation.

Aims: Advances in neural engineering now enable modelling of selected pathological aspects of neurodegenerative disease in human neural networks *in vitro*. Of particular interest is how neurodegenerative pathology may manifest and affect network behaviour at the microscale and mesoscale, i.e., before it progresses to affect the entire network. In this study, we utilized multi-nodal human neural networks carrying the Parkinson's related LRRK2 G2019S mutation and healthy isogenic control networks to study early expression of pathology.
Methods: We engineered multi-nodal neural networks from human iPSC-derived neural stem cells with and without the LRRK2 G2019S mutation on custom-designed microfluidic devices. The axon tunnels and synaptic compartments of the microfluidic devices allowed for the selective manipulation and isolated investigation of neurites and their organelles, as well as their synaptic elements, i.e. network sites particularly related to early manifestation of neurodegenerative disease pathology. Furthermore, combining the microfluidic devices with an MEA interface in parallel assays allowed for investigation of network electrophysiology.
Results: We found that the LRRK2 G2019S neurons self-organized into networks exhibiting aberrant morphology and containing neuritic mitochondria moving at heightened speeds, compared to the healthy isogenic controls ($p = 0.0038$) . Furthermore, following a transient excitatory event, the LRRK2 neural networks exhibited behaviour suggestive of an impaired response, i.e. displaying less signs of neurite remodelling, synaptic plasticity, and a smaller relative change in total network correlation, compared to the healthy control neural networks.

Conclusions: Micro- and mesoscale signs of neurodegeneration manifest early in the development of self-organizing human neural network carrying the LRRK2 G2019S mutation *in vitro.* Furthermore, the combination of neural engineering and microfluidic devices, together with MEAs, make powerful tools for modelling and for further elucidation of pathological processes in early stages of neurodegenerative disease development.

Aims: Parkinson's disease (PD) is a neurodegenerative disease characterized by the spread of a-synuclein throughout the CNS. Most cases are sporadic but approximately 10% of cases are inherited due to genetic mutations in genes, such as the Leucine-rich repeat kinase 2 (LRRK2) gene. PD causing mutations in this gene lead to the hyperactivity of the LRRK2 protein. Therefore, inhibiting LRRK2 is thought to be of therapeutic benefit, however the effects of this inhibition on a-syn spreading remain unclear. The objective of the present study is to investigate the effects of LRRK2 inhibition on gut-to-brain a-syn spreading in novel PD mouse models.
Methods: Two new PD mouse models, Vitras and Vitras6J, have been used in this study. The former expresses human, 1-120 truncated a-syn in the gut and olfactory epithelium in an a-syn null background, while the latter expressed the same transgenic a-syn in a murine a-syn background. The LRRK2 inhibition was performed by supplementing the diet of adult mice with LRRK2 kinase inhibitor (MLi-2) for 3 months.
Results: The 3-month MLi-2 treatment did not affect animal survival but prevented animal weight gain in transgenic mice lacking endogenous a-synuclein. The increased faecal output, usually present in Vitras and Vitras6J mice, was reduced after MLi-2 treatment, showing that LRRK2 inhibition normalised bowel transport of the transgenic mice. Ongoing experiments are investigating whether LRRK2 inhibition influences a-synuclein spreading from gut to brain.
Conclusions: The MLi-2 treatment performed in the novel PD transgenic mice described above, will be valuable to assess whether the inhibition of the LRRK2 impacts periphery-to-brain transfer of a-syn. The results from this study will help shed light on whether LRRK2 inhibition could be a therapeutic target capable of slowing down PD progression.

FLUORESCENT CELLULAR MODELS OF MITOPHAGY FOR DRUG SCREENING OF THE PINK1/PARKIN SIGNALLING PATHWAY

POSTERS: C01.B. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LRKK2, PARKIN, PINK1, DJ-1

Patricia Villace, Rosa M Mella, Meritxell Roura, Clarisa Salado, Miguel Peco
INNOPROT, Cellular And Molecular Lab, DERIO, Spain

Aims: It is widely accepted that the pathogenic mechanisms in a subset of people with PD is the mitochondrial stress linked to dysfunctional regulation of mitophagy. PINK1 regulates PARKIN translocation in impaired mitochondria and drives their removal by selective mitophagy maintaining cellular energy homesostasis. Image-based cellular models for monitoring PINK1/PARKIN signalling have been used to screen a chemical library of 1,280 molecules to identify compounds that modulate the cellular mitophagy. The hit compounds were chosen for further testing, based on the strength of the initial response and lack of cytotoxicity. The results indicated that this assay is a robust (Z' > 0.5) and valid strategy to test potential candidates for preclinical studies and to facilitate the drug discovery process.
Methods: Generation of stable cell line: Cell lines were obtained with a single-cell dispenser by fluorescence sorting F-Sight (Cytena GmbH). **Liquid Handling and phenotype-based screening assay:** For dispensing of the liquid media containing cells and compounds, the Hamilton's Microlab Star automated liquid handling workstation was used. Cells were treated with CCCP or FCCP (positive controls) for 3 hours and the library of compounds at 10 µM for 24 hours in Optimem medium before image acquisition. **Image acquisition and analysis:** Fluorescence images were acquired in the CellInsight™ CX7 High Content Analysis Platform with a x20 dry objective.
Results: - Screening of 1,280-compound library was performed. Eight positive compounds were identified. - Image cellular redistribution assay of Parkin_ mitochondria and PINK1 in the presence of positive compounds was performed at 10 µM. - Dose-response curves of the positive compounds were assayed.
Conclusions: Fluorescent cell-based models can be applied for the screening of compound libraries in multiple High Content Bioimaging Platforms

BACTERIAL AMYLOIDS SECRETED BY S. AUREUS INDUCE ALPHA-SYNUCLEIN AGGREGATION PROMOTING KEY PATHOLOGICAL FEATURES OF PARKINSON'S DISEASE

POSTERS: C01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELL TO CELL TRANSMISSION, SPREADING OF PATHOLOGY, PRION-LIKE

Maria Izco Gaviria[1], Jaione Valle[2], Lydia Alvarez-Erviti[3]
[1]Fundación Rioja Salud, Molecular Neurobiology, Logroño, Spain, [2]Instituto de Agrobiotecnología (IDAB). CSIC-Gobierno de Navarra, Molecular Biology Of Bacterial Pathogens, Pamplona, Spain, [3]Fundacion Rioja Salud, Molecular Neurobiology, Logroño, Spain

Aims: Recent studies show that persons with neurodegenerative disorders have an altered microbiome, moreover, studies in animal models pointed to a central role of microbiota in PD pathology. Initial results have shown that the gastrointestinal microbiome expresses functional amyloids as scaffold components of its biofilm and cross-seeding of amyloidogenic proteins by bacterial amyloids has been documented both in vivo and in vitro. The overall goal of this proposal is to investigate if bacterial amyloids secreted by S*. aureus* induce alpha-synuclein aggregation promoting key pathological features of Parkinson's disease.
Methods: SH-SY5Y cells expressing alpha-synuclein were treated with Bap preformed fibrils (rBap-PFF) to evaluate alpha-synuclein aggregation. Mice received unilateral intrastriatal injection of rBap-PFF or vehicle and were sacrificed 7 months later to assess alpha-synuclein pathology, dopaminergic degeneration and microglia and astrocyte activation.
Results: The treatment with rBapB-PFF amyloids resulted in an increase of phosphorylated alpha-synuclein aggregates in SH-SY5Y cells. The intrastriatal injection of rBapB-PFF amyloids in wildtype mice caused impairment in fine motor performance. These behavioural changes were associated with a unilateral loss of dopaminergic innervation in the striatum and a loss of dopaminergic neurons in the substantia nigra pars compacta (SNpc). The PD pathology was associated with the presence of phosphorylated alpha-synuclein aggregates in the SNpc, cortex and thalamus. The neurodegenerative process was not associated with a neuroinflamatory response to Bap fibrils.
Conclusions: Bacterial amyloids secreted by *S. aureus* have direct impact on alpha-synuclein aggregation and pathology.

THE ROLE OF SMALL EXTRACELLULAR VESICLES IN A-SYNUCLEIN TRANSMISSION

POSTERS: C01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELL TO CELL TRANSMISSION, SPREADING OF PATHOLOGY, PRION-LIKE

Dimitra Sotiria Karampela[1], Marina Pantazopoulou[2], Anastasios Delis[1], Ronald Melki[3], Kostas Vekrellis[1]

Aims: Small extracellular vesicles (sEVs) have recently emerged as key players in cellular communication in both physiological and pathological processes in the brain, particularly in synucleinopathies. Our recent work indicates that brain-derived sEVs are internalized by glial cells (microglia and astrocytes) through macropinocytosis and are sorted to endolysosomes for subsequent processing. The current study aims to examine the intracellular trafficking pathway of sEVs in glial cells linked with the sEV-associated α-synuclein (α-Syn) transmission.
Methods: Glial primary cultures were incubated with DiI-stained mouse brain-derived sEVs, in the absence or presence of recombinant fibrillar human α-Syn (pre-formed fibrils, PFFs). The internalization and trafficking pathways in cells treated with pharmacological reagents that block the major endocytic pathways, were analyzed by immunofluorescence, using the Imaris analysis software.
Results: PFFs were internalized by both microglia and astrocytes at early time points of PFF incubation. In microglia, PFF uptake occurred within 15 min, whereas in astrocytes PFFs were efficiently internalized 1h post-incubation. In the presence of sEVs, a delay in the PFF uptake was observed in both glial cell types. Treatment with dynasore, that inhibits dynamin-dependent endocytosis, affected PFF uptake only in the absence of sEVs. sEV-associated PFFs seemed to utilize macropinocytosis and/or phagocytosis as the main pathway of endocytosis. Fibrillar α-Syn when associated with sEVs enter the endosomal pathway and are targeted to the lysosome for subsequent degradation. In the absence of sEVs, only a small portion of fibrillar α-Syn is sorted to the endolysosomal pathway.
Conclusions: Our data indicate that brain-derived sEVs serve as scavengers and mediate a rather slow cell-to-glia transfer of pathological α-Syn which is targeted to the endolysosomal pathway, suggesting a beneficial role in glia-mediated clearance of toxic protein aggregates, present in numerous neurodegenerative diseases.

MUTATION-INDUCED GLUCOCEREBROSIDASE DEFICIENCY EXACERBATES ALPHA-SYNUCLEIN PATHOLOGY IN THE VAGAL SYSTEM

POSTERS: C01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELL TO CELL TRANSMISSION, SPREADING OF PATHOLOGY, PRION-LIKE

Pietro La Vitola, Eva Szegoe, Rita Pinto Costa, Angela Rollar, Eugenia Harbachova, Donato Di Monte
DZNE (German Center for Neurodegenerative Diseases), Neurodegeneration And Neuroprotection In Parkinson's Disease, Bonn, Germany

Aims: The dorsal motor nucleus of the vagus nerve (DMV) represents a primary site where pathological alpha-synuclein (A-SYN) aggregates are formed and from where A-SYN pathology could spread rostrally throughout the brain in Parkinson's disease (PD). Variants in the glucocerebrosidase gene (*GBA1*) are common PD genetic risk factors and have been linked to earlier PD onset and more severe disease progression. The aim of this study was to investigate the relationship between *GBA1* mutations and A-SYN aggregation and spreading in a mouse model of overexpression-induced A-SYN pathology.
Methods: Experiments were carried out in heterozygous *Gba1* mice carrying a L444P knock-in mutation (L444P/+) and non-transgenic (NTG) littermates. Overexpression of human A-SYN targeting the DMV was induced by a unilateral injection of adeno-associated vectors (AAVs) delivering hA-SYN DNA into the vagus nerve. Mice were sacrificed 6 weeks post-injection.
Results: Frozen brain tissue was used to measure glucocerebrosidase (GCase) activity that was significantly decreased in naive L444P/+ as compared to NTG mice. After vagal AAV injections, hA-SYN aggregation was detected using proximity ligation assay and found to be markedly enhanced in mice carrying the L444P mutation. To assess spreading, tissue sections were collected throughout the brain and processed for immunohistochemistry with anti-hA-SYN. Data revealed a significant increase in number of hA-SYN-positive axons in the pons, midbrain and forebrain of transgenic as compared to control animals.
Conclusions: Our findings support an increased vulnerability to A-SYN pathology associated with L444P mutation-induced GCase deficiency. We demonstrate that, in the presence of GCase deficiency, enhanced A-SYN expression in the vagal system is accompanied by more severe aggregate pathology. As importantly, under these conditions, A-SYN spreading is promoted, resulting in its enhanced transfer toward brain regions rostral to the DMV-containing medulla oblongata.

REM-SLEEP BEHAVIORAL DISTURBANCES IN MICE FOLLOWING SEEDED ALPHA-SYNUCLEINOPATHY

POSTERS: C01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELL TO CELL TRANSMISSION, SPREADING OF PATHOLOGY, PRION-LIKE

Hansoo Yoo[1], Russell Luke[2], Brittany Dugan[2], Jimmy Fraigne[2], Jefferson Steltz[3], Jonah Lourie[3], Lauren Torres[3], John Peever[2], Kelvin Luk[3]
[1]Yonsei University, Neurology, Seoul, Korea, Republic of, [2]University of Toronto, Cell & Systems Biology, Toronto, Canada, [3]University of Pennsylvania, Pathology And Laboratory Medicine, Philadelphia, United States of America

Aims: To develop a mouse model of REM-sleep behavioral disorder using a synuclein fibril targeting approach
Methods: Alpha-synuclein fibrils were stereotactically targeted to the sublateraldorsal tegmental region (SLD) of wildtype (C57Bl6/C3H) mice. Animals were then assessed using electroencephalography (EEG), electromyography (EMG), behavioral testing (motor and cognitive), and histologically at 1, 3, 6, and 12 months post injection with preformed fibrils.
Results: Synucleinopathy was initiated by fibril injection into the SLD, and disseminated through the associated connectome over time. Immunohistochemical analysis revealed selectively vulnerable neuron and non-neuronal populations that were affected over time. EEG/EMG examination also showed abnormalities, specifically an increase in muscle activity during REM-sleep.
Conclusions: Targeting of alpha-synuclein PFFs drives the formation of pathology in the SLD and associated brain regions. These cumulatively result in the development of a phenotype that recapitulates a subset of prodromal synucleinopathy subjects. Additional studies are underway to understand the substrate for these alterations.

SOLUBLE PROTEIN POST-TRANSLATION MODIFICATIONS: UNEXPECTED REGULATORS OF PATHOLOGICAL PROTEIN TRANSMISSION

POSTERS: C01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELL TO CELL TRANSMISSION, SPREADING OF PATHOLOGY, PRION-LIKE

Chao Peng[1], Virginia Lee[2], Shujing Zhang[1], Hilal Lashuel[3], James Petersson[2]
[1]University of California Los Angeles, Department Of Neurology, Los Angeles, United States of America, [2]University of Pennsylvania, Pathology & Lab Medicine, Philadelphia, United States of America, [3]Swiss Federal Institute of Technology, Laboratory Of Molecular And Chemical Biology Of Neurodegeneration, Brain Mind Institute, Lausanne, Switzerland

Aims: Cell-to-cell transmission and subsequent amplification of pathological proteins promotes neurodegenerative disease progression. Most research on this has focused on pathological protein seeds, but how their normal counterparts, which are converted to pathological forms during transmission, regulate transmission is less understood.
Methods: We used various novel cell models and in vitro seeding assays to evaluate whether soluble α-synuclein modulate the transmission of pathological α-synuclein. We also performed mulitple rounds of LC-MS/MS studies to identify novel PTMs on soluble α-synuclein.
Results: We show in cultured cells that phosphorylation of soluble, non-pathological α-Syn at previously identified sites dramatically affects the amplification of pathological α-Syn, which underlies Parkinson's disease (PD) and other α-Synucleinopathies, in a conformation- and phosphorylation site-specific manner. We performed LC-MS/MS analyses on soluble α-Syn purified from PD and other α-Synucleinopathies, identifying many novel α-Syn post-translational modifications (PTMs). In addition to phosphorylation, acetylation of soluble α-Syn also modified pathological α-Syn transmission in a site- and conformation specific manner. Moreover, phosphorylation of soluble α-Syn could modulate the seeding properties of pathological α-Syn. Our study represents the first systematic analysis how of soluble α-Syn PTMs affects the spreading and amplification of pathological α-Syn, which may affect disease progression. Moreover, our recent study demontrated that the regulation of pathological protein amplification by soluble protein is not limited to α-Syn. We found that soluble tau PTMs could also dramatically modulate the transmission of pathological tau.
Conclusions: Our study demenstrated that souble protein PTMs represents a novel mechanism that modulate the transmission of pathological protein in neurodegenrative diseases.

DETECTION OF ALPHA SYNUCLEIN MISFOLDED AGGREGATES BY SEED AMPLIFICATION ASSAY

POSTERS: C01.C. DISEASE MECHANISMS, PATHOPHYSIOLOGY: CELL TO CELL TRANSMISSION, SPREADING OF PATHOLOGY, PRION-LIKE

Michelle Pinho, Claudio Soto, Sandra Pritzkow
Mitchell Center for Alzheimer's Disease and Related Brain Disorders, Department of Neurology, University of Texas McGovern Medical School at Houston, Houston, TX, USA, Neurology, Houston, United States of America

Aims: Alpha-synuclein (αSyn) misfolding, aggregation, and cerebral accumulation is associated with neurodegenerative diseases like Parkinson's disease (PD), multiple system atrophy (MSA) and dementia with Lewy bodies (DLB). While research has primarily focused on the role of αSyn deposits in the central nervous system, emerging evidence suggests that αSyn may also be distributed throughout the peripheral system, including the autonomic nervous system and peripheral organs. This study aims to assess the utility of a seed amplification assay (αSyn-SAA) for the detection of αSyn aggregates in peripheral tissues.
Methods: Peripheral tissue samples, including stomach, small intestine, heart, liver, kidney, spleen, and colon, were collected from PD, MSA, DLB patients, and controls. Samples were homogenized, diluted to 10^{-3}, 10^{-4}, and placed in the αSyn-SAA reaction containing recombinant αSyn, buffer, 0.1% sarkosyl, silica beads, and thioflavin T. The signal of αSyn-SAA in the presence of different samples was analyzed by the thioflavin T fluorescence over time.
Results: Our results showed detection of αSyn aggregates in various peripheral tissues using αSyn-SAA. Seed-competent aggregated αSyn was reliably detected in the small intestine, heart, and colon in patients affected by PD and DLB and to a lower extent in MSA. Controls, including people who have died of unrelated diseases or patients affected by Alzheimer's disease, did not show any signal in αSyn-SAA.
Conclusions: Our study demonstrates that αSyn-SAA is useful for detection of αSyn aggregates in peripheral tissues. Our findings indicate that αSyn accumulation does not only occur in the brain, but also becomes deposited in various peripheral organs. Our data will contribute to understanding the biology and pathogenesis of synucleinopathies. **Funding**: Grant from Michael J. Fox Foundation to SP.

Aims: Besides *GBA*, variation in other lysosomal storage disorder (LSD) genes are associated with Parkinson's disease (PD) risk, and knockdown of these genes in experimental models enhances alpha-synuclein (α-Syn) mediated neurodegeneration. Our goal is to elucidate mechanisms by which *partial loss-of-function* in *GBA* contributes to Parkinson's disease (PD) along with the determinants of *GBA* penetrance.
Methods: LSD genes, variants, and their combinations were prioritized based on analyses of PD case/control cohorts with genome sequencing, along with our published results on genetic modifiers of α-Syn in *Drosophila* models. Combinatorial genetic manipulations in fly *Gba1b* and other implicated LSD genes (e.g. double-heterozygous and other synthetic genotypes), are being examined for impact on CNS structure, function, and metabolism (e.g. histology, locomotor function, electrophysiology, lysosomal markers, and lipidomics).
Results: Among PD cases, 21% harbor damaging variants in 2 or more LSD gene variants. Multi-allelic combinations between *GBA* and other causes of sphingolipidoses are 4-fold more likely than other LSD subtypes, and a similar enrichment was not seen among controls. In preliminary cross-species studies, *Gba1b* haploinsufficiency in *Drosophila* causes mild locomotor phenotypes and perturbations in sphingolipid metabolism. Partial loss-of-function in the fly ortholog of *ATP13A2*, strongly interacts with *Gba1b* heterozygozity. Lipidomic analysis of heads from α-Syn transgenic flies additionally reveals elevated ceramide species. Follow-up studies and interaction tests with other prioritized, conserved LSD genes are ongoing, including causes of sphingolipidoses (*SMPD1, SCARB2*), mucopolysaccharidoses (*MANBA*), and cholesterol storage disorders (*NPC1/2*).
Conclusions: Our preliminary findings support a hypothetical model in which partial, haploinsufficient loss of function in *GBA* alters lysosomal function and interacts with other LSD gene variants to increase vulnerability to α-Syn mediated neurodegeneration.

Aims: Different a-synuclein (α-syn) species, including different strains and post-translationally modified forms of the protein, are likely to possess distinct properties; through these properties, they may play different roles in pathogenetic processes such as aggregate formation and interneuronal α-syn spreading. The objective of this study was to determine the relationship between α-syn nitration, a common modification of the protein seen in Parkinson's disease (PD) brain, and α-syn assembly and spreading.
Methods: Experiments were carried out in mice. Immunohistological and biochemical techniques were used to assess neuronal integrity and pathological α-syn changes (in particular, protein aggregate formation) in brain tissue sections. A new proximity ligation assay was developed and used for detection and quantification of nitrated α-syn.
Results: revealed that, under conditions of oxidant stress (e.g., neuronal hyperactivity or exposure of mice to the herbicide paraquat), intraneuronal accumulation of nitrated α-syn paralleled the formation of protein aggregates; it was also associated with a significant enhancement of neuron-to-neuron protein transfer and consequent α-syn brain spreading. Strategies aimed at reducing oxidant burden (e.g., by increasing superoxide dismutase expression) decreased the levels of nitrated α-syn and, at the same time, counteracted protein aggregation and spreading.
Conclusions: Together, these findings indicate that detection of nitrated α-syn in human brain or PD experimental models characterizes neurons that, due to oxidant stress, become not only highly vulnerable to inclusion formation but also more active sites of α-syn transfer. *In vitro* experimental evidence suggests that nitrative modifications can generate α-syn species with a greater propensity to pass from cell to cell. It is conceivable therefore that, under pro-oxidant conditions in PD and/or PD models, nitration of pathogenic α-syn species could itself promote their interneuronal brain spreading.

Aims: Mechanisms of dopaminergic neuron cell death in Parkinson's Disease (PD) is complex and combinatorial, with impairments in multiple cellular pathways impacting mitochondrial function and endosomal/lysosomal protein degradation. Mutations in leucine-rich repeat kinase 2 (LRRK2) and glucocerebrosidase (GBA), have been shown to both impact kinetics of the autophagic-lysosomal pathway (ALP) and contribute to PD-associated protein accumulation and aggregation. This study uses induced pluripotent stem cells (iPSCs)-derived dopaminergic neurons (iCell DopaNeurons) generated from apparently healthy normal donors (AHN) and clinically diagnosed PD patients harboring *LRRK2* G2019S or *GBA1* N370S mutations (derived from iPSCs provided by Parkinson's Progression Markers Initiative (PPMI), part of The Michael J. Fox Foundation (MJFF)) to investigate their utility in evaluating ALP changes associated with PD.
Methods: Endosome and lysosome protein expression was quantified in iPSC-derived dopaminergic neurons at 7, 14, and 21 days using high throughput imaging of specific antibodies from Cell Signaling Technology (CST). Exogenous modulators of autophagy (Torin 1) and mitochondrial stress (Rotenone) were applied to the LRRK2, GBA and AHN dopaminergic neurons to evaluate the effect of pathway stressors on ALP protein expression. Within all conditions, neural survival and synapse formation were also quantified.
Results: We show both AHN and patient-derived iCell DopaNeurons express dopaminergic (ie., TH, FOXA1), synaptic (ie., PSD95, Synapsin-1, GAP43, VAMP2), and ALP (ie., LAMP-1, LC3, Cathepsin, Galectin 3) specific markers via immunocytochemistry. These lines were applied to high content imaging to develop methods to evaluate pathophysiological phenotype differences in synapse development, ALP kinetics, and responses to mitochondrial and autophagy stressors between control and patient-derived PD dopaminergic neurons.
Conclusions: These data demonstrate the utility of high-throughput immunocytochemistry and patient-derived iPSC dopaminergic neurons for investigating lysosomal, mitochondrial, and neurodegenerative pathway dynamics.

Aims: Alzheimer's (AD) and Parkinson's disease (PD) feature progressive neurodegeneration in a remarkably regionally selective manner. *Post mortem* studies have posited a role for cell autonomous mechanisms driving this, so we aimed to examine a live human induced pluripotent stem cell (iPSC) model to see whether it can replicate the phenomenon of selective neuronal vulnerability, so to better determine disease mechanisms and therapeutic targets.
Methods: iPSC-derived neurons offer a rare opportunity to examine cell autonomous vulnerability in live human cells. iPSCs from patients with AD-related presenilin-1 mutations (n=6), PD-related leucine rich repeat kinase 2 mutations (n=6), and isogenic corrected (n=4) and healthy controls (n=4) have been differentiated into both cortical and midbrain dopaminergic neurons to enable comparison of pre-formed fibril induced pathology in different neuronal subtypes from the same patient. We then examined lysosomal number, morphology, degradation, pH, and calcium using live imaging assays, alongside mitochondrial biology, and electrophysiology to understand underlying drivers of vulnerability in the cell types.
Results: Upon insult with alpha-synuclein PFFs, AD and PD dopaminergic neurons produce substantial Lewy-like pathology, whereas cortical neurons remain relatively resilient to alpha-synuclein aggregation, suggesting cell-type vulnerability. PSEN1-Intron-4-Deletion cortical neurons, however, had significantly elevated pathology. These lines displayed hyperactivity on microelectrode arrays and abnormal lysosomal biology, including increased LAMP1 and dysregulated calcium. PFF-insulted AD cortical neurons also have impaired neurite outgrowth, while PD cortical neurons are resilient.
Conclusions: These preliminary results show relative vulnerability of AD against PD cortical neurons, and dopaminergic against cortical neurons to alpha-synuclein aggregates for the first time. These suggest the selective vulnerability to proteinopathy in these diseases is reflected by the iPSC neuronal model and support the notion that cell intrinsic factors like autophagy drive vulnerability.

NOX1 TRIGGERS FERROPTOSIS AND FERRITINOPHAGY, CONTRIBUTES TO NEURODEGENERATION

POSTERS: C01.D. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AUTOPHAGY, LYSOSOMES, UBIQUITIN, PROTEASOME

Huiqing Wang, Wenwei Mao, Yuhan Zhang, Baohua Cheng, Fuling Yan
Southeast University, Medical College, Nanjing, China

Aims: Parkinson's disease (PD) is a neurodegenerative disorder. Ferroptosis-specific genes related to PD remain uncertain. Exploring the effects of NADPH oxidase enzyme-1 (NOX1) with the ferroptosis pathway.
Methods: We have developed an *in vitro* and *in vivo* model of PD to investigate the potential underlying mechanism of NOX1. We have manipulated the expression of NOX1 through overexpression or knockdown techniques to assess its impact on dopaminergic neurons, as well as ferroptosis and ferritinophagy. Additionally, we have utilized transcriptome sequencing to identify the involvement of the RUNX2/STK32A pathway. Furthermore, we have employed online site prediction and CO-IP experiments to identify the upstream ubiquitinating molecules associated with NOX1.
Results: Three potential ferroptosis-related genes (INOS, BECN1, NOX1) were identified, displaying favorable diagnostic properties. The present study reveals that NOX1-associated ferroptosis genes are significantly upregulated in both in vitro and in vivo models of Parkinson's disease (PD). This upregulation is influenced by the ubiquitination process of the upstream transcription factor FBXW7, which is notably reduced in PD, consequently leading to heightened NOX1 expression. Besides, the activation of the RUNX2/STK32A pathway by NOX1 facilitates ferritinophagy, thereby intensifying mitochondrial dysfunction and promoting ferroptosis, ultimately resulting in additional impairment of dopaminergic neurons.
Conclusions: In summary, our research reveals the significant role played by the upregulation of neuronal NOX1 and the activation of ferroptosis in neurodegeneration.

MECHANISMS OF INTERACTION OF ALPHA-SYNUCLEIN AND AMYLOID-BETA CO-PATHOLOGY

POSTERS: C01.D. DISEASE MECHANISMS, PATHOPHYSIOLOGY: AUTOPHAGY, LYSOSOMES, UBIQUITIN, PROTEASOME

Samuel Wycoff, Jessica Restivo, John Cirrito
Washington University in St Louis, Neuroscience, St Louis, United States of America

Aims: There remains a large gap in knowledge about the pathological overlap of Alzheimer Disease (AD) and Parkinson's Disease (PD). Approximately half of all AD patients exhibit formation of Lewy Bodies containing α-syn, and in the roughly 30% of PD patients with dementia (PDD), amyloid plaque burden is strongly correlated to severity of dementia. The two principal proteins involved in these diseases, α-syn and Aβ, promote each other's aggregation and have synergistic toxicity in cells, while not affecting each other's protein expression. Therefore we hypothesized that common clearance mechanisms of both proteins are involved in the increased toxicity. Additionally, membrane interaction has been suggested to be key to Aβ/α-syn interaction, and key to the co-promotion of aggregation. α-syn is a naturally disordered protein, but can interact with membranes, leading to a higher rate of aggregation and interaction with Aβ. We propose that disengaging α-syn from the membrane reduces aggregation of both Aβ and α-syn and mitigates cellular toxicity.
Methods: To understand the relationship of co-pathology of Aβ and α-syn on cellular autophagy, we employed SH-SY5Y cell culture, exogenously added Aβ oligomers and α-syn fibrils, and measured autophagy with IHC and western blot. Additionally we measured levels of these proteins in a co-pathology AD/PD mouse model using reverse-microdialysis and ELISA.
Results: We show that α-syn and Aβ both inhibit ALP, with co-pathology having a multiplicative effect in vivo and in vitro. We also propose that disengaging α-syn from the membrane reduces aggregation of both Aβ and α-syn and mitigates cellular toxicity.
Conclusions: We therefore conclude that dysregulation of autophagy is an important factor in the enhanced toxicity seen in co-pathology of AD and PD. We propose that membrane interaction of asyn is another important pathway.

Aims: α-synuclein plays a central role in the pathogenesis of Parkinson disease. Misfolded α-synuclein accumulates in neurons and forms Lewy pathology, leading to dopaminergic neurodegeneration. These Lewy pathology and dopaminergic neurodegeneration are major pathological features of Parkinson's disease. Despite extensive efforts, the pathological molecular changes caused by misfolded α-synulein in neurons remain to be elucidated. We aimed to understand the molecular mechanism in the early phase of Parkinson disease.
Methods: To selectively obtain PFF-injected dopaminergic neurons, we adapted the α-synuclein preformed fibrils (PFF) model to a Ddc-hKO1 reporter mouse to selectively acquire α-synuclein PFF-injected dopaminergic neurons. We harvested dopamine neurons from α-synuclein PFF-injected mice in the early phase and analyzed them with RNA-sequencing.
Results: We found that lipid-related process genes, followed by protein modification and degradation-related process genes, were up-regulated in the dopaminergic neurons from α-synuclein PFF-injected mouse brain. The activation of fatty acid-binding protein 1 was particularly evident. FABP1 accumulation in dopaminergic neuron was confirmed by immunohistochemistry of Pakinson disease patients.
Conclusions: We revealed the molecular events during the early phase of α-synuclein accumulation using α-synuclein PFF-injected mouse model. Up-regulation of FABP1 in both α-synuclein PFF injection model and Parkinson disease patients' brain suggests that FABP1 plays a role in the pathogenesis of Parkinson disease.

INTRACELLULAR A-SYNUCLEIN INTERFERENCE WITH MYELINATION, ACTIN REMODELING, AND LIPID METABOLISM IN HUMAN INDUCED OLIGODENDROCYTES

POSTERS: C01.E. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LIPIDS, LIPOPROTEINS AND MEMBRANE TRAFFICKING

Kristina Battis[1], Jeanette Wihan[1], Denise Balta[1], Tanja Kuhlmann[2], Jürgen Winkler[1]
[1]University Hospital Erlangen, Molecular Neurology, Erlangen, Germany, [2]University Hospital Münster, Neuropathology, Münster, Germany

Aims: Functions of oligodendrocytes are severely affected in multiple system atrophy (MSA), a rare and devastating movement disorder with fast progression. MSA is classified as synucleinopathy due to the accumulation of α-synuclein (α-syn) within oligodendroglial cytoplasmic inclusions as one of the major neuropathological hallmarks of the disease. The accumulation of α-syn results in a severe myelin deficit, however, without concurrent loss of oligodendrocytes in human and murine brains. Therefore, we hypothesized that intracellular accumulation of α-syn interferes with myelination of oligodendrocytes.
Methods: A human model for MSA was established to address the underlying cellular and molecular pathogenesis. After oligodendrocyte differentiation from human induced pluripotent stem cells (hiPSCs), their cellular identity was confirmed by a thorough phenotypical characterization. Functionally, the myelinating potential of control human oligodendrocytes was demonstrated by ensheathment of nanofibers and neurites of hiPSCs-derived neurons.
Results: In a co-culture model of human, lentivirally infected α-syn-oligodendrocytes with inert nanofibers, intraoligodendroglial α-syn accumulation led to a severe reduction of myelinogenesis. These morphological changes were accompanied by an increased actin filament assembly and a dysregulation of actin binding. Additionally, several genes associate to lipid metabolism were altered, including *ABCA8*, *CAV1*, and *ANO4*. Thus, metabolomics analysis of α-syn-oligodendrocytes was exhibited and revealed disturbances predominantly in the groups of amino acids and lipids. Among the lipids the class of phospholipids as main component of myelin was mainly affected.
Conclusions: Taken together, the present findings suggest a link between α-syn overexpression, actin remodeling and lipid metabolism of oligodendrocytes associated with a profound impact on myelination. By modelling α-syn induced myelin deficits, the present human disease model represents an important tool to further delineate the mechanistic cascade underlying oligodendroglial dysfunction and may pave the way for developing promising interventional approaches.

TARGETING IRON METABOLISM AND IRON-MEDIATED LIPID PEROXIDATION IN NEURODEGENERATIVE DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

POSTERS: C01.E. DISEASE MECHANISMS, PATHOPHYSIOLOGY: LIPIDS, LIPOPROTEINS AND MEMBRANE TRAFFICKING

Holly Spence, Fergal Waldron, Jenna Gregory
Institute of Medical Sciences, University of Aberdeen, Institute Of Medical Sciences, Aberdeen, United Kingdom

Aims: Patterns of regional iron increases are observed across neurodegenerative diseases including Parkinson's disease (PD) and Alzheimer's disease (AD). These increases in iron have been linked with higher disease severity and faster rate of progression. Exceedingly high iron-mediated lipid peroxidation can lead to ferroptosis and oxidative damage which are thought to underly these iron-neurodegeneration relationships.
Methods: Here we present a systematic review and meta-analysis comparing studies which assess the use of drugs targeting the iron-mediated lipid peroxidation pathway in the treatment of neurodegenerative disease. This systematic review and meta-analysis also evaluates the evidence for changes in iron-mediated lipid peroxidation pathway and downstream effects in human studies of those with neurodegenerative disease.
Results: Several drugs targeting this pathway including iron chelation drugs are entering phase 2 and 3 clinical trials for AD and PD.
Conclusions: Treatments targeting this pathway therefore show promise for use across several neurodegenerative diseases.

THE IDENTIFICATION OF DRUGGABLE NEUROINFLAMMATORY PATHWAYS INVOLVED IN LEWY BODY DEMENTIA

POSTERS: C01.F. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Jermaine Ross, Yoonjeong Cha, Mohamedi Kagalwala
Alleo Labs, Neuroscience, San Francisco, United States of America

Aims: Inflammation plays a significant role in the development and progression of many neurodegenerative diseases, including several subtypes of dementia such as Alzheimer's disease (AD) and Lewy body dementia (LBD). The focus of this study is the discovery and characterization of neuroinflammatory pathways related to LBD and potential mechanisms for disease-modifying therapies.
Methods: We compared bulk RNA sequencing data sampled from the postmortem dorsolateral prefrontal cortex (DLPFC) of LBD and cognitively normal (CN) controls subjects that participated in the Religious Orders Study and Rush Memory and Aging Project. LBD (n=64) and control (n=169) subjects were stratified using neuropathology as well as neuropsychological assessments. We subsequently employed a standard RNA-seq analysis workflow to identify differential expressed genes using limma R package, followed by Gene Set Enrichment Analysis (GSEA).
Results: We identified 846 differentially expressed genes (DEGs) in the DLPFC of LBD subjects compared to CN controls (adjusted p-value < 0.05), made up of 419 up-regulated and 417 down-regulated genes. Among the top statistically significant DEGs, we observed up-regulation of astrocytic markers Interleukin-17 receptor B (IL17RB) and Calcium-Activated Neutral Proteinase 2 (CAPN2). Recent meta-analysis studies found that both IL17RB and CAPN2 were also up-regulated in the substantia nigra of Parkinson's patients. Consistent with these findings, GSEA pathway analysis revealed positive enrichment of multiple inflammatory-related pathways including but not limited to cytokine-cytokine receptor interaction, toll-like receptor signaling, JAK/STAT signaling cascade, NF-kB signaling, and IL-1R signaling (adjusted p-value < 0.05).
Conclusions: In this study, we found a significant relationship between neuroinflammation and LBD, including IL17RB and related inflammatory signaling cascades. Given current development of clinical candidates for IL-17 inhibitors, these results may highlight potentially druggable therapeutic mechanisms implicated in LBD.

Aims: Parkinson's disease (PD) is a degenerative disease of the nervous system. Our previous study found that Wuzi Yanzong Pill (WYP) has a good therapeutic effect on PD mouse model, and is related to the regulation of inflammatory factors. The activation of NF-κB by MAPK signaling pathway promotes the formation of inflammatory factors in RAGE signaling. Combined with the results of network pharmacology and molecular docking technology, based on the PD mouse model induced by MPTP activation levels of key molecules in AGEs-RAGE signaling pathway, and to provide a new idea and experimental basis for the treatment of PD with WYP.
Methods: Male C57BL/6 mice were divided into Normal group, MPTP group, WYP Low+MPTP group, WYP Medium+MPTP group, WYP High+MPTP group, TTP488+MPTP group, The best dose WYP group. MPTP group, WYP Low+MPTP group, WYP Medium+MPTP group, WYP High+MPTP group, TTP488+MPTP group to prepare PD model. The injection dosage was D1:15mg/kg. D2:20 mg/kg; D3: d7:30 mg/kg. Meanwhile, Normal group, MPTP group and TTP488+MPTP group were given normal saline (50mL/kg/d) by gavage. WYP solution (4g/kg/d, 8g/kg/d, 16g/kg/d) was administered by gavage in low, medium and high dose groups.Immunofluorescence staining, Western blot, ELISA and other methods were used to study the molecular mechanism of WYP treatment in PD mice.
Results: Compared with the MPTP group, the secretion of AGEs, RAGE, PP38, P-NF-κB, TNF-α, IL-1β, IL-6 and increased IL-10 protein levels in the MPTP+WYP group were reduced by WYP treatment.
Conclusions: WYP may improve the expression of inflammatory factors by inhibiting AGEs-RAGE signaling pathway.

S100A9 PROTEIN: A NEW PLAYER IN INFLAMMATION-MEDIATED NEURONAL LOSS

POSTERS: C01.F. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Katryna Pampuscenko[1], Ramune Morkuniene[1], Vytautas Smirnovas[2], Vilmante Borutaite[1]
[1]Lithuanian University of Health Sciences, Neuroscience Institute, Kaunas, Lithuania, [2]Vilnius University, Life Sciences Center, Institute Of Biotechnology, Vilnius, Lithuania

Aims: Parkinson's disease (PD) is a neurodegenerative disease pathobiologically characterized by the progressive loss of dopaminergic neurons in *substantia nigra* and intraneuronal alpha-synuclein aggregates, so-called Lewy bodies[1]. Recently it was found that another pro-inflammatory and highly amyloidogenic protein S100A9 also participates in PD pathogenesis potentially through stimulation of alpha-synuclein aggregation[2]. However, it remains unknown whether S100A9 is toxic to neurons by itself.
Methods: In this study, neuronal-glial co-cultures from rat cerebellum were incubated with pre-aggregated recombinant S100A9 protein for 48-72h and then cell viability, number and microglial phagocytic activity were evaluated by fluorescence microscopy.
Results: Our results show that pre-aggregated recombinant S100A9 cause loss of viable neurons in rat neuronal-glial co-cultures without any sign of apoptosis and necrosis. Neuronal loss in S100A9-treated cultures was accompanied by microglial proliferation, altered morphology, as well as increased phagocytic activity. Depletion of microglial cells attenuated S100A9-induced neuronal loss suggesting that S100A9 acts through microglial activation. Treatment of neuronal-glial co-cultures with S100A9 also was found to induce exposure of phosphatidylserine on the outer leaflet of the neuronal plasma membrane acting as “eat-me” signal for microglial cells.
Conclusions: These data suggest that pre-aggregated S100A9 can be neurotoxic by itself and can induce loss of viable neurons through phagocytic uptake which is also known as death by primary phagocytosis or phagoptosis[3]. Aims: Activation of the immune sensor NOD-, LRR- and pyrin domain-containing protein 3 (NLRP3) inflammasome and associated immune dysfunction has been suggested as a key pathogenic mechanism in Parkinson's disease (PD), preceding and accompanying neuronal damage and cell death in PD. Inflammatory mediators released into the cerebrospinal fluid (CSF) may potentially serve as biomarkers of NLRP3 pathway activation and immune dysfunction. Currently, only a few studies have investigated the levels of NLRP3 and related neuroinflammation markers in the CSF of people living with Parkinson's (PwP) compared to controls. Multiple clinical trials aiming to modulate the neuroinflammatory response in PwP are currently underway exemplifying the need for a better understanding of the levels and relevance of these biomarkers in the diagnosis and monitoring of disease progression in PD.
Methods: We performed a meta-analysis on sixteen biomarkers related to specific components of the neuroinflammatory response, including those of the NLRP3 pathway in the CSF of PwP and controls.
Results: Random-effects meta-analyses show that the levels of selected cytokines downstream of the NLRP3 pathway (e.g. IL-1ß) as well as markers for glial cells (e.g. sTREM-2, S100) and neuroaxonal damage (NfL) are elevated in the CSF of PwP compared to controls.
Conclusions: These results support the relevance of the NLRP3 pathway and immune dysfunction in PwP, and provide increased confidence in modulating neuroinflammation as a promising therapeutic avenue in the treatment of PD.

Aims: Previous investigations have provided numerous indications of a disrupted hypothalamic-pituitary-adrenal axis in the context of neurodegenerative diseases. For that reason, this study aims to investigate a potential dysregulation of the hypothalamic-pituitary-adrenal axis and its downstream effects in Parkinson's disease (PD). Therefore, we investigate glucocorticoid sensitivity of splenocytes in a wild-type human α-synuclein overexpressing mouse model for Parkinson's disease (V1S/SV2).
Methods: To assess chronic stress in V1S/SV2 transgenic murine splenocytes, a glucocorticoid sensitivity assay was employed. In addition, a panel of ten inflammatory cytokines as well as corticosterone levels in V1S/SV2 plasma samples were measured by ELISA. To gain insight into potential mediating effects flow cytometry, Western and qPCR analyses were used.
Results: At 16 months of age, V1S/SV2 splenocytes showed a weaker response to corticosterone, indicating a glucocorticoid resistance in our V1S/SV2 mouse model. In contrast, at the age of 20 months glucocorticoid resistance in V1S/SV2 mice was not visible anymore. For physiological stress parameters like spleen and adrenal gland weight no alteration could be observed at 16 and 20 months. Furthermore, a significant increase of TNF-α and IFN-γ in plasma of 20 months old V1S/SV2 mice suggesting a preceding inflammatory status of PD mice. Measurement of plasma corticosterone levels detected an increase in V1S/SV2 mice with proceeding age, potentially correlating with the preceding PD phenotype.
Conclusions: Our preliminary findings suggest the presence of glucocorticoid resistance in our PD V1S/SV2 mouse model at 16 months of age. This observation hints at a potential dysregulation within the hypothalamic-pituitary-adrenal axis. The potential mediating effects underlying glucocorticoid resistance and a dysregulated hypothalamic-pituitary-adrenal axis remain unexplored, providing several approaches for further research.

THE INTERPLAY OF INFLAMMATORY CYTOKINES AND ALPHA-SYNUCLEIN IN NEURONAL CYTOSKELETON PATHOLOGY

POSTERS: C01.F. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Veronika Sigutova[1], Elizaveta Gerasimova[1], Wei Xiang[2], Jürgen Winkler[2], Beate Winner[1], Iryna Prots[3]
[1]University Hospital Erlangen, Stem Cell Biology, Erlangen, Germany, [2]University Hospital Erlangen, Molecular Neurology, Erlangen, Germany, [3]University Hospital Erlangen, Dental Clinic 1 - Restorative Dentistry And Periodontology, Erlangen, Germany

Aims: In Parkinson's disease (PD), neuroinflammation impairs neuronal structure and function, yet the specific mechanisms remain elusive. Emerging evidence implicates pro-inflammatory cytokines as crucial mediators of neuronal degeneration. While initial data indicate that the cytokine TNF-α can interfere with neuronal microtubules and axonal transport, critical questions persist regarding the role of other cytokines in cytoskeleton pathology, their combined effects, and their contribution to PD pathology. We therefore investigated the direct impact of pro-inflammatory cytokines on the neuronal cytoskeleton and hypothesized that an increased α-synuclein dosage in PD exacerbates cytokine-induced cytoskeletal deficits.
Methods: iPSC-derived cortical neurons from healthy controls and patients with α-synuclein gene locus duplication (SNCA dupl) were treated with PD pathology-related cytokines IL-17A, TNF-α, IFN-γ, or a combination thereof. Cytokine receptor expression, axonal transport, and microtubule components and their post-translational modifications were assessed on transcriptional and protein levels.
Results: SNCA dupl neurons exhibited an increased IL-17 receptor expression and consequently displayed impaired cytokine receptor homeostasis in response to IL-17A. Mitochondrial axonal transport was differentially affected by IL-17A, TNF-α and cytokine mix depending on α-synuclein dosage, with IL-17A slowing and cytokine mix reducing mitochondrial movement specifically in PD neurons. Furthermore, cytokines exacerbated the basally elevated tubulin acetylation in SNCA dupl neurons, while displaying neurite segment-specific effects in healthy cells. Additional SNCA dupl cytoskeletal pathologies, including tubulin polyglutamylation and tau beading, were further intensified by cytokine combination.
Conclusions: Our work elucidates the detrimental effects of pro-inflammatory cytokines, particularly IL-17A, on human neuronal cytoarchitecture. We also highlight their interactions with α-synuclein pathology, suggesting that inflammation represents a second hit to the vulnerable cytoskeleton in PD.

Aims: Animal models cannot recapitulate many human neurodegenerative disease features. The ability to produce functional neuronal cells from hiPSCs and neuronal cell lines allows to study neurological disorders. But despite this progress, most protocols used hiPSCs to differentiate into neurons based on 2D methods which cannot recapitulate the function and complexity of in-vivo neuronal circuits. These limitations have led to the development of organoid models that mimic the functional characteristics of human brain tissues using hiPSCs.
Methods: We explored organoid technology to generate midbrain organoids. For this purpose, we developed a system of midbrain organoids from hiPSCs. Characterization of organoids will be done using immunohistochemistry and whole-mount immunostaining. EVs were isolated from the plasma of the PD subject and sex and aged-matched HC using size exclusion chromatography and quantified using nanoparticle tracking analysis. The functional effects of plasma-derived EVs on midbrain organoids were investigated using flow cytometry and immunohistochemistry.
Results: Whole-mount immunostaining of organoids showed that neurons are successfully differentiated at day 30 and labeled with beta-tubulin III, indicating the mature neuronal cell identity. Midbrain organoids were positively labeled with TH antibody after day 30, and astrocytes expressing GFAP after six weeks of maturation. Preliminary data on plasmatic PD-derived EVs showed increased neurotoxicity in neurons and activation of inflammatory pathways in glia cells.
Conclusions: We successfully generated midbrain organoids from hiPSCs with distinct layers of neuronal cells with functionally mature midbrain dopaminergic neurons and produced neuromelanin-like granules. Plasma-derived EVs from PD patients may exert toxic effects on neurons in midbrain organoids and influence the initiation and progression of the disease.

INVESTIGATING A-SYNUCLEIN AND INFLAMMATORY RESPONSES IN THE OLFACTORY CIRCUITRY OF MICE NASALLY INOCULATED BY A NEURONOTROPIC VIRUS

POSTERS: C01.F. DISEASE MECHANISMS, PATHOPHYSIOLOGY: INFLAMMATION

Karim Zahr Eddin, Michaela Lunn, Nathalie Lengacher, Julianna Tomlinson, Earl Brown, Michael Schlossmacher
University of Ottawa, Cellular And Molecular Medicine, Ottawa, Canada

Aims: The importance of the olfactory system in the pathogenesis of Parkinson disease is supported by the presence of prodromal hyposmia and Lewy pathology in the olfactory bulb. We previously published that α-synuclein is expressed in dendrites, cytoplasm and axons of olfactory neurons, and that it protects mice from microbial infections. We hypothesized that viral infections of the nasal cavity could induce changes in α-synuclein metabolism and incite post-translational modifications concurrent with inflammatory responses by the host within anterior olfactory structures.
Methods: We inoculated adult C57BL wildtype mice with GFP-expressing vesicular stomatitis virus (VSV-GFP). Sagittal skull sections were analyzed microscopically at various timepoints to look at the temporal distribution of VSV-GFP and quantify the immunoreactivity of glial cells regarding phenotypical parameters. The viral burden in distinct anatomical regions was measured by peak titers, as was the presence of viral proteins. Changes in α-synuclein were monitored by monoclonal antibodies and Western blotting to assess for any changes due to the infection.
Results: Inoculation with VSV-GFP generated a progressive encephalitis, accompanied by robust microglial and astrocytic responses that peaked at 4 and 6 days post-infection (dpi), respectively. α-Synuclein was found to co-localize with VSV-GFP at points of viral entry in anterior olfactory structures. α-Synuclein formed aggregates in olfactory sensory neurons and more pSer129-α-synuclein reactivity was detected in glomeruli and mitral cells, as well as of p62 reactivity. Endogenous α-synuclein levels were also increased in infected brains when compared to mock-treated animals.
Conclusions: Infection of murine brain by a neuronotropic RNA virus can lead to changes in α-synuclein metabolism that could be of relevance to human synucleinopathies, including Parkinson disease. Future studies will explore whether such neuropathological changes are transient, chronic or progressive.

Aims: Parkinson's disease (PD) affects more than one million people in the EU. It has currently no definitive cure, hence patients rely only on symptomatic treatments, which themselves are burdened by side effects. The need for advancements in both knowledge and available treatments is thus heartfelt by patients, caregivers, and health operators. This unmet need sparked the idea of orchestrating a collaborative effort via a common network – IMMUPARKNET. IMMUPARKNET COST Action focuses on PD challenges and the crosstalk with immune response. Although widely recognised, the role of immunity in the onset and development of PD is still unclear. The main goal of IMMUPARKNET is to fill this knowledge gap, establishing an innovative, multi-interdisciplinary research network, fostering expertise exchange among specialists from different countries and institutions.
Methods: Gathering scientists and clinicians studying immunity in PD and related fields, IMMUPARKNET will establish the first nucleus of a multidisciplinary ecosystem that aims at harmonising efforts and approaches, both in research and clinical practice, for boosting the development of ground-breaking treatments for PD. Through meetings, training schools, webinars, position papers and review manuscripts, IMMUPARKNET will lead fruitful exchanges of know-how among experts in the field.
Results: IMMUPARKNET Action structure relies on 5 working groups. To date, IMMUPARKNET has 119 active members from 26 different European countries. Of all these active members, 51% are young researchers, while 34% come from inclusiveness target countries.
Conclusions: IMMUPARKNET outputs will allow a better sharing and development of research resources, straightening the road to novel treatments, or pointing to drug-repurposing of existing ones, and, ultimately and hopefully, a cure for PD. **Acknowledgments:** Based upon work from COST Action CA21117 IMMUPARKNET, supported by COST (European Cooperation in Science and Technology). www.cost.eu; https://immuparknet.eu/

TYPE-I INTERFERONS IN THE AGING BRAIN POTENTIATE THE ALPHA-SYNUCLEIN-INDUCED NEUROINFLAMMATORY RESPONSE IN A MOUSE MODEL OF PARKINSON'S DISEASE

POSTERS: C01.G. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Shuyan Chen, Harrison Waters, Peter Crack, Juliet Taylor
The University of Melbourne, Biochemistry And Pharmacology, Melbourne, Australia

Aims: To determine the contribution of type-I interferons to the microglial response in the alpha-synuclein pre-formed fibril (alpha-syn PFF) model of Parkinson's disease.
Methods: Alpha-synuclein PFFs (8µg) or PBS were stereotaxically injected into the right dorsal striatum of wildtype (C57BL/6) or interferon-alpha receptor-1 knockout (IFNAR1$^{-/-}$) mice at 8-12 weeks (young) or 46-50 weeks of age (aged) (n=5-8). The neuroinflammatory response in the brain was determined by qPCR, western blot analysis and immunohistochemistry at 3- and 6-months, post injection (p.i). Changes in gait were assessed by DigiGait analysis.
Results: Alpha-synuclein PFF's induced a pro-inflammatory response in aged wildtype mice at 3 months (midbrain and striatum) and 6 months (striatum) p.i. Increased expression of key interferon-stimulatory genes IRF7 and STING, and the classical pro-inflammatory cytokines IL-1beta and TNF-alpha were only observed in the aged, and not young alpha-syn PFF-injected wildtype mice. Critically, age-matched alpha-syn PFF-injected IFNAR1$^{-/-}$mice displayed an attenuated neuroinflammatory profile at both timepoints. Microglial morphology analysis revealed distinct differences in branch length and cell radius in alpha-syn PFF-injected wildtype brains, compared to PBS-injected, with no difference seen in IFNAR1$^{-/-}$ mice. Significantly, alpha-syn PFFs induced significant locomotor changes in stride length and stance/swing at 3 months p.i in aged wildtype but not IFNAR1$^{-/-}$ mice.
Conclusions: This study implicates type-I interferons in mediating the age-related neuroinflammatory changes in the alpha-synuclein PFF model and supports a detrimental role for neuroinflammation in driving the progression of Parkinson's disease.

Aims: This study aimed to investigate the influence of alpha-synuclein (a-syn) levels on microglial function with reduced glucocerebrosidase (GCase) activity in the context of Parkinson's disease (PD). To achieve this, we developed a method for creating human midbrain organoids (hMOs) incorporating microglia derived from human embryonic stem cells (hESCs).
Methods: Using CRISPR/Cas9, we inserted EGFP into the *TMEM119* locus of hESCs, a specific microglia marker. Subsequently, we performed another round of gene editing to generate a *TMEM119*-EGFP::*GBA* (encodes GCase) knock-out (KO) cell line. Following these manipulations, we differentiated hESCs into haematopoietic progenitor cells (HPCs) and then into microglia. We verified successful differentiation through the assessment of CD43 and Iba1 expression, markers for HPCs and microglia, respectively. Additionally, we conducted a comprehensive transcriptomic analysis of the differentiated microglia. To assess microglial functionality, we employed a pHrodo conjugation phagocytosis assay and studied their response to a-syn pre-formed fibrils (PFFs). These microglia were co-cultured with hMOs generated from both H9-wildtype and H9-GBA KO cell lines, which was previously established in our lab.
Results: Our study revealed the impact of reduced GCase levels on microglial function. Transcriptomic analysis provided valuable insights into the molecular changes occurring in these microglia, elucidating the mechanisms involved in a-syn pathology. Functional assays demonstrated alterations in microglial phagocytic activity and their response to a-syn PFFs.
Conclusions: This study underscores the intricate balance maintained by microglia within the complex brain environment and the consequences of prolonged activation, particular in the context of PD and aberrant a-syn accumulation. By developing a method to incorporate microglia into hMOs, we can bridge the gap between animal models and human pathophysiology, providing a clinically relevant model to explore fundamental cellular mechanisms and evaluate potential therapeutic strategies for PD.

Aims: Misfolded and aggregated α-synuclein (α-Syn) is the pathological hallmark of synucleinopathies. Preformed fibrils (PFFs), the synthetic active fibrils of α-Syn, have been demonstrated to cause synaptic loss, however, the underlying mechanisms remain elusive. Previously, we have reported that activating 18 kDa translocator protein (TSPO) causes synaptic loss via promoted microglial engulfment of synaptic materials. Here, we aim to investigate the potential mechanism of PFF-induced synaptic loss and explore the effect of PFFs on microglial functionality, in particular their phagocytic activity towards synaptic materials.
Methods: PFFs (or PBS) were stereotactically delivered to subcortical regions of 2-month-old Thy1-eGFP mice. After 5 months of inoculation, brains of both cohorts were harvested. The density and morphology of dendritic spines of GFP-labelled cortical neurons were analysed. Microglia, including their lysosomes and containing synaptic materials, were immunolablled, scanned using super-resolution microscopy and analysed using 3D reconstruction. *Tspo*$^{-/-}$ mice were employed for validation of TSPO dependency of the observed alterations.
Results: In the cortical region with confirmed spreading of aggregated α-Syn, we observed a decreased density of dendritic spines. Moreover, compared to PBS-injected mice, microglia of PFFs-injected mice showed heightened TSPO expression, coupled with increased synaptic materials (PSD95) inside lysosomes (CD68), indicating a promoted phagocytic activity towards synapses. Both effects were inhibited upon genetic depletion of TSPO, supporting the TSPO dependency of the PFFs-induced microglial synaptic engulfment.
Conclusions: Collectively, we have demonstrated that PFFs induce synaptic loss via promoted TSPO-mediated microglial engulfment of synapses. Our findings support the perspective of TSPO as a potential therapeutic target for rescuing synaptic loss induced by misfolded and aggregated α-Syn.

STAT3-MEDIATED FERROPTOSIS IS INVOLVED IN A-SYNUCLEIN PATHOLOGY

POSTERS: C01.G. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Danyu Lin[1], Han Zhang[2], Kaixun Huang[1], Jieli Zhang[1], Enxiang Tao[1]
[1]The Eighth Affiliated Hospital, Sun Yat-sen University, Department Of Neurology, Shenzhen, China, [2]Nanfang Hospital, Southern Medical University, Department Of Neurology, Guangzhou, China

Aims: Oligomeric α-synuclein had been proved to activate microglia in Parkinson's disease (PD) pathogenesis. Our previous studies have found a decline of IL6ST and its downstream target JAK2/STAT3 pathway in α-syn-induced HMC3 cells. Accumulating investigations have illustrated that STAT3 regulates the expression of ferroptosis-related genes and finally influences the proliferation of cells. In this study, we aim to explore the exact role of STAT3 in α-synuclein pathology.
Methods: Firstly, we determined the expression of IL6ST/ STAT3/HIF-1α pathway in α-syn-induced HMC3 cells. Secondly, we performed transcriptomic analysis for α-syn-induced HMC3 cells and in α-syn-induced PD mouse models. GSEA analysis was used to screen out the STAT3-associated ferroptosis pahtway. By regulating the expression of STAT3, we detected the level of ferroptosis positive regulation (FPR) genes, lipid peroxidation and iron metabolism, as well as the change of mitochondria.
Results: We explored the exact role of STAT3 in α-synuclein pathology. α-syn could impair cell activity and the stalely by inhibiting the IL6ST/ STAT3/HIF-1α pathway in α-syn-induced HMC3 cells. Besides, we performed transcriptomic analysis for α-syn-induced PD models and GSEA indicated an association with ferroptosis pathway. The reduction in P-STAT3 resulted in the transcriptional activation of ferroptosis positive regulation (FPR) genes and significant morphological changes of mitochondria. P-STAT3 mediated ferroptotic cell death in α-syn-induced HMC3 cells by modulating lipid peroxidation and iron metabolism levels. An in vivo study revealed that the IL6ST/JAK2/STAT3/HIF-1α pathway was upregulated in PD mouse models.
Conclusions: Our research illustrated the relationship of the JAK2/STAT3/HIF-1α axis and ferroptosis in the pathological process of α-syn both in vitro and in vivo, providing new topics of interest regarding the inflammation damage hypothesis and pathogenesis in PD.

MICROGLIAL ACTIVATION IN AN ALPHA-SYNUCLEIN MOUSE MODEL OF PARKINSON'S DISEASE

POSTERS: C01.G. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MICROGLIA

Laurent Potvin-Trottier[1], Robin Guay-Lord[1], Lionel Breuillaud[2], Simone Zehntner[2], Elodie Brison[2], Barry Bedell[2,3]
[1]Biospective Inc, Technology, Montreal, Canada, [2]Biospective Inc., Preclinical, Montreal, Canada, [3]Research Institute of the McGill University Health Center, Department Of Neurology And Neurosurgery, Montreal, Canada

Aims: Microglia are thought to play a key role in neurological diseases, including Parkinson's disease and Alzheimer's disease [1]. In these diseases, microglial activation is often linked with pathologic progression and disease severity. The objective of this work was to quantitatively assess microglial activation in a human α-synuclein preformed fibril (hPFF) seeding and spreading mouse model of Parkinson's disease.
Methods: We have developed a novel, fully-automated method for analysis of microglial morphology in neuroanatomical regions-of-interest on immunohistochemistry (IHC) sections stained for Iba-1 leveraging advanced computer vision and machine-learning (ML) models. We have applied this methodology to tissue sections from transgenic M83+/- mice, which overexpress α-synuclein with an A53T mutation, that have undergone unilateral stereotaxic inoculation of recombinant hPFFs into the anterior olfactory nucleus.
Results: We found that cells classified as activated by our ML model had very different morphological features that were consistent with previous reports, such as a larger, less circular soma and compact, highly branched processes (Fig. 1). Measurement of the density of activated cells provided a more sensitive metric than the Iba-1 stain density, with greater fold-change that had higher statistical significance (Fig. 2 top vs bottom). In addition, using other measures, such as a continuous activation score, we show how both the distribution of morphological phenotypes and the number of microglia change in the disease model, thereby illustrating how such metrics can provide a finer quantification of the microglial
morphology.

Aims: Astrocytes perform pivotal roles in sustaining brain physiology and function. Accumulating evidence shows that disrupted astrocytic activity contributes to neurodegenerative disorders, including Parkinson's disease (PD). Over the past decade, various methods have been developed to generate more pertinent astrocytic models to interrogate disease mechanisms, namely using human induced pluripotent stem cells (iPSC). However, the properties of astroglia generated through different methods are inconsistent, which complicates the selection of an appropriate protocol for a given research question. Thus, we aimed to compare two approaches for the generation of iPSC-derived astrocytes that differ in their duration and serum utilization.
Methods: We obtained human iPSC-derived astrocytes employing a widely used long, serum-free ("LSF") method and an in-house established short, serum-containing ("SSC") protocol. The latter method involves the purification of expandable neural stem cells. We employed high-content confocal imaging and bulk RNA sequencing to characterize the resulting cultures.
Results: LSF and SSC protocols generate astrocytes that differ considerably in their properties. While the LSF method is more labor-intensive involving manual cutting of astrospheres and a longer cultivation time (~5 vs ~2 months), the generated cells more robustly expressed traits of mature astrocytes. This notion was strengthened by data resulting from cell-type deconvolution analysis that was applied to bulk transcriptomes from each culture to assess their similarity with human postmortem astrocytes.
Conclusions: Overall, our data highlight the need to carefully consider the advantages and disadvantages of any given differentiation method, when designing functional or drug discovery studies involving iPSC-derived astrocytes.

GLIAL AND NEURONAL ALPHA-SYNUCLEIN PATHOLOGY OCCURS ACROSS ALPHA-SYNUCLEINOPATHIES WITH ASTROCYTIC PATHOLOGY AFFECTING PREDOMINANTLY THE LIMBIC SYSTEM OF CASES WITH DEMENTIA

POSTERS: C01.H. DISEASE MECHANISMS, PATHOPHYSIOLOGY: ASTROGLIA

Maria Otero-Jimenez, Javier Alegre-Abarrategui, Marcelina Wojewska, Vincenzo De Paola
Imperial College London, Department Of Brain Sciences, London, United Kingdom

Aims: Alpha-synucleinopathies are neurodegenerative diseases including Dementia with Lewy bodies (DLB), Parkinson's disease (PD), Parkinson's Disease Dementia (PDD) and Multiple System Atrophy (MSA) characterised by the accumulation of pathological alpha-synuclein (α-syn) aggregates. Although α-syn aggregation is a key shared property, they differ in the extent of glial versus neuronal α-syn pathology and neuroanatomical regions affected in a stereotypical pattern. MSA is characterised by the presence of α-syn aggregates in oligodendrocytes, termed glial cytoplasmic inclusions (GCIs), whereas in PD, PDD and DLB α-syn aggregates are mainly present in neurons as Lewy bodies. Neuronal inclusions are present in MSA although less widespread than GCIs. Glial pathology in PD, PDD and DLB is also present but its role in pathogenesis is still unclear. We aim to investigate the hypotheses that neuropathogenesis is promoted by synergistic interaction of glial and neuronal α-syn pathology which could be detected using a machine learning (ML) based approach.
Methods: Immunohistochemistry was used to explore the cellular-specificity of α-syn pathology in a cohort including MSA, DLB, PDD (n=15) and early or late stage PD (n=20) cases using QuPath software. Analysed brain regions included those affected differentially across conditions along disease stages, including brainstem, limbic system and neocortex.
Results: ML revealed the presence of neuronal α-syn pathology in some MSA cases and widespread glial α-syn pathology in PD, PDD and DLB cases. Moreover, astrocytic α-syn pathology was predominant in the limbic system of cases with dementia in a stereotypical pattern with morphology of astrocytic α-syn pathology paralleling its severity.
Conclusions: To conclude, glial and neuronal α-syn pathology can be differentially detected using ML and is present across all alpha-synucleinopathies appearing at early disease stages while astrocytic α-syn pathology might correlate with presence of dementia.

EFFECTS OF NPT520-34 ON MITOCHONDRIAL DYSFUNCTION AND INFLAMMATORY PATHWAYS RELEVANT TO NEURODEGENERATIVE DISEASES

POSTERS: C01.J. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

Adrianne Pike[1], Agata Habas[1], Ildiko Szabo[2], Diana Price[3], Douglas Bonhaus[1]
[1]Neuropore Therapies, Inc., In Vitro Pharmacology, San Diego, United States of America, [2]University of Padova, Department Of Biology, Padova, Italy, [3]Neuropore Therapies, Inc., In Vivo Pharmacology, San Diego, United States of America

Aims: The clinical stage development candidate NPT520-34 has yielded promising results in animal models of Parkinson's disease (PD) and other neurodegenerative disorders (NDs). We previously demonstrated that NPT520-34, which binds to the mitochondrial Complex 1 subunit NDUFB8, modulates inflammasome activation specifically associated with mitochondrial dysfunction. The aim of the current study was to characterize the actions of NPT520-34 on the mitochondrial production of reactive oxygen species (ROS) in comparison to secreted cytokine patterns.
Methods: Biochemical techniques including multiplex quantification of cytokine secretion, western blotting, and ROS assays were employed to gain insight into ROS production and NPT520-34-mediated inhibition of NLRP3 inflammasome activation in THP-1 cells. Established inflammasome activators and Complex I inhibitors were applied to cells after pretreatment with a concentration gradient of NPT520-34.
Results: All inflammasome activators tested led to increased ROS and cytokine production by THP-1 cells. NPT520-34 decreased NLRP3 inflammasome-mediated IL-1β and TNF-α secretion in response to Complex I inhibitors but not TLR ligands. NPT520-34 also decreased superoxide production induced by rotenone or LPS, but not by piericidin A, imiquimod, or Pam3.
Conclusions: NPT520-34 shows a selective ability to inhibit ROS production and NLRP3 inflammasome activation induced by Complex I inhibitors. These results suggest that NPT520-34 is neither a direct inflammasome inhibitor nor a simple antioxidant, but rather acts to maintain mitochondrial function by a direct action on Complex I. These beneficial actions on mitochondrial function may account for the robust actions of NPT520-34 in animal models of neurodegenerative diseases.

STRATIFYING PEOPLE WITH SPORADIC PARKINSON'S DISEASE BY PATHOLOGICAL MECHANISM IN PATIENT-DERIVED FIBROBLASTS

POSTERS: C01.J. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

Toby Burgess, Thomas Payne, Stephen Bradley, Sarah Roscoe, Katy Barnes, Oliver Bandmann, Heather Mortiboys
SITRAN, Neuroscience, Sheffield, United Kingdom

Aims: The aim of this study was to stratify a new cohort of Sporadic Parkinson's disease (sPD) patients into small, homogeneous subgroups defined by specific mitochondrial and lysosomal dysfunction.
Methods: sPD is widely recognised as a heterogeneous disorder, both clinically and mechanistically. Several dysfunctional mechanisms have been identified, including mitochondrial and lysosomal dysfunction. However, clinical trials select participants without considering mechanism heterogeneity and continually fail to reach efficacy outcomes. We investigated mitochondrial and lysosomal dysfunction, two key mechanisms of sPD and promising targets for therapeutics. Imaging and biochemical assays assessed 13 mitochondrial and lysosomal health parameters in fibroblasts from a new cohort consisting of 35 sPD patients and 24 healthy individuals. The sPD population was then stratified by assessing patterns of dysfunction across these parameters. Validation of these subgroups is currently being undertaken in the patient fibroblasts and induced Dopaminergic Neurons.
Results: The sPD population was significantly more heterogeneous in 88% of mitochondrial and lysosomal parameters, but population means were only significantly different in 7.7% parameters demonstrating the diversity amongst patients. Stratification of this cohort by distinct patterns of dysfunction identified four unique subgroups, defined by mitochondrial dysfunction, lysosomal dysfunction or both. The top three patients in each subgroup were selected for validation and mechanism studies, which discovered a significant reduction in maximal respiration in the pure mitochondrial dysfunction subgroup and Cathepsin D activity deficit in the lysosomal dysfunction subgroup.
Conclusions: This study suggests that it is possible to stratify cohorts of sPD patients providing a possible model for clinical trial recruitment in order to aid the effectiveness, and therefore approval, of new therapeutics and support an approach to personalised treatment plans.

PARKINSON'S DISEASE ASTROCYTES EXHIBIT ALTERATIONS IN MITOCHONDRIAL OXIDATIVE PHOSPHORYLATION AND QUALITY CONTROL PROTEINS

POSTERS: C01.J. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

Chun Chen[1], David Mcdonald[2], Amy Vincent[1], Gavin Hudson[1]
[1]Newcastle University, Wellcome Centre Of Mitochondrial Research, Newcastle upon Tyne, United Kingdom, [2]Newcastle University, Flow Cytometry Core Facility,, Newcastle upon Tyne, United Kingdom

Aims: Mitochondrial dysfunction in neurons, particularly in the substantia nigra, is well-documented in Parkinson's disease (PD). However, the impact of this dysfunction on astrocytes, reliant on mitochondria, remains less clear. Impaired astrocytic support for neuronal health may play a key role in PD progression and neurodegeneration. This study aimed to investigate mitochondrial health in PD astrocytes, importantly, exploring their relationship to nearby neurons, Lewy body distribution and clinical phenotypes.
Methods: Post-mortem human brain sections from PD patients and age-matched controls underwent imaging mass cytometric analysis of key enzymes and factors of OxPhos and the mitochondrial quality control (MQC) system (PMID37553379 & 33980828). Imaging mass cytometry enables simultaneous detection of up to 47 targets at a single-cell level using lanthanide metal-conjugated antibodies. Statistical analysis included Bayesian estimation, Mann-Whitney U tests, and mixed linear regression modelling using R.
Results: We observed significant variability in astrocytic mitochondrial protein expression among individuals, with evidence of OxPhos enzyme deficiencies. These changes, particularly in mitochondrial mass, associated with PD, not solely aging. (PMID: 34779538). Additionally, lower protein abundance of key mitophagy regulator Parkin, intramitochondrial chaperone HSP60, and mitofusion2 (MFN2) was detected in PD astrocytes versus controls. This suggests impaired MQC machinery, including mitophagy and mitochondrial proteases, in PD astrocytes. Ongoing work includes examining associations between astrocytic mitochondrial proteostasis disruption, neuronal dysfunction, Lewy bodies, and clinical parameters.
Conclusions: Our data highlight mitochondrial dysfunction in PD astrocytes, impacting OxPhos and mitochondrial homeostasis. This suggests that astrocytes, similar to neurons, are susceptible to mitochondrial defects that could affect their support for neurons in PD, potentially accelerating disease progression. Future plans include utilizing a neuronal-astrocytic co-culture model to further evaluate these disease-relevant pathways, offering deeper insights into pathogenic mechanisms and potential PD therapeutic strategies.

POLG-ASSOCIATED PARKINSONISM

POSTERS: C01.J. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

André Fernandes, Daniel Oliveira, Rui Araújo
Centro Hospitalar e Universitário São João, Neurology, Porto, Portugal

Aims: We aim to raise awareness to a rare cause of neurogenerative parkinsonism.
Methods: We report a patient with pathogenic POLG mutation who presented with early-onset parkinsonism.
Results: A 43-year-old female presented with an 8-year history of a bilateral upper limb tremor. Additionally she complained about episodes of abnormal posturing of the left foot and pain during stressful events and resting, causing gait disturbances. She had a previous history of ocular misalignment, which led to a strabismus surgery, and important systemic reactions to viral illnesses and vaccination. Family history revealed a maternal grandfather with history of Parkinson's Disease with age of at 45-years-old. The neurological examination revealed opthalmoparesis with esotropia of the left eye and abduction restriction and a mild right eyelid ptosis. She displayed postural tremor on the upper limbs. Bilateral bradykinesia was observed in the finger tapping, hand movements and foot tapping maneuvers. Additionally, a dystonic posturing of the left foot was noted. Brain MRI was unsuspicious and the DatSCAN was compatible with right preference degeneration of dopaminergic neurons of nigostriatal pathways. The patient revealed a marked improvement after initiation of rotigotine 2mg id. A next generation sequencing panel of Parkinson's Disease and Parkinsonism detected a variant in heterozygosity in POLG, c.1402A>G (p.Asn468Asp), classified as pathogenic. The patient was treated with increasing dose of dopamine-agonist (rotigotine up to 4mg/d), with sustained dopaminergic-response.
Conclusions: Mitochondrial dysfunction has emerged as one of the possible mechanisms associated with neurodegenerative parkinsonism. The co-occurrence of other neurological and systemic symptomatology may underpin a mitochondrial disorder. POLG mutations should be suspected as a genetic cause of a neurodegenerative parkinsonism regardless of age and family history, particularly when features suggestive of a mitochondrial disorder are present.

SPATIAL TRANSCRIPTOMICS IDENTIFIES MOLECULAR SIGNATURES OF PRODROMAL AND ADVANCED ALPHA-SYNUCLEIN PATHOLOGY

POSTERS: C01.J. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

Lin Lin[1], Diana Gomes Moreira[2], Vasileios Theologidis[2], Yonglun Luo[1], Poul Jensen[3], Marina Romero-Ramos[1], Nathalie Van Den Berge[2], Jens Nyengaard[4], Asad Jan[1]
[1]Aarhus University, Department Of Biomedicine, Aarhus C, Denmark, [2]Aarhus University, Department Of Clinical Medicine, Aarhus N, Denmark, [3]Aarhus University, Danish Research Institute Of Translational Neuroscience, Department Of Biomedicine, Aarhus C, Denmark, [4]Aarhus University, Department Of Clinical Medicine, Core Center For Molecular Morphology, Aarhus N, Denmark

Aims: We investigated the transcriptomic profiles associated with prodromal and advanced stages of alpha-synuclein (aSyn) aggregation in mouse brain, within their histological context, using spatial transcriptomics.
Methods: We induced aSyn aggregation *in vivo* by intramuscular delivery of fibrillar (mouse) aSyn in the hindlimb of heterozygous transgenic M83 mice overexpressing the human mutant A53T aSyn. Spatial cDNA library construction was performed through 10X Genomics Visium platform, using brains section (n=4/cohort) from the following cohorts: i) Controls (vehicle), ii) Early stage (45 days post-injection, with non-significant phenotype), and iii) Terminal stage pathology (70-86 days post-injection with paralysis). See publication (PMID 34136810) for details on pathology and associated phenotypes in the model.
Results: Our differential gene expression analyses reveal remarkably distinct transcript modules in the affected brain regions at the two stages. In the prodromal (non-symptomatic) phase, we observe significant upregulation of pathways involved in the energy metabolism (ie. Oxidative phosphorylation, glucose homeostasis, fatty acid metabolism and cholesterol biogenesis), and protein translation. Intriguingly, there is a dramatic decline in these metabolic pathways at the end-stage (phenotype: paralysis), with substantial enrichment of inflammatory markers (eg, complement, interferon response). Crucially, we also identified differential expression of unique gene clusters highlighting the effects of pathological aSyn aggregation in the components of white matter, choroid plexus and brain vasculature, which otherwise remain underrepresented features in studies of Parkinson disease (PD) and related disorders. Lastly, data from validation studies involving select candidate markers in PD patient-derived microarrays datasets and immunohistochemical analyses in post-mortem brain specimen will also be presented
Conclusions: We consider that these findings will have significant implications for obtaining a refined mechanistic understanding concerning the role of aSyn aggregation in neurodegeneration and potentially hold promise for the discovery of surrogate biomarkers in PD and other synucleinopathies.

FUNCTIONAL VALIDATION OF A MITOCHONDRIA-SPECIFIC POLYGENIC RISK SCORE IN PATIENT-BASED MODELS FOR STRATIFICATION OF IDIOPATHIC PARKINSON'S DISEASE

POSTERS: C01.J. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

Zied Landoulsi[1], Giuseppe Arena[1], Armelle Vitali[1], Sylvie Delcambre[1], Paul Antony[1], Ibrahim Boussaad[1], Lukas Pavelka[2], Enrico Glaab[1], Dajana Grossmann[3], Manu Sharma[4], Anne Grünewald[1], Patrick May[1], Rejko Krüger[1,5]
[1]University of Luxembourg, Luxembourg Centre For Systems Biomedicine, Belvaux, Luxembourg, [2]Luxembourg Institute of Health, Transversal Translational Medicine, Strassen, Luxembourg, [3]University Medical Center Rostock, University of Rostock, Translational Neurodegeneration Section "albrecht-kossel", Department Of Neurology, Rostock, Germany, [4]University of Tübingen, Centre For Genetic Epidemiology, Institute For Clinical Epidemiology And Applied Biometry, Tübingen, Germany, [5]Centre Hospitalier de Luxembourg, Parkinson Research Clinic, Luxembourg, Luxembourg

Aims: Strong evidence points to mitochondrial dysfunction as a major cause of PD pathogenesis. We hypothesize that a fraction of idiopathic Parkinson's disease (iPD) cases may harbor a pathogenic combination of common variants in mitochondrial genes ultimately resulting in mitochondrial dysfunction. We aim to functionally validate mitochondrial polygenic risk profiles (mitoPRS) in patient-based cellular models to define mitochondrial pathways potentially involved in neurodegeneration in subgroups of iPD patients.
Methods: We used PD GWAS SNPs data from the Luxembourg Parkinson's study (412 iPD and 576 controls), and calculated mitoPRS to capture the cumulative effect of common variants in mitochondrial genes on PD risk. The COURAGE-PD consortium (7270 iPD and 6819 controls) was used as a replication dataset. Skin fibroblasts and iPSC-derived neuronal progenitor cells (NPCs) from iPD patients were identified based on their mitoPRS and then subjected to a comprehensive mitochondrial phenotyping.
Results: We found that distribution of mitoPRS was significantly associated with PD in both Luxembourg Parkinson's study and COURAGE-PD. Extending the PRS approach to selected mitochondrial pathways, we demonstrated that common variants in genes regulating *Oxidative Phosphorylation (OXPHOS*-PRS*)* were associated with a higher PD risk (OR=1.31[1.14-1.50], FDR-adj *p*=5.4e-04 and OR=1.23[1.18-1.27], FDR-adj *p*=1.5e-29, respectively for the Luxembourg Parkinson's Study and COURAGE-PD). Functional characterization of skin fibroblasts and corresponding iPSC-derived NPCs from iPD patients classified based on *OXPHOS*-PRSs revealed significant alteration of mitochondrial oxygen consumption rates in the high *OXPHOS*-PRS group. Finally, individuals with high *OXPHOS*-PRS tended to have earlier AAO and longer disease duration compared to low-risk patients, a phenotype particularly significant in the larger COURAGE-PD dataset.
Conclusions: We developed and functionally validated novel mitochondria specific PRSs that could be used as a genetic tool to stratify the heterogeneous group of iPD patients.

Aims: Alpha-synuclein (alpha-syn) is the primary component of lewy bodies, the hallmark of Parkinson's disease (PD) pathology. Accumulation and aggregation of toxic alpha-syn species in PD, such as those with enhanced phosphorylation at serine 129 (pS129), promote synaptic dysfunction and transcription and epigenetic dysregulation, ultimately leading to cell death. Interestingly, the presence of alpha-syn pS129 has also been connected to other neurodegenerative disorders (NDs) including Huntington's (HD), Alzheimer's (AD) and Frontotemporal dementia (FTD). However, the role of alpha-syn pS129 in the etiology and progression of those NDs is still unknown. We have recently shown alpha-syn-pS129 is increased in HD affected tissues correlating with enhanced expression of Protein kinase CK2 alpha prime (CK2alpha'). CK2alpha' haploinsufficiency (CK2alpha'$^{+/-}$) in an HD mouse decreased alpha-syn-pS129 levels and ameliorated HD-related phenotypes. We concluded that CK2alpha'/alpha-syn-pS129 mediated toxicity in HD occurred via specific alteration of glutamatergic-related synaptic (GRS) gene expression. Intriguingly, we found increased CK2a' in affected tissues of AD and FTD mouse and human samples implying a potential shared mechanism of neurodegeneration in HD, AD and FTD. We aim to explore the contribution of this pathway in AD and FTD.
Methods: We crossed AD (Tg576) and FTD (PS19) mice with CK2alpha'$^{+/-}$ mice. We then examined cognitive function via Barnes Maze and Y-maze, and looked at gene expression via qPCR and other pathological markers using immunoblot and brain slice immunofluorescence
Results: In the Tg2576; CK2alpha'$^{+/}$ and PS19; CK2alpha'$^{+/-}$ mice we found improved cognitive behavior along with restored expression of GRS genes and ameliorated pathology.
Conclusions: These findings confirmed the similarities by which cells undergo synaptic dysfunction and neurodegeneration between these different NDs and suggested CK2a' as a potential therapeutic target to decrease alpha-syn-pS129 for the treatment of multiple NDs.

BIOENERGETIC AND LYSOSOMAL DEFECTS IN BLOOD-DERIVED GBA-PARKINSON'S DISEASE MACROPHAGES

POSTERS: C01.J. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

Gerardo Ongari[1], Micol Avenali[2,3], Antonio Pisani[3,4], Fabio Blandini[5], Silvia Cerri[1]
[1]IRCCS Mondino Foundation, Unit Of Cellular And Molecular Neurobiology, Pavia, Italy, [2]IRCCS Mondino Foundation, Neurorehabilitation Unit, Pavia, Italy, [3]University of Pavia, Department Of Brain And Behavioural Sciences, Pavia, Italy, [4]IRCCS Mondino Foundation, Movement Disorders, Pavia, Italy, [5]IRCCS Policlinico Maggiore Hospital, Scientific Director, Milano, Italy

Aims: Glucocerebrosidase 1 (GBA1) mutations are the most important risk factor for Parkinson's disease (PD), which primarily affect macrophages due to their intrinsic features and vulnerability for disturbances in ceramide metabolism. While it is known that GBA1-associated lysosomal dysfunctions can trigger the inflammatory response in macrophages, no studies explored the effects of GBA1 mutations on mitochondrial metabolism and oxidative stress in these cells. We then investigated mitochondrial dysfunction in macrophages of patients with GBA mutations, in association with lysosomal alterations and α-synuclein accumulation.
Methods: Thirty-four patients were recruited in the study: 10 controls (HC), 10 patients with sporadic PD (iPD), 10 PD patients with GBA mutations (PD-GBA+) and 4 healthy subjects carrying GBA mutations (HC-GBA+). Macrophages were differentiated from monocytes and stimulated to M1 and M2 phenotypes. Glucocerebrosidase and beta-hexosaminidase activities were quantified using fluorometric assays. Metabolic characterization was performed with a Seahorse Analyzer. Alpha-synuclein levels were quantified using an ELISA.
Results: Glucocerebrosidase activity was halved in PD-GBA+ and HC-GBA+ subjects compared with HC and iPD, whereas beta-hexosaminidase activity was reduced in PD-GBA+ compared to HC. Lysosomal alterations in PD-GBA+ is associated with increased α-synuclein levels, compared with iPD and HC macrophages. HC-GBA+ subjects showed α-synuclein levels similar to PD-GBA+. M2 stimulated PD-GBA+ macrophages displayed an impairment in the oxygen consumption compared to iPD, while no differences have been found between HC and iPD. Conversely, M1 macrophages of PD groups showed a decrease of respiratory parameters compared to HC, reaching the statistical significance in PD-GBA+. Preliminary results in HC-GBA+ indicated higher respiration values in M1 and M2 macrophages compared to PD-GBA+.
Conclusions: This study pointed out specific bioenergetic alterations in macrophages from PD subjects with GBA1 mutations suggesting their potential contribution in disease pathogenesis.

Aims: Parkinson's disease is a complex and multifactorial neurodegenerative disorder characterized by the demise of dopaminergic neurons and the accumulation of α-synuclein (α-syn). Although many mechanisms are proposed to target the disease, α-syn accumulation and altered mitochondrial dynamics are the main features in the pathogenesis of PD. In light of these findings, the objective of the current study was to evaluate the impact of α-syn on mitochondrial function and metabolism in iPSC-derived midbrain neurons from controls and PD patients.
Methods: We differentiated iPSCs from healthy controls, sporadic and α-syn-mutant (A53T and *SNCA* triplication) PD patients into midbrain dopaminergic neurons. We performed single-cell RNA-sequencing, high-content imaging, mtDNA integrity analysis and metabolomics with stable isotope tracers at three different time points of differentiation to evaluate how the accumulation of a-syn drives mitochondrial dysfunction and metabolic alterations.
Results: RNA sequencing analysis revealed differences in the neuronal expression profile between controls and PD patients at days 14, 30 and 45 of differentiation. We could observe higher α-syn expression in all investigated PD lines compared to control cells. Interestingly, this difference further increased over time. In addition, our experiments revealed a shift from oxidative phosphorylation towards glycolysis in the PD compared to the control cultures.
Conclusions: Our data indicate that α-syn accumulation occurs in PD patient midbrain neurons and uncovered changes in the cellular metabolism of these cells. Further investigations will be performed to analyze how α-syn exerts its toxicity and to obtain insights into the functional relationship between α-syn and mitochondrial metabolism.

MITOCHONDRIAL STRESS IN THE GUT EPITHELIUM OF MICE OVEREXPRESSING ALPHA SYNUCLEIN

POSTERS: C01.J. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MITOCHONDRIAL DYSFUNCTION, OXIDATIVE DAMAGE

Ashwaq Yehya[1], Nathan Pham[1], Linsey Stiles[1], Nuria Martinez-Lopez[1], Hoa Lam[2], Rajat Singh[1], Nigel Maidment[2], Elizabeth Videlock[1]
[1]UCLA, Medicine, Los Angeles, United States of America, [2]UCLA, Psychiatry And Biobehavioral Sciences, Los Angeles, United States of America

Aims: Mitochondrial dysfunction and inflammation (both intestinal and systemic) are strongly implicated in PD. Mitophagy (autophagic removal of damaged mitochondria) suppresses mitochondrial damage-induced inflammation and mitigates disease in both PD and colitis models. Intestinal epithelial cells (IECs) are particularly vulnerable to mitochondrial stress due to their high energetic needs. The aim of this study was to test the hypothesis that IEC mitochondria are altered in a mouse model of PD.
Methods: Intestinal crypts of mice overexpressing human wild-type α−synuclein (hα-Syn) under the neuron-specific Thy1 promoter (Thy1-hα-Syn) were used to measure the Oxygen consumption rate (OCR) in a Seahorse XF96 analyzer. Manual counts of the number of crypts per well were used for data normalization. Transmission electron microscopy was performed in the UCLA Brain Research Institute Electron Microscopy Core Facility. Analysis was performed in ImageJ with 'analyze particles' and the JACoP plugin. Intestinal epithelial organoids diameters and Western blot of Tom20 were measured and analyzed using ImageJ. Cytokines were measured by ELISA.
Results:

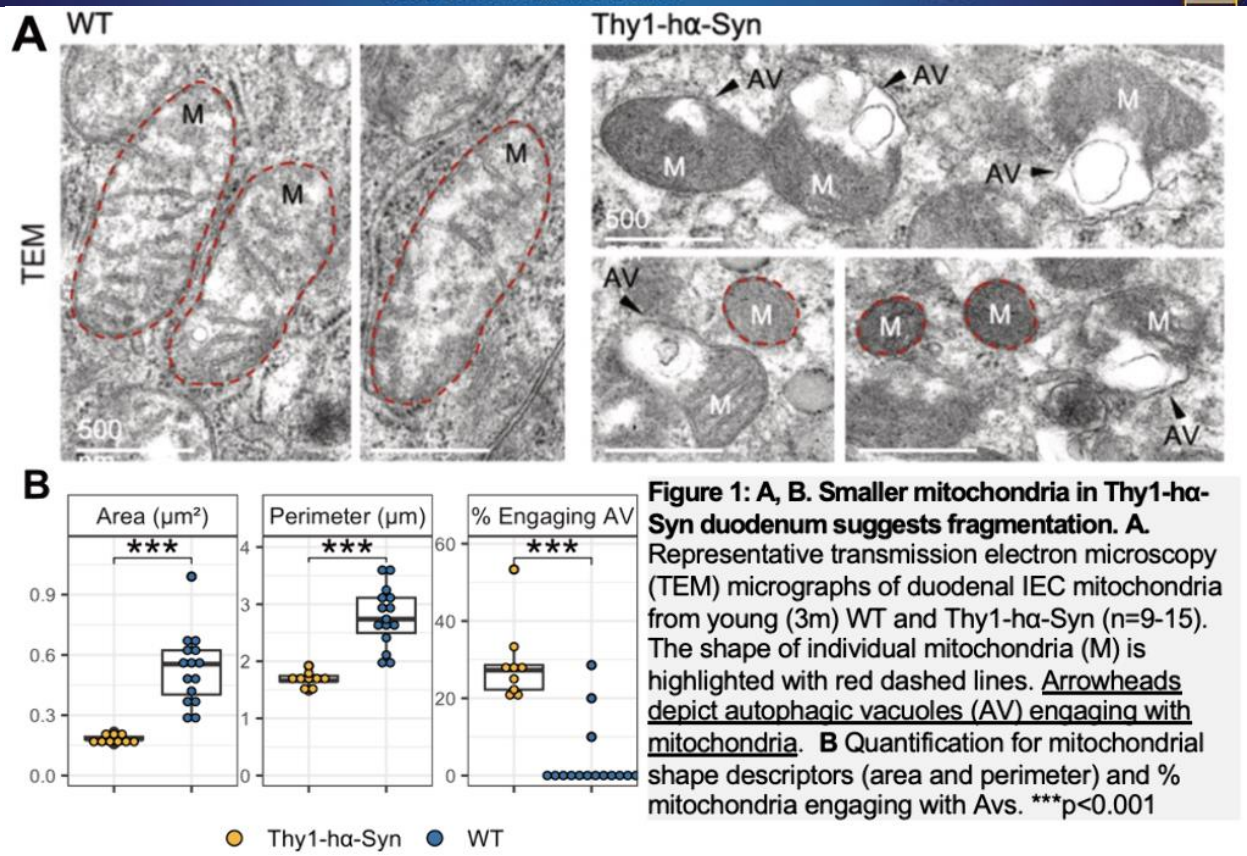

Figure 1: A, B. Smaller mitochondria in Thy1-hα-Syn duodenum suggests fragmentation. A. Representative transmission electron microscopy (TEM) micrographs of duodenal IEC mitochondria from young (3m) WT and Thy1-hα-Syn (n=9-15). The shape of individual mitochondria (M) is highlighted with red dashed lines. Arrowheads depict autophagic vacuoles (AV) engaging with mitochondria. **B** Quantification for mitochondrial shape descriptors (area and perimeter) and % mitochondria engaging with Avs. ***p<0.001

OCR was increased in Thy1-hαSyn vs WT mice ($p < 0.005$) with a greater increase in older mice. Thy1-hα-Syn mice had smaller mitochondria in duodenal tissue (Fig 1). Increased association with autophagic vesicles may suggest heightened mitophagy. IL-1β and KC (IL-8 equivalent) were higher in tissue and isolated crypts from 12-month-old Thy1-hα-Syn mice. Colonic epithelial organoids from Thy1-hα-Syn mice had smaller diameters, suggesting potential impairment in gut epithelial health compared to WT.
Conclusions: These findings provide initial support for the hypothesis that there is increased mitochondrial stress in the gut epithelium in PD. Mitochondrial stress in IECs may augment the intestinal inflammatory response to enteric neuron α-Syn, thereby producing systemic inflammation and promoting CNS α-Syn pathology in 'gut-first' PD.

ALPHA-SYNUCLEIN PATHOLOGY DISRUPTS CORTICOSTRIATAL SYNAPSES IN A RODENT MODEL OF PD

POSTERS: C01.K. DISEASE MECHANISMS, PATHOPHYSIOLOGY: SYNAPSE PATHOLOGY, NEURAL NETWORKS, PLASTICITY, NEUROGENESIS

Charlotte Brzozowski[1], Harshita Challa[1], Dominic Hall[2], Nicole Chambers[2], Ignacio Gallardo[2], Michael Millet[2], Douglas Nabert[2], Nolwazi Gcwensa[1], Laura Volpicelli-Daley[1], Mark Moehle[2]

Aims: Neuronal inclusions of α-synuclein aggregates are pathological hallmarks of Dementia with Lewy Body (DLB) and Parkinson's Disease (PD). Corticostriatal projection neurons in the supplementary motor area (SMA) in humans - secondary motor cortex (M2) in mice - are specifically vulnerable in PD, and show large burdens of α-synuclein pathology. Here, we endeavor to understand how pathological corruption of α-synuclein impairs M2, a critical brain area involved in executive functions known to be impaired in DLB and PD, to striatal connections and related behaviors.
Methods: We performed whole-cell patch clamp recordings from spiny projection neurons (SPNs) 6 weeks after α-synuclein pre-formed fibrils (PFFs) inoculations into the striatum or directly into M2. The optogenetics construct Chrimson-R was used to record light-elicited M2-striatal projection specific evoked glutamate release. Expansion Microscopy (ExM) was utilized to assess for abnormalities in synaptic morphology in presence of α-synuclein pathology. Additionally, Y maze and Erasmus ladder we used to assess for motor impairments and executive dysfunction.
Results: We show impaired evoked corticostriatal glutamate release onto SPNs in striatal and M2 PFF-injected animals compared to controls. Additionally, we found significant impairments of SPN excitability in the PFF group. M2 PFF injections caused robust layer 5 pathology throughout M2 and adjacent cortical areas and neuritic pathology overlapping with cortical terminal markers in the striatum. Using ExM superresolution imaging, we show a decrease of corticostriatal glutamatergic synapses and and overall loss of volume of presynaptic terminals in mice with α-synuclein inclusions.
Conclusions: Our combined efforts in physiology and high-resolution imaging point to a critical dysfunction of corticostriatal synapses in neurons harboring α-synuclein inclusions and our future efforts will elucidate how our findings on corticostriatal synapse abnormalities contributes to executive dysfunction in PD and DLB.

PARKINSON'S DISEASE DNAJC13 P.N855S KNOCK-IN MOUSE MODEL EXHIBITS GLUTAMATERGIC MACHINERY DEFICITS, ALTERED EXCITATORY SIGNALLING, AND INTACT DOPAMINERGIC NETWORKS AND KINETICS

POSTERS: C01.K. DISEASE MECHANISMS, PATHOPHYSIOLOGY: SYNAPSE PATHOLOGY, NEURAL NETWORKS, PLASTICITY, NEUROGENESIS

Jesse Fox
University of British Columbia, Neuroscience, Health Sciences Mall, Canada

Aims: In 2014, DNAJC13 was linked to late-onset autosomal dominant Parkinson's disease (PD) in a multi-incident kindred with post-mortem SNpc neuronal loss and Lewy body pathology. Neuronally expressed DNAJC13 localizes to endosomal compartments where it functions in protein trafficking by partitioning endosomal membranes. Interestingly, all neuronally expressed DNAJ class-III (DNAJC) members (DNAJC5/CSPα, DNAJC6/auxilin, DNAJC12/HSP40, DNAJC13/RME-8 and DNAJC26/GAK) have been implicated in parkinsonism, although with disparate synaptic-endosomal properties. Here, we examine glutamatergic and dopaminergic michinery and kinetics in Dnajc13 p.N855S knock-in (DKI or Het) mice, as well as underlying molecular mechanisms and downstream effects of observed changes in relation to the onset and progression of PD.
Methods: Animal behaviour, immunohistochemistry, fast-scan cyclic voltammetry, patch-clamp electrophysiology recording, high performance liquid chromatography, western blotting, ELISA, cell culturing, immunocytochemistry, transfections, laser-scanning confocal microscopy, electron microscopy, synaptosome isolation.
Results: We show Dnajc13 p.N855S knock-in (DKI or Het) mice exhibit significant reductions in vesicular glutamate transporter 1 and altered response to a prolonged repetitive stimulation train, but with normal basal excitatory signaling and dopamine (DA) machinery and release/reuptake kinetics. Further, synaptic vesicle organization and content are presented.
Conclusions: We show Dnajc13 p.N855S knock-in mice exhibit significant alterations to synaptic homeostatic and signaling mechanisms, thereby supporting the assignment of this mutation as disease causing in humans.

Aims: In mice overexpressing α -Synuclein (SNCA), cortical synapse loss is already evident at 3 months of age, long before the onset of motor symptoms and coinciding with translational dysfunction at the synapse. We aimed to explore the regulatory networks leading up to this phenomenon.
Methods: RNA- and micro-RNA-sequencing were used to characterize the transcriptome and regulome at the onset of SNCA-mediated synaptic loss. Human iPSCs of an α-Synuclein triplication line (AST) and its CRISPR-corrected isogenic equivalent (CAS) were differentiated to cerebral organoids as well as neurons and subjected to immunohistochemical assays, gene expression assays and translatome sequencing. Genetic manipulation of miRNA levels was performed by administration of anti-miRs and miRNA mimics. Micro-RNA target genes were identified by pulldown assays.
Results: The miRNA 183/96/192 cluster was significantly upregulated during the onset of SNCA-dependent synaptic loss, while glutamatergic synaptic markers were downregulated during this phase. Human cerebral organoids as well as iPSC-derived neurons recapitulated this phenotype. miRNA-183/96/182 target genes revealed a strong enrichment for intracellular membrane-bound organelles as well as synaptic gene ontology terms.
Conclusions: We uncovered a role for the miRNA-183/96/182 cluster in early synaptic loss during the pathogenesis of α -Synucleinopathies. Experiments on iPSC-derived cerebral organoids and neurons demonstrate this process to be conserved among humans. We hypothesize that elevated levels of miRNA 183/96/182 decrease local protein synthesis at the synapse, ultimately resulting in synapse loss. Further experiments are being performed to investigate whether this is a direct or indirect effect.

And Joanne Knight Alzheimer Disease Research Center, St. Louis, United States of America, [3]University of Exeter, Neuropathology, Exeter, United Kingdom

Aims: Parkinson disease (PD) is defined by the accumulation of aggregated alpha synuclein (asyn) in Lewy bodies and neurites. As high as 80 percent of PD patients eventually develop dementia, which is associated with neocortical accumulation of asyn. However, neuronal loss and asyn accumulation also occur in multiple subcortical nuclei, including serotonergic neurons in the dorsal raphe nuclei, which have widespread projections to cortical and limbic regions. We utilized measurements of a marker for serotonergic axons to evaluate whether the loss of serotonergic projections to cortical and limbic regions contribute to the development of cognitive impairment in PD.
Methods: In this study, we analyzed markers of serotonergic innervation in 8 different brain regions from PD autopsy cases. For comparison, we also analyzed the same 8 brain regions from control autopsy cases. We used a sandwich ELISA to analyze each brain region for serotonin transporter (SERT), which mediates serotonin reuptake in serotonergic neurons.
Results: We observed significantly lower SERT levels in PD compared to control cases for three of the five cortical regions analyzed. The sum of SERT levels in the five cortical regions inversely correlated with the Clinical Dementia Rating (CDR) sum of boxes score, a measure of global cognitive impairment. These results indicate a role for the loss of serotonergic projections to cortical regions in the development of cognitive impairment in PD. Analysis of relationships between SERT levels and additional neuropsychological measures is ongoing.
Conclusions: These results indicate a role for the loss of serotonergic projections to cortical regions in the development of cognitive impairment in PD.

THE PLATELET TRANSCRIPTOME CHANGES DURING THE DEVELOPMENT OF SYNUCLEINOPATHIES STARTING AT PRODROMAL STAGE AND DEFINING PHENOCONVERSION

POSTERS: C01.L. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TRANSCRIPTIONAL & TRANSLATIONAL REGULATION, MICRO RNAS

Laura Arnaldo[1,2], Jorge Mena[2], Dolores Vilas[3], Ramiro Álvarez[3], Pau Pastor[3], Alex Iranzo[4], Katrin Beyer[1,2]
[1]Universitat Autònoma de Barcelona, Biochemistry, Molecular Biology And Biomedicine, Bellaterra, Spain, [2]Research Institute Germans Trias i Pujol, Neuroscience, Badalona, Spain, [3]Germans Trias i Pujol Research Institute, Neurogenerative Diseases, Badalona, Spain, [4]Hospital Clínic de Barcelona, IDIBAPS, CIBERNED, Neurology Service, Sleep Disorders Center, Barcelona, Spain

Aims: We have studied the platelet miRNome in dementia with Lewy bodies (DLB) compared to controls and found a biosignature of diminished miRNAs. As consequent alterations in the platelet transcriptome can be expected, we analyzed it in DLB, Parkinson disease (PD), as another synucleinopathy, and isolated REM sleep behaviour disorder (IRBD), which is considered a prodromal stage of synucleinopathies. Thus, we aimed to identify the earliest changes associated with the development of synucleinopathies, and changes resulting in the phenoconversion to either DLB or PD.
Methods: Platelets were obtained from patients diagnosed with IRBD, PD or DLB (n=12, each) and 14 control individuals (CTRLs). Total platelet-RNA samples were pooled pairwise. Libraries were prepared using Illumina Stranded Total-RNA Prep-kit and sequenced with a NovaSeq-6000 (Illumina). RNA expression was analyzed using DESeq2-package in R (version 4.3.0), comparing DLB, PD and IRBD with CTRLs, and DLB and PD with IRBD. Pathway analysis was performed with String.
Results: Compared to CTRLs, 4206 genes were expressed differentially in IRBD, 24 in PD and 5970 in DLB platelets. Whereas 1241 of these genes were specifically deregulated in IRBD, 2950 genes were similarly expressed in IRBD and DLB, and 14 genes in IRBD and PD. Only 3 genes were deregulated in all three, IRBD, DLB and PD. Pathway analyses revealed that the most deregulated genes in IRBD were related with immune response. Comparing with IRBD, 137 genes differentially expressed in DLB were mainly associated with the ribosome pathway, and 1064 genes differentially expressed in PD with mitochondrial function.
Conclusions: Altered immune response in IRBD could be an early change during the development of synucleinopathies. Subsequent phenoconversion could be driven by ribosomal dysfunction in DLB and to by mitochondrial dysfunction in PD.

Aims: NF-kB transcription factors family is a transcriptional regulator of inflammation that contributes to pathological processes associated with neurodegeneration. We previously reported that NF-κB/c-Rel deficient mice develop a late-onset parkinsonism. Recently, we demonstrated that post-mortem brain and peripheral blood mononuclear cells (PBMCs) of PD patients displayed a significant reduction of NF-kB/c-Rel DNA-binding activity when compared with age-matched healthy controls (HC) ones, although no differences in NF-kB/c-Rel protein level were observed. NF-kB/c-Rel DNA-binding activity has been shown to depend on post-translational modifications (PTMs) such as O-linked-β-N-acetylglucosamine (O-GlcNAc), a nutrient-sensing PTM. Interestingly, altered O-GlcNAc glycosylation (O-GlcNAcylation) has been found in multiple neurodegeneration-related pathway.
Methods: PBMCs from PD patients and HC were isolated from blood samples drawn in both fasting and postprandial conditions and NF-kB/c-Rel activity was assessed in protein extracts by customized DNA-based ELISA. The extent of total protein and NF-kB/c-Rel-specific O-GlcNAcylation was evaluated by western blot and co-immunoprecipitation assays, respectively. The impact of O-GlcNAcylation on NF-kB/c-Rel activity was assessed *in vitro* on primary culture of PBMCs from selected PD and HC subjects stimulated with high glucose concentration. Finally, O-GlcNAc transferase (OGT) and hydrolase (OGA) mRNA levels were analysed by RT-qPCR.
Results: NF-kB/c-Rel DNA-binding in PBMCs is enhanced after food intake in HC but not in PD subjects, while only stimulated HC PBMCs displayed an increase in NF-kB/c-Rel DNA-binding activity when compared with not stimulated ones. Fresh and cultured PBMCs from PD patients were characterized by lower levels of total protein and NF-kB/c-Rel-specific O-GlcNAcylation, while higher mRNA expression of OGT and OGA highlights a dysregulated O-GlcNAcylation.
Conclusions: Taken together, these data suggest that NF-kB/c-Rel dysregulation is involved in the pathophysiology of PD, whereas an altered O-GlcNAcylation state could explain the defect in NF-kB/c-Rel DNA-binding activity.

MICRORNA EXPRESSION PROFILING IN GBA1-PARKINSON'S DISEASE AND DEMENTIA WITH LEWY BODIES BRAINS

POSTERS: C01.L. DISEASE MECHANISMS, PATHOPHYSIOLOGY: TRANSCRIPTIONAL & TRANSLATIONAL REGULATION, MICRO RNAS

Anthony Klokkaris, Jonathan Mill, Anna Migdalska-Richards
University of Exeter, Department Of Clinical And Biomedical Sciences, Exeter, United Kingdom

Aims: Parkinson's disease (PD), Parkinson's disease dementia (PDD) and Dementia with Lewy bodies (DLB) are heterogeneous disorders and their causes are still incompletely understood. The most common genetic risk factor for PD (*GBA1*), shows incomplete penetrance, with only a minority of carriers developing the disease. Additional factors beyond genetics are likely to play a role and previous work has identified microRNA (miRNA) expression alterations in these disorders. We aim to start investigating whether miRNA expression in the brain varies according to *GBA1* mutation status in PD, PDD and DLB individuals.
Methods: RNA was extracted from the prefrontal cortex of 96 individuals consisting of PD, PDD, DLB and controls, with each group subdivided into individuals with and without *GBA1* mutations. Following reverse transcription to cDNA, the TaqMan OpenArray Human Advanced MicroRNA Panel was used to quantify the expression of 754 miRNAs. Analysis is currently underway, with linear regression being used to identify differentially expressed miRNAs between the different groups.
Results: The OpenArray data is currently being analysed to identify differentially expressed miRNAs, comparing PD, PDD and DLB each to controls as well as the different synucleinopathies to each other and the *GBA* vs non-*GBA* carriers within each group.
Conclusions: This is one of the first miRNA studies to subdivide synucleinopathy individuals by *GBA1* status. The findings will highlight whether miRNA expression in the brain varies according to both disease and *GBA1* mutation status. We have also generated genome-wide DNA methylation data in different brain cells types and SNP data on these samples. We plan to integrate these datasets to identify novel genes involved in these disorders and improve mechanistic understanding.

Aims: Multiple System Atrophy (MSA) is a devastating rapidly progressive neurodegenerative disease histologically characterized by glial cytoplasmic inclusions (GCIs) of aggregated alpha-Synuclein in Oligodendrocytes, for which no potent symptomatic nor causal treatment is available to date. Since the underlying pathomechanisms and the contribution of the different cell types in the brain to the disease is still only poorly understood, the aim of this study is to characterize the transcriptomic profiles of different cell types in differentially affected brain regions of MSA patients and healthy controls.
Methods: Droplet-based single-nuclei RNA-sequencing and subsequent bioinformatic analysis was performed on approximately 240.000 nuclei isolated from the superior frontal cortex, frontal white matter and occipital white matter of 10 MSA patients and 5 healthy controls. In addition, RNAScope and Western blot analysis as well as immunohistochemical and immunofluorescence stainings were performed.
Results: After preprocessing and quality control, the major six brain cell types were annotated, where no significant differences or shifts in the major cell type composition could be observed. Cell type-wise differential gene expression analysis revealed numerous differentially expressed genes across all three brain regions, which were most abundantly identified in oligodendrocytes, followed by astrocytes and microglia and enriched for genes associated with other neurological and especially neurodegenerative diseases. In parallel, we were able to validate and confirm particular findings on the RNA as well as on the protein level.
Conclusions: Our study presents a large and powerful dataset helping to unravel underlying molecular mechanisms and processes in MSA and providing potential new links for molecular targets for diagnostic and/or therapeutic intervention.

A DIGITAL SEED AMPLIFICATION ASSAY FOR QUANTIFYING A-SYNUCLEIN AGGREGATES

POSTERS: C01.M. DISEASE MECHANISMS, PATHOPHYSIOLOGY: PROTEIN AGGREGATION, MISFOLDING, CHAPERONES

Tal Gilboa[1], Zoe Swank[2], David Walt[1]
[1]Harvard Medical School, Wyss Institute, Brookline, United States of America, [2]Brigham and Women's Hospital, Pathology, Boston, United States of America

Aims: This study aimed to to develop digital Seed Amplification Assays (SAAs) to quantify α-synuclein aggregates in patient biofluids and monitor the aggregation process in-vitro.
Methods: We developed digital SAAs by compartmentalizing the aggregation reaction into microwells, droplets, and hydrogel microcapsules. We used pre-formed α-synuclein fibrils as reaction seeds and explored various reaction conditions, including pH, temperature, and salt concentration, to optimize the assay sensitivity. Additionally, we introduced a bead-based digital SAA where pathological seeds were captured with antibody-coated magnetic beads before compartmentalization. We also implemented image analysis techniques to quantify aggregate growth and structural changes in the presence of aggregation inhibitors.
Results: The digital SAAs that we developed were capable of quantifying α-synuclein aggregates at concentrations as low as 4 pg/mL, with the hydrogel microcapsule SAA exhibiting the best sensitivity. The bead-based SAA significantly increased the sample volume that can be analyzed, albeit with a bias toward larger aggregates. We successfully multiplexed the bead-based SAA using different colored beads to detect various α-synuclein aggregate conformations. Furthermore, we characterized the effect of aggregation inhibitors on α-synuclein aggregation using custom image analysis pipeline.
Conclusions: Our study presents a promising advancement in quantifying α-synuclein aggregates in patient biofluids using digital SAAs. These assays offer potential applications in early PD diagnosis, disease staging, and therapeutic screening. The digital SAAs provide a platform for further research into α-synuclein aggregation and its interaction with therapeutic compounds, paving the way for a better understanding of Parkinson's disease and related synucleinopathies.

Aims: FICD, the predominant human AMP transferase, is implicated in neuronal integrity targeting key proteins of the lysosome and endoplasmic reticulum (ER). However, the role of FICD-mediated AMPylation in neurodegeneration is unclear. Considering the crucial role of protein dyshomeostasis in Parkinson´s disease (PD), we explored the interplay between the FICD-AMPylation pathway and alpha-synuclein (aSyn) pathology.
Methods: To examine the pathological relevance of FICD, we analyzed human post-mortem PD brains, brains from transgenic PD rats expressing human aSyn (BAC-SNCA), and iPSC-derived dopaminergic (DA)-neurons from a PD patient with SNCA duplication ($SNCA^{Dupl}$). For mechanistic insights, we employed H4 neuroglioma cells overexpressing aSyn and FICD variants, including the constitutively active FICD-E234G variant. To identify AMPylated proteins, we applied click chemistry-based mass spectrometry.
Results: Analysis of human and rat brains unveiled a predominant FICD expression within DA-neurons in the substantia nigra (SN). Notably, in BAC-SNCA rats, FICD levels were decreased in the striatum and SN, but increased in the cortex. This distinct topographical difference suggests that FICD levels are particularly reduced in regions characterized by a severe neuronal and synaptic DA loss. Mass spectrometry-based AMPylation profiling revealed a remarkable increase in AMPylation within $SNCA^{Dupl}$ neurons when compared to isogenic neurons with corrected SNCA dosage. Notably, lysosomal and ER proteins were identified as especially susceptible targets to this modification. Mechanistically, AMPylation of lysosomal cathepsins, key enzymes for aSyn degradation, was associated with reduced peptidase activity in H4 cells overexpressing both aSyn and FICD-E234G. Moreover, FICD-E234G overexpression increased levels of aSyn aggregation and apoptosis.
Conclusions: Our findings provide mechanistic insights into the modulatory role of the FICD-AMPylation pathway in lysosomal and ER impairment, aSyn pathogenesis, and ultimately apoptosis, suggesting pathological significance of this pathway in PD.

EFFECTS OF INDUCTION OF CHAPERONE-MEDIATED AUTOPHAGY IN THE OLFACTORY SYSTEM IN A TRANSGENIC RAT SYNUCLEINOPATHY MODEL

POSTERS: C01.M. DISEASE MECHANISMS, PATHOPHYSIOLOGY: PROTEIN AGGREGATION, MISFOLDING, CHAPERONES

Zoe Petraki[1], Sofia Dimopoulou[1], Olaf Reiss[2], Maria Xilouri[1], Leonidas Stefanis[1,3]
[1]Biomedical Research Foundation, Academy of Athens, Clinical- Experimental Surgery & Translational Research, Athens, Greece, [2]University of Tuebingen, Institute Of Medical Genetics And Applied Genomics, Tübingen, Germany, [3]National and Kapodistrian University of Athens, School Of Medicine, athens, Greece

Aims: Examine the evolution of α-synuclein (AS) accumulation in the olfactory system of WT human AS overexpressing BAC transgenic rats and investigate whether AAV-mediated overexpression of LAMP2A, the lysosomal transmembrane receptor which represents the rate-limiting step in the Chaperone-Mediated Autophagy (CMA) pathway, could counteract and/or reverse the aberrant AS deposition and its resultant behavioural effects both in early and later stages.
Methods: We used immunohistochemistry as well as Western immunoblotting with various AS antibodies in material derived from various areas within the olfactory system, such as the olfactory bulb (OB), the anterior olfactory nucleus (AON) and the piriform cortex (Piri) of WT and BAC Tg rats. We also performed behavioral experiments assessing olfaction using an odor descrimination task (Habituation/Cross Habituation test). We injected AAV-HA-Lamp2a or AAV-GFP in the AON in 3 or 5 month-old BAC Tg rats and assessed AS pathology and behavioral effects 2 months later in each case.
Results: In BAC transgenic rats there was accumulation of total, human and phosphorylated AS in the OB, AON and Piri in all time points examined (4, 8 and 12 weeks of age) and an olfactory dysfunction at the age of 12 weeks. AAV-HA-Lamp2a injection at both time points led to a modest (around 20%) amelioration of AS accumulation in olfactory regions and a mild improvement of the olfactory behavioral deficit, compared to AAV-GFP-injected rats.
Conclusions: Induction of CMA activity led to partial amelioration of incipient and established synucleinopathy in the olfactory system of hAS BAC Tg rats and a slight amelioration of the olfactory deficit. Relatively limited transduction of the olfactory system may be responsible for the lack of a more pronounced effect.

PATHOLOGICAL INTERACTION OF OLIGOMERIC ALPHA-SYNUCLEIN AND TAU IN SYNUCLEINOPATHIES

POSTERS: C01.M. DISEASE MECHANISMS, PATHOPHYSIOLOGY: PROTEIN AGGREGATION, MISFOLDING, CHAPERONES

Sudipta Senapati, Nicha Puangmalai, Nemil Bhatt, Sagar Gaikward, Mauro Montalbano, Cynthia Jerez, Kenya Moore, Rakez Kayed
University of Texas Medical Branch, Department Of Neurology, Galveston, United States of America

Aims: Accumulation of α-synuclein aggregates in large inclusion bodies is a hallmark of synucleinopathies, including Parkinson's disease (PD), dementia with Lewy bodies (DLB), and multiple system atrophy (MSA). Several studies indicate that oligomers are the primary toxic species that disrupt neuronal functions and contribute to the progression of disease pathologies. Our lab has previously shown that PD and DLB pathologies exhibit elevated levels of oligomers of both α-synuclein and tau proteins, with these diseases frequently showing a concurrent presence of both proteins. Oligomeric α-synuclein polymorphs, different oligomeric forms exhibiting strain-specific biochemical profiles, and morphologies, interact differentially with tau, resulting in oligomeric tau polymorphs that differ from those associated with fibrillar synuclein. However, little is known about brain-derived α-Syn oligomeric (BDSO) polymorphs, their structural, morphological, and biological characteristics, and their role in tau aggregation, propagation, and polymorphisms.
Methods: We isolated BDSO polymorphs from human synucleinopathy cases of AD (Alzheimer's disease), PD, and DLB using sucrose gradient separation and immunoprecipitation techniques. Size, morphology, and structural characteristics were detected using Cryo-EM and AFM. Proteolytic stability profile of BDSO polymorphs was performed to identify distinct conformation. Interaction of BDSOs and tau in tau aggregation and propagation was investigated using various biochemical, biophysical, immunological, and cell-based assays.
Results: We observed differences in immunological properties, morphology, and sensitivity to proteolysis among the BDSOs. Using molecular and cellular techniques, we found that the tau aggregates cross-seeded with BDSO polymorphs had distinct biochemical and biological properties, indicating the formation of tau polymorphs.
Conclusions: The oligomeric polymorphs of α-Syn can trigger polymorphism in tau, which might play a role in the neurodegeneration associated with synucleinopathy. Therefore, targeting α-Syn or tau polymorphs, or a combination of both, can lead to effective therapeutics for synucleinopathy.

UNVEILING NEW LINKS BETWEEN TYPE-2 DIABETES AND NEURODEGENERATIVE DISEASES: IDE DYSFUNCTION AS A PROMOTER OF COGNITIVE AND MOTOR IMPAIRMENTS

POSTERS: C01.M. DISEASE MECHANISMS, PATHOPHYSIOLOGY: PROTEIN AGGREGATION, MISFOLDING, CHAPERONES

Aims: The causal association between type-2 diabetes and neurodegenerative diseases is gaining new views and perspectives. Our team is focusing on this relationship, and we recently observed that diabetes drives to the loss of Insulin-Degrading Enzyme (IDE) in the brain. The main aim of this work was to investigate if IDE KO mice develop neurodegenerative outcomes.
Methods: Eight-week-old wild-type (WT) and IDE KO mice were subjected to a 16-week High Fat Diet (HFD) regimen, anestablished model of prediabetes. Metabolic assessments, including glucose and insulin tolerance tests, were conducted at 8 and 22 weeks of age. We evaluated cognitive, motor, and olfactory performance at 23 weeks. Brain tissue was collected at 25 weeks and subdivided into various regions. aSyn and IDE levels were measured.
Results: Our findings revealed dysregulated glucose metabolism in IDE KO mice, exacerbated by HFD. Both WT and IDE KO HFD-fed mice displayed impaired motor performance. Moreover, IDE KO mice exhibit heightened anxiety-like behavior, particularly under HFD conditions. Importantly, IDE protein levels decreased in most brain regions, except the hippocampus, while aSyn levels increased in the hippocampus and cerebellum. Notably, an inverse correlation between aSyn and IDE levels was observed in the cerebellum and brain stem.
Conclusions: This study unveils that the loss of IDE in brain may lead to behavioral dysfunction, a phenotype aggravated by prediabetes. Furthermore, the inverse correlation between aSyn and IDE levels, recapitulating observations in the pancreas of diabetic patients, strengthens a potential link between IDE dysfunction and aSyn pathogenesis. Our findings suggest that IDE failure may trigger neurodegenerative outcomes, leading to the main question if IDE failure compensation could be an important therapeutic target for neurodegenerative diseases.

SYNCHROTRON X-RAY ANALYSIS OF NANOSCALE METAL DISTRIBUTIONS IN HUMAN OLFACTORY BULB

POSTERS: C01.N. DISEASE MECHANISMS, PATHOPHYSIOLOGY: METAL IONS

Jake Brooks[1], James Everett[2], Naomi Visanji[3], Christopher Morris[4], Peter Sadler[5], Neil Telling[2], Joanna Collingwood[1]
[1]University of Warwick, School Of Engineering, Coventry, United Kingdom, [2]Keele University, School Of Pharmacy And Bioengineering, Stoke-on-Trent, United Kingdom, [3]University of Toronto, Tanz Centre For Research In Neurodegenerative Diseases, Toronto, Canada, [4]Newcastle University, Newcastle Brain Tissue Resource, Newcastle-upon-Tyne, United Kingdom, [5]University of Warwick, Department Of Chemistry, Coventry, United Kingdom

Aims: Chronic exposure to air pollution is a recognised risk-factor for both Alzheimer's and Parkinson's disease, however the role of the smallest airborne particles is poorly understood. The olfactory bulb is amongst the first brain regions affected by hallmark protein pathology in both disorders, whilst also being vulnerable to the deposition of inhaled metal-rich particulates. The objective of this work was to better characterise nanoscale metal distributions in human olfactory bulb.
Methods: In situ characterisation of nanoscale metal deposits with relation to the surrounding biological milieu requires a unique combination of spatial resolution, sensitivity, and specificity, crucially without disrupting the native tissue chemistry. Synchrotron x-ray spectromicroscopy was used for this purpose. Post-mortem fresh-frozen olfactory bulb tissue from two Parkinson's disease, one Alzheimer's disease and one neurologically healthy control case were resin embedded, microtome-sectioned and examined using nanoscale x-ray fluorescence (XRF) and scanning transmission x-ray microscopy (STXM) at Diamond Light source beamlines I14 and I08, respectively. Careful measures were taken to prevent metal contamination, avoiding any metal contact with tissue during sample preparation.
Results: Multi-element XRF maps revealed evidence of titanium- and chromium-rich sub-micron sized deposits in all four cases studied, as well as nanoscale deposits of iron, nickel, copper, and manganese. STXM analysis revealed iron-rich deposits consistent with the iron oxide mineral maghemite in one Parkinson's case, with additional magnetic characterisation required to confirm iron speciation.
Conclusions: Findings from this work raise intriguing questions regarding the origin of observed metal-rich deposits, particularly for titanium which has no recognized biochemical function, suggesting an environmental origin. Ongoing investigation using advanced chemical imaging techniques will advance crucial understanding of the biochemical environment in human olfactory bulb, with relevance to burgeoning associations between neurodegeneration and air pollution.

DISTINCT REGIONAL AND CELLULAR PATTERNS OF IRON DEPOSITION DISTINGUISH CLINICAL SUBTYPES OF MULTIPLE SYSTEM ATROPHY

POSTERS: C01.N. DISEASE MECHANISMS, PATHOPHYSIOLOGY: METAL IONS

Seojin Lee[1,2], Ivan Martinez-Valbuena[2], Anthony Lang[3], Gabor Kovacs[1,2,4,5]
[1]University of Toronto, Department Of Laboratory Medicine And Pathobiology, Toronto, Canada, [2]University of Toronto, Tanz Centre For Research In Neurodegenerative Diseases, Toronto, Canada, [3]Toronto Western Hospital, University Health Network And The University Of Toronto, Toronto, Canada, [4]University Health Network, Krembil Brain Institute, Toronto, Canada, [5]Toronto Western Hospital, Movement Disorders Clinic, Toronto, Canada

Aims: Multiple system atrophy (MSA) is a primary oligodendroglial synucleinopathy, characterized by pronounced iron deposition in the early-affected subcortical nuclei. Due to the complex involvement of iron in compounding neurodegenerative pathways, the exact role of iron in MSA pathogenesis is yet undefined. For elucidation, evaluation of iron deposition at the cellular level is critically needed, especially in relation to α-synuclein cytopathology.
Methods: Using a unique histology method which combines iron staining with immunohistochemistry, we performed the first cellular characterization of subcortical iron deposition in post-mortem human MSA brains (α-synuclein-affected and -unaffected neurons, oligodendrocytes, astroglia, and microglia), distinctly in MSA-parkinsonian (MSA-P) and cerebellar (MSA-C) subtypes. We examined mRNA expression changes in key iron- and closely related oxygen-homeostatic genes for insight into underlying mechanisms.
Results: MSA-P and MSA-C showed distinct regional patterns of subcortical iron deposition. We identified microglia as key iron-accumulating cell population in MSA-affected brains, which was more distinct in MSA-P. MSA-C showed relatively heterogenous deposition which astroglia showed greater or similar accumulation. Notably, iron deposition was also observed outside cellular bodies and cellular iron deposition minimally associated with α-synuclein cytopathology. Hierarchal cluster analysis revealed pattern of cellular vulnerability to iron accumulation, rather than of α-synuclein pathology load in the subtype-related systems, to distinguish MSA subtypes. Our gene expression analysis further highlighted dysregulation of oxygen homeostasis in the same regions.
Conclusions: Our study reveals cellular vulnerability pattern to iron deposition as a novel pathophysiological feature that distinguishes MSA subtypes, further reinforcing the involvement of iron dysregulation in disease progression at subtype-specific levels. Our findings support the role of iron dysregulation as an early affecter of disease pathology rather than consequent of synuclein pathology. We inform iron chelation therapies at the disease and cellular-specific levels.

USING METALLOMIC PROFILES TO DISTINGUISH DEMENTIA WITH LEWY BODIES, PARKINSON'S, AND ALZHEIMER'S DISEASE BRAINS

POSTERS: C01.N. DISEASE MECHANISMS, PATHOPHYSIOLOGY: METAL IONS

Melissa Scholefield[1], Stephanie Church[1], Jingshu Xu[2], Garth Cooper[1]
[1]University of Manchester, Division Of Cardiovascular Sciences, Manchester, United Kingdom, [2]University of Auckland, School Of Biological Sciences, Auckland, New Zealand

Aims: Dementia with Lewy bodies (DLB) is a neurodegenerative disease characterised by cognitive decline followed by Parkinsonian motor dysfunction. Due to its many clinical and neuropathological similarities with both Alzheimer's disease (AD) and Parkinson's disease dementia (PDD), the correct diagnosis of DLB remains difficult. Previous studies have shown multiple metallomic alterations in AD and PDD brains, including widespread copper deficiencies; here, we aimed to ascertain whether these changes were also present in DLB, or whether metallomic profiles could distinguish post-mortem DLB, AD, and PDD brains.
Methods: Fifteen clinically diagnosed and neuropathologically characterised DLB cases and fifteen controls were obtained from the NIH NeuroBioBank. Using inductively-coupled plasma mass spectrometry, the levels of eight essential metals (Na, Mg, K, Ca, Mn, Fe, Cu, and Zn) and Se were measured across ten regions of the case and control brains. Mann-Whitney U tests were used to determine case-control differences. Results were compared to those obtained in previous analyses of the AD and PDD brain, and PCA plots were used to determine whether metallomic profiles could successfully distinguish DLB from AD and PDD brains.
Results: DLB cases showed several metallomic changes, including Na increases and Cu decreases in five of the ten investigated regions, as well as more localised alterations in Mn, Fe, Ca, and Se. Using data from the cingulate gyrus and middle temporal gyrus, DLB and AD cases could be successfully separated using PCA. DLB and PDD cases could be successfully separated using only data from the primary visual cortex.
Conclusions: Copper deficiencies appear to be widespread throughout the DLB, PDD, and AD brain. However, despite such similarities, DLB can be distinguished from either AD or PDD at post-mortem using their respective metallomic profiles.

INVESTIGATING THE INVOLVEMENT OF POLLUTION EXPOSURE AND HEAVY METAL REGULATION PATHWAYS IN COGNITIVE DECLINE IN PARKINSON'S DISEASE.

POSTERS: C01.N. DISEASE MECHANISMS, PATHOPHYSIOLOGY: METAL IONS

Holly Spence[1], Fergal Waldron[1], Fiona Read[1], Hamish Johnson[2], Jenna Gregory[1]
[1]Institute of Medical Sciences, University of Aberdeen, Institute Of Medical Sciences, Aberdeen, United Kingdom, [2]School of Geosciences, University of Aberdeen, School Of Geosciences, Aberdeen, United Kingdom

Aims: Air pollution has been identified as an emerging risk factor for both Parkinson's disease and dementia. Due to the established associations between increased brain iron and progression of cognitive symptoms in Parkinson's disease, we hypothesise that heavy metal changes resulting from exposure to ambient air pollution underly the association between air pollution and dementia in Parkinson's disease.
Methods: Here, dwelling based pollution data are compared with post-mortem assessment of heavy metal metabolism, lipid metabolism and inflammation in post-mortem tissue from the motor cortex and putamen of a unique cohort of PD and control subjects stratified into the following groups (i) PD with dementia (n=19), (ii) PD without dementia (n=13), (iii) Controls with dementia (n=2), (iv) controls without dementia (n=9).
Results: Preliminary findings show that comparison of Ferritin and Glutathione peroxidase 4 staining in the motor cortex identifies 3 groups, 1) PD with Dementia, 2) Healthy controls, and 3) PD without dementia - an intermediate group. These results suggest that disruption of the iron-mediated lipid peroxidation pathway is associated with dementia in PD rather than universally observed in PD.
Conclusions: This study characterises the links between air pollution, PD and dementia, evaluating potential mechanisms that underly these relationships to identify potential biomarkers of increased risk of dementia in PD.

MONITORING PARKINSON'S DISEASE SYMPTOM PROGRESSION WITH WEARABLE DEVICES

POSTERS: C01.O. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MODELING OF DISEASE PROGRESSION

Ro'Ee Gilron, Aiden Arnold, Tiffany Jansen, Witney Chen
Rune Labs, Neuroscience, San Francisco, United States of America

Aims: Assess long term trends in wearable data to characterize symptom progression.
Methods: In 900+ subjects with Parkinson's disease with wearable data, we assessed long term trends in tremor, dyskinesia, gait, vitals, and sleep. For metrics with high daily variability, such as tremor and dyskinesia, we used windowing functions and statistical aggregation to assess changes across time. We applied an algorithm to identify statistical changes in metric trajectory, which we compared against known therapeutic interventions such as medication changes or deep brain stimulation programming updates. Further, we applied a normative modeling approach to identify patient-specific deviations in the progression rate of different symptoms. In a subcohort with data prior to disease diagnosis, we explored wearable data trends during the prodromal period.
Results: We found highly variable trends across subjects, including instances of worsening symptoms and improving symptoms. In patients with worsening trends, increases in double support time and decreases in walking speed and step length were observed. Longitudinal tracking of sleep metrics showed that decreasing sleep time was also associated with increases in sleep fragmentation. Normative modeling provides a structure to help distinguish between the effects of clinical interventions and symptom progression across multiple modalities.
Conclusions: Worsening symptoms can be identified and characterized with wearable devices, reflecting inadequate therapeutic maintenance and/or worsening disease. Conversely, subjects with improved metrics may indicate good symptom management. Data-driven approaches for assessing longitudinal symptom change and how individual patients deviate from one another in progression patterns may yield insights on disease progression phenotypes.

MIRNA AND GLYCOSPHINGOLIPIDS AS A PATTERN SIGNATURE OF PARKINSON'S DISEASE

POSTERS: C01.O. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MODELING OF DISEASE PROGRESSION

Aims: Parkinson's disease (PD) is characterized by α-synuclein (α-syn) aggregates, mitochondrial dysfunction, and lysosomal impairment. We recently highlighted the importance of aging and lysosomal defects in the sensitivity of dopaminergic neurons to α-syn toxicity in an aged mouse model of Parkinson disease injured with α-syn protofibrils (PFF) and conduritol-B-epoxide (CBE, an irreversible inhibitor of GCase). In this model mimicking main PD features, we monitored miRNA and complex lipids, at different disease stages in order to establish pattern signature of the disease.
Methods: RT-qPCR was used to assess miRNA expression profiles in the brain of young mice, aged mice, and aged α-syn/CBE mice. LC-MS/MS was used to quantify circulating complex glycosphingolipids, known markers of lysosomal dysfunction.
Results: We identified a panel of several miRNAs in young versus aged mice, and versus α-syn/CBE mice changing over the time. Dysregulated miRNAs are involved in lysosomal functions, α-syn expression, neuronal survival, mitochondrial dysfunction, oxidative stress, and inflammation, all critical pathways implicated in PD. Simultaneously, lipidomic profiling revealed parallel accumulation of glucosylsphingosine in the PD model, emphasizing lipid dysregulation. We extended our analysis to plasma and CSF, enabling the identification of circulating miRNAs biomarkers for disease monitoring.
Conclusions: In conclusion, our study unveils a multimodal approach to understanding PD and following disease progression, by monitoring miRNAs in tissues and fluids and lipid biomarkers. miRNAs, pivotal post-transcriptional regulators, are informative on the regulation of specific pathways, illuminating the multifaceted pathophysiology of PD.

CAROTID SINUS NERVE ABLATION MITIGATES NEURODEGENERATIVE OUTCOMES INDUCED BY DYSMETABOLISM IN A PREDIABETES RAT MODEL

POSTERS: C01.O. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MODELING OF DISEASE PROGRESSION

Inês Ferreira De Almeida, Adriana Capucho, Ana Chegão, Fátima Martins, Joana Sacramento, Sílvia Vilares Conde, Hugo Vicente Miranda
NOVA Medical School, Nms Research, Lisboa, Portugal

Aims: The carotid bodies (CBs) were recently described as metabolic sensors. While in type-2 diabetes mellitus (T2D), this organ is hyperactive, its ablation was demonstrated to lessen T2D outcomes. Knowing the association between T2D and neurodegenerative diseases, we aim to investigate if blocking CBs activity via resection of the carotid sinus nerve (CSN), its sensitive nerve, can prevent neurodegenerative outcomes induced by dysmetabolism in a prediabetic rat model.
Methods: Male Wistar rats aged three months were fed a normal-chow (NC) or a high-fat high-sucrose diet (HFHSu) for 15 weeks, followed by random assignment to CSN resection or sham surgery. After 22 weeks, proteins from the frontal cortex and hippocampus were analysed using Western blot to assess insulin resistance, neurodegeneration, inflammation, and synaptic markers.
Results: HFHSu diet promoted a decrease in Insulin receptor (IR) and Protein kinase B (AKT) levels in the cortex. In the prefrontal cortex, HFHSu animals exhibit a significant increase in the levels of the glutamate receptor, N-methyl-D-aspartate (NMDA) receptor 2, alpha-synuclein (αSyn), and β-Amyloid precursor protein (APP). Interestingly, in HFHSu-CSN resected animals, the increase of NMDA2, αSyn and APP was ameliorated.
Conclusions: Our findings suggest that HFHSu contributes to a brain insulin-resistance phenotype and to the accumulation of αSyn and APP, which are proteins associated with neurodegenerative diseases such as Parkinson's and Alzheimer's. Significantly, CSN ablation can reduce the levels of αSyn and APP, thus suggesting that the CBs can be therapeutic targets for mitigating neurodegenerative outcomes induced by dysmetabolic conditions. We consider exploring the underlying molecular mechanisms connecting CBs and neurodegeneration essential. Moreover, we aim to evaluate the long-term outcomes and the potential therapeutic interventions stemming from CB modulation.

Aims: As a complex degenerative disease, Parkinson's disease (PD) affects motor abilities across diverse domains, even prior to initiation of dopaminergic therapy (DT). This work demonstrates how composite scores (CS) consisting of re-weighted combinations of the items from MDS-UPDRS Parts II and III can better detect meaningful changes in motor progression.
Methods: This study analyzed the Parkinson's Progression Markers Initiative MDS-UPDRS data Parts II and III in subjects with confirmed PD naïve to DT. Patients were censored from the analysis once DT was initiated. The sensitivity of individual items to disease progression was assessed using partial least square regression. Selected items were weighted using the model coefficients and summed to create the CS. CS responsiveness to change was assessed using a 1-year mean-to-standard-deviation ratio (MSDR).
Results: CS were generated for untreated subjects (n=428) across items from Parts II and III individually, and as a combined motor composite score (MCS). The three most responsive items (with their combined weights) were: turning in bed, getting out of bed/car/chair, and tremor (45%) for Part II, and leg agility (left) and rest tremor amplitude – left and right (34%) for Part III. The MSDRs increased from 0.5431 to 0.5647, and 0.6341 to 0.7040, which increases power 3% and 8%, respectively. Items from Part II and III contributed to 37.4% and 62.6% of the weighed MCS. Similar items were retained in the MCS as in the individual CSs, and the MSDR increased from 0.7615 to 0.8591, increasing power 8%.
Conclusions: Endpoints derived from the CS reflecting items from combined domains can measure clinically meaningful progression of motor symptoms and the impacts with greater sensitivity compared to using the totality of items from existing tools.

EXPLORING THE POTENTIAL OF POLYPHENOL METABOLITES IN A PARKINSON'S DISEASE BRAIN-CHIP MODEL

POSTERS: C01.O. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MODELING OF DISEASE PROGRESSION

Inês Figueira[1], Inês Silva[1], Daniela Marques[1], Rafael Carecho[1,2], Alexander Mosig[3], Cláudia Nunes Dos Santos[1,2,4]
[1]NOVA Medical School, Molecular Nutrition And Health Lab, Lisboa, Portugal, [2]ITQB, Itqb, Oeiras, Portugal, [3]Center for Sepsis Control and Care, Jena University Hospital, Institute Of Biochemistry Ii, Jena, Germany, [4]iBET, Ibet, Oeiras, Portugal

Aims: Polyphenols, abundant in fruits and vegetables, have emerged as pleiotropic compounds against PD. We identified gut-derived polyphenol metabolites (PMs) as abundant in the bloodstream [1], capable of crossing the blood-brain barrier (BBB), protective against neurodegeneration and neuroinflammation [2], particularly in a 3D neuronal model [3]. However, PMs' mechanisms in a comprehensive/translatable model of the full brain for Parkinson's disease (PD) have never been explored. By taking advantage of a new microphysiological system (MPS) of a brain-on-a-chip, we will disclose PMs' molecular potential against PD.
Methods: The new two-compartment model will employ a dopaminergic insult applied into human brain microvascular endothelial cells (HBMEC), at the blood site, and dopaminergic neurons (LUHMES) [3], with astrocytes (HASTR/ci35) and microglia (HMC3), at the brain site. PMs (individually or as a mixture) will be infused from the blood site and alterations in the different cell types monitored.
Results: Full system differentiation status will be unveiled. The response of brain cells to the dopaminergic neurotoxicant in the MPS will be disclosed. PMs/PMs mixture role in tackling PD-related hallmarks will be uncovered, including their benefits in BBB impairment, dopaminergic cell death, oxidative stress, neuroinflammation, cell crosstalk, and a-synuclein phosphorylation.
Conclusions: In the end, we hope to provide physiologically relevant insights for the nutritional management of PD by unveiling PMs' physiologic mode of action in an avant-gard cell model of the pathology, bypassing the need for animal experimentation. **References:** 1.Pimpão BrJNutr 2015; 2.Figueira SciRep 2017; 3.Carecho MolNutrFoodRes 2022 **Acknowledgments:** to EU, for ERC - Grant No. 804229; to FCT, for financial support of R.C. INVESTIGATING THE GENERATION OF ALPHA-SYNUCLEIN PRE-FORMED FIBRILS USING THIOFLAVIN T STAINING, FLUORESCENCE MICROSCOPY AND MOTOR SKILLS EVALUATION

POSTERS: C01.O. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MODELING OF DISEASE PROGRESSION

Rayanne Guimarães, Miguel Mesquita, Márcia Renata Mortari
University of Brasília, Department Of Physiology, Brasília, Brazil

Aims: This work aims to compare and describe a protocol for the generation of alpha-synuclein pre-formed fibrils (PFFs) from monomers, establish a cost-effective pre-infusion quality control methodology for the identification of successful PFFs generation and report early deficits in the motor behavior of mice after PFFs administration into striatum.
Methods: All procedures were approved by local ethics committee (CONCEA/CEUA-UnB nº23106.124642/2021-53). Monomers (1.25 mg/ml) were incubated at 37 ºC, shaking at 400 or 1000 rpm for 7 days, followed by sonication. Thioflavin T (ThT) staining and epifluorescence microscopy were used to confirmed fibril presence. Transmission electron microscopy (TEM) validated ThT staining and epifluorescence microscopy as pre-surgery quality control. PD models were established by intracerebral PFF injection (n=8), control group received vehicle (n=4). Motor skills were assessed through weekly rotarod tests (4 to 40 rpm in 300 seconds).
Results: The shaking process at 1000 rpm was shown to be more effective for the formation of PFFs. Images obtained using epifluorescence microscopy point to the presence of fluorescent bodies, indicating the interaction between ThT and amyloid-like fibrils. TEM results provide evidence for the presence of PFFs. PFFs decreased latency to fall 5 weeks ($p=0.0005$ vs. PFFs pre-surgery) and 8 weeks ($p<0.005$ vs. vehicle) after infusion.
Conclusions: ThT assay and visualization of fibrils using epifluorescence microscopy can be used as quality control to prove the presence of aSYN PFFs before infusion into rodent brains for the generation of an animal model of PD. PFFs are capable of causing early motor deficits in mice 5 weeks after administration. This study offers valuable insights into PD modeling and assessment.

Aims: Hepatolenticular degeneration in which copper metabolic dysfunction leads to copper accumulation in the midbrain region, which causes neurological manifestations. However, how excess copper damages the midbrain is unknown. This study aimed to elucidate the intracellular mechanisms by which overload copper-induced mitochondrial lipoylation in the tricarboxylic acid cycle, which promotes both of tauopathy and synucleinopathy.
Methods: In this study, we used human embryonic stem cell-derived midbrain organoids for in vitro modeling of copper accumulation-induced degenerative liver-brain axis. Comprehensive genetic and proteomic analyses of cellular RNA and exosomal miRNA enable mechanism exploration and biomarker discovery.
Results: We observed that copper-stimulation reduced the viability of neurons and astrocytes evidenced with MAP2 and tyrosine hydroxylase by 20% while promoting the reactivity of astrocytes evidenced with GFAP by 25%. Also, we elucidated the upregulation of neurotoxic proteins, including phosphorylated alpha-synuclein and phosphorylated tau by 25%, in addition to reducing synaptic function evidenced with synapsin I by 20% upon copper-stimulation. Then, we discovered the upregulation of ferredoxin-1 (FDX1) and lipoyltransferase-1 (LIPT1) as a mediator of copper-induced mitochondrial lipoylation promoting neurodegeneration. In addition, we confirmed that copper-stimulation induces neurodegenerative (APP, MAPT, SNCA) and neuroinflammatory genes (NF-kB and mTOR) in both human cell and exosome samples.
Conclusions: Overall, this study clarifies the contribution of copper to neurodegenerative diseases suggesting a potential for future research and therapeutic development.

A NEW PARKINSON'S DISEASE MODEL - INTRACOLONIC ROTENONE CAUSES ALTERATIONS OF GUT MICROBIOTA AND INDUCES A-SYNUCLEIN AGGREGATION IN THE BRAIN

POSTERS: C01.O. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MODELING OF DISEASE PROGRESSION

Yoon-Seong Kim, Minkyung Song
Robert Wood Johnson Medical School at Rutgers, Neurology, Piscataway, United States of America

Aims: This study aimed to establish the Gut-Brain model of Parkinson's disease by inducing α-synuclein pathology and microbiome changes in the gut by intracolonic gavage of rotenone for 6 weeks.
Methods: C57B6 mice were treated with rotenone (30 mg/kg, 100-150ul) or vehicle (4 % carboxymethyl cellulose) by intracolonic gavage every day for 6 weeks. Fecal samples were collected before, immediately after, and 28 weeks after rotenone or vehicle administrations. 28 weeks after rotenone or vehicle injection, a rotarod test was carried out. All mice were sacrificed the next day, and the proximal colon and brain were extracted for the analysis of α-synuclein pathology, gut inflammation, and neurodegeneration. Fecal microbiomes were analyzed using 16S rRNA sequencing.
Results: We observed that intracolonic administration of rotenone induced impaired intestinal barrier and gut inflammation. α-synuclein expression and pS129 were increased in the gut mucosal layer and myenteric plexus, respectively, right after 6 weeks of rotenone administration and remained until 28 weeks. α-synuclein aggregations were limited in the DMV region at 12 weeks after the last rotenone administration, but it was significantly increased in the SN after 28 weeks, which suggests that α-synuclein pathology in the gut eventually leads to dopaminergic neuronal death in the SN. The motor deficit was observed in the rotenone-treated group. The changes in gut microbiome persist even 28 weeks after rotenone administration. Firmicutes/Bacteroidetes ratio was significantly increased by rotenone and a negative correlation between Lactobacillus and the number of dopaminergic neurons was found.
Conclusions: Our novel gut-brain PD model successfully demonstrates that α-synuclein pathology originated in the colon propagates to the brain, leading to dopaminergic neuronal loss in the SN, and dysbiosis of the gut microbiota might contribute to this process.

COGNITIVE PROFILES AT PRESENTATION AND SUBSEQUENT COGNITIVE DECLINE IN PARKINSON'S DISEASE

POSTERS: C01.O. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MODELING OF DISEASE PROGRESSION

Saira Mirza[1], Sarah Duff-Canning[2], Mark Mapstone[3], Susan Fox[4], Mario Masellis[5], Connie Marras[6]
[1]Sunnybrook Research Institute, Medicine, Toronto, Canada, [2]University of Toronto, Psychology, Toronto, Canada, [3]University of California, Department Of Neurology, Institute For Memory Impairments And Neurological, Irvine, United States of America, [4]University of Toronto, Tanz Centre For Research In Neurodegenerative Diseases, Toronto, Canada, [5]Sunnybrook Research Institute, Hurvitz Brain Sciences Program, Toronto, Canada, [6]Toronto Western Hospital, Krembil Research Institute, Toronto, Canada

Aims: To determine cognitive profiles in Parkinson's disease and study the relationship between baseline cognitive profiles and subsequent cognitive decline in two cohorts
Methods: We included PD patients with or without cognitive impairment(CI) from the Toronto Western Hospital(TWH) and Ontario Neurodegenerative Diseases Research Initiative(ONDRI) cohorts [TWH cohort:138 persons followed up annually for 5 years;ONDRI:96 persons with an annual follow-up of 2 years;combined N=234]. In both cohorts, a comprehensive neuropsychological test battery was administered at all visits; PD-MCI was diagnosed by MDS Task Force Level 2 criteria. Eight neuropsychological tests(equivalent across cohorts) assessing attention and processing speed, executive functions, memory, language, and visuospatial function were used to create cognitive profiles at baseline by cluster analyses. We calculated a global cognitive z-score at all visits by averaging z-scores for all tests. Cognitive decline was determined by change in global cognitive z-score using a linear mixed-effects model, including age, sex, education, time from baseline(TFB), interaction between cognitive profiles and TFB, and random intercept clustered over subjects
Results: Sample demographics: Mean age=69.4±6 years, mean education=15.6±2.8 years, women=30%. We identified 4 cognitive profiles at baseline: 1.Normal cognition(n=108), 2.Lower memory score(n=47), 3.Lower memory and executive function scores(n=59), and 4.Global CI(n=20). Compared to cluster 1, all clusters had lower global scores at baseline, and showed greater cognitive decline over time (β=difference in slope)(cluster 2: = β-0.4, 95% CI=-0.5,-0.2; cluster 3: β= -0.96, 95% CI=-1.1,-0.8; cluster 4: β=-2.0, 95% CI: -2.3,-1.7). Cluster 3(β=-0.6, 95% CI=-0.8,-0.4) and 4(β=-1.6, 95%CI=-1.9,-1.3) showed greater decline than cluster 2 and cluster 4 showed a greater decline than cluster 3(β=-1.0, 95% CI=-1.3,-0.7).
Conclusions: Identification of cognitive profiles in PD patients may help predict their cognitive trajectory and guide therapeutic interventions to improve the natural pathologic course.

DOSE-DEPENDENT EFFECT OF ALPHA-SYNUCLEIN OVEREXPRESSION ON DOPAMINERGIC CELLS

POSTERS: C01.O. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MODELING OF DISEASE PROGRESSION

Miraj Ud Din Momand, Karolína Albertusová, Diana Mjartinová, Ľubica Fialová, Dominika Fričová
Slovak Academy of Sciences, Institute Of Neuroimmunology, Bratislava, Slovak Republic

Aims: Despite the identification of alpha-synuclein (a-Syn) as a pivotal player in Parkinosn's disease (PD), the precise molecular mechanism that leads to its aggregation and related neurodegeneration remains a mystery. In this study, we aim to create a novel approach to understanding the complexity of a-Syn-induced pathological changes at the cellular level in the ReNVM neural progenitor cells, that can readily differentiate into dopaminergic neurons. Additionally, we aim to analyze in greater detail intracellular changes and differences in extracellular signaling induced by a-Syn in a dosage-dependent manner.
Methods: We created novel neuronal cell models of PD in ReNVM cells background, stably overexpressing GFP-tagged a-Syn either wild type (WT) or its A53T mutant version via lentivirus transduction. Cells were then sorted into three sub-populations based on GFP expression and analyzed for a-Syn levels and intracellular distribution comparing sub-populations among themselves, between WT and A53T as well as with cells not overexpressing a-Syn. We then qualitatively profiled various species of a-Syn including its phosphorylated or aggregated forms along with investigating the effects on cell viability, and mitochondrial morphology and function. Excitingly, we started to investigate the intercellular spreading of a-Syn-related signaling through extracellular vesicles (EVs) isolated from these cell models.
Results: We successfully characterized novel cellular models for the investigation of the role of a-Syn. Our study revealed differences in cellular responses based on a-Syn levels, along with comparative investigation of the effects of WT and A53T a-Syn overexpression. Moreover, we analyzed the differences in the spreading of pathological a-Syn signals mediated by EVs depending on the a-Syn level.
Conclusions: Findings from this study clarify the complex cellular processes that underlie a-Syn-related pathologies in PD. This study was supported by: APVV-20-0331, SASPRO 2_1085/01/02, ICGEB CRP/SVK22-04_EC, APVV-20-0447

NF-KB/C-REL DEFICIENT MOUSE AS A MODEL OF BODY-FIRST PARKINSON'S DISEASE

POSTERS: C01.O. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MODELING OF DISEASE PROGRESSION

Vanessa Porrini, Edoardo Parrella, Michele Mario Gennari, Marina Benarese, Giulia Abate, Mariachiara Pucci, Daniela Uberti, Arianna Bellucci, Marina Pizzi
University of Brescia, Department Of Molecular And Translational Medicine, Brescia, Italy

Aims: A growing body of evidence links Parkinson's disease (PD) to the gastrointestinal tract. Borghammer and colleagues proposed that PD pathology first appears in the enteric nervous system and spreads to the brain. According to this theory, the vagal nerve plays a crucial role in gut-to-brain propagation of alpha-synuclein (AS) pathology. The resection of gastric vagal nerve (vagotomy) decreases PD pathology in animal models. Finally, epidemiological studies show that vagotomy is associated with a decreased risk for PD in humans. NF-κB/c-Rel deficient (c-rel$^{-/-}$) mice develop a progressive PD-like phenotype, presenting both prodromal and motor symptoms as well as nigrostriatal dopaminergic neurons degeneration and progressive caudo-rostral brain deposition of AS. Aims of this study were: 1) the characterization of intestinal pathology and 2) the role of vagal nerve in the gut-to-brain spreading of AS, by assessing monolateral vagotomy (hemivagotomy), in c-rel$^{-/-}$ mice.
Methods: Progressive intestinal pathology as well as hemivagotomy effect on AS spreading were evaluated by confocal microscopy, biochemical analysis and behavioral tests in c-rel$^{-/-}$ and wt mice from 2 to 12 months of age.
Results: c-rel$^{-/-}$ mice display early and progressive accumulation of both native and phosphorylated AS in the myenteric plexus of proximal colon, accompanied by an increase in oxidative stress and inflammation markers. Moreover, AS deposition was prevented in the ipsilateral side of the dorsal motor nucleus of the vagus in hemivagotomized c-rel$^{-/-}$ mice at 12 months of age. However, hemivagotomy did not rescue anxiety-like behavior and motor deficits.
Conclusions: Taken together, these results indicate that the c-rel$^{-/-}$ mice develop a progressive PD pathology at intestinal levels. Furthermore, the vagal nerve is involved in the gut-to-brain spreading of AS in this PD mouse model.

Hoffmann-La Roche Ltd., Product Development Data Sciences, Data And Statistical Sciences, Basel, Switzerland, [5]F. Hoffmann-La Roche Ltd., Product Development Neuroscience, Basel, Switzerland

Aims: To characterize the natural history of Parkinson' disease (PD) progression and evaluate the impact of clinical endpoint selection on the probability of success of clinical trials for disease-modifying treatments in PD.
Methods: Longitudinal data from 401 individuals with early-stage PD from the Parkinson's Progression Markers Initiative (PPMI) were used to characterize disease progression of non-motor aspects of experiences of daily living (MDS-UPDRS part I), motor aspects of experiences of daily living (MDS-UPDRS part II), and motor signs (MDS-UPDRS part III). Further, MDS-UPDRS progression before PD diagnosis was assessed using PPMI prodromal cohort data (65 subjects) to estimate the lag time between first motor signs onset (MDS-UPDRS part III) and development of functional impairment (MDS-UPDRS part II). A simulation framework was used to calculate the probabilities of study success with either MDS-UPDRS part III or part II as study endpoints.
Results: For early-stage PD, estimated increase in MDS-UPDRS parts I, II and III was approximately 1, 1 and 3 points per year, respectively. Backward extrapolation of MDS-UPDRS scores progression leveraging the prodromal cohort showed that, in the earliest stage of the disease, part III worsening precedes part II by about 5 years at the cohort level. Finally, the probability of success of a clinical trial, when using part II as primary endpoint, was found to be consistently lower than when using part III despite assuming the same relative disease-modifying effect on both parts.
Conclusions: Leveraging longitudinal data contributes to a better understanding of disease progression. Such a framework can support the clinical development of therapeutic strategies for PD patients by identifying endpoints that effectively measure the progression of PD and the potential clinically meaningful treatment effect of novel therapeutics.

Fox Foundation, N/a, Hagerstown, United States of America, [11]Institute for Neurodegenerative Disorders, N/a, New Haven, United States of America, [12]Northwestern University, Neurology, Chicago, United States of America

Aims: Biological staging of disease represents a paradigm shift in catalyzing drug development by targeting earlier stages of the disease prior to onset of clinical symptoms. A novel biological staging framework for Neuronal alpha-Synuclein Disease (NSD) grounded in innovative advances in biomarkers and genetics is highlighted.
Methods: Regulatory agencies recommend that public private partnerships comprised of multiple stakeholders are key to advancing data driven translational tools that focus on underlying pathophysiology of the disease. Examples of biological staging frameworks with profound impact on drug development focused on early intervention include Type 1 Diabetes and Huntington's disease. The experience of Critical Path Institute as a neutral convener was key in these examples. A data driven iterative path to advancing a biological staging framework for NSD was initiated by regulatory agency leaders in 2022.
Results: Critical success factors for ensuring efficient data driven advancement of biological staging of disease are the ability to appropriately stage the disease process through the integration of translational platforms, clinical outcome assessment tools, biomarkers, genetics and quantitative solutions to optimize trial design. A series of iterative multistakeholder meetings took place in 2022-2023 to review emerging scientific advances within the Parkinson's disease (PD) and dementia with Lewy bodies (DLB) fields aimed at establishing biological definitions of disease and a new biological staging paradigm for clinical trials. The role of public private partnerships has been key in all cases to advancing the evolution and adoption of biological staging that is inclusive to regulatory agencies and has emphasis on patient centricity.
Conclusions: The precompetitive global collaboration framework pioneered by multiple stakeholders is primed to catalyze the path to the generation of disease modifying therapies targeting neuronal synucleinopathies with true promise for prevention on the horizon.

shanxi university of chinese medicine, Shanxi University Of Chinese Medicine, shanxi province, China

Aims: Parkinson's disease is a common neurodegenerative disease in the elderly, with high disabilities. Levodopa supplement therapy is the main method in the clinic, but its side effects are large. Our previous study found that Wuzi Yanzong Pills (WYP) has a good prevention and treatment effect on PD, and its treatment mechanism is probably related to the regulation of BDNF signaling pathway. Recent studies have reported that electroacupuncture (EA) can also play a protective role in PD by regulating BDNF signaling molecules. We hypothesized that EA combined with WYP may play a synergistic effect on PD treatment by co-regulating BDNF signaling pathway.
Methods: C57BL/6 male mice were randomly divided into control group, model group, ANA-12 (Trk B antagonist) group, WYP group, WYP+ANA-12 group, EA group, EA+ANA-12 group, WYP+EA group, WYP+EA +ANA-12 group. The PD model of mice was established by MPTP (except normal group and ANA-12 group). At the same time, oral administration of all WYP was carried out twice a day for 14 consecutive days, EA stimulation at Baihui (GV20) and Taixi (KI3) was applied to PD mouse in all EA groups for 2 weeks, intraperitoneal injection ANA-12 (0.5mg/kg) to all ANA-12 groups. Mouse motor function was evaluated by gait, stick climbing, suspension and open field test. The expression levels of tyrosine hydroxylase (TH) was determined by immunofluorescence analysis. The expression levels of TH, BDNF, Trk B, CREB was determined by Western Blot.
Results: Following 2 weeks of WYP, EA and WYP+EP treatment, the abnormal behavioral impairment induced by MPTP was alleviated, but ANA-12 can reverse the protective effects.
Conclusions: WYP combined with EA play a synergistic effect on PD treatment by co-regulating BDNF signaling pathway.

PARKINSON'S DISEASE-RELATED CHANGES IN OLIGODENDROGLIAL SUBPOPULATIONS

POSTERS: C01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Eun-Jin Bae, Dayana Pérez-Acuña, Ka Hyun Rhee, Seung-Jae Lee
Seoul National University, Biomedical Sciences, Seoul, Korea, Republic of

Aims: A specific loss of dopaminergic neurons is a hallmark of Parkinson's disease (PD). Few studies have looked at changes in oligodendroglia, despite the fact that the majority of PD research to date has concentrated on neurons and, to some extent, glia.
Methods: Here, we investigated the heterogeneity of oligodendrocytes from PD patients compared with those of control cases by analyzing single-nuclei transcriptomes.
Results: These analyses revealed the presence of distinct oligodendrocyte populations in Parkinson's disease patients, indicating corresponding variations in molecular features such as inflammatory response activation, response to protein folding stress, and myelination abnormalities. In α-synuclein preformed fibril-injection mouse model of Parkinson's disease, we confirmed myelination defects and responses to protein folding stress.
Conclusions: These findings imply that in Parkinson's disease, oligodendrocytes acquire disease-associated characteristics and may contribute to the subsequent neurodegeneration.

RE-WEIGHTING MDS-UPDRS PART II ITEMS FOR OPTIMAL SENSITIVITY TO PARKINSON'S DISEASE PROGRESSION USING PARKINSON'S PROGRESSION MARKERS INITIATIVE NATURAL HISTORY DATA

POSTERS: C01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Sam Dickson[1], Basia Rogula[2], Jordan Dubow[3], Nick Kozauer[4], Lauren Powell[2], Michele Potashman[5], Kim Crimin[6], Patrick O'Keefe[1], Ellen Korol[2], Madeline Crabtree[2], Fernanda Nagase[2], Vlad Coric[7], Suzanne Hendrix[8], Gil L'Italien[5]
[1]Pentara Corporation, Statistics, Millcreek, United States of America, [2]Broadstreet HEOR, Health Economics & Outcomes Research, Vancouver, Canada, [3]Clintrex, LLC, Chief Medical Officer, Sarasota, United States of America, [4]Biohaven Pharmaceuticals, Inc, Clinical Development & Regulatory Strategy, New Haven, United States of America, [5]Biohaven Pharmaceuticals, Inc, Clinical Outcomes Assessments And Health Economics, New Haven, United States of America, [6]Biohaven Pharmaceuticals, Inc, Biostatistics, New Haven, United States of America, [7]Biohaven Pharmaceuticals, Inc, Ceo, New Haven, United States of America, [8]Pentara Corporation, Ceo, Millcreek, United States of America

Aims: Parkinson's disease (PD) clinical trials require careful planning to progress beyond Phase 2. Many in the PD community recognize the need for improvements in communication, education, funding, recruitment, and compliance, but the need to measure disease with optimized outcome is underappreciated. This work demonstrates how composite scores (CS) of re-weighted combinations of the MDS-UPDRS PART II items can better detect meaningful changes and increase success for efficacious disease-modifying treatments.
Methods: This study analyzed Parkinson's Progression Markers Initiative data in subjects with confirmed PD. Three cohorts were defined based on use of levodopa or dopamine agonists (lev/DA) and presence of motor complications: untreated, early-lev/DA (motor complications absent), and later-lev/DA with motor complications (≥25% time of waking day in OFF-state and/or dyskinesia assessed on MDS-UPDRS). Sensitivity of individual items to disease progression was assessed using partial least square regression. Selected items were weighted using model coefficients and summed to create the CS. CS responsiveness to change was assessed using a 2-year mean to standard deviation ratio (MSDR) for treated and 1-year for untreated (due to data limitations).
Results: CS were generated for untreated (n=428), early-lev/DA (n=424), and later-lev/DA (n=536) cohorts separately. The three most responsive items (with their combined weights) were: turning in bed, getting out of bed/car/chair, tremor (45%); turning in bed, getting out of bed, and speech (56%); and turning in bed, speech, and handwriting (53%) respectively. The MSDRs increased from 0.5431 to 0.5647, 0.4265 to 0.4994, and 0.3128 to 0.3849, respectively. Corresponding sample size decreases were ~7%, 27%, and 34%, reflecting powering improvements of ~3%, 11% and 13%.
Conclusions: Endpoints derived from the three CS presented can measure clinically meaningful progression with greater sensitivity compared to existing tools.

COGNITIVE PERFORMANCE AND DYNAMIC ORGANIZATION OF LEG'S MOTOR ACTS IN PARKINSONIAN PATIENTS

POSTERS: C01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Yacov Balash[1], Riyad Idries[1], Evelin Mate[1], Amos Korczyn[2]
[1]Kaplan Medical Center, Neurology, Rehovot, Israel, [2]Tel Aviv University, Departments Of Neurology And Physiology And Pharmacology, Tel Aviv, Israel

Aims: Dynamic organization of leg movements has been insufficiently studied in Parkinson's disease (PD). Its links to mental changes that developed in PD remain unclear. Aims: To detect subclinical mental changes enforced to bipedal vs. one-legged monopedal motor performance in PD patients.
Methods: Eighteen non-demented PD patients and 12 age and sex matched controls performed MoCA and two types of probes characterizing the dynamic organization of leg movements. As bipedal tests, a reciprocal coordination of heels and toes (Oseretzky, 1931) and its timed variation – the speed of putting on inverted sneakers were investigated. As monopedal tests, alternate tapping of the right and left foot (Luria, 2000), motor programming for each foot as a change of three consecutive positions "heel-edge-toes" (Luria-leg), conflicting instructions, and Go–no-Go (Dubois et al, 2000) were studied. The results of the cognitive bi-and monopedal tests were video registered and compared between PD patients and healthy individuals.
Results: The mean scores of the MoCA verbal fluency and both bipedal tasks were statistically significantly worse in PD (Mann–Whitney U=0.039, 0.041 and 0.012). Negative Pearson's correlation between the number of generated words and reciprocal coordination of heels-toes scores was –0.647 ($p<0.05$). As PD worsened, the patients avoided a bipedal and preferred the monopedal strategy when performing inverted sneakers test, which slowed down it's velocity. Pearson's correlation between the speed of putting on inverted sneakers and UPDRS III was severe (0.742, $p<0.05$).
Conclusions: In PD, the worst bipedal performance is associated with disorder in the word fluency domain and related to disruption of the premotor systems of the brain and the corpus callosum, so they may be useful to detect early mental changes.

MODELING LEWY BODY DISEASE WITH SNCA TRIPLICATION IPSC-DERIVED CORTICAL ORGANOIDS AND IDENTIFYING THERAPEUTIC DRUGS

POSTERS: C01.O. DISEASE MECHANISMS, PATHOPHYSIOLOGY: MODELING OF DISEASE PROGRESSION

Na Zhao
Mayo Clinic, Neuroscience, Jacksonville, United States of America

Aims: Aggregated α-synuclein (α-SYN) proteins, encoded by the *SNCA* gene, are hallmarks of Lewy body disease (LBD), affecting multiple brain regions. However, the specific mechanisms underlying α-SYN pathology in cortical neurons, crucial for LBD-associated dementia, remain unclear.
Methods: In this study, we generated cortical organoids from two *SNCA* triplication iPSC lines of LBD patients and two healthy controls, including two subclones for each line. After 2 months of culture, we assessed α-SYN levels and conducted single-cell RNA sequencing (scRNA-seq) to identify relevant molecular pathways. Organoid functionality was verified through mitochondrial stress tests and neuronal activity measurements. Furthermore, we performed single-nucleus RNA sequencing (snRNA-seq) on human brain cortices, comparing molecular pathways with our organoid models. In addition, we employed real-time quaking-induced conversion (RT-QuIC) to screen 1,280 FDA-approved compounds for their ability to inhibit α-SYN seeding, using human brain lysates. Promising drugs were subsequently evaluated on *SNCA* triplication organoids, with computational modeling exploring their mechanism of inhibiting α-SYN aggregation.
Results: We found that *SNCA* triplication iPSC-derived organoids had increased soluble total and phosphorylated α-SYN levels and high-molecular-weight insoluble α-SYN aggregates. ScRNA-seq and functional validation revealed synaptic and mitochondrial dysfunction in excitatory neurons with high *SNCA* expression, mirroring the findings from the autopsy-confirmed LBD human brains cortices. Four FDA-approved drugs (Entacapone, Tolcapone, Phenazopyridine hydrochloride, and Zalcitabine) showed strong capacity of inhibiting α-SYN seeding in RT-QuIC assays, reduced α-SYN aggregation and improved mitochondrial function in *SNCA* triplication organoids and excitatory neurons. Computational modeling suggested drug binding at specific α-SYN sites, involving Lys43 and Tyr39 residues, causing structural shifts that disrupted protein interactions and aggregation propensity.
Conclusions: Our findings establish human cortical LBD models and suggest novel therapeutic drugs targeting α-SYN aggregation for LBD and its associated dementia.

IDENTIFICATION OF FREEZING OF GAIT IN PARKINSON'S DISEASE DURING 360° TURNING – CNN-BASED APPROACH

POSTERS: C01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Sang-Myung Cheon[1], Young Jin Jeong[2], Jae Woo Kim[1]
[1]Dong-A University School of Medicine, Neurology, BUSAN, Korea, Republic of, [2]Dong-A University School of Medicine, Nuclear Medicine, BUSAN, Korea, Republic of

Aims: To verify the modeling approach using visual images for identification of gait freezing in Parkinson's disease.
Methods: The subjects of this study were each 30 PD patients with and without freezing of gait and 30 healthy control subjects. Subjects patients performed the 360° turning tasks in an off state of medication. Position and acceleration time-series data were converted into new imaging and trained with a classification modeling approach using visual images (Convolutional Neural Network, CNN algorithm) technique. The performance of the three-group classification model was evaluated using accuracy.
Results: The body segments with the highest performance in classifying freezers, non-freezers, and controls were the left elbow at 61%, right tibia at 60%, and right ankle at 60% in the image-based position time-series data when using the Recurrence Plot (Rec) algorithm and were the left upper arm at 60% and left knee at 60% when using the Gramian Angular Summation Field (GASF) algorithm. In addition, the left toe at 62% and right toe at 58% were found in the image-based acceleration time-series data when using the Rec algorithm.
Conclusions: The time-series gait pattern was useful for identification of gait freezing during 360º turning. And these results suggest uncoordinated gait pattern and troubled automatic movement of turning in freezers. Therefore, the CNN technique based on time-series gait data imaging might be used as an objective indicator and an effective research tool for revealing pathophysiology of gait freezing in PD patients.

NOVEL 3D CELL CO-CULTURE MODEL REVEALED PARKINSON'S DISEASE MIDBRAIN ORGANOIDS TO BE VULNERABLE TO T CELL MIGRATION

POSTERS: C01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Elizaveta Gerasimova[1], Veronika Sigutova[1], Pavel Shelyganov[2], Sebastian Zundler[3], Beate Winner[1], Iryna Prots[4]
[1]University Hospital Erlangen, Stem Cell Biology, Erlangen, Germany, [2]University of Windsor, Department Of Chemistry And Biochemistry, Windsor, Canada, [3]University Hospital Erlangen, Department Of Medicine 1, Translational Research Center, Erlangen, Germany, [4]University Hospital Erlangen, Dental Clinic 1 - Restorative Dentistry And Periodontology, Erlangen, Germany

Aims: Recent studies indicate that adaptive immune system plays a role in neurodegenerative disorders, including Parkinson's disease (PD), and T cells are emerging as potential mediators of this pathology. T cells are suggested to migrate into brain and play a crucial role in PD pathogenesis by mediating cell death and neuroinflammation. To study T cell migration mechanisms into central nervous system (CNS) and investigate spatial interactions of T cells and neurons we aim to develop a co-culture system of peripheral blood T cells and stem cell-derived human midbrain organoids (hMOs). Moreover, we compared T cell infiltration and impact on hMOs of PD patients and controls, hypothesizing that PD hMOs are more vulnerable to T cell migration and T cell driven effects.
Methods: hMOs were differentiated from induced pluripotent stem cells derived from PD patients with α-syn gene locus duplication and controls. hMOs were co-cultured with T cells or left untreated, and assessed for neuronal, immunological, cell migration and cell adhesion markers, and cell death.
Results: We determined that T cell migrate into hMOs and localize in the proximity of MAP2-positive neurons. Indeed, neurons express lymphocytes adhesion molecules such as ICAM1 and VCAM1. Differential T cell migration into control and PD hMOs was demonstrated pointing to the relevance of T cells in PD pathogenesis. Moreover, T cell presence was shown to increase cell death within hMOs tissue and decrease MAP2 signal, suggesting that T cells cause neuronal cell loss. This pathology was enhanced in hMOs harboring PD phenotype.
Conclusions: Our work suggests a novel 3D cell co-culture model as a promising tool to investigate peripheral immune cell impact on CNS and delineates the neurotoxic effect of T cells in PD pathology.

INVESTIGATION OF THE NOSE-TO-BRAIN TRANSPORT OF EXOGENOUS MICROPARTICLES USING MANGANESE CONTRAST-ENHANCED MRI TECHNIQUE

POSTERS: C01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Yasuyoshi Kimura[1], Makoto Osanai[2], Yuji Komaki[3], Hideki Hayakawa[1], Yuki Uemura[2], Chika Matsushita[3], Naoki Hasegawa[4], Kensuke Ikenaka[1], Kousuke Baba[1], Takafumi Seto[5], Hajime Mushiake[6], Rikinari Hanayama[7], Hideki Mochizuki[1]

Aims: Exposure to ambient fine particulate matter is considered a risk factor for neurodegenerative disorders such as Parkinson's disease and Alzheimer's disease, but the mode of propagation to the brain and the biological response have not been fully elucidated. In this study, we investigate the nose-to-brain transport of exogenous microparticles using manganese contrast-enhanced MRI technique.
Methods: (1) Manganese chloride (MnCl2), manganese oxide nanoparticles (MnO2), or solvent were intranasally administered to mice, and imaging was performed by manganese contrast enhanced MRI over time (N=6~7/group, 9.4 Tesla MRI). (2) MnO2 or solvent was repeatedly administered intranasally to the mice and imaging was performed in the same manner (N=6~8/group, 7 Tesla MRI). Statistical analysis was performed using Student's t test.
Results: (1) MnCl2-treated group showed significant signal changes in the olfactory bulb and pisiform cortex at 26 hours ($p<0.01$), and some signals in the pisiform cortex remained after 1 week ($p<0.05$); MnO2-treated group showed significant signal changes in the thalamus and substantia nigra at 26 hours, and midbrain signals remained after 1 week ($p<0.05$). (2) When MnO2 was repeatedly administered, signal changes were detected in deep brain regions includiing the amygdala, hippocampus, thalamus, and substantia nigra in addition to the olfactory bulb and pisiform cortex at 24 hours ($p<0.01$). Signals in the hippocampus and thalamus remained even after 2 weeks ($p<0.01$).
Conclusions: The results suggest that insoluble exogenous microparticles may reach to the deep brain at an early stage, and accumulate at least for 2 weeks. Our result support that ambient fine particulate matter can be a risk for neurodegenerative disorders.

DOES LOW DOSE INJECTIONS OF TETANUS TOIXIN INTO THE RAT BASAL GANGLIA INDUCE PARKINSON'S-LIKE MOTOR IMPAIRMENTS?

POSTERS: C01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Patrik Meglić, Petra Šoštarić, Ivica Matak
School of Medicine University of Zagreb, Pharmacology, Zagreb, Croatia

Aims: The onset of movement disorders like dystonia and parkinsonism is primarily linked to abnormalities in basal ganglia activity. The basal ganglia and associated nuclei are crucial for motor control. Tetanus toxin (TeNT) disrupts normal neuronal inhibition by selectively blocking inhibitory GABA or glycinergic synapses. This study's objective was to investigate does neuronal disinhibition in the basal ganglia, induced by low, non-convulsive doses of TeNT, produces Parkinson's like motor impairments.
Methods: Male Wistar rats underwent unilateral stereotaxic injections of tetanus toxin into the caudate putamen (CPu), globus pallidus internus (GPi), and substantia nigra (SN). The effects of tetanus toxin (TeNT) were evaluated on the 7th, 10th, and 14th day post-injection. Various motor and behavioral tests were conducted to analyze the impact of TeNT-induced disinhibition on normal motor function. On the 10th day following the injection, the animals were subjected to an amphetamine-induced rotation test.
Results: Following unilateral injection of TeNT into the CPu, animals exhibited contralateral hind paw misplacement during the beam-walk test. Animals receiving injections in the CPu and GPi displayed a propensity for circling behavior towards the injected side in both the open field and swimming tests, a tendency that was further highlighted during the amphetamine-induced rotation test. In the CatWalk analysis, animals injected in the CPu and GPi demonstrated increased stride frequency and reduced swing time.
Conclusions: Animals injected in GPi and CPu exhibit Parkinson's-like motor impairments, showing comparable rotational behavior and gait-related issues. CPu injections also reveal a proprioceptive deficit. This highlights the interplay between inhibitory and dopaminergic transmission in the basal ganglia, crucial for motor control and function. Further investigation is needed to pinpoint the affected transmission pathways, potentially explaining tetanus-induced Parkinson-like motor impairments?

FINANCING DRUG DISCOVERY AND DEVELOPMENT FOR PARKINSON'S BY PATIENT ORGANISATIONS

POSTERS: C01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Arthur Roach
Parkinson's UK, Parkinson's Virtual Biotech, London, United Kingdom

Aims: The Parkinson's Virtual Biotech is a patient community led and financed Seed and Series A funder dedicated to enabling early companies to develop compelling drug candidates for the treatment of Parkinson's. We aim to provide over $50m in funding over the coming ten years, with a strong focus on meeting important unmet needs of patients, and the sustainability of programmes based on strong science, clinical insight and credible teams.
Methods: The Parkinson's Virtual Botech obtains its funds from patient organisations in the US and Europe. Companies and entrepreneurs request funding for their projects by application to virtualbiotech@parkinsons.org.uk or through encounters at scientific and partnering meetings. Aspects reviewed include target validation, technical approach, probability of technical success, patient involvement, strength of team, stability of company, commitment to Parkinson's drug development, budget and prospects for follow-on funding. Typical investments are of $1m-$4m over one to three years, and may be followed by further rounds. We have a track record of investing solo, and alongside other non-profit and private investors. Investment terms are designed to provide to the Parkinson's community a financial return similar to that which a private early-stage investor might expect.
Results: Over seven years we have invested over $25m in 12 projects. The full portfolio is shown at **www.parkinsonsvirtualbiotech.co.uk**. Funded projects include: - disease-modifying and symptomatic drugs - drug discovery projects - IND enabling studies - phase 2 clinical trials - registration trials in exceptional cases. Five of the first 12 projects have received a second round of funding from the Parkinson's Virtual Biotech following successful completion of their research plan.
Conclusions: Through the Parkinson's Virtual Biotech the patient community is helping innovative companies create new treatments for Parkinson's.

EXTRACELLULAR VESICLES AND THEIR RENIN-ANGIOTENSIN CARGO AS A LINK BETWEEN METABOLIC SYNDROME AND PARKINSON'S DISEASE

POSTERS: C01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Ana Isabel Rodríguez Pérez[1,2], Maria A. Pedrosa[1], Carmen M. Labandeira[3], Nerea Lago-Baameiro[4,5], Rita Valenzuela[1,2], María Pardo[4,5], José Luis Labandeira-García[1,2]

Aims: Several studies have shown an association between metabolic syndrome (MetS) and Parkinson's disease (PD). The linking mechanisms remain to be clarified. MetS promotes low-grade peripheral oxidative stress and inflammation, and dysregulation of adipose renin-angiotensin system (RAS). Interestingly, brain RAS dysregulation is involved in the progression of dopaminergic degeneration and PD. Circulating extracellular vesicles (EVs) from MetS fat tissue can cross brain-blood barrier and may act as linking signals. However, the possible effects of MetS EVs RAS cargo on dopaminergic degeneration and astrocytic function are not known. In the work reported here, we studied whether EVs from MetS show RAS dysregulation cargo and if it could be a major link between MetS and PD development and progression.
Methods: We isolated and characterized EVs from MetS and control rats, and analyzed their mRNA and protein cargo using RT-PCR and the single particle interferometric reflectance imaging sensor platform ExoView R200, respectively. Furthermore, cultures of N27 dopaminergic neurons and C6 astrocytes were treated with EVs from MetS rats.
Results: EVs were highly increased in MetS rat serum, which was inhibited by treatment with the angiotensin type-1 receptor blocker candesartan. Furthermore, EVs from MetS rats showed increased prooxidative/proinflammatory and decreased anti-oxidative/anti-inflammatory RAS components, which was inhibited in candesartan-treated MetS rats. In cultures, EVs from MetS rats increased the dopaminergic neuron death and modulated the astrocytic function, upregulating markers of neuroinflammation and oxidative stress, which were inhibited by pre-treatment of cultures with candesartan.
Conclusions: In conclusion, our results show, for the first time, that the MetS may generate circulating EV_{MetS} that may increase the progression of neuroinflammation and dopaminergic neurodegeneration through RAS dysregulation in recipient cells, and that this process can be inhibited by treatment with AT1 receptor blockers.

AUTOANTIBODIES ACTING ON ANGIOTENSIN TYPE-1 RECEPTORS AND ACE2 INDUCE PROGRESSION OF DOPAMINERGIC DEGENERATION

POSTERS: C01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Ana Isabel Rodríguez Pérez[1,2], Carmen M. Labandeira[3], Maria A. Pedrosa[1], Aloia Quijano[1], Rita Valenzuela[1,2], Pablo Garrido-Gil[1,2], José Luis Labandeira-Garcia[1,2]
[1]Cellular and Molecular Neurobiology of Parkinson´s disease, Research Center for Molecular Medicine and Chronic diseases (CIMUS), Idis, Santiago de Compostela, Spain, [2]CIBERNED, Networking Research Center On Neurodegenerative Diseases, Madrid, Spain, [3]University Hospital of Ourense, Neurology Service, Ourense, Spain

Aims: The role of autoimmunity in neurodegeneration has been increasingly suggested. The renin-angiotensin system (RAS) autoantibodies play a major role in several peripheral inflammatory processes. Dysregulation of brain RAS has been involved in neuroinflammation and neurodegeneration. We aimed to know whether angiotensin type-1 receptor autoantibodies (AT1-AA; AT1 agonists) and angiotensin-converting enzyme 2 autoantibodies (ACE2-AA; ACE2 antagonists) may be involved in Parkinson's disease (PD) progression and constitute a new therapeutical target.
Methods: Serum levels of AT1-AA, ACE2-AA, cytokine LIGHT; IL-6; IL-17 and 27-hydroxycolesterol were measured in PD patients and in controls. Possible mechanisms involved in neoantigen production were analyzed in an animal model of PD induced by injection of the neurotoxin 6-OHDA. Possible enhancement of dopaminergic death and proinflammatory effects mediated by AT1-AA were measured in rat primary neuron-glia mesencephalic cultures.
Results: AT1-AA and ACE2-AA serum levels were higher in PD patients (n=117) than in controls (n=106). Serum AT1-AA levels correlated with several cytokines, particularly with LIGHT, and with 27-hydroxycholesterol. Serum ACE2-AA correlated with AT1-AA. In the cerebrospinal fluid (CSF) of four PD patients, both autoantibodies were identified. Consistent with these results in patients, dopaminergic degeneration induced by 6-hydroxydopamine, increased levels of autoantibodies in serum and CSF in rats, as well as LIGHT levels and transglutaminase activity in rat substantia nigra. In primary mesencephalic cultures, administration of AT1-AA promoted a significant increase in dopaminergic degeneration and in neuroinflammation markers that were inhibited by the administration of the AT1 antagonist, candesartan.
Conclusions: The results suggest dysregulation of RAS autoantibodies as a new mechanism that can contribute to PD progression. Therapeutical strategies blocking the production, or the effects of these autoantibodies may be useful for PD treatment. The results further support repurposing AT1 blockers (ARBs) as a treatment against PD progression.

RNA SEQUENCING OF OLFACTORY BULB IN PARKINSON'S DISEASE REVEALS GENE ALTERATIONS ASSOCIATED WITH OLFACTORY DYSFUNCTION.

POSTERS: C01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Cécilia Tremblay, Sidra Aslam, Jessica Walker, Anthony Intorcia, Ileana Lorenzini, Thomas Beach, Geidy Serrano
Banner Sun Health Research Institute, Brain And Body Donation Program, Sun City, United States of America

Aims: The olfactory bulb is involved early in the pathophysiology of Parkinson's disease (PD), which is consistent with the early onset of olfactory dysfunction. Identifying the molecular mechanisms through which PD affects the olfactory bulb could lead to a better understanding of the etiology of olfactory dysfunction and the pathophysiology of PD. We specifically aimed to assess gene expression changes and affected pathways by whole transcriptomic profiling of the olfactory bulb of subjects with clinicopathologically defined PD in comparison to controls.
Methods: Bulk RNA sequencing was performed on frozen human olfactory bulbs of 20 PD and 20 controls without dementia or any movement disorder, from the Arizona Study of Aging and Neurodegenerative disorders (AZSAND) and the Brain and Body Donation Program (BBDP).
Results: Differential expression analysis revealed a total of 2164 significantly differentially expressed genes (DEGs). Significantly downregulated pathways included neurodegeneration, Parkinson's disease, oxidative phosphorylation, and olfactory transduction. Upregulated pathways were involved in the immune and inflammatory responses as well as cellular death. An overrepresentation of microglial and astrocytes related genes was observed amongst upregulated genes, and excitatory neurons related genes amongst downregulated genes. UPSIT olfactory identification score correlated with gene expression of genes coding for G-coupled protein, calcium binding protein including proteins expressed in glial olfactory ensheathing cells, neuropeptides expressed in GABAergic granule neurons such as neurogranin and somatostatin, and dopaminergic, GABAergic and cholinergic receptors. Co-expression network analysis revealed LAIR1 and PPARA as hub genes with a high discriminative power between PD and controls
Conclusions: This this work reveals gene alterations associated with neuroinflammation, multi-neurotransmitter dysfunction and disruptions of factors involved in the initiation of olfactory transduction signaling that may be involved in PD-related olfactory dysfunction.

LOWERING OF ALPHA-SYUCLEIN TOXICITY BY TARGETING AGGREGATION-PRONE ALPHA SYNUCLEIN TO LIPID DROPLETS

POSTERS: C02.A. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: A-SYNUCLEIN

Andreas Müller-Schiffmann[1], K Paulvannan[2], Deben Dey[2], N Deyarman[2], Suganyah Selvarajah[2], Vishwanath Lingappa[2], Carsten Korth[1]
[1]Heinrich Heine University of Düsseldorf, Neuropathology, Düsseldorf, Germany, [2]Prosetta Biosciences, Chemistry, San Francisco, United States of America

Aims: Hijacking the cellular autophagy system is a common strategy of viruses to drive efficient replication. However, disrupting autophagy leads to aberrant proteostasis that can ultimately promote protein aggregation and the development of neurodegenerative diseases. We recently reported that influenza virus infection led to the aggregation of alpha-synuclein, a major molecular hallmark for Parkinson´s disease, by interfering with the autophagic pathway. Here, we hypothesized that small molecule anti-influenza compounds that specifically target the autophagy system could also be identified to benefit for alpha-synuclein (aSyn) homeostasis independent of infection.
Methods: A library of novel antiviral drugs that are directed against cellular factors, was screened in human neuroblastoma cells and differentiated LUHMES cells showing aSyn aggregation after influenza infection or rotenone treatment. The cellular targets were identified by Drug-resin-affinity-chromatography (DRAC).
Results: We identified several drugs that abolished both influenza infectivity and aSyn aggregation, including in the absence of infection. One subseries increased the association of aSyn to lipid droplets, while diminishing aSyn aggregates. This also led to a rescue of dopamine and rotenone mediated synapto- and neurotoxicity. DRAC identified several target proteins involved in autophagy, especially autophagosome maturation. The lead compound increased the association of the autophagy marker LC3 to aSyn loaded lipid droplets, inducing autophagic flux and increasing alpha-synuclein clearance.
Conclusions: We indirectly confirmed a connection between influenza infection and aSyn aggregation by identifying a drug that inhibits both by targeting a protein of the autophagy system. Interestingly, this involved facilitating the turn-over of aSyn by targeting it to lipid droplets and the induction of macroautophagy.

TARGETING TAU, AMYLOID AND A-SYNUCLEIN IN ALZHEIMER'S DISEASE AND PARKINSON'S DISEASE: DRUG DEVELOPMENT.

POSTERS: C02.A. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: A-SYNUCLEIN

Ravi Pratap Barnwal
Panjab University, Biophysics, Chandigarh, India

Aims: In this work, we would present work in our lab targeting these three proteins. And any molecule inhibiting the aggregation of these proteins will open new avenues for treatment. The research will provide new opportunities to investigate pharmaceutical treatment for neurodegenerative diseases associated with these proteins.
Methods: Small molecule inhibitors are gaining popularity among well-known treatments in this field of medicine, so, we aim to design a few small molecules that could efficiently reduce or delay the aggregation process of these proteins. For this, in brief, the methodology will be. **1) *In-silico* studies**- **2) In-vitro work a) Expression and purification of the proteins**- **b) Structural and biophysical studies**- **3) Cell culture studies**
Results: *In-silico* work has been performed for three proteins using the in-house library of molecules (200+). A few molecules have demonstrated a greater binding affinity against them.
Conclusions: In the last several decades, there has been progress in developing a medicine to treat AD and PD, for symptomatic relief, no proper cure for this disease is available, so there is an urgent need for novel therapeutic discoveries for fighting against AD. Despite several promising treatment ideas for PD and AD in clinical trials, there are still several challenges that need to be addressed before these drugs can be widely used in patients. One challenge is that it is difficult to deliver drugs to the blood-brain barrier. It is likely that a combination of therapeutic approaches will be needed to effectively treat these diseases. The development of drugs that target tau, Aβ, and α-synuclein has the potential to revolutionize the treatment of these devastating diseases. Our proposed drugs will pave the way for new regime of treatment for these diseases in future.

Aims: Turmeric decreases protein aggregation on muscle wall of NL5901 Caernohabditis elegans mutant strain. NL5901 strain shows a decline on mobility and reproduction due to protein aggregation on muscle wall.Turmeric solution shown an effect on a dependent manner on characteristics such as life span, mobility and reproduction. Protein aggregation on the muscle wall leads to Matricidal effect, due to the lack of muscle contractions that result on the Matricidal effec
Methods: Maintenance and cultivation of C elegans mutant strain Longevity assay Worms on stage L4, after bleaching adults, were taken and placed on a new plate. Locomotion assay Reproduction assay Quantifying protein aggregates Statistical Analysis
Results: Our findings indicate that Turmeric affects alpha-synuclein aggregation by reducing the amount of its aggregates and the effects on phenotypic characteristics. Turmeric shown to decrease protein aggregation in a dose-dependent manner, by treating worms under 1.5 mg/ml protein aggregates decreased by 50% in relation to the Control strain. Life span increased from 18 Days (Control strain) to 26 under 1.0 mg/ml of turmeric solution. Reproduction and mobility increased on higher concentrations of Turmeric solution, Reproduction assay showed an increase in offspring on overall life cycle, 116 Worms against 43 (Control Strain). As protein aggregation is conducted to the nematode worm and by decreasing protein aggregation mobility increases 19 bends per minute under 1.5 mg/ml Turmeric solution against 8 angles (Control strain)
Conclusions: Reduction of protein aggregates

[1]ABL Bio Inc, Abl Bio, Seongnam-si, Korea, Republic of, [2]Sanofi, Rare And Neurologic Diseases, Cambridge, United States of America, [3]Sanofi, Large Molecule Research, Cambridge, United States of America

Aims: Synucleinopathies, which include Parkinson's disease and multiple systems atrophy, are a class of devastating neurodegenerative diseases characterized by the presence of alpha-synuclein (aSyn) rich aggregates in the brains of patients. Passive immunotherapy targeting these aggregates is an attractive disease-modifying strategy. Such an approach must not only demonstrate target selectivity towards aSyn aggregates, but also achieve appropriate brain exposure to have the desired therapeutic effect.
Methods: SAR446159/ABL301 is a bispecific antibody composed of an aSyn-binding IgG and an engineered insulin-like growth factor receptor (IGF1R) binding moiety acting as a shuttle to transport an antibody across blood-brain barrier (BBB). We tested SAR446159 binding to various forms of aSyn to demonstrate selectivity for aggregates. Then, we used cell-based assays, a transgenic mouse model, and a preformed-fibril (PFF) induced synucleinopathy mouse model to demonstrate the efficacy of this molecule.
Results: SAR446159 bound tightly to aSyn aggregates and prevented their uptake *in vitro* and seeding *in vivo*. In wild type (WT) mice injected in the striatum with aSyn PFFs, treatment with SAR446159 reduced aSyn pathology and lowered the severity of motor phenotypes. Additionally, in 9-month-old transgenic mice overexpressing aSyn, SAR446159 reduced pSer129 aSyn levels in the brain. The potent activity of this antibody was enabled by the engineered IGF1R binding moiety, which enhanced brain exposure by shuttling the antibody across the BBB, and by its high selectivity for aggregated conformers of aSyn over monomeric aSyn. Moreover, the IGF1R-binding shuttle enabled greater uptake into the endo-lysosomal trafficking pathway of neurons, potentially allowing this antibody to engage aSyn aggregates both intracellularly and extracellularly.
Conclusions: The *in vitro* and *in vivo* properties of SAR446159 supported the clinical translation of this next-generation immunotherapeutic molecule. Phase I clinical trials were started in late 2022.

Aims: Parkinson's disease (PD) is a common neurodegenerative disorder associated with misfolding and aggregation of α-synuclein protein (α-syn). Recently, it has been strongly suggested that A53T mutated α-syn represents the different phenotype of the PD model. However, it is still unclear how different effects of each period induced by A53T mutated α-syn involve neurodegeneration and whether targeting this pathway has therapeutic potential.
Methods: A53T-α-syn overexpressed transgenic mice (line G2-3) is widely used as a PD animal model (Lee et al., 2002). Mice (7 mo, 12 mo A53T TG and littermate WT) were administrated with blebbistatin (BLEB, 10 mg/kg, i.p.) daily once for two weeks. Also, we developed the in vitro PD model, A53T overexpression in cultured cortical neuron by adeno associated viral vector system. We investigated how BLEB treatment influences transgenic mouse models by mediating molecular changes in cortex region using quantitative real-time polymerase chain reaction (qRT-PCR), western blot, immunohistochemical, and behavioral analysis.
Results: We demonstrated that the treatment of BLEB, a non-muscle myosin II inhibitor, improves mitochondrial dysfunction and hyperlocomotion caused by A53T-α-syn in the in-vitro and in-vivo model. After α-syn overexpression, dynamin-related protein 1 (Drp1, mitochondrial fission marker) level significantly increased in PD model, whereas the elevated Drp1 level was suppressed in the BLEB co-treated groups. Also, Similarly, peroxisome proliferator-activated receptor gamma coactivator 1-α (PGC1-α, mitochondrial homeostasis marker) and sirtuin 1 (Sirt-1, mitochondrial homeostasis marker) levels significantly decreased in PD model, whereas the decreased levels were suppressed in the BLEB co-treated groups. The behavioral showed hyperlocomotion in transgenic mice model was rescued by BLEB.
Conclusions: Our study reveals that BLEB could play a role in alleviating the symptoms of PD in A53T PD model.

Aims: Develop small molecule therapeutics for PD that inhibit production of toxic α-synuclein oligomers, reduce aggregate formation, and improve neuronal functions, by targeting all sources of oligomer generation. α-synuclein oligomers bind membranes, receptors and organelles, and disrupt metabolic and neuronal pathways, resulting in dysfunction and neurotoxicity. We harness biophysics-based analytics to target two source mechanisms that produce these transient intermediates with high precision: (i) primary nucleation, catalysed by lipid membranes, and (ii) secondary nucleation, catalysed by α-synuclein fibrillar aggregates.
Methods: Precision *in vitro* protein aggregation assays using recombinant α-synuclein along with advanced biophysics-based analytics were used to profile small molecule compounds, supported by analyses in multiple disease-relevant cellular and animal models, including iPSC-derived dopaminergic neurons, and seeded M83 transgenic mice. We leveraged a variety of oligomer and aggregate biomarker technologies to measure target engagement and disease progression.
Results: Wavebreak's compounds significantly inhibited both primary and secondary nucleation of α-synuclein oligomer formation, blocking catalytic sites on fibrils with low stoichiometry. Lead optimisation further enhanced potency, oral pharmacokinetics and brain penetration. First generation inhibitors demonstrated efficacy across cell and mouse models, reducing oligomers and aggregates. Second generation inhibitors were even more potent in inhibiting the oligomer source mechanisms and demonstrated significant efficacy in aggressive seeded models in cells and in vivo. Importantly, second generation inhibitors also effected neuronal protection and attenuated atrophy in fibril-seeded M83 mice.
Conclusions: Wavebreak's small molecule α-synuclein oligomer inhibitors delivered robust *in vitro*, cellular and *in vivo* efficacy, demonstrating potent inhibition of oligomer production and aggregate formation. We are advancing these first-in-class molecules for the treatment of PD, initially, along with oligomer biomarker technology to measure both target engagement and the impact of oligomer inhibition on disease progression in human clinical trials.

Aims: Using a novel biophysical assay developed by us, the first small molecule inhibitor of nonamyloidogenic α-synuclein (aSyn) oligomerization was discovered. This compound was identified in a chemical library of drug-repurposing compounds but was never used in the context of neurodegenerative diseases. Dopamine-induced oligomers (DOIOs) and spontaneous oligomers (SPOs) formed upon incubation of 10 μM aSyn are the two species targeted by our compound.
Methods: Both DOIOs and SPOs were characterized using a combination of biophysical techniques, including Transmission Electron Microscopy, Dynamic Light Scattering, SDS-PAGE, Size-Exclusion Chromatography and immunochemistry. Oligomer toxicity in SH-SY5Y cells was quantified from the observations of labelled F-actin and using MTT and caspase-3 activity assays. The presence of the compound in the cerebrospinal fluid (CSF) of SV129 mice was measured using High-Resolution Electrospray Ionization Mass Spectroscopy (ESI-MS).
Results: Compound concentrations <5 μM suppress the formation of both DOIOs and SPOs *in vitro*. Of the two oligomeric species, only SPOs increased cell death and induced cytoskeleton disruption in SH-SY5Y cells. None of the oligomers has morphological or tinctorial properties resembling amyloid fibrils. The toxicity of SPOs is rescued if aSyn is incubated in the presence of the inhibitor. Our preliminary pharmacokinetic studies confirm the presence of the compound in the CSF of SV129 mice after intraperitoneal injection.
Conclusions: DOIOs and SPOs of aSyn are two species produced under physiologically relevant conditions and strongly implicated in PD pathogenesis. We identified a potent inhibitor of DOIOs/SPOs oligomerization and characterized its mechanism of action. As a drug-repurposing small molecule, this compound has favourable pharmacokinetic and toxicological profiles that were confirmed in our preliminary preclinical tests. These results warrant further investigation towards a novel therapy preventing the formation and proliferation of neurotoxic aSyn aggregates.

NANOBODY-BASED TARGETING OF PATHOGENIC ALPHA-SYNUCLEIN AS A PROMISING DIAGNOSTIC AND THERAPEUTIC APPROACH IN PARKINSON'S DISEASE

POSTERS: C02.A. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: A-SYNUCLEIN

Nishant Vaikath[1], Issam Hmila[1], Indulekha Sudhakaran[1], Simona Ghanem[1], Vijay Gupta[1], Nour Majbour[1], Ilham Abdi[1], Hoauri Abdesselem[1], Daniel Erskine[2], Omar El-Agnaf[1]

Aims: α-Synuclein (α-syn) aggregates are central to the pathology of Parkinson's disease and represent a promising target for therapeutic intervention. Nanobodies, characterized by their small size, epitope accessibility, stability, solubility, ease of labeling, scalability, and engineering adaptability, offer an ideal tool for selectively targeting pathogenic α-syn.
Methods: We constructed nanobody phage display libraries using RNA isolated from camels immunized with α-syn monomers or fibrils. Following multiple rounds of panning and selection, we successfully isolated nanobodies and subjected to thorough characterization using a range of biochemical techniques and assays.
Results: Three nanobodies that specifically target α-syn were identified and subsequently engineered into bivalent formats to enhance their binding affinity. Notably, these nanobodies exhibited remarkable specificity, as they recognized α-syn aggregates while showing no cross-reactivity with aggregates or monomers of other amyloid proteins. Epitope mapping revealed distinct binding regions: two nanobodies targeted the C-terminal region, while the third recognized a region containing numerous mutations associated with early-onset Parkinson's disease. Additionally, these nanobodies displayed variations in their conformational specificity. One nanobody recognized α-syn oligomers with a beta-sheet conformation, while another recognized oligomers with and without beta-sheet structure. Importantly, all three nanobodies effectively inhibited α-syn aggregation in an in vitro seeding assay. Furthermore, in an in-vitro cell model using HEK cells expressing α-syn, the nanobodies successfully inhibited seed-dependent aggregation and reduced the formation of insoluble phosphorylated α-syn at Ser 129. Lastly, all identified nanobodies detected Lewy bodies pathology in post-mortem brain tissues from Parkinson's disease cases, underscoring their potential value as research tools.
Conclusions: These nanobodies hold significant promise for both diagnostic and therapeutic applications in Parkinson's disease and associated disorders, with their unique characteristics and specificities making them valuable candidates for further exploration.

IN CELLULO LIBRARY-DERIVED PEPTIDE-BASED INHIBITORS OF ALPHA-SYNUCLEIN AGGREGATION AND TOXICITY

POSTERS: C02.A. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: A-SYNUCLEIN

Jody Mason, Richard Meade, Robert Williams
University of Bath, Department Of Life Sciences, Bath, United Kingdom

Aims: A major group focus is the design and selection of peptides that target amyloidogenic proteins involved in age-related diseases. Amyloid proteins are known to be important in a number of such diseases that include Alzheimer's, Parkinson's, Lewy Body Dementia, Huntington's, and CJD.
Methods: We use a novel *in cellulo* library-screening platform to select peptides that can bind amyloidogenic target proteins to sequester and detoxify them. Utimising a Protein-fragment Complementation approach (PCA), we have identified both strand and helix-based peptide antagonists of α-synuclein proteins implicated in PD and related synucleinopathies. PCA is multiplexed, making no mechanistic assumptions about the target oligomeric state or conformer populated. Rather, library members must bind to and reduce associated toxicity to become selected.
Results: Peptides that either generate, or fail to prevent formation of a toxic species, result in cell death or retarded cell growth rates relative to effective binders. Library members that confer the most rapid bacterial growth are then selected from the PCA by increased stringency during further competition selection.
Conclusions: Our antagonists have been characterised using a range of biophysical and cell-based approaches and been downsized / refined using truncation, alanine-scanning, and incorporation of structure-inducing constraints and non-natural sequences. Our work in this area is currently funded by an Alzheimer's Research UK Major Project Award.

TRKB MODULATOR OT-003 REDUCES DOPAMINERGIC CELL LOSS, MITOCHONDRIAL STRESS, ALPHA-SYNUCLEIN AGGREGATION AND MOTOR DYSFUNCTION IN PARKINSON'S DISEASE MODELS

POSTERS: C02.A. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: A-SYNUCLEIN

Thomas Pfeiffer, Man-Ling Ho, Edward Duckworth, Louise Tear, Zdravko Zahariev, Lila Khederlarian, Alleyn Plowright
Pangea Botanica Ltd, R&d, Sevenoaks, United Kingdom

Aims: To assess the cellular efficacy and potency of proprietary lead compound OT-003, an orally available small molecule Tropomyosin receptor kinase B (TrkB) modulator, in preclinical Parkinson's disease models.
Methods: OT-003 was tested at a broad range of concentrations in separate experiments on primary rat neuronal cell cultures of dopaminergic neurons either injured with MPP+ or alpha-synuclein preformed fibrils (PFF), respectively. To enable this, rat mesencephalic neuronal cultures enriched in dopaminergic neurons were prepared from embryos obtained from pregnant female Wistar rats. In both experimental settings, OT-003 and positive control agents were pre-incubated on day 6 of culture for 1h before MPP+ and alpha-synuclein PFF exposure, respectively. Subsequently, the number of TH-positive neurons, complexity of the neurite network, mitochondrial ROS and alpha-synuclein levels were assessed using immunostaining and quantified using automated image analysis. Statistical significance was tested using one-way ANOVA followed by Fisher's LSD test. $p<0.05$ was considered significant.
Results: In the MPP+ assay, OT-003 significantly reduced mitochondrial ROS generation in dopaminergic neurons after 4h of MPP+ application. After 48h of MPP+ application, OT-003 significantly increased the survival of TH-positive neurons, protected the neurite network and reduced the aggregation of alpha-synuclein. In the alpha-synuclein PFF experiments, OT-003 significantly and dose-dependently reduced TH-positive neuronal cell loss, loss of neurite network and alpha-synuclein aggregation 96h after addition of the alpha-synuclein PFFs. This positive cellular data was reproduced in a Parkinson's disease mouse model in vivo, where chronic oral dosing of OT-003 significantly reduced PD pathologies and improved motor function.
Conclusions: These results in conjunction with additional compelling in vitro and in vivo data are supportive of OT-003's potential to be a novel disease-modifying therapy for patients suffering from Parkinson's disease.

EXPLORING A-SYNUCLEIN POST-TRANSLATIONAL MODIFICATIONS AS BIOMARKERS AND THERAPEUTIC TARGETS FOR PARKINSON'S DISEASE

POSTERS: C02.A. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: A-SYNUCLEIN

Shaohua Qi, Li Yang, Michael Chan, Bill Chan, Zheng Yin, Stephen Wong
Houston Methodist Academic Institute, T. T. & W. F. Chao Center For Brain, Houston, United States of America

Aims: Parkinson's disease (PD) is a challenging neurodegenerative disorder characterized by abnormal clumps of α-synuclein (α-Syn) in the brain. Post-translational modifications (PTMs) of α-Syn contribute to its misfolding and aggregation, triggering inflammation in the brain and exacerbating PD pathology. Understanding the role of α-Syn PTMs and utilizing a systematic screening approach is crucial for identifying potential biomarkers and therapeutic targets of PD.
Methods: We summarized different types of α-Syn PTMs and developed a comprehensive library of α-Syn point mutation vectors to mimic or block specific PTMs, facilitating *in vitro* 3D cell culture experiments. The GFP-labeled α-Syn was captured with a high content screening scanner (ImageXpress Micro, Molecular Devices) to assess conformations and aggregation. We explored biomarkers and therapeutic targets by matching compounds with the drug library using automated screening, followed by drug toxicity assessment and pharmacokinetics in a PD mice model.
Results: PTMs play a key role in generating distinct toxic forms across synucleinopathies, resulting in various types of misfolding of α-Syn and influencing α-Syn conformation and aggregation. Phosphorylated α-Syn emerged as a biomarker during the synucleinopathic process of PD. The ubiquitin-dependent proteasome degradation system mediated α-Syn phosphorylation, modulating α-Syn interchange between the nucleus and cytoplasm. The drug screening system successfully identified and confirmed 4 novel drug candidates that maintained α-Syn biological activity while reducing toxic forms.
Conclusions: Post-translational modifications of α-Syn significantly contribute to the formation of toxic α-Syn aggregation, affecting its misfolding and cellular translocation. Modulating or reversing these PTMs through targeted drug intervention holds promise in mitigating α-Syn pathogenesis, potentially leading to functional and protective outcomes. Our research paves the way for further investigations and therapeutic strategies targeting α-Syn PTMs in Parkinson’s disease.

ELECTROCONVULSIVE SEIZURES (ECS) RESCUE MOTOR IMPAIRMENTS AND PROMOTE A-SYNUCLEIN CLEARANCE IN A MOUSE MODEL OF PARKINSON'S DISEASE

POSTERS: C02.A. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: A-SYNUCLEIN

Alysia Ross, Sophie Bechkos, Delenn Hills, Jeff Correa, Stephanie Hobbs, Shawn Hayley, Hongyu Sun
Carleton University, Neuroscience, Ottawa, Canada

Aims: Recent work has highlighted the potential of electroconvulsive therapy (ECT) in relieving motor symptoms in Parkinson's Disease (PD) patients. While this suggests that modulation of neuronal excitability influences motor severity, the mechanisms behind this improvement remains unknown. The aggregation and accumulation of toxic alpha synuclein (a-Syn) fibrils represent a key trigger for neurodegeneration. As such, targeting the mechanisms regulating and clearing a-Syn is a promising disease-modifying strategy. Thus, we sought to assess the impact of neuroexcitability on aggregation, accumulation and localization of a-Syn. This information is critical for informing clinical practices around the use of ECT in PD.
Methods: We presently assessed whether electroconvulsive seizures (ECS), the mouse model of ECT, either early or late in disease progression, would influence PD pathology and motor symptoms provoked by the well-established A53T PFF mouse model.
Results: We found that ECS, regardless of timing, rescued deficits on rotarod, horizontal ladder and wire hang tests. ECS did not have any significant effects on TH or DAT levels, but reduced levels of phosphorylated a-Syn at s129 and modestly reduced degenerative effects on dopamine neurons in the substantia nigra. In fact, ECS markedly increases activation of relevant basal ganglia structures, consistent with motor deficit improvements. ECS also seems to alter the localization of a-Syn, with most s129 positive inclusions moving from intra-nuclear to cytoplasmic following ECS treatment.
Conclusions: These data suggest that the beneficial effects of ECT on PD motor symptoms may be due in part to alterations in basal ganglia excitability and a-Syn aggregation and accumulation that may be relevant for informing clinical practices and, at the very least, suggestive of novel mechanisms that should be further explored.

Aims: Parkinson's disease and related alpha-synucleinopathies are increasingly prevalent due to an aging population, lacking effective disease-modifying therapies. Alpha-synuclein, a key player in Parkinson's disease, forms aggregates in Lewy bodies and is linked to neurodegeneration in hereditary conditions. This study introduces a nuclease-dead S. aureus Cas9 (sadCas9) CRISPR interference (CRISPRi) system for alpha-synuclein downregulation, both in vitro and in vivo.
Methods: In vitro, we screened 32 single guide RNAs (sgRNAs) targeting the human SNCA promoter. In vivo, we assessed a lead sgRNA in a humanized alpha-synuclein mouse model by delivering it through an all-in-one AAV9 construct, co-expressing sadCas9 and the sgRNA via unilateral stereotactic injections into the substantia nigra of four-month-old mice.
Results: In vitro, several sgRNAs effectively downregulated alpha-synuclein in HEK cells and human iPSC models. Cas9-mediated alpha-synuclein downregulation in patient iPSC-derived neuronal cultures reduced oxidative stress and mitigated mitochondrial DNA damage. In vivo, we observed sustained sadCas9 expression and substantial reduction in alpha-synuclein mRNA and protein levels at one and six months post-surgery. Initial microglia activation subsided over time, with no significant differences in microglia markers Iba1 and CD16/32 between the groups at the six-month mark.
Conclusions: This study showcases the efficacy of Cas9 interference technology in reducing alpha-synuclein mRNA and protein levels in both in vitro and in vivo settings. These promising pre-clinical results suggest the potential for advancing towards a disease-modifying genetic therapy for Parkinson's disease and related alpha-synucleinopathies.

INSULIN-DEGRADING ENZYME PLAYS A NEUROPROTECTIVE ROLE IN AN IN VITRO MODEL OF SYNUCLEINOPATHIES

POSTERS: C02.A. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: A-SYNUCLEIN

Luís Sousa, Mariana Guarda, Ana Rita Marçal, Ana Chegão, Paula Macedo, Hugo Vicente Miranda
NOVA Medical School, Nms Research, Lisbon, Portugal

Aims: Recent findings suggests that Insulin Degrading Enzyme (IDE) suppresses alpha-synuclein (aSyn) oligomerization and accumulation *in vitro*. In addition to its insulin degradation role, IDE plays chaperone, heat-shock protein, and proteasome modulator functions. Herein, we aimed to explore the therapeutic potential of genetically modulating IDE against aSyn pathology using an H4 cell culture model.
Methods: H4 cells were co-transfected 24 hours post-seeding with aSyn or SynT, an aSyn aggregation-prone variant, together with IDE-WT or IDE-E111Q, a catalytically inactive variant. At 48 hours post-transfection, we collected cells and evaluated cytotoxicity via lactate dehydrogenase release, aSyn levels, and aSyn solubility at 1% Triton-X100. We evaluated the impact of IDE's degradative activity for its interaction with aSyn through co-immunoprecipitation and characterized SynT aggregates by immunocytochemistry.
Results: We observed that IDE reduces aSyn-dependent neurotoxicity. IDE-E111Q exhibits reduced efficacy, suggesting that while aSyn is not a direct degradative substrate of IDE, degradative active IDE has a higher suppressing capacity. Furthermore, we observed a stronger interaction between aSyn and IDE-WT compared to the degradative-inactive IDE. Cells overexpressing IDE present higher levels of aSyn, and bigger aSyn aggregates, although aSyn solubility remained unaltered.
Conclusions: This study showcases IDE's potential to attenuate aSyn-induced neurodegeneration in an activity-dependent manner. Notably, the observed reduction in toxicity, coupled with an increase in aSyn aggregate size but no solubility alterations, suggests IDE's potential chaperone role, possibly favoring monomer or high-weight aSyn fiber formation over oligomeric species. Future research should explore targeting brain IDE as a therapeutic avenue for Parkinson's disease (PD) progression. Given IDE's relevance in type 2 diabetes (T2D), a crucial PD risk factor, repurposing existing IDE-targeted drugs may hold promise in PD treatment.

Aims: Accumulation of alpha-Synuclein (aSyn) aggregates in specific brain regions is a hallmark of Parkinson's disease (PD) and related synucleinopathies. The propagation of aSyn has been suggested to be the underlying mechanism by which aggregates spread throughout the brain. The human aSyn preformed fibril (PFF) striatal injection model is a widely used animal PD model that recapitulates key disease characteristics, including aSyn aggregation, propagation, dopaminergic cell loss, and behavioral deficits. Herein, we investigated the potential beneficial role of non-invasive endogenous aSyn down-regulation via AAV.PHP.eB-GFP capsids on the spreading of aSyn-related pathology *in vivo*.
Methods: PHP.eB-GFP AAVs carrying either short hairpin RNA (shRNAs) or microRNA sequences, both targeting endogenous murine *Snca* encoding for aSyn, or respective scrambled control sequenceswere intravenously administered to 8-week-old male C57/Bl6 mice. One week post-injection, human aSyn PFFs were unilaterally injected into the right dorsal striatum. Three months post-injection,behavioral and histochemical analyses were performed to evaluate the effects of endogenous aSyn down-regulation on the haSyn PFF-mouse model.
Results: Intravenous administration of both types of PHP.eB-GFP AAVs was accompanied by widespread GFP transduction throughout the brain, including the substantia nigra, the area mainly affected in PD. Importantly, both *Snca*-targeted approaches (shRNA and microRNA), resulted in a significant reduction of endogenous aSyn levels within the transduced dopaminergic neurons, decreased the levels of pathology-related Ser129-phosphorylated aSyn and mitigated the dopaminergic celland terminal loss in the nigrostriatal axis. This amelioration of dopaminergic system degeneration was notably reflected in motor phenotype
Conclusions: Our approaches employing thePHP.eB-GFP-shRNA- or microRNA-targeted *Snca* capsids enabled the efficient downregulation of endogenous aSyn and hampered the propagation of aSyn-related pathology, setting the stage for novel, non-invasive therapeutic interventions for PD and related synucleinopathies.

CONVERGENCE OF POST-TRANSLATIONAL MODIFICATIONS OF TAU AND _-SYN MAY INFLUENCE THE TOPOGRAPHICAL DISTRIBUTION OF PATHOLOGICAL PROTEIN AGGREGATES IN DLB.

POSTERS: C01.P. DISEASE MECHANISMS, PATHOPHYSIOLOGY: OTHER

Lauren Walker[1], Ahmad Khundakar[2], Kirsty Mcaleese[1], Johannes Attems[1]
[1]Newcastle University, Translational And Clinical Reserch Institute, Newcastle upon Tyne, United Kingdom, [2]Teeside University, National Horizons Centre, Darlington, United Kingdom

Aims: Dementia with Lewy bodies (DLB) is neuropathologically defined by inclusions of α-synuclein (α-syn). However, concomitant Alzheimer's disease (AD) pathologies, hyperphosphorylated tau (HP-*T*) and β amyloid, are observed frequently at *post-mortem* examination, with 50-70% of DLB cases found to have medium to high- level of AD neuropathologic change. Mixed pathologies are associated with an accelerated cognitive decline, which can make diagnosis challenging. An increased burden of all three pathologies in end- stage dementia suggests a potential synergistic interaction between these proteins and is supported by studies that demonstrate α-syn and HP-*T* are co-localised. Proteins can undergo numerous alterations, which can affect their structure and enhance toxicity, however little is known regarding which post-translational modifications (PTMs) of α-syn and tau are co-localised, and are associated with specific clinical symptoms.
Methods: Tissue microarray (TMA) slides that incorporate 15 anatomically distinct brain regions from DLB cases with high and low AD neuropathology were double immunolabelled with PTMs of α-syn and tau (i.e α-syn phosphorylated at serine 129 (α-syn pS129), MC1, CP13, Alz 50 and PHF-1) and topographical distribution of pathological protein aggregates investigated.
Results: Co-localisations between α-syn pS129 and all tau markers were observed in multiple brain region in particular the amygdala and topographical distributions differed between DLB cases with low and high levels of concomitant AD related neuropathology.
Conclusions: The interaction between α-syn and tau has to be further elucidated and clincal trials should explore the feasibility of combination therapies targeting both α-syn and tau pathologies.

EVALUATING NUCLEAR RECEPTOR LIGANDS AS POTENTIAL THERAPEUTICS IN CELLULAR MODELS OF PARKINSON'S DISEASE

POSTERS: C02.A. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: A-SYNUCLEIN

Arati Tripathi, Heba Alnakhala, Lisa Brontesi, Dennis Selkoe, Ulf Dettmer
Brigham and Women's Hospital/Harvard Medical School, Department Of Neurology, Boston, United States of America

Aims: Disease-modifying strategies for Parkinson disease (PD), the most common synucleinopathy, represent a critical unmet medical need. Accumulation of the neuronal protein alpha-synuclein (αS) and abnormal lipid metabolism have each been implicated in PD pathogenesis. Nuclear receptors are ligand-activated transcription factors that regulate gene expression linked to lipid metabolism and cellular fitness. Here, we identify and elucidate how nuclear receptor signaling impacts PD-associated αS and lipid alterations.
Methods: Pharmacological and genetic approaches in cellular PD models were used to investigate the impact of nuclear receptor signaling on fatty acid metabolism and αS homeostasis.
Results: We show that nuclear receptor agonists ameliorate cytotoxicity elicited by αS expression. Our data demonstrate that nuclear receptor agonism regulates fatty acid desaturase, SCD, and influences lipid droplets. Activation of these receptors normalizes alpha-synuclein homeostasis in cellular models of Parkinson's Disease. The effect of nuclear receptor activation on lipid droplets, fatty acid desaturase, and alpha-synuclein is reversed by an RXR antagonist, supporting pathway specificity.
Conclusions: Nuclear receptor activating ligands can alter fatty acid metabolism and correct perturbation in αS homeostasis to alleviate cytotoxicity and confer benefit in cellular models of PD. Our study offers a new paradigm to investigate nuclear receptor ligands for therapeutic potential in synucleinopathies.

Aims: Phosphorylation of α-synuclein at serine-129 (pS129) is generally accepted as a marker of neurotoxic Lewy Bodies deposition within defined regions of the brain, the primary pathological hallmark of Parkinson's disease (PD). Moreover, pS129 α-synuclein is considered an aggregation-prone form that exacerbates disease progression. Phosphorylation can be blocked by O-GlcNAcylation, the addition of beta-D-*N*-acetylglucosamine (GlcNAc) to serine to form O-linked N-acetylglucosamine (O-GlcNAc). Here, we investigated whether increasing brain O-GlcNAc levels by using Thiamet-G, a potent inhibitor of the enzyme O-GlcNAc hydrolase (OGA) that removes this modification from cellular proteins, could perturb pS129 α-synuclein aggregation.
Methods: Two-month-old wild type α-synuclein transgenic mice (mThy1-hSNCA) were administered vehicle, or Thiamet-G at low (200 mg/kg/day) or high (500 mg/kg/day) doses for 10 months. Locomotive and cognitive assessments were conducted throughout the treatment period to profile the longitudinal effects on behavior. Brain tissue was collected at the study end to quantitate deposition of pS129 α-synuclein aggregates.
Results: Thiamet-G treatment at both doses increased brain O-GlcNAc levels by approximately 5 folds. Both treatments also led to large and significant reductions of pS129 α-synuclein aggregates within dopaminergic brain regions. There was no significant reduction of total α-synuclein, indicating strong specificity in depleting α-synuclein aggregates. As early as one month of treatment, mice demonstrated improved locomotion in open field and pole descending tests with no observable cognitive abnormalities.
Conclusions: Our findings align with the beneficial effects of OGA inhibitors observed in various neurodegenerative diseases including PD and support pursuing OGA inhibitors, which have now advanced into the clinic, as a novel disease modifying treatment for slowing progression of PD. Further research on the mechanism of action by which OGA inhibitors act in PD may uncover precise neuroprotective effects of this pharmacological approach.

A NOVEL DISEASE MODIFYING THERAPY FOR PARKINSON'S DISEASE

POSTERS: C02.B. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: IMMUNOTHERAPY

Ish Khanna, Sivaram Pillarisetti, Marcus Malkmus, Kathrin Kortschak
NeuroPn Therapeutics, Drug Discovery, Peachtree Corners, United States of America

Aims: Neuroinflammation and mitochondrial dysfunction with associated oxidative/endoplasmic reticulum (ER) stress work synergistically to accelerate Parkinson's disease (PD) progression. Epoxyeicosatrienoic acids (EETs) are the endogenous mediators that stimulate the inflammation resolution pathway and attenuate mitochondrial stress and neurotoxicity. The EETs are, however, degraded rapidly by the soluble epoxide hydrolase (sEH) to inactive metabolite. Recent studies in PD patients confirm that sEH expression in the human brain increases in tandem with rising synuclein aggregates and correlates with a reduction in dopaminergic neurons. The animal studies also confirm that sEH plays crucial role in driving neurodegeneration in PD. Collectively, these data suggest sEH as an important target for pharmacological intervention in PD. We envisaged that a brain penetrating, oral sEH inhibitor could block neurodegeneration and arrest PD progression. The efficacy of **NP-319** in alpha-synucleinopathy PD model will be presented as a potential breakthrough therapy for Parkinson's disease.
Methods: NP-319 was evaluated in alpha-synucleinopathy PD model in aged mice that reproduces neuropathological features of human PD (motor function defects, loss of dopaminergic neurons, a-syn aggregation). **NP-319** was dosed (*oral, q.d.*) both in a preventive (starting day -1) and therapeutic setting (starting day +7) post stereotaxic injection of a-syn fibrils in the brain. The motor coordination was evaluated after 3-weeks while impact on neuroprotection, a-syn aggregation, and neuronal inflammation was evaluated at the sacrifice of animals after 4-weeks of **NP-319** treatment.
Results: NP-319 therapy given in a preventive or therapeutic setting fully rescues motor function (mobility, motor coordination and slips), shows complete protection of dopaminergic neurons, prevents a-syn aggregation in the substantia nigra and blocks neuronal inflammation (microgliosis) and the mitochondrial dysfunction.
Conclusions: NP-319 has potential to be the *first* disease-modifying therapy in Parkinson's Disease

Aims: Synucleinopathies, including Parkinson's disease (PD), are believed to be primarily caused by the continuous build-up of misfolded alpha-Synuclein (aSyn) in the brain. Vaccines targeting aSyn represent a promising, innovative approach to treating these disorders. However, the immunogenicity of the current generation of PD vaccines remains a limiting factor. To enhance effectiveness and specificity of PD vaccination, we have developed a highly potent and adaptable platform termed WISIT (Win the Skin Immune System Trick). This novel class of neoglucoconjugate vaccines is designed to harness the capabilities of skin immune cells by targeting their C-type lectin receptors. This approach resulted in the production of several vaccine candidates with unprecedented immunological efficacy.
Methods: The leading WISIT candidates, differing in B cell - and T helper epitopes, are evaluated in comparison for their immunological (titer, specificity for aggregated aSyn) and therapeutic potential (inhibition of in vitro and in vivo aSyn propagation). The objective is to identify the top three candidates for progression into clinical testing as part of the Nexgen-PD project funded by Horizon Europe.
Results: The leading PD vaccine candidates from WISIT elicit robust and highly specific Ab responses with exceptional avidity for aSyn aggregates. Consequently, they significantly outperform conventional benchmark vaccines. Antibodies induced by chosen WISIT candidates have been demonstrated to inhibit aSyn aggregation in a dose-dependent manner, both in vitro and in vivo. The top candidates identified are set to undergo preclinical safety and tolerability studies. Additionally, their production process is currently being upgraded to GMP standards.
Conclusions: Our studies validate the concept for our top three aSyn WISIT vaccine candidates, demonstrating their immunological and in vivo efficacy, as well as safety. These findings provide substantial support for their translation towards clinical development.

Aims: The accumulation of misfolded alpha synuclein (aSyn) and the cell-to-cell transmission of resulting aSyn aggregates propagate disease pathology in Parkinson's disease (PD) and other synucleinopathies. Thus, aSyn is considered a target for disease modification. ACI-7104.056, an aSyn-targeting immunotherapy currently being tested in a phase 2 clinical trial (NCT06015841), is designed to trigger an antibody response specifically binding to aSyn aggregates to halt their propagation. Here, we have assessed the safety and immunogenicity of ACI-7104.056 in non-human primates (NHP) and further characterized the quality of induced antibodies.
Methods: NHPs received multiple intramuscular injections of ACI-7104.056 and serum was collected at different time points. The animals were closely monitored for tolerability and safety throughout the entire in-life phase. Anti-aSyn aggregate-specific antibody levels in serum of immunized animals were analyzed by ELISA. The capacity of elicited antibodies to interfere with the accumulation of intracellular aSyn aggregates induced by human preformed fibrils was tested in rat primary cortical neurons using immunocytochemistry.
Results: ACI-7104.056 was safe and well tolerated in NHP with only a few transient local injection site reactions. A strong IgG response against aSyn aggregates was observed already after two immunizations and maintained at a high level until study end. Elicited antibodies reduced the number of intracellular aSyn aggregates in a primary neuron seeding assay demonstrating efficient blockage of aSyn propagation.
Conclusions: The evaluation of the phase 2 clinical stage ACI-7104.056 immunotherapy in a safety and immunogenicity study in NHP supports the use of this drug chronically in humans. The ability of elicited antibodies to interfere with the propagation of aSyn aggregates in living neurons further supports the development of ACI-7104.056 as a potential disease modifying therapy for PD and other synucleinopathies.

Aims: Mutant forms of β-Glucocerebrosidase (GCase) found in Gaucher´s Disease, Parkinson's Disease and Dementia with Lewy Bodies are less stable than wild-type (WT) GCase, which contributes to endoplasmic reticulum (ER) stress and lysosomal dysfunction due to ineffective trafficking. This leads to increased accumulation of lysosomal glucosylceramide and/or toxic α-synuclein aggregates. Therapeutics aimed at enhancing GCase trafficking and lysosomal activity are therefore of high relevance.
Methods: To this end we have established a comprehensive panel of *in vitro* and cellular assays to evaluate direct target engagement of small molecules against GCase and their mechanism of action. The assays have been validated using literature tool compounds and implemented in multi-well format enabling simultaneous multiple compounds testing.
Results: This platform includes assays to determine *in vitro* and cellular target engagement (e.g., X-ray Crystallography, Isothermal Titration Calorimetry, Cellular Thermal Shift Assay, Nano-Glo GCase-HiBiT assay), as well as assays to interrogate compound effects on GCase enzyme activity, protein stability, intracellular localisation and endogenous substrate levels in WT and mutant patient cell lines using a range of biochemical, high-content imaging and LC-MS methods. This has been applied to support fragment-based and structure-guided drug discovery against new potentially druggable sites on the protein surface.
Conclusions: We have developed a platform that enables profiling of GCase small molecule modulators. The assays can be used to assess target engagement and investigate mechanism of action. Identifying compounds that improve GCase trafficking and function may lead to the development of novel therapeutics for neurodegenerative diseases.

PRECLINICAL IN VIVO CHARACTERIZATION OF IRL1117; A NOVEL DOPAMINE D1/D2 AGONIST FOR THE TREATMENT OF PARKINSON'S DISEASE

POSTERS: C02.D. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: DOPAMINE, ACETYLCHOLINE, NEUROTRANSMITTERS

Daniel Andersson, Sabina Brandin, Angelica Johansson, Karin Önnheim, Kristina Möller, Li Rousk, Jenny Gunnergren, Sverker Von Unge, Nicholas Waters, Clas Sonesson, Joakim Tedroff
IRLAB Therapeutics AB, Research & Development, Göteborg, Sweden

Aims: The objective of the current study was to characterize the novel dopamine D1/D2 agonist IRL1117 in the 6-OHDA-lesioned rat model of Parkinson's Disease.
Methods: The methods employed in the current studies were a combination of tests assessing motor function (cylinder test for motor asymmetry and the induced rotations assay) and the standard AIMs test for assessing extent of treatment-induced dyskinesias. Both acute and chronic studies have been performed, with the longest study following a 16 days once-daily treatment protocol.
Results: indicate that IRL1117 induces a long-lasting behavioral effect in the induced rotations assay (>12h) after a single oral dose, and that the restorative effect on motor function (as measured by the cylinder test) are maintained during chronic once-daily oral IRL1117 treatment for 16 days. In parallel, no or minimal induction of treatment-induced dyskinesias was observed during chronic treatment with IRL1117. Furthermore, when substituting L-DOPA with IRL1117 in rats with established L-DOPA induced dyskinesias, the dyskinesias were gradually diminished until largely absent while a functional motor response as measured by the cylinder test appears instead. Of note is also that these effects attained during chronic treatment with IRL1117 occur without the development of D1-related tachyphylaxis.
Conclusions: In conclusion, the data show that chronic treatment of 6-OHDA-lesioned rats with IRL1117 results in a robust effect on motor function without the simultaneous development of treatment-induced dyskinesias or the development of D1-mediated tachyphylaxis. Consequently, IRL1117 may constitute a novel chemical entity for once-daily treatment of the motor symptoms in Parkinson's disease, providing robust efficacy without the development of treatment-induced dyskinesia.

THERAPEUTIC TARGETING OF SYNAPTIC VESICLE GLYCOPROTEIN 2C (SV2C) IN PARKINSON'S DISEASE

POSTERS: C02.D. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: DOPAMINE, ACETYLCHOLINE, NEUROTRANSMITTERS

Meghan Bucher[1], Farhad Forouhar[2], Gary Miller[1]
[1]Columbia University Irving Medical Center, Environmental Health Sciences, New York, United States of America, [2]Columbia University Irving Medical Center, Herbert Irving Comprehensive Cancer Center, New York, United States of America

Aims: Dopamine mishandling has been a recognized feature of Parkinson's disease (PD) since the 1960s when decreased dopamine was observed in post-mortem PD brain tissue and it was discovered that L-DOPA supplementation rescued motor deficits. Our work suggests *synergistic action* between vesicular monoamine transporter 2 and synaptic vesicle glycoprotein 2C (SV2C) to regulate vesicular dopamine homeostasis. Several SNPs in SV2C have been implicated for PD including variants that modify differential responses of PD patients to L-DOPA. There is precedent for therapeutically targeting SV2 proteins demonstrated by the efficacy of the SV2A modulator Levetiracetam for epilepsy treatment. We believe a pharmacotherapeutic modulator of SV2C may improve motor symptoms for PD patients either as a monotherapy or by improving L-DOPA efficacy. We sought to use theoretical modeling approaches and functional assays of SV2C activity to identify and test putative SV2C-targeted pharmacotherapeutics.
Methods: Induced-Fit docking (Schrödinger software) of small molecules against a reliable Alpha-Fold model of the full-length SV2C were used to evaluate interactions between SV2C and therapeutic compounds containing -racetam moieties. Compounds with high docking scores were tested in an *in vitro* plate-reader based assay utilizing a fluorescent dopamine analogue (FFN206) for effects on SV2C activity.
Results: Functional assays identified inhibitory effects (-39%) of the -racetam compound Padsevonil on FFN206 uptake at high (e.g., 100μM) dose, although no effects were identified with Levetiracetam. Additional compounds identified by theoretical modeling were prioritized for analysis resulting in the identification of "compound 29," which increased FFN206 uptake (+8%) at low (e.g., 0.001μM) dose.
Conclusions: Theoretical modeling can be paired with functional assays to identify and test putative compounds for SV2C activity. Future studies will expand this catalogue of potential SV2C-modifying compounds for translation into *in vivo* models of PD.

BENEFICIAL AND ADVERSE OUTCOMES FROM BDNF SUPPLEMENTATION IN BDNF-DEFICIENT PARKINSONIAN RATS WITH STRIATAL DOPAMINE GRAFTS.

POSTERS: C02.E. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: CELL TRANSPLANTATION

Carlye Szarowicz[1,2], Kathy Steece-Collier[2], Molly Vander Werp[2], Jennifer Stancati[2], Caryl Sortwell[2], Margaret Caulfield[2]
[1]Michigan State University, Pharmacology And Toxicology, East Lansing, United States of America, [2]Michigan State University, Translational Neuroscience, Grand Rapids, United States of America

Aims: Mechanisms underlying graft-induced dyskinesia (GID), a potential side effect in individuals with Parkinson's disease (PD) and striatal dopamine (DA) grafts, remain controversial. One potential genetic contribution to this therapeutic outcome is a common single nucleotide polymorphism (SNP), rs6265, found in the gene for brain-derived neurotrophic factor (BDNF), a SNP which results in decreased BDNF release. Using rs6265 knock-in rats, we previously demonstrated that homozygous rs6265 (Met/Met) parkinsonian rats engrafted with wild-type (WT; Val/Val) DA neurons uniquely developed GID. Based on the necessity of BDNF for DA neuron maturation, we hypothesize that decreased BDNF release in rs6265 carriers impairs maturation and synaptogenesis of grafted DA neurons, leading to GID, and that infusion of exogenous BDNF will allow for graft maturation, normalization of graft-derived synaptic innervation, and GID prevention.
Methods: Male parkinsonian Met/Met rats were transplanted with intrastriatal embryonic WT DA neurons. Infusion cannulas were stereotaxically inserted 3μm dorsal to grafted cells with a 28-day Alzet™ osmotic minipumps containing BDNF or vehicle phosphate buffered saline (PBS). Pumps were removed after four weeks. Levodopa-induced dyskinesia (LID) and GID severity were evaluated over 10 weeks post-engraftment.
Results: DA-grafted animals infused with PBS or BDNF exhibited significant amelioration of LID compared to non-grafted animals, demonstrating successful engraftment. Contrary to our hypothesis, BDNF infusion in grafted animals increased amphetamine- and levodopa-mediated GID behavior in Met/Met hosts. BDNF infusion also increased contralateral amphetamine-induced rotational behavior.
Conclusions: Behavioral results are indicative of excess DA in the grafted striatum, a phenomenon reported in some grafted individuals with PD and GID. Histological and molecular analyses of graft neurochemical phenotypes are ongoing. These data highlight the necessity of careful therapeutic tailoring for optimization of clinical outcomes for individuals with PD.

Aims: Parkinson's disease (PD) trigger protein misfolding associated with accumulation of a-synuclein (a-syn) aggregation and neurodegeneration. Rotenone (ROT), a mitochondrial complex I inhibitor, trigger protein aggregation in the pathogenesis of PD. Mesenchymal stem cells treating neurodegenerative diseases mainly attributed their beneficial effects from their secretome during differentiation mainly consist of extracellular vesicles, proteasomes, microRNA, and neurotropic factors. In this study, we examined the exosomes isolated from neurogenic differentiation of human adipose tissue-derived stem cells (NI-hADSC-Exo) against ROT-induced PD model in rats
Methods: Male Sprague-Dawley rats (200-250 g; 8~9 weeks old) were obtained, Rotenone in a dose of 1 mg/kg b.wt. daily for 28 d for induction of PD. NI-hADSC-Exo were suspended in PBS slowly injected into the tail vein at 500 mg/kg b.wt. at days 15, 18, 21, 24, and 27. At end of the experimental period, rats were sacrificed by terminal anesthesia and transcranially perfused, brains were rapidly removed, midbrain and striatum were located, and lysates were prepared for Western blotting. Whole brains were used for immunohistochemistry.
Results: The results obtained in the present study revealed that ROT toxicity significantly reduced tyrosine hydroxylase expression in midbrain and striatum regions. ROT also increased the phospho-Ser129-a-syn in Triton X-100-soluble and -insoluble cell lysate fractions from midbrain and stratum subregions along with increased total a-syn except in midbrain Triton X-100-insolbule fraction. However, NI-hADSC-Exo induced increase in TH expression and TH-positive cells also reduced the phospho-Ser129-a-syn in Triton X-100-soluble and -insoluble cell lysate fractions from midbrain and stratum.
Conclusions: These results suggest that NI-hADSC-Exo involved in improving neurological functions in rats, thus, may presents critical insight in future studies on PD and other neurodegenerative disorders.

Aims: Microglia are key players in neuroinflammation linked to neurodegenerative diseases such as AD and PD. Several studies suggest that pharmacological blockade of Kv1.3 in rodent microglia reduces neuroinflammation and enhances neuroprotection, indicating its potential as a novel therapeutic approach. A lack of selective, small molecule Kv1.3 blockers with CNS exposure has however prevented the study of Kv1.3 in the context of neuroinflammation in vivo so far. We present here the effect of a potent, selective brain penetrant Kv1.3 blocker on T cells and microglia in the context of inflammatory stimulation in vitro and in vivo.
Methods: Selectivity of compounds was determined by patch-clamp electrophysiology in heterologous cells. Compounds were tested in the context of disease pathology relevant inflammatory stimuli in vitro in human PBMC derived T cells and hIPSC derived microglia and in vivo in human microglia xenografted into mice and wildtype rodent models challenged with pro-inflammatory stimuli both centrally and peripherally. Assessment of cytokine release and gene expression analyses by qPCR and/or RNA-seq were performed on T cells and microglia.
Results: We identified small molecules with low double-digit nanomolar potency for Kv1.3, high selectivity against other Kv1 family members, and excellent brain pharmacokinetics. These compounds exert anti-inflammatory effects both on human T cells and microglia in vitro and in vivo across several different pro-inflammatory stimuli. Transcriptional analyses from xenografted hIPSC microglia showed that Kv1.3 blockade in vivo normalized a pro-inflammatory gene signature.
Conclusions: These results support Kv1.3 as a novel drug target for the treatment of brain disorders with prominent neuroinflammation. Kv1.3 blockade impacts both T cells and microglia, suggesting synergistic effects in the context of neurodegenerative disorders accompanied by peripheral and central inflammation.

Aims: Bemdaneprocel is an investigational cellular therapy composed of pluripotent stem cell–derived dopaminergic neuron precursor cells under development for the treatment of Parkinson's disease (PD). At 1-year post-transplantation, bemdaneprocel was generally safe and well tolerated in all 12 participants in a phase 1 study. Here, we report data exploring the impact of bemdaneprocel on non-motor symptoms in participants with PD.
Methods: In this open-label, non-controlled study, 12 participants received 1 of 2 different doses of bemdaneprocel bilaterally to the post-commissural putamen and a 1-year immunosuppression regimen. Exploratory outcomes assessed at 12 months included the impact of bemdaneprocel on non-motor symptoms. Assessments will be repeated at 18 months, 6 months post-discontinuation of immunosuppression.
Results: At 12 months, participants receiving the higher dose of bemdaneprocel showed an improvement in non-motor symptoms, including a median (Q1, Q3) change from baseline of −28.7% (−58.5%, −1.2%) on the Non-Motor Symptom Scale total score and a median (Q1, Q3) change from baseline of −83.3% (−100%, −50.0%) on the Neuropsychiatric Inventory Questionnaire. Measures of activities of daily living and quality of life remained stable during this time, with a median (Q1, Q3) change from baseline of −9.1% (−42.9%, 11.1%) in part II of the MDS-UPDRS and a median (Q1, Q3) change from baseline of −9.9% (−55.1%, 47.4%) on the PDQ-39 summary index. Participants in the low dose cohort had a median (Q1, Q3) change from baseline of −21.9% (−46.7%, 12.5%) on the PDQ-39 summary index.
Conclusions: Overall, some participants receiving the higher dose of bemdaneprocel had improvement or no worsening from baseline in non-motor outcomes. Data from additional cognitive assessments and 18-month follow-up (6 months post-discontinuation of immunosuppression) will be presented at the congress.

PEA-OXA EXERTS NEUROPROTECTIVE EFFECTS BY MODULATING THE AUTOPHAGIC PATHWAY IN A MOUSE MODEL OF PARKINSON'S DISEASE

POSTERS: C02.F. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-INFLAMMATORY, ANTI-OXIDANT

Alessio Ardizzone[1], Irene Paterniti[2], Deborah Mannino[1], Salvatore Cuzzocrea[1], Emanuela Esposito[1]

Aims: Objective: Parkinson's disease (PD) is the second most frequent neurodegenerative disease, and it is characterized by degeneration of nigrostriatal dopaminergic neurons that cause disabling motor disorders. Growing evidences support the impairment of autophagy in PD pathogenesis, thus, its regulation has been considered an attractive therapeutic target in the development of novel PD treatments. In this framework, many scientific articles highlighted the neuroprotective properties of Palmitoylethanolamide (PEA), an endogenous lipid molecule belonging to the N-acetylethanolamines (NAEs) class. PEA is produced "on demand" by our body, in response to stressful conditions or inflammatory stimuli, thus denoting its key role in maintaining cellular homeostasis. Since the administration of PEA suffers from problems related to its metabolism, it was synthetized new derivates such as N-Palmitoylethanolamide-Oxazoline (PEA-OXA), which resulted successful in inhibiting NAAA PEA-degrading enzyme and decreasing neuroinflammation. On this basis, the aim of this study was to deep the neuroprotective effects of PEA-OXA in a murine model of PD.
Methods: Methods: Nigrostriatal degeneration was induced by intraperitoneal injection of MPTP (80 mg/kg), then PEA-OXA 10 mg/kg was administered daily by oral gavage starting from 24 h after the first administration of MPTP. Mice were killed 7 days after MPTP induction, and their brains were processed for histological evaluations and molecular biology analyses.
Results: Results: Our results demonstrated that PEA-OXA treatment significantly improved behavioral deficits and reduced the impairment of PD hallmarks such as tyrosine hydroxylase and dopamine transporter deficit as well as a-synuclein accumulation. Furthermore, PEA-OXA administration mediated a neuroprotective effect through increasing markers of autophagic pathway and modulating apoptosis.
Conclusions: Conclusions: Therefore, in the light of these findings, PEA-OXA could be considered a valuable therapeutic approach by enhancing dopaminergic neurons survival and renewal in PD patients.

Aims: Parkinson's disease manifests as a spectrum of motor and non-motor deficits including selective dopaminergic degeneration, alpha synuclein accumulation and inflammasome activation. Given the complex multifactorial aetiology of PD, emerging evidence suggests that targeting multiple pathological processes could be is essential to achieve disease modification. We recently confirmed that RRx-001, a Phase 3 small molecule chemoprotective and radioprotective agent, is a direct NLRP3 inflammasome inhibitor. In this study, we evaluated if RRx-001 could be developed as a novel disease-modifying therapy for PD.
Methods: For this study we used a combination of mechanistically distinct animal models of PD including the 6-OHDA model and the PFF-synuclein model. For our in vitro models, we used a combination of primary microglia, primary neurons and dopaminergic cell lines such as N27 cells.
Results: We confirmed that daily dosing with RRx-001 (10 mg/kg) reduced NLRP3 inflammasome activation markers in the 6-OHDA model. In the synuclein PFF model, RRx-001 therapy reduced markers of immune and inflammasome activation. In RRx-001 treated animals, we found activation of the neuroprotective NRF2 pathway in the nigrostriatal system. Our *in vitro* mechanistic studies with RRx-001 in dopaminergic neurons and microglia also confirmed that RRx-001 inhibits NLRP3 activation with nanomolar potency. In dopaminergic neurons, RRx-001 prevented mitochondrial fragmentation induced by the Parkinsonian neurotoxicant MPP^+. RRx-001 also improved markers of mitochondrial function and biogenesis in these studies.
Conclusions: Our results highlight RRx-001 as a unique therapeutic agent which can target multiple pathological mechanisms relevant to PD. Given the clinical safety record of RRx-001 in human studies to date, our results suggest that RRx-001 treatment could be an attractive neuroprotective strategy to slow or halt disease progression in PD. Clinical studies with RRx-001 in PD are planned for 2024.

TIANQI PINGCHAN GRANULE PROMOTES RECOVERY OF GLYMPHATIC SYSTEM FUNCTION IN RATS MODEL OF L-DOPA-INDUCED DYSKINESIA

POSTERS: C02.F. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-INFLAMMATORY, ANTI-OXIDANT

Zhenguo Liu, Zhihua Liu, Shuyuan Yang, Shuwei Wang, Lu Song, Yu Zhang, Ying Wan, Jing Gan, Na Wu
Xinhua Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Neurology, Shanghai, China

Aims: To explore the therapeutic effects of TPG(a traditional Chinese medicine for the treatment of Parkinson's disease with an anti-inflammatory protective effect) on the glymphatic systemfunction inparkinsonian rats with L-DOPA-induced dyskinesia (LID)
Methods: 6-hydroxydopamine-hemilesioned rats were injected with L-DOPAfor three weeks to create a model of LID. Then, rats received intragastric administrations of TPG(2.8, 5.6and 11.2 g/kg, respectively) or saline once a day for 3 weeks. The pharmacological effects of TPGonLID were investigated by behavioral test, immunofluorescence and Enzyme-linked immunosorbent assay for the functions of glymphatic system.
Results: showed that TPG (5.6 and 11.2 g/kg) significantly alleviated abnormal involuntary movements score. Moreover, TPG (5.6g/kg) treatment increased CSF tracer influx andreduce amyloid-β deposition in the cortex and striatum. In addition, TPG markedly improved the perivascular aquaporin-4 (AQP4) polarization and exhibited a decrease in glial activation and AQP4expression compared with saline treatment.
Conclusions: This study shows for the first time that glymphatic systemfunctionis impaired in LID and TPG attenuates abnormal involuntary movements in rats with LID by protectingthe glymphatic system

NEUROIMMUNE MODULATION IN THE PATHOGENESIS AND THERAPEUTICS OF SYNUCLEINOPATHIES OF THE AGING POPULATION

POSTERS: C02.F. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-INFLAMMATORY, ANTI-OXIDANT

Eliezer Masliah[1], Michiyo Iba[2], Changyoun Kim[2]
[1]National Institute on Aging, Division Of Neuroscience And Lng, Bethesda, United States of America, [2]National Institute on Aging, Laboratory Of Neurogenetics, Bethesda, United States of America

Aims: Synucleinopathies of the aging population includes an heterogeneous group of neurodegenerative disorders with alpha-synuclein (alpha-syn) accumulation and includes Dementia with Lewy bodies (DLB), Parkinson's disease (PD) and PD dementia. We have shown that extracellular α-syn that propagates from neurons to glial cells triggers via the TLR2, LRRK2 and NFATc2 axis neuroinflammation and neurodegeneration. Aging is associated with increased accumulation of alpha-syn and neuroinflammation. These abnormal responses involve both adaptive and innate immunity leading to synaptic dysfunction and neurodegeneration involving signaling pathways such as p38MAPK. The main objective of this study is to evaluate the effcts of modulating these signaling pathways in developing novel therapeutics for DLB and PD.
Methods: We investigated the effcts of Immunotherapy with antibodies that block selected T cell populations and NKT's such as CD1d, we also investigated the effects of blocking NFAT signaling with 11R compound, p38MAPK with SKF compounds and deleting microglia with PLX in models of synucleinopathy. We evaluated neuroinflammation, neurodegeneration, transcriptomics, behaviour, signaling, flow cytometry, and proteomics effects.
Results: We have shown that passive immunization with an antibody against CD1d reduces neuroinflamation and neurodegeneration. Treatment with the anti-CD1d antibody did not have effects on CD3 (T cells), slightly decreased CD4 and increased CD8 lymphocytes in the mice. Treatment with CD1d antibody blunted this cytokine response that was associated with reduced astrogliosis and microgliosis in the CNS of the α-syn tg mice treated with CD1d antibody. We have also investigated the effects of blocking NFAT signaling with 11R compound and and targeting p38 in models of synucleinopathy and found that neuroinflammtion is an important mediator of synaptic degeneration
Conclusions: These results suggest that reducing inflammation might be a potential therapeutical approach for DLB/PD.

SAFFRON (CROCUS SATIVUS L.) IN ALZHEIMER'S DISEASE: A SYSTEMATIC REVIEW

POSTERS: C02.F. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-INFLAMMATORY, ANTI-OXIDANT

Reza Mosaddeghi-Heris[1], Ali Norouzi Norouzi[2], Mahnaz Talebi[1], Sarvin Sanaie[1], Amirreza Naseri[3]
[1]Tabriz university of medical sciences, Neurosciences Research Center (nsrc), Tabriz, Iran, [2]Tabriz University of Medical Sciences, Tabriz, Iran, Student Research Committee, Tabriz, Iran, [3]Tabriz university of medical sciences, Student Research Committee, Tabriz, Iran

Aims: Animal studies have provided evidence of saffron antidiabetic, anti-inflammatory, anti-atherosclerotic, antitumor, immunomodulatory, and antioxidant effects. Besides, human studies have brought saffron consumption in Alzheimer's disease (AD) patients to a challenge and the outcomes are not the same and can be discussed. This systematic review aims to evaluate the literature on the effect of saffron, as the main therapeutic agent or as the supplementation on AD.
Methods: This systematic review was conducted based on the methods mentioned in the Cochrane Handbook for Systematic Reviews of Interventions and Preferred Reporting Items for Systematic Reviews and Meta-Analyses 2020 (PRISMA) statement. In this study, we electronically searched the databases PubMed, Embase, Scopus, and Web of Science. To be included in the systematic review, a study had to follow the next eligibility criteria: (a) designed as a randomized controlled trial, (b) human studies only; (c) subjects were given saffron orally and compared to either placebo or any approved anti-AD drug or nothing; and (d) cognitive performance was evaluated through objective standardized tests before and after the intervention.
Results: A total of 565 studies were identified in the initial comprehensive search, but only 4 met the criteria. Three studies discovered that saffron significantly improved cognitive outcomes compared to a placebo and only in one study there was no significant difference between the saffron and placebo groups in patients treated with donepezil after 12 weeks.
Conclusions: Saffron, as the main treatment, is found to be beneficial in improving cognitive functions in patients with AD which is comparable to approved drugs for AD with acceptable safety issues. Adding saffron to the main treatments as supplementation may lead to improved inflammation and oxidative stress status.

BERRY GOOD NEWS: (POLY)PHENOL-RICH DIET AS A PREVENTIVE STRATEGY AGAINST PARKINSON'S DISEASE

POSTERS: C02.F. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-INFLAMMATORY, ANTI-OXIDANT

Rafael Carecho[1,2], Ana Filipa Raimundo[1], María Ángeles Ávila-Gálvez[1,3], Hugo Lopes[1], Bernardo Rocha[1], Catarina Pinto[1], Catarina Sequeira[1], Sofia Pereira[1], Natasa Loncarevic-Vasiljkovic[1], Cláudia Nunes Dos Santos[1,2,4]
[1]NOVA Medical School, Molecular Nutrition And Health Lab, Lisboa, Portugal, [2]ITQB, Itqb, Oeiras, Portugal, [3]CEBAS-CSIC, Laboratory Of Food & Health, Research Group On Quality, Safety, And Bioactivity Of Plant Foods, Murcia, Spain, [4]iBET, Ibet, Oeiras, Portugal

Aims: The rising global burden of chronic neurodegenerative disorders, particularly Parkinson's disease (PD), prompts the need for more effective preventive strategies and treatments. (Poly)phenols, natural compounds abundant in plant-derived foods, were studied for their role in preventing or mitigating neurodegenerative diseases. This research endeavored to delve the advantages of a (poly)phenols-rich diet in countering PD's key pathological markers in mice challenged by 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) and to unveil the metabolic fingerprint behind these effects.
Methods: Mice were fed for 6 weeks with a mixture of (poly)phenol-rich foods (comprising blueberries, raspberries, and blackberries) before PD-like phenotype was induced following an acute protocol of MPTP. The study evaluated motor abilities, dopaminergic neurons damage, inflammatory response, and thiolome profile, aiming to develop an in-depth understanding of dietary phenolics' impact on PD brains.
Results: We demonstrated that the berry-enriched diet was able to alleviate motor deficits in the MPTP-intoxicated mice and delayed dopaminergic neuronal damage in the midbrain. Neuroinflammation was ameliorated by attenuating microglial reactivity in MPTP-treated mice fed with berries in midbrain, striatum, and motor cortex and decreasing mRNA levels of pro-inflammatory IL-6. The berry-enriched diet also interfered with the cysteine-related thiolome. Glutathione levels in MPTP-intoxicated mice fed with (poly)phenol-rich food approached those of control levels, indicating an enhanced capacity to manage the oxidative stress resulting from MPTP toxicity.
Conclusions: These results support the potential of a (poly)phenol-rich diet in delaying and alleviating PD-like symptoms. This study contributes to the broader understanding of dietary interventions' role in neurodegenerative disorders, highlighting the potential role of dietary phenolics in preventing or delaying PD progression. **Acknowledgments:** To the European Research Council (ERC) - Grant Agreement No. 804229; to FCT, for financial support of R.C. STUDY OF NEW PHARMACOLOGICAL TARGETS FOR THE TREATMENT OF PARKINSON'S DISEASE

POSTERS: C02.F. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-INFLAMMATORY, ANTI-OXIDANT

Irene Paterniti, Deborah Mannino, Alessio Ardizzone, Salvatore Cuzzocrea, Emanuela Esposito
University of Messina, Chemical, Biological, Pharmaceutical And Environmental Sciences, Messina, Italy

Aims: Objectives: Parkinson's disease (PD) is the second most frequent neurodegenerative disease characterized by progressive and chronic degeneration of dopaminergic neurons in the substantia nigra pars compacta (SNpc). Considered research into the etiological mechanisms of PD has demonstrated that the accumulation of damaged proteins such as the α-synuclein protein, the main component of Lewy bodies, is closely related to the alteration of intracellular mechanisms responsible for the degradation of abnormal proteins and damaged organelles such as autophagy. Therefore, pharmacological induction of autophagy and reduction of neuroinflammation could improve the clearance of intracytoplasmic protein aggregates reducing PD progression. Recent scientific research has showed powerful anti-inflammatory and neuroprotective effects of two N-acylethanolamines: palmitoylethanolamide (PEA) and oleoylethanolamide (OEA). Based on this evidence, the aim of the study was to better test the neuroprotective effects of PEA and OEA and investigate their probable mechanism on autophagic processes in an *in vivo* model of PD induced by 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP).
Methods: Methods: The experimental model of PD involved four intraperitoneal injections of MPTP (20 mg/kg) at two hours intervals in one day. After twenty-four hours PEA and OEA were administered (orally and intraperitoneally, respectively) both at the dose of 10 mg/kg for seven days.
Results: Results: Our results confirmed that administration of PEA and OEA significantly reduced the alteration of the hallmarks of PD, attenuating the neuroinflammatory state. Furthermore, we demonstrated that the neuroprotective effect observed following PEA and OEA treatment could be linked to the modulation of the autophagic pathway.
Conclusions: Conclusions: In conclusion, given the potent neuroprotective effect of PEA and OEA, both molecules could be considered valid therapeutic approaches for the treatment of PD.

ASSOCIATION OF ANTI-INFLAMMATORY THERAPY USE WITH THE INCIDENCE OF PARKINSON'S DISEASE: A PERSON-TIME ANALYSIS AMONG PATIENTS WITH AUTOIMMUNE DISEASES

POSTERS: C02.F. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ANTI-INFLAMMATORY, ANTI-OXIDANT

Michele Potashman[1], Jennifer Haas[2], Ambrish Pandit[3], Dana Stafkey[3], Vlad Coric[4], Wolfgang Singer[5], Gil L'Italien[1]
[1]Biohaven Pharmaceuticals, Inc, Clinical Outcomes Assessments And Health Economics, New Haven, United States of America, [2]Xcenda GmbH (Cencora Inc.), Real World Evidence, Hannover, Germany, [3]Cencora Inc., Heor, Conshohocken, United States of America, [4]Biohaven Pharmaceuticals, Inc, Ceo, New Haven, United States of America, [5]Mayo Clinic, Neurophysiology, Rochester, United States of America

Aims: Examine the association between the incidence of Parkinson's Disease (PD) and anti-inflammatory drug exposure, specifically anti-tumor necrosis factor (anti-TNF) and anti-interleukin (IL)-17, in patients diagnosed with autoimmune disease (rheumatoid arthritis, ulcerative colitis, Crohn's disease, ankylosing spondylitis, or psoriasis/psoriatic arthritis).
Methods: This retrospective cohort study analyzed data from the US Komodo Health claims database (2015-2022). Conditions and therapies were identified using established diagnosis and product codes. The comparative risk of PD associated with anti-TNF/anti-IL-17 exposure was examined by designing two cohorts of patients diagnosed with an autoimmune disease, exposed and unexposed to specified anti-inflammatory treatment. Person-time incidence rates of PD were calculated, and incidence rate ratios (IRRs) derived. Person-time incidence rates (per 100 person-years [PY]) by anti-TNF/anti-IL-17-exposure quintiles were derived to evaluate for a potential treatment response.
Results: Among 2,135,733 patients with an autoimmune disease, 122,319 received anti-TNF/anti-IL-17 treatment and 2,013,414 were untreated. The incidence of PD among the exposed cohort was 0.709 per 100-PY, whereas incidence in the unexposed cohort was 1.013 per 100-PY. The IRR between exposed and unexposed was 0.699 (95% CI: 0.675, 0.726). PD incidence rate by anti-inflammatory drug, anti-TNF or anti-IL-17 only respectively, was 0.713 (95% CI: 0.688, 0.739) and 0.558 (95% CI: 0.451, 0.683). The IRR between anti-IL-17 and anti-TNF therapy suggested anti-IL-17-treated patients have a lower risk of developing PD (0.782 [95% CI: 0.634, 0.965)]. Person-time incidence rates suggested a treatment-response relationship, with an incidence in the lowest and highest exposure quintiles, respectively of 6.221 (95% CI: 5.852, 6.608) and 0.153 per 100-PY (95% CI: 0.135, 0.172).
Conclusions: A lower incidence of PD among anti-TNF/anti-IL-17-treated patients with autoimmune disease was observed. This may suggest that lowering levels of systemic inflammation can reduce the risk of PD.

Aims: Parkinson's disease (PD) is characterized by the loss of dopaminergic neurons (DNs) in the substantia nigra pars compacta (SNpc). The SNpc DNs have an exceptionally high energy demand due to high axonal arborization and autonomous pacemaker activity, which renders the SNpc DNs more vulnerable to mitochondrial dysfunction and oxidative stress. Mesencephalic astrocyte-derived neurotrophic factor (MANF) has been shown to have cytoprotective effects in DNs and other cell types. Although the neuroprotective effects of MANF show promise, MANF function at the cellular level is poorly understood. The aim of this study is to elucidate the cellular and neuroprotective mechanisms of endogenous MANF in the context of oxidative stress.
Methods: In this study, we established an in vitro model to study human dopaminergic neurons. Wildtype and MANF knockout (KO) human embryonic stem cells (hESCs) were differentiated into DNs. Wildtype and MANF KO hESCs and DNs are compared using a wide range of functional assays. We used methods such as RNA sequencing, bioenergetic measurements, and electron microscopy to study the effects of MANF knockout on cell profiles at different developmental time points.
Results: Our results show that MANF KO hESCs differentiate efficiently into DNs. However, the MANF KO hESCs and DNs show deficits in their bioenergetic and antioxidant profiles and increased vulnerability to oxidative stress. In addition, we observe ultrastructural differences between wildtype and MANF KO cells.
Conclusions: Our data on MANF KO hESCs and DA neurons indicate a role for MANF in mitochondrial respiration and protection against oxidative stress.

Aims: With ongoing effort to test and optimize anti-amyloid monoclonal antibodies, the evidence of a significant improvement in cognitive outcome measures without any major side effect concerns is rather limited. We have been studying a novel AD target synaptojanin 1 (synj1), a brain-specific phosphoinositol bisphosphate (PIP_2)-degrading enzyme that modulates lipid homeostasis and endo-lysosomal function. Evidence suggests by reducing synj1, multiple disease processes can be modulated at once.
Methods: We identified an FDA-approved drug, nimodipine that reduces synj1 protein expression. Nimodipine has proven human safety profiles with excellent pharmacokinetic (PK) properties and blood-brain barrier (BBB) penetrability as a starting point for drug discovery. On the other hand, nimodipine manifested some short-term benefits but failed to show any sustained cognitive benefits with chronic treatments in AD mouse models *in vivo*. We then developed nimodipine structural analogs using medicinal chemistry approaches to potentiate its synj1-lowering effects (on-target effects) and reduce its calcium channel activity (off-target effects), which resulted in the discovery of two promising synj1-lowering compounds, Cpd#9 and Cpd#6 as lead candidates.
Results: Two nimodipine derivatives (Cpd#9 and Cpd#6) showed superior beneficial effects *in vitro* and improved oral bioavailability *in vivo*. More importantly, both lead compounds manifested a sustained *in vivo* efficacy of cognitive improvement after chronic oral administration in familial and sporadic AD mouse models. Single-cell RNA-sequencing (scRNA-seq) analysis identified brain cell type-specific changes in microglial signature, reversing disease-related microglial signatures observed in AD human and mouse brains.
Conclusions: In summary, we describe key findings of two novel disease modifying small molecules targeting the brain PIP_2-synj1 pathway that could prevent and slow down cognitive decline in AD mouse models. The mechanisms of action involve changes in microglial signature and modulation of neuro-inflammation.

Aims: Neuron-glia interactions and neuroinflammation may be dysfunctional in neurodevelopmental and neurodegenerative disorders. Complex cell biology in vitro models for investigating such interactions for drug discovery are lacking. We therefore set out to establish high-capacity, high-quality in vitro assays using rodent primary cortical cultures, consisting of neurons and astrocytes with human iPSC-derived (hiPSC) microglia. Our novel assays will investigate neuronal function and cell health and are promising tools for the testing of molecules with the potential to modulate neuroinflammation.
Methods: Chimeric cultures of rodent primary cortical cultures and hiPSC microglia were generated in 384 well-format. After 10-14 days, cell cultures were treated with LPS at different concentrations and timepoints. 1-5 days after LPS addition, neuronal, astrocytic and microglial morphology and TNF-alpha release was quantified. Further, optical electrophysiology was used to investigate effects on neuronal network activity.
Results: The chimeric model resulted in well-integrated hiPSC microglia, with morphology resembling homeostatic microglia, as well as healthy neurons and astrocytes. Addition of LPS resulted in a clear shift of hiPSC microglia to an amoeboid morphology as quantified by HCA, an increased TNF-alpha secretion and an increased electric field stimulation-evoked response. Changes in microglia were aligned with an activated pro-inflammatory status.
Conclusions: The results indicate that it is possible to generate biologically relevant neuroinflammation models for drug discovery, where both morphological and functional phenotypes such as cytokine release and neuronal network activity can be investigated for the functional profiling of molecules developed for clinical use.

ELUCIDATING THE NEUROPROTECTIVE MECHANISMS OF HUMAN MICROGLIAL REPLACEMENT THERAPY IN A MODEL OF PARKINSON'S DISEASE

POSTERS: C02.G. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: MICROGLIA

Sarah Naguib, Eileen Ruth Torres, Maitreyee Bhagwat, Li Fan, Shiaoching Gong, Li Gan
Weill Cornell Medicine, Neuroscience, New York, United States of America

Aims: Microglia are the most prevalent immune cell in the central nervous system (CNS) and interact with neurons in both physiological and pathological conditions. In multiple neurodegenerative diseases, including Parkinson's Disease (PD), microglia become activated and relocate to the site of damage. In our studies we aim to study the roles of both adaptive and innate immunity in PD pathology. Our lab and others have shown that progranulin (PGRN) is important in multiple neurodegenerative diseases, including PD. As such, we aim to implement a PGRN microglial gene therapy approach in order to protect against neurodegeneration.
Methods: We bilaterally injected α-synuclein PFFs into immunodeficient ($Rag2^{-/-}$, $IL2R^{-/-}$, human m-$CSF^{KI/KI}$) and C57Bl/6 mice. We performed behavioral analysis on these mice using the pole test to assess movement disorder phenotypes. For microglial cell replacement, we injected another cohort of immunodeficient mice with PBS or α-synuclein to induce Parkinsonian pathology in the striatum. Two weeks later, we treated mice with control or PLX-5622 diet to deplete microglia and after three weeks, we bilaterally injected PBS, wildtype HPCs, or PGRN-overexpressing HPCs. After four months, we performed similar behavioral analyses.
Results: In examining the role of adaptive immunity in α-synuclein pathology, we found that the immunodeficient mice spent significantly more time completing the pole test than their wildtype controls. After four months, we observed that the spread of α-synuclein was significantly increased in the immunodeficient mice suggesting the necessity for an adaptive immune response to prevent α-synuclein spread.
Conclusions: Using our model, we have demonstrated that microglia are an important component in the progression of neurodegeneration. Together, our results highlight the feasibility of a cell therapy approach to combat neurodegeneration in Parkinson's Disease.

BRAIN-DERIVED NEUROTROPHIC FACTOR DECREASES LEWY BODY-LIKE INCLUSIONS INDUCED BY PRE-FORMED ALPHA-SYNUCLEIN FIBRILS IN MOUSE PRIMARY NEURONS

POSTERS: C02.I. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: PROTEIN AGGREGATION, MISFOLDING, CHAPERONES

Airavaara Mikko Tuomas, Irena Hlushchuk, Veera Kulmala, Tomi Rantamäki, Andrii Domanskyi, Safak Er
University of Helsinki, Faculty Of Pharmacy, Helsinki, Finland

Aims: Parkinson's disease is the second most common progressive neurodegenerative disease characterized by loss of dopamine neurons in the substantia nigra and Lewy bodies - intraneuronal inclusions- as neuropathological hallmarks. The aim of this study is to investigate if brain-derived neurotrophic factor (BDNF) can reduce pre-formed fibril (PFF) induced Lewy body-like alpha-synuclein aggregation in mouse primary dopaminergic and hippocampal neurons.
Methods: Dopaminergic neurons isolated from the ventral midbrain floor of 13.5 mouse embryos were plated in 96-well plates and maintained in a culture medium without neurotrophic factors until the day *in vitro* (DIV)8. Glial cell line-derived neurotrophic factor (GDNF) was used as a positive control since it reduces the aggregation of alpha-synuclein in cultured dopaminergic neurons and the mouse brain. BDNF was added on a DIV8 1 hour after the PFF-treatment, or on DIV12. The cultures were fixed on DIV15 and stained with tyrosine hydroxylase (TH) and phosphoSer129-alpha-synuclein (pS129-alpha-syn) antibodies. Quantifying TH+ neurons and pS129-alpha-syn+ and TH+ neurons was performed with unbiased image analysis using CellProfiler™ software.
Results: and conclusions: Neither GDNF nor BDNF added at the late stages of culturing did not significantly affect the survival of TH+ neurons. Like GDNF, BDNF added either on DIV8 or DIV12 decreased pS129-alpha-syn positive aggregates in dopaminergic neurons. The effect of BDNF was slightly more pronounced when added earlier on DIV8 instead of on DIV12.
Conclusions: BDNF treatment similarly to GDNF treatment decreased the numberr of pasyn-s129-positive neurons in our model system. Research on neurotrophic factors' protective effects on multiple neuropathologies can help the development of new therapies against Parkinson's disease.

Aims: Glucocerebrosidase (GCase) deficiency is linked to pathophysiological features in Parkinson's disease (PD), including heightened endoplasmic reticulum (ER) stress. This dysregulation contributes to the accumulation of misfolded alpha-synuclein, leading to dopaminergic neuron degeneration. This study aims to uncover the mechanism by which GT-02287, Gain Therapeutics' PD drug candidate, targets GCase and impacts the disease's underlying biological processes.
Methods: Gain Therapeutics applied its innovative proprietary drug discovery platform, SEE-Tx™, to the development of orally bioavailable and brain penetrant GT-02287. GCase functionality, ER stress and protein quality control were evaluated in patient-derived fibroblasts harbouring mutated GCase. A mutated GCase-HaloTag-HEK293 cell-based model was used to measure GCase transport to the lysosome.
Results: The L444P GCase mutation delays its conformational maturation in the ER, shown by prolonged association with ER-resident lectin chaperone calnexin. GCase retention in the ER triggers an unfolded protein response, shown by overexpression of ER stress markers BiP and GRP94. GCase retained in the ER is eventually degraded by the ubiquitin-proteasome system. GT-02287 treatment accelerated conformational maturation of mutant GCase, thus promoting release from calnexin. Reduced retention of the mutant protein in the ER alleviated cellular stress, as shown by return to physiological BiP and GRP94 levels and enhanced lysosomal transport. Accordingly, GT-02287 increased lysosomal GCase activity which led to a reduction in levels of its substrate, glucosylceramide.
Conclusions: Through interaction with GCase in the ER, GT-02287 aids correct GCase folding and prevents it undergoing protein quality control-mediated ER retention and ER-associated degradation. Enhanced stability of GCase promotes its release from the ER, alleviating cellular stress and allowing trafficking towards lysosomes, where GCase accomplishes its enzymatic activity. The enhanced lysosomal activity ensures that GCase substrate is efficiently processed, further contributing to cell health.

Aims: Transthyretin (TTR) is a plasma protein known as a transporter of thyroxine and retinol but also can inhibit the formation of amyloid β-peptide (Aβ) fibrils and catalyze the proteolysis of apolipoprotein A-I and Aβ. Here, recombinant TTR is shown to have proteolytic activity against specific conformations of α-synuclein (aSyn), a protein that accumulates in intraneuronal inclusions characteristic of Parkinson's disease (PD). Our discovery stemmed from the observation of a marked decrease in aSyn aggregation in the presence of submicromolar concentrations of TTR.
Methods: We integrate multiple biophysical approaches, including fluorescence spectroscopy, electron microscopy, gel electrophoresis and mass spectrometry to show that the conformation of aSyn must be changed before TTR-mediated proteolysis occurs.
Results: We found that aSyn aggregation is prevented due to the proteolytic cleavage of free aSyn by TTR, in a reaction that is slower for S-glutathionylated TTR and faster for TTR preparations containing vestigial amounts of ~70 kDa TTR oligomers (oTTR). Interestingly, this proteolysis-trigger effect is not unique to oTTR since it can also be induced by Teflon and glass surfaces independently of which TTR preparation is tested.
Conclusions: The link between protein misfolding and the pathogenesis of PD, AD or TTR-related amyloidosis remains poorly defined especially in the non-hereditary forms of such disorders. Our study additionally shows that the proteolytic activity of TTR against aSyn is determined by conformational changes arising from physical interactions of aSyn with solid surfaces. On the side of TTR, S-glutathionylation is shown to influence the proteolytic activity of TTR, probably due to the introduction of steric hindrances to substrate binding. The proteolysis of misfolded aSyn emerges as a possible TTR function with implications for the understanding of different neurodegenerative disorders.

DIRECT CELLULAR REPROGRAMMING IN PARKINSON´S DISEASE USING CRISPR/CAS9

POSTERS: C02.J. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: GENE THERAPY AND GENE EDITING

Iolo Balken
Helmholtz Munich, Institute Of Developemental Genetics, Neuherberg, Germany

Aims: Parkinson´s disease is a neurodegenerative disorder, mainly characterized by the specific degeneration of nigrostriatal dopaminergic neurons in the substantia nigra pars compacta. So far no causal treatment option exists and therapy is primarily symptomatic. However, several attempts are realized utilizing in situ direct cellular reprogramming of somatic cells, like fibroblast or astrocytes, to generate dopaminergic neurons as a curative option. The efficiencies of generating functional dopaminergic neurons were not satisfying so far and it was found that one limitation during reprogramming is induced cell death via apoptosis and ferroptosis. So this work focuses on reducing cell death via apoptosis and ferroptosis in combination with multiplexed *in vitro* and *in vivo* activation of transcription factors to reprogram astrocytes into dopaminergic neurons.
Methods: This is achieved by using a CRISPR/Cas9 activator system to upregulate the transcription factors Ascl1, Lmx1a, Nr4a2 or Ascl1, miR124, miR9, Pitx3, Foxa2 to facilitate the reprogramming and additionally the transcription factors Mcl1 and Bcl2 as well as Gpx4 and Fsp1 to inhibit apoptosis and ferroptosis respectively.
Results: In this ongoing project an improved upregulation of transcription factors used for reprogramming was achieved. Using CRISPRa a sufficient upregulation of transcription factors inhibiting apoptosis and ferroptosis could be established on RNA as well as on protein level. It could be shown that Gpx4 and Fsp1 increase cell viability upon Ferroptosis induction. The beneficial effect of the increased cell viability on direct reprogramming is being analyzed.
Conclusions: Inhibiting Apoptosis and Ferroptosis during direct cellular reprogramming is a suitable method to increase the reprogramming efficiency of astrocytes to dopaminergic neurons. Ongoing *in vivo* experiments are investigating the effect of this reprogramming in a Parkinson´s Disease mouse model.

INTRONIC ENHANCERS OF HUMAN SNCA GENE PREDOMINANTLY REGULATE ITS EXPRESSION PROVIDING NEW TREATMENT TARGET

POSTERS: C02.J. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: GENE THERAPY AND GENE EDITING

Fubo Cheng, Wenxu Zheng, Thomas Ott, Kathrin Grundmann, Olaf Riess
Univesity of Tuebingen, Institute Of Medical Genetics And Applied Genomics, Tuebingen, Germany

Aims: Alpha-synuclein (SNCA) is a key gene in the pathogenesis of Parkinson's disease (PD). Evidences from both human PD patients and SNCA overexpressing transgenic animal models supported that increased human α-synuclein levels contribute to PD pathogenesis. However, little is known about the transcription control of the human SNCA gene in brain. Our previous report showed decreased SNCA expression in both THAP1 patients' iPSCs derived middle brain dopaminergic (mDA) neurons and THAP1 heterozygous knock-out SH-SY5Y cells, but the detailed mechanisms are still unclear.
Methods: In this study, multi-omics approaches combined with multiple cellular and animal models were used to characterize the transcriptional regulation of *SNCA* gene in vitro and in vivo.
Results: We found that THAP1 regulates expression of SNCA through controlling the activities of its promoter and enhancers via both direct and indirect pathways. Chromatin conformation capture analysis proved the physical interaction between the enhancers in intron 4 of the *SNCA* gene and the promoter region. Further luciferase report assay confirmed the role of SNCA intronic enhancer in controlling its expression. Furthermore, knocking-out one enhancer fragment of the *SNCA* intronic enhancer regions in both dopaminergic SH-SY5Y cells repress the expression of SNCA. In our human SNCA transgenic rat models, deletion of the large intronic region drastically reduced the expression of SNCA in the whole brain.
Conclusions: Taking together, our study revealed how DYT6 gene product THAP1 regulates the expression of SNCA, which potentially links two dopaminergic pathway associated diseases. Both in vitro and in vivo data supported the critical role of SNCA enhancers in regulating its own expression, which may provide new gene therapy approaches for SNCA aggregated neurodegenerative diseases.

SYNTHETIC SENSOR-ACTUATOR CIRCUIT FOR UNTANGLING THE COMPLEXITY OF ENVIRONMENTAL ORIGIN OF SPORADIC NEURODEGENERATIVE DISORDERS

POSTERS: C02.J. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: GENE THERAPY AND GENE EDITING

Mychal Grames, Xinli Tian, Madison Elsaadi, Kelsea Keys, Xiao-Hong Lu
LSU Health, Pharmacology, Toxicology, And Neuroscience, Shreveport, United States of America

Aims: PD is the second-most prevalent neurodegenerative disease, where the majority of incidences have no identifiable inheritance and occur in a sporadic form. Environmental risk factors (e.g., pesticide/herbicides, exposure to metals, solvents, PCBs, virus infection, and head trauma) have been speculated as a trigger to sporadic PD.
Methods: To explore the causal and pathogenic evidence of environmental triggers, we exploited long-standing observations that genotoxic DNA damage can significantly increase permissivity to AAV transduction, and host cell DNA damage response (DDR) is an innate antiviral defense mechanism and is thus inhibitory to viral life cycles. We harnessed the recombinant adeno-associated virus (rAAV) genome-processing machinery and the instability of a hypermutable repeat sequence to detect neuronal genomic instability and visualize neurodegeneration in post-mitotic differentiated neurons. Viral genetic probe sensitively detected genotoxic stressed neurons exposed to environmental toxicant Paraquat. Targeted next-generation sequencing validated genetic variation in poly-G repeat on the rAAV genomic region.
Results: Moving beyond traditional genetic perturbation in all cells, we developed a synthetic sensor-actuator circuit as a "Cellular Robot," which enables precise genetic engineering in cells damaged by exposure to environmental toxicants. A genetic actuator was implemented via a Cre-dependable conditional shRNA to knockdown ATM, a major orchestrator of the DDR for slowing down the progression of neurodegeneration. Conditional knockdown of ATM in DNA-damaged burdened cells ameliorated the progression of paraquat-aggravated synucleinopathy, motor decline, and cognitive deficits.
Conclusions: These studies can pave the way for new paradigms to determine the causal and pathogenic roles of environment-driven genotoxic stress in the progression of neurodegenerative disease and highlight potential therapeutic avenues.

Aims: Potential strategies to develop new treatments for Parkinson`s disease (PD) target specific, disease-associated proteins like alpha-Synuclein (aSyn). A promising new approach to lower aSyn protein levels is the therapeutic use of small RNAs. Efficient delivery of small RNA is challenging due to their instability and the need to bypass the blood-brain barrier. Therefore, we developed a nanoparticle-based approach for intranasal delivery of small RNAs, opening this gene therapy strategy to broad clinical application.
Methods: In this project, seven different polymeric nanoparticles (NPs) were tested *in vitro* for their ability to penetrate neuronal cells. Differentiated SH-SY5Y neuroblastoma cells were incubated with NPs loaded with fluorescent-labeled control RNA and evaluated by confocal microscopy. Furthermore, we administered different control RNA-NPs intranasally to aSyn overexpressing (Thy1-aSyn) mice once daily on four consecutive days. For functional experiments, Thy1-aSyn mice received either nanoparticles loaded with small RNA targeting human *SNCA* mRNA (SNCA-NPs) or with control RNA intranasally. Mice were sacrificed and brains collected for immunohistochemical, western blot and qPCR analysis.
Results: All tested NPs were able to penetrate SH-SY5Y neuroblastoma cells. Furthermore, all labeled NPs reached the brain after intranasal application. They distributed extensively across the brain and were detectable in different regions including the olfactory bulb, substantia nigra and prefrontal cortex. Quantitative evaluation revealed that cationic polymers reached the brain in the highest amount. Mice showed no overt adverse behavioral effects nor increased reactivated microglia. After only four days of intranasal administration, SNCA-NPs significantly reduced brain aSyn levels with a polymer-dependent efficacy.
Conclusions: Non-invasive NP-mediated intranasal application of small RNA to aSyn overexpressing mice is able to reduce aSyn levels in the brain and could be a novel therapeutic approach to treat PD.

Aims: Recent works show that blood-brain barrier (BBB) leakage represents a disease-driving feature of PD, as shown by the reduction of tight junction proteins and the increased BBB paracellular permeability in animal models. Accordingly, BBB disruption was also shown in the substantia nigra of PD patients. Here, we screened the effect of a subcommissural organ-spondin-derived peptide (NX210c) known to be beneficial in PD models, on BBB integrity *in vitro* and *in vivo*.
Methods: Mouse endothelial cell (EC) monolayers (bEnd.3) and human BBBs (EC, astrocytes, pericytes) in static or microfluidic conditions, were treated with NX210c (1-100µM), or its vehicle (water). 3- and 21-month-old mice were treated intraperitoneally with NX210c at 10mg/kg or its vehicle for 5 days once a day and brains collected at day6.
Results: In mouse EC, NX210c induced a transient increase in occludin levels after 24h treatment (+37%, 100µM; western-blot). Claudin-5 levels were also increased after 24h (+43%, 100µM) and 72h (immunocytochemistry). Accordingly, NX210c decreased by half the permeability to a 40 kDa-FITC-Dextran and increased transendothelial electrical resistance (TEER). In the human static BBB model, NX210c increased by 30% the TEER at 100µM after 3 and 5 days. NX210c also increased TEER in the human 3D dynamic BBB model at 100µM after 4h, and reduced the permeability to a 4 kDa-FITC-dextran. NX210c restored aging-induced reduction of claudin-5 and occludin levels in the cortex and/or hippocampus. This is in alignment with positive signals of BBB repair after repeated intravenous injections of NX210c in elderly healthy volunteers in a phase 1b clinical trial.
Conclusions: NX210c is a promising drug candidate for modifying PD course, notably by reducing BBB leakage. Therefore, we are now evaluating if NX210c promotes BBB repair in a PD mouse model.

MULTI-TARGETED STRATEGIES TO ARREST PARKINSON'S DISEASE: THE UTILITY OF REPURPOSING DRUGS FOR NEUROPROTECTIVE APPROACHES

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Rita Silva[1,2], Bruna Araújo[1,2,3], Richard Wade-Martins[4], Hugo Fernandes[4], Fábio Teixeira[1,2]
[1]Institute for Research and Innovation in Health (i3S), Neurobiology & Neurologic Disorders, Porto, Portugal, [2]Center for Translational Health and Medical Biotechnology Research, Translational Health And Medical Biotechnology Research, Porto, Portugal, [3]PT Government Associated Lab, Icvs/3b's Associate Lab, Braga, Portugal, [4]University of Oxford, Department Of Physiology, Anatomy & Genetics, Oxford Parkinson's Disease Centre, Oxford, United Kingdom

Aims: Repositioning disease-modifying approaches is imperative to achieve meaningful translational gains in Parkinson's Disease (PD) research. Under this concept, two drugs have demonstrated promising effects in dopaminergic system preservation and PD mechanistic modulation, namely N-acetylcysteine (NAC) and Felodipine (FEL). Therefore, this study aimed to target PD major hallmarks using a multimodal approach combining NAC and FEL's potential neuroprotective/disease-modifying abilities, rather than establishing an isolated approach to modulate PD brain parenchyma and compromised DAn in affected brain regions.
Methods: To better understand the impact of NAC and FEL on DAn functional recovery, a specific cell model of PD (Lund Human Mesencephalic (LUHMES)-derived dopaminergic neurons) was characterized. For recovery studies, cells were treated with 10μM of NAC, 100nM of Felodipine and the combination. As readouts, we evaluated the main mechanisms associated with PD pathology and how our drugs could modulate them. Following this step, we analyzed the most effective therapeutic approach for PD. An in-house PD rat model was used, mimicking PD symptoms and pathology. NAC (1200mg/kg) and FEL (20mg/day) were administered individually or conjugated to study their effect on multiple PD dimensions.
Results: Preliminary in vitro and in vivo studies revealed promising findings. Notably, the treated group appeared to modulate specific mechanisms associated with PD degeneration compared to controls. Indeed, modifications in DAn networks/signaling pathways, functional outcomes, and histological and molecular-cellular features were observed.
Conclusions: In retrospect, with the pilot results acquired in this study, we provided an important proof-of-concept milestone regarding therapeutical combinatorial applications. Following such research approach will allow the development of a targeted-based strategy that can generate clinical benefits, including a novel treatment opportunity for individuals in prodromal stages, potentially delaying clinical manifestation in high-risk patients.

IMPACT OF ABROGATION OF ADULT HIPPOCAMPAL CYTOGENESIS ON PARKINSON'S DISEASE PRE-CLINICAL MODEL

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Bruna Araújo[1,2,3,4], Rita Silva[2,4], Per Svenningsson[5,6], Luísa Pinto[1,3], Fábio Teixeira[2,4]
[1]Life and Health Sciences Research Institute (ICVS), ¬School of Medicine, Neuroscience Domain, Braga, Portugal, [2]Center for Translational Health and Medical Biotechnology Research, School of Health, Porto Polytechnic Institute, School of Health, Porto Polytechnic Institute, Translational Health And Medical Biotechnology Research (tbio), Porto, Portugal, [3]PT Government Associated Lab, Icvs/3b's Associate Lab, Braga, Portugal, [4]Institute for Research and Innovation in Health (i3S), Neurobiology & Neurologic Disorders, Porto, Portugal, Portugal, [5]Karolinska Institutet, Clinical Neuroscience, Stockholm, Sweden, [6]Karolinska Institutet, Department Of Clinical Neuroscience, Stockholm, Sweden

Aims: Deficits in adult hippocampal neurogenesis (AHN) is a common feature of depression and Parkinson's Disease (PD). Indeed, depressive disturbances occur in 40–50% of patients with PD, influencing many clinical aspects of the disease. Adult-born hippocampal cells showed abnormal morphological development and altered differentiation markers' expression, exhibiting singular AHN signatures in PD patients. Additionally, the number of proliferating cells in the subventricular zone and dentate gyrus (DG) was reduced in PD patients and mice models. Since both regions comprise dopaminergic innervation and inputs from the nigrostriatal areas, it has been hypothesized that dopaminergic system may exert some control over or under cytogenic brain regions, representing a promising therapeutic target for depression in PD patients.
Methods: Firstly, we used a transgenic rat (glial fibrillary acidic protein (GFAP)-thymidine kinase (TK)) to induce a PD model. Then, to determine the effect of cytogenic abrogation on a PD pre-clinical model, the antiviral drug ganciclovir was administrated for 18 days. Due to its interaction with TK and its impact on cell replication blockage, the TK-GFAP-TK animals exhibit reduced newborn cells in DG, oppositely to WT-GFAP-TK rats. Since non-motor symptoms play a key role in leading to severe disability, we characterized the anxiety/depressive-like behavior of the animals.
Results: Analysis demonstrated that cytogenesis abrogation may potentiate the anxiety/depressive-like phenotype of PD rats, indicating that the modulation of neurogenesis may have a role in the functional performance of PD.
Conclusions: Understanding the impact of the modulation of AHN and the role of non-motor symptomatology in PD may allow us to study early cellular/molecular and functional alterations promoted by age-related events. By following this, novel perspectives about new potential mechanisms and therapeutic targets could be opened for PD.

INVESTIGATION OF THE MECHANISM OF ACTION OF AN ANTIPARKINSONIAN NEUROPROTECTIVE PEPTIDE

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Gabriel Campos, Diogo Vieira Tibery, Márcia Renata Mortari
University of Brasilia, Institute of Biological Sciences, Department Of Physiological Sciences, Laboratory Of Neuropharmacology, Asa Norte, Brasília, Brazil

Aims: Parkinson's Disease (PD) is a relentless and progressively debilitating neurodegenerative disorder that brings economic, social, and psychological burden to its patients. Neurodegeneration in PD involves multiple cell death pathways, representing a great challenge in pharmacological treatment aiming for neuroprotection. In this work we studied a synthetic peptide bioinspired by a toxin isolated from the venom of the social wasp *Polybia occidentalis*. This peptide, called Neurovespina, has been studied previously, exhibiting a neuroprotective effect in an animal model of parkinsonism induced by 6-OHDA. To investigate the mechanism of action responsible for Neurovespina's neuroprotective effect, we performed binding and reuptake assays, as well as patch clamp assays, targeting two potentially neuroprotective mechanisms.
Methods: We used radioactive glutamate and cortical synaptosomes in receptor binding and reuptake assays to evaluate the effect of multiple concentrations of Neurovespina on glutamate neurotransmission. Neurovespina at a concentration of 50 µM was also studied using the patch clamp whole-cell technique to evaluate inhibition or modulation of voltage-gated calcium channels (Cav 1.2, Cav 1.3, Cav 2.1, Cav 2.2, and Cav 2.3).
Results: We observed no competition between Neurovespina and glutamate on mice cortical receptors, nor modulation of glutamate reuptake on synaptosomes. However, at 50 µM, Neurovespina inhibited calcium current amplitude between 14-18% in all channels tested, and this current inhibition was reversible after washing. Current inhibition occurred without changing the probability of channel opening, as demonstrated by the absence of modulation in the conductance curves.
Conclusions: Our results reveal that Neurovespina inhibits voltage-gated calcium channels. This mechanism is consistent with neuroprotection, as observed with other channel blockers, such as those from the dihydropyridine class. Yet, it is possible that the antiparkinsonian effect this peptide showed is associated with more than one target.

AMANTADINE DIFFERENTIALLY EFFECTS STRIATAL DIRECT AND INDIRECT SPINY PROJECTION NEURONS IN BRADYKINETIC AND DYSKINETIC STATES IN PARKINSONIAN MICE

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Gaurav Chattree[1], Radosław Chrapkiewicz[2], Jane Li[2], Yanping Zhang[2,3], Mark Schnitzer[2,3]
[1]Stanford University, Neurology & Neurological Sciences, Stanford, United States of America, [2]Stanford University, Cnc Program, Stanford, United States of America, [3]Howard Hughes Medical Institute, Hhmi, Stanford, United States of America

Aims: Amantadine is a unique medication that improves both bradykinetic and dyskinetic movements, but its use is limited by serious side effects and its mechanism of action is unknown. **The aim of this study is** to determine Amantadine's effects on striatal direct and indirect spiny projection neurons (dSPNs and iSPNs) in bradykinetic and dyskinetic states to gain insight into Amantadine's mechanism of action. This may be useful for the development of new, improved treatments for Parkinson's disease.
Methods: We used two-photon calcium imaging to simultaneously record the firing activity of dSPNs and iSPNs in the dorsolateral striatum of mice as they ran on a wheel. We first recorded behavior and neural activity in the pre-lesion baseline state, then injected mice with 6-OHDA in the ipsilateral substantia nigra pars compacta (SNc) to induce unilateral dopamine depletion. We then recorded behavior and neural activity in dopamine depleted mice receiving the following intraperitoneal injections: Saline (vehicle control), Amantadine 60mg/kg, L-DOPA 10mg/kg, and L-DOPA 10mg/kg + Amantadine 60mg/kg.
Results: In dopamine depleted mice, compared to Saline alone, Amantadine increased the maximum achieved running speed and mean dSPN calcium event rate per trial. Additionally, compared to L-DOPA 10mg/kg alone, Amantadine (when given with L-DOPA 10mg/kg) reduced the percentage of time mice spent having dyskinetic movements and increased the mean iSPN calcium event rate per trial.
Conclusions: Amantadine improves bradykinesia and increases dSPN activity in dopamine depleted mice. Amantadine also reduces dyskinesias and increases iSPN activity in dopamine depleted mice given high-dose L-DOPA. This data suggests that increasing iSPN activity may be a useful strategy for treating dyskinesias. This could be used to guide the development of selective, novel treatments for dyskinesias with better side effect profiles than Amantadine.

CHANGES IN QUALITY OF LIFE, DEPRESSION, AND SATISFACTION IN WOMEN WITH PARKINSON'S DISEASE FOLLOWING DEEP BRAIN STIMULATION

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Sun Ju Chung[1], Sungyang Jo[1], Kye Won Park[1], Seung Hyun Lee[2], Yun Su Hwang[3], Mi Sun Kim[1,2]
[1]Asan Medical Center, Neurology, Seoul, Korea, Republic of, [2]Seoul Medical Center, Neurology, Seoul, Korea, Republic of, [3]Jeonbuk National University Hospital, Neurology, Jeonju, Korea, Republic of

Aims: To investigate the changes in quality of life (QoL), depression, and satisfaction of women with Parkinson's disease (PD) following deep brain stimulation (DBS).
Methods: This mixed-method case study involved the analysis and categorization of completed interviews with participants. Data were collected through questionnaires, individual in-depth interviews, and a review of electronic medical records. Patients were recruited between December 2019 and April 2020 to gather qualitative data. Additionally, we analyzed quantitative data using the United Parkinson's Disease Rating Scale (UPDRS), Beck Depression Inventory (BDI), and the 39-item Parkinson's Disease Questionnaire (PDQ-39) both before and after DBS implantation.
Results: Twelve women with PD who underwent DBS implantation participated in this study. The average age was 57.5±8.8 years with an average implantation period of DBS of 5.9±5.0 years. The patient's baseline UPDRS part III significantly improved after the surgery (39.3±10.4 vs 25.0±16.8; p=0.038). The axial symptoms (p=0.003) and off duration (p=0.008), and mean modified Hoehn and Yahr stage (p=0.017) significantly improved after DBS implantation. However, PDQ-39 scores (60.3±24.2 vs 56.9±22.7) and BDI scores (20.3±11.5 vs 17.1±7.7) before and after surgery were not significantly different ($0.45<p<0.70$). The reasons for subjective dissatisfaction included "stress due to external changes seen by others," "pain at the implantation site," "reduction in DBS implantation effect," "economic burden of battery replacement surgery," and "anxiety when DBS goes off."
Conclusions: This study found that female patients with PD did not exhibit significant difference in their self-reported quality of life (QoL) and levels of depression before and after the procedure, although they had improvement in motor symptoms after DBS surgery. These results underscore the importance for medical service providers to recognize and address patients' discomfort and concerns from a therapeutic perspective.

TT-P34: A NOVEL FIRST-IN-CLASS PEPTIDE DRUG FOR TREATMENT OF PARKINSON'S DISEASE

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Anders Dalby[1], Nathalie Berge[2], Mathias Ollendorff[1], Simon Jensen[1]
[1]Teitur Trophics, R&d, Aarhus, Denmark, [2]Aarhus University Hospital, Department Of Nuclear Medicine And Pet, Aarhus, Denmark

Aims: TT-P34 is a novel cyclic peptide drug which has been developed by Teitur Trophics, a biotech company based I Aarhus, Denmark. The peptide induces mitochondrial and lysosomal biogenesis through upregulation of master regulators PGC1a and TFEB. It is well established that α-synuclein aggregation and propagation leads to dysfunction of both mitochondria and the lysosomal autophagy system (LAS), resulting in axonal degeneration and neuronal death. Here, we assessed the therapeutic efficacy of TT-P34 as a first-in-class peptide in Parkinson's Disease. The aim was to investigate the potential of TT-P34 to protect against dopaminergic cell loss and reduce pathological α-synuclein inclusions as a result of restoring the affected mitochondrial and lysosomal pathways mitochondrial.
Methods: The peptide was evaluated in two different rodent models; 1) the MPTP mouse model and in 2) a brain-initiated Parkinson's disease rat model using recombinant alpha-synuclein fibrils injected unilaterally into the amygdala of aged (14 months old) rats.
Results: In the MPTP mouse model, once-daily administration of TT-P34 significantly increased locomotor activity in the open field test in a dose-dependent manner as well as completely rescued grip strength. These behavioral improvements were accompanied with significant rescue of TH^+ neurons in substantia nigra pars compacta area (SNc). Once daily treatment with TT-P34 (0.2mg/kg) of the PFF-rat model led to a 75% reduction of α-synuclein inclusions and dramatic increase in TH^+ neurons in SNc.
Conclusions: By driving gene transcription of key regulators, PGC1a and TFEB, in neuronal health TT-P34 offers a unique approach to target multiple affected cellular pathways in Parkinson's. Taken together, this validates the therapeutic efficacy of TT-P34 as a novel and first-in-class drug for Parkinson's Disease and other neurodegenerative diseases.

LONG-TERM EFFECTS OF GLIAL CELL-LINE DERIVED NEUROTROPHIC FACTOR (GDNF) IN HUMANS

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Lotta Granholm[1], John Slevin[2], Anah Gilmore[3], Isaac Colvett[3], Frederick Schmitt[2], Tritia Yamasaki[2], Samuel Guzman[4], Jorge Quintero[5], Craig Van Horne[5], Greg Gerhardt[5]
[1]University of Colorado Denver Anschutz Medical Campus, Neurosurgery, Aurora, United States of America, [2]University of Kentucky, Neurology, Lexington, United States of America, [3]University of Colorado Anschutz Medical Campus, Neurosurgery, aurora, United States of America, [4]University of Colorado Anschutz Medical Campus, Pathology, Aurora, United States of America, [5]University of Kentucky, Neurosurgery, Lexington, United States of America

Aims: Glial cell line-derived neurotrophic factor (GDNF) is a member of the TGF-beta superfamily of growth factors with neurotrophic activity on midbrain dopaminergic neurons and on motoneurons of the brainstem and spinal cord. Our group previously showed that GDNF administration can rescue dopaminergic cell loss in the 6-OHDA lesioned rat and that GDNF knockout mice are born without dopaminergic neurons. Patients with Parkinson's disease (PD) have reduced levels of GDNF and are dependent on GDNF for dopaminergic neuronal survival. This led to the first clinical trials of infusion of GDNF into the putamen of patients with PD. A few years ago, two studies were published, showing modest clinical benefits of GDNF infusion in two different cohorts of patients. We now present data from two *postmortem* brains from patients who received intra-putaminal GDNF infusions over 20 years ago.
Methods: Two patients who received unilateral GDNF infusions died from unrelated causes during the last few years. The brains were extracted, and anatomical regions were dissected and fixed according to the NIA-AA protocol for brain processing. The tissue was paraffin embedded and 5-micron sections were de-paraffinized and processed for immunohistochemistry, using antibodies directed against tyrosine hydroxylase (TH) and alpha-synuclein. The following brain regions were investigated: middle frontal gyrus, the head of the caudate nucleus, putamen/globus pallidus, and substantia nigra.
Results: Preliminary studies support an increase in TH innervation in the putamen of the GDNF-infused hemisphere. In depth bilateral comparisons of innervation densities are currently ongoing.
Conclusions: Preliminary data suggest that a 24-month infusion of GDNF gave rise to a long-lasting increased dopaminergic innervation in the ipsilateral putamen, suggesting that longer term infusions of GDNF may produce more sustained effects on damaged dopamine neurons.

GOLEXANOLONE, A GABAA RECEPTOR-MODULATING STEROID ANTAGONIST, IMPROVES FATIGUE, ANXIETY, DEPRESSION AND SOME COGNITIVE AND MOTOR ALTERATIONS IN 6-OHDA RATS

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Yaiza María Arenas Ortiz[1,2], Paula Izquierdo-Altarejos[1], Mar Martinez-García[1], Gergana Mincheva[1], Magnus Doverskog[3], Thomas P. Blackburn[3], Marta Llansola[1], Vicente Felipo[1]
[1]Centro de Investigación Príncipe Felipe, Neurobiology, valencia, Spain, [2]INCLIVA, Neurological Impairment, valencia, Spain, [3]Umecrine Cognition AB, Umecrine Cognition Ab, Solna, Sweden

Aims: Enhanced GABAergic neurotransmission contributes to Parkinson's disease (PD) pathogenesis and to some motor and non-motor symptoms. In animal models, GABA levels are increased in substantia nigra pars compacta, leading to reduced expression of tyrosine hydroxylase (TH) in neurons which contributes to the behavioural deficits. The aim was to evaluate whether treatment with golexanolone, a well-tolerated $GABA_A$ receptor-modulating steroid antagonist in clinical development, that reduces $GABA_A$ receptors activation and neuroinflammation, may improve some motor and non-motor deficits in a rat model of PD.
Methods: We used the unilateral 6-OHDA rat model. Rats positive in the apomorphine-induced rotation test were included, together with sham-operated controls. Golexanolone treatment (50 mg/kg, daily, intragastric) started four weeks after surgery. Motor symptoms were assessed by motorater and CatWalk tests. The following non-motor behaviour was evaluated: fatigue (treadmill), anhedonia (sucrose preference test), anxiety (open field) and short-term memory (Y maze). Neuroinflammation and key proteins involved in PD pathogenesis were analyzed by immunohistochemistry and western blot
Results: 6-OHDA rats showed impaired motor coordination and locomotor gait alterations measured by motorater and CatWalk tests. Golexanolone treatment improved motor coordination and reversed some of the locomotor gait alterations. Regarding non-motor deficits, 6-OHDA rats showed increased fatigue in the treadmill test, anxiety in the open field test, anhedonia in the sucrose preference test and impaired short-term memory in the Y maze. These alterations were reversed by golexanolone treatment. Golexanolone also reversed some neuroinflammation parameters.
Conclusions: Golexanolone treatment may be useful to improve different symptoms that affect the patients' quality of life: anxiety, depression, fatigue, some aspects of motor coordination and locomotor gait, and some cognitive alterations. These beneficial effects would be due to a reduction of GABAergic neurotransmission and neuroinflammation.

ASSESSING BIOINSPIRED PEPTIDE FRATERNINE-24 ANTOPARKINSONISM EFFECT IN MICE AND RATS IN 6-OHDA PARKINSON'S DISEASE MODEL

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Caio De Azevedo, Márcia Renata Mortari, Andréia Mayer, Gabriel Campos, Henrique Amaral, Danilo De Oliveira, Solange Rego, Adolfo Carlos De Souza, Raffael De Castro, Anamélia Bocca
University of Brasilia, Institute of Biological Sciences, Department Of Physiological Sciences, Laboratory Of Neuropharmacology, Asa Norte, Brasília, Brazil

Aims: Develop a peptide bioinspired in the natural form Fraternine, which presented promising effects for treating Parkinson. Fraternine presented neuroprotective effects and improvement in motor coordination, however, it is quickly degraded from blood serum. Consequently Fraternine-24 was developed looking to, improve motor coordination model, reduce the activation of the microglia and proinflammatory cytokines levels and decrease dopaminergic neurons depletion in the *Substantia Nigra* (SN).
Methods: Therapeutic efficacy was evaluated using 6-OHDA toxin model, the peptide was delivered through a guide canula, the doses were 20, 10 and 5 µg/animal. The tests utilized were apomorphine-induced rotational behavior test to assess the lesion and two Rotarod test for motor coordination. Neuronal depletion was assessed through counting TH-reactive cells and comparing the 6-OHDA-lesion side and the non-lesion side. Pro-inflammation rates were measured with capture enzyme-linked immunosorbent assay, accounting for TNF-α, IL-1β and IL-6.
Results: Fraternine-24 did not present significant difference in the Rotarod tests in comparison to the 6-OHDA group. The dose 20µg/animal was the only one to stay less time in the rotarod then the SHAM group suggesting neuromuscular toxicity. All doses had a lower number of rotations when compared to the L-DOPA group in the Apomorphine test. Furthermore, the highest dose showed significantly different from the 6-OHDA group. Dose 10µg/animal and 20µg/animal presented more dopaminergic neurons than 6-OHDA group, having significant difference.
Conclusions: Fraternine-24 exerted a potential neuroprotective and anti-inflammatory effect in the 6-OHDA-induced model of hemiparkinsonism. The dose of 20 µg/animal preserved dopaminergic neurons in the SN and reduced apomorphine-induced rotations. However, it did no effect motor coordination, and the higher dose was toxic possibly causing motor impairment. Toxicity is a challenged that requires further studies. This work was supported by FAPDF, CAPES and CNPq.

SINEUPS: A NOVEL RNA TOOL FOR THE NEUROPROTECTION OF DOPAMINERGIC NEURONS IN PARKINSON'S DISEASE

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Carlotta Bon[1], Bianca Pierattini[1], Stefano Espinoza[2], Sabrina D'Agostino[1], Gloria Ros[1], Omar Peruzzo[1], Piero Carninci[3], Francesca Persichetti[2], Remo Sanges[4], Claudio Santoro[2], Stefano Gustincich[1]
[1]Istituto Italiano di Tecnologia, Rna Lab, Genova, Italy, [2]Universita' del Piemonte Orientale, Department Of Health Sciences And Research Center On Autoimmune And Allergic Diseases (caad), Novara, Italy, [3]Human Technopole, Genomics Research Center, Functional Genomics Programme, Milano, Italy, [4]SISSA, Area Of Neuroscience, Trieste, Italy

Aims: SINEUPs are a functional class of natural and synthetic antisense long non-coding RNAs that enhance the translation of partially overlapping sense mRNAs. Their activity depends on the combination of two domains: the overlapping region that dictates the specificity, and the embedded inverted SINEB2 element that acts as the effector domain controlling the enhancement of mRNA translation (Carrieri *et al.*, Nature 2012). By artificial engineering, synthetic SINEUPs can increase the translation of virtually any target gene of interest. We have previously developed active SINEUPs for the Glial cell-derived neurotrophic factor (GDNF), which is a well-established neurotrophic factor promoting the survival of dopaminergic (DA) neurons and a potential agent to halt neurodegeneration in Parkinson's disease (PD). Upon stereotaxic injection of AAV-SINEUP-GDNF, endogenous GDNF protein levels increased up to 3-fold and ameliorated motor deficits and neurodegeneration of DA neurons in a PD neurochemical mouse model (Espinoza *et al.*, Molecular Therapy 2020). Yet, several pieces of evidence suggest the need for additional SINEUPs targeting genes, which increased expression could be combined to efficiently protect DA neurons *in vivo*.
Methods: We designed SINEUP RNAs for GDNF and RET and multiSINEUPs targeting both transcripts at the same time. SINEUP activity was evaluated by measuring endogenous GDNF and RET protein levels by western blot. Their post-transcriptional control of target gene expression was monitored with qRT-PCR.
Results: Here we show that single and multi-target SINEUP RNAs can increase endogenous protein levels of molecules with therapeutic interest by about 2-fold.
Conclusions: Our study provides first evidence that multiSINEUPs can increase endogenous levels of more than one candidate therapeutic molecule for PD at the same time paving the way for a new RNA therapeutic strategy for multitarget drugs in neurodegenerative diseases.

THE PREVENTIVE EFFECTS OF ANGIOTENSIN-CONVERTING ENZYME INHIBITORS ON THE PNEUMONIA IN PATIENTS WITH PARKINSON'S DISEASE

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Aryun Kim[1], Jun Yeon Cho[2]
[1]Chungbuk National University Hospital, Department Of Neurology, Cheongju, Korea, Republic of, [2]Chungbuk National University Hospital, Department Of Internal Medicine, CHEONGJU-SI, Korea, Republic of

Aims: Cough is one of the most common adverse events of angiotensin-converting enzyme (ACE) inhibitors. Previously, there has been controversy on the protective effect of ACE inhibitors on pneumonia in the general population and patients with stroke possibly related to this adverse event. We aimed to elucidate the effects of ACE inhibitors on the pneumonia in patients with Parkinson's disease.
Methods: We analysed National Health Insurance System (NHIS) database in South Korea from January 1, 2004 to December 31, 2019. The inclusion criteria are; (1) Older than 40 years, (2) Newly diagosed Parkinson's disease (PD) with V124 code, (3) Hypertension previous than PD. They were devided into two groups including ACE inibitor users and non-users.
Results: The total number of patients was 1,302,897. The number of each group was 38,919 when matched by sex, age, disease duration, and Charlson Comorbidity Index (CCI). More bacterial pneumonia developed in patients with female gender, older age, history of pneumonia in the previous year, higher CCI score, and longer disease duration. The strongest risk factor was history of pneumonia during the previous year. In addition, use of ACE inhibitors for any duration did not affect the incidence of pneumonia. It decreased the risk of pneumonia only when used for more than 60 days.
Conclusions: According to our nation-wide cohort study, ACE inhibitors can decrease the risk of aspiration pneumonia in patients with PD. However, its preventive effects are significant only during the period of use.

EXPLORING THE MULTIPLE MECHANISMS UNDERLYING HER-096 NEUROPROTECTION AND REGENERATION

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Natalia Kulesskaya, Kira Holmström, Henri Huttunen
Herantis Pharma, Scientific Department, Espoo, Finland

Aims: HER-096 is a brain-penetrating peptidomimetic derived from the active site of human CDNF protein and is developed as a disease-modifying treatment for Parkinson's disease. The aim of this study is to improve understanding of the multimodal mechanism of action of HER-096.
Methods: In vivo effects of HER-096 were studied in an aged mouse model with intranigral injection of alpha-synuclein oligomers and systemic glucocerebrosidase inhibition. HER-096 was administered subcutaneously three times a week starting one week after alpha-synuclein injection. Neurotransmitter, metabolite and protein levels were analysed from nigrostriatal lysates by mass spectrometry and immunoassays. Transcriptomic changes were analysed from dissected striatum and substantia nigra and spatial transcriptomics focused on substantia nigra. Regenerative mechanisms were studied using hiPSC motor neuron cultures in microfluidic chambers which were subjected to mechanical axotomy. Corresponding changes in protein biomarker levels both in vivo and in vitro will also be studied.
Results: In the aged mouse synucleinopathy model, HER-096 protected dopamine neurons and reduced alpha-synuclein aggregation. This was accompanied by normalized nigrostriatal levels of dopamine and dopamine turnover correlating with improved motor function (bar walking test, grid walking test). Protein levels of tyrosine hydroxylase and dopamine transporter were increased supporting the increased number of dopamine neurons and terminals. In an axotomy model, HER-096 strongly enhanced axonal regeneration of hiPSC motor neurons, without affecting non-axotomized motor neurons. The on-going transcriptomic and protein biomarker analysis is expected to provide further insight into underlying multimodal biological mechanisms.
Conclusions: A multi-omics approach was employed to uncover the multimodal mechanism underlying the effects of HER-096 on functional recovery in chronic and acute degeneration. Our results suggest that HER-096 promotes functional recovery and regeneration of stressed neurons via multiple complementary ways.

NX210C PEPTIDE: A PROMISING DRUG CANDIDATE FOR NEUROPROTECTION IN PARKINSON'S DISEASE

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Sigihld Lemarchant[1], Juliette Le Douce[1], Alexandre Henriques[2], Noëlle Callizot[2], Yann Godfrin[1,3]
[1]Axoltis Pharma, -, Lyon, France, [2]Neuro-Sys, -, Gardanne, France, [3]Godfrin Life-Sciences, -, Caluire-et-Cuire, France

Aims: PD is characterized by the accumulation of α-synuclein and blood-brain barrier disruption, thereby contributing to the loss of dopaminergic neurons in the substantia nigra. Here, we have evaluated the effect of a subcommissural organ-spondin-derived peptide (NX210c) on PD progression using *in vitro* and *in vivo* rat models.
Methods: Primary rat dopaminergic neurons were exposed for 48h to human α-synuclein and treated simultaneously with NX210c (100, 250, 500 µg/mL) or its vehicle (water), or to 6-OHDA and then treated for 2h with NX210c or its vehicle. Neuronal survival, neurite growth, microglial activation and/or α-synuclein aggregation were evaluated by immunocytochemistry. Sprague Dawley rats were subjected to an injection of AAV1/2-hA53T-α-synuclein or an empty AAV (control) in the substantia nigra, and treated 2 days later with NX210c at 2.5, 5 or 10 mg/kg and then once a day for 41 days. Rats were sacrificed on D42 to measure dopamine levels (LC-MS/MS), dopamine transporters (autoradiography), and α-synuclein aggregation (ELISA) in the striatum.
Results: NX210c reduced α-synuclein-induced neurite network retraction, neuronal death and microglial activation in dopaminergic neuron cultures, when applied in parallel of α-synuclein regardless of the dose used. Dopaminergic neurons were also protected from 6-OHDA when post-treated for 2h with NX210c at 500 µg/mL, likely due to the decrease in α-synuclein aggregation (-71%, $p=0.004$, $n=4$-5). *In vivo*, daily treatment with NX210c at 5 mg/kg significantly increased dopamine levels and its transporters in the striatum compared with that of untreated PD rats ($n=9$-11, $p<0.05$. No effect was observed at 2.5 and 10 mg/kg. In this model, NX210c did not reduce α-synuclein aggregation ($p>0.05$).
Conclusions: NX210c is a promising drug candidate for reducing neuropathological changes in PD, notably the loss of dopaminergic neurons.

GAMMA AUDITORY STIMULATION CONTRIBUTES TO NEUROMODULATORY EFFECTS ASSESSED BY EEG IN PARKINSON'S DISEASE RAT MODEL

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Sheng Ke Lin[1,2], Jun-Qi Huang[1,2], Hou-Hsuan Lee[2], Chi-Wei Kuo[2], Tsung-Hsun Hsieh[2]
[1]Chang Gung University, Department Of Biomedical Sciences (master's Program In Clinical Trials Assessment), Taoyuan City, Taiwan, [2]Chang Gung University, School Of Physical Therapy And Graduate Institude Of Rehabilitation Science, Taoyuan City, Taiwan

Aims: Parkinson's disease (PD) is the second most prevalent neurodegenerative disorder. Previous studies on PD have suggested that alterations in abnormal electroencephalography (EEG) patterns may reflect the neural communication and underlying neuronal dysfunction. Additionally, studies have demonstrated that gamma-frequency sensory stimulation could improve the cognitive and memory functions in Alzheimer's disease mouse model. However, the effects of gamma-frequency sensory stimulation on PD remain uncertain. Therefore, this current research specifically aims to apply the PD animal model to investigate the neuromodulatory effects following gamma auditory stimulation.
Methods: 6-hydroxydopamine (6-OHDA) was injected into the left medial forebrain bundle to induce a hemiparkinsonian rat model. EEG data were collected using five electrodes implanted in the left/right frontal lobes, parietal lobe, and occipital cortex. The EEG data were then analyzed across multiple frequency bands (delta, theta, alpha, beta, low/high gamma) within a time frame that included pre-, during-, and post-gamma auditory stimulation.
Results: We observed a decrease in EEG power especially in low-gamma frequency (30-48 Hz) in the sham-PD lesion rats after stimulation compared to pre-stimulation period. Additionally, a similar pattern was found in the PD rats, indicating a reduction in low-gamma frequency following gamma auditory stimulation.
Conclusions: This study demonstrated the role of gamma auditory stimulation in neuromodulation, as assessed by EEG, in a PD rat model. Future research could focus on enhancing gamma frequency oscillations with the purpose of improving motor cortex plasticity in PD.

EFFECT OF EARLY DEEP BRAIN STIMULATION IN THE PARKINSON'S DISEASE RODENT MODEL INDUCED BY INTRACEREBRAL INFUSION OF 6-HYDROXYDOPAMINE.

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Miguel Cesar Merino Ruiz[1], Gabriely Penha[2], Ingrid Araujo[2]
[1]Sarah Network of Reabilitation Hospitals, Neurologic Rehabilitation., Brasília, Brazil, [2]Unb, Neuropharmacology, Brasília, Brazil

Aims: - To test the early brain stimulation model in the rodent model of Parkinson's disease (PD) induced by 6-hidroxidopamine (6-OHDA).
- To develop a deep brain stimulation device to be used in mice after induction of hemiparkinsonism by injection of 6-OHDA.
- Evaluate the motor response in different behavioral tests (rotarod test, apomorphine and cylinder test).
- To evaluate the impact of deep brain stimulation on the animals clinical condition.
Methods: Animals: Swiss mice (20 to 35g) were allocated to 3 experimental groups by simple randomization. Each group consisted of 8 individuals and was structured as follows: Group 1: DBS implants, activated, and left nigrostriatal lesion (6-OHDA + DBS). Group 2: DBS implants, inactive, and left nigrostriatal lesion (6-OHDA). Group 3: No DBS implant and no nigrostriatal lesion (Naive). Parkinsonism was induced by injecting 6-hydroxydopamine (6-OHDA) into the left striatum, and at the same time, a deep brain stimulation electrode was implanted in the ipsilateral subthalamic nucleus. High-frequency deep brain stimulation (DBS) using constant current square waves (130 Hz, 60 μs, 100 μA) were delivered for a period of 3 hours a day, for four days. To quantify DBS impact, we performed the Cylinder test and Rotarod test, as well as corporal mass changings.
Results: We found favorable responses in the animals submitted to DBS when compared to parkinsonian mice without brain stimulation, in terms of recovery of body mass and motor performance recorded by the cylinder and rotarod tests.
Conclusions: Early DBS in the rodent model of Parkinson's Disease shows effectiveness in corporal mass recovery, as well as motor performance improvement.

EVALUATION OF THE ANTIPARKINSONIAN EFFECT OF FRATERNINE-10 IN MICE AND RATS IN MODEL OF PARINSON'S DISEASE

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Márcia Renata Mortari, Andréia Mayer, Henrique Amaral, Danilo De Oliveira, Gabriel Campos, Solange Rego, Adolfo Carlos De Souza, Raffael De Castro, Anamélia Bocca
University of Brasilia, Institute of Biological Sciences, Department Of Physiological Sciences, Laboratory Of Neuropharmacology, Asa Norte, Brasília, Brazil

Aims: This study aimed to synthesize the peptide Fraternine-10 based on the natural fraternine, which had demonstrated neuroprotective properties against dopaminergic lesions induced by 6-OHDA. However, the original peptide was quickly degraded in the bloodstream, so improving its properties was crucial. Fraternine-10 was designed to reduce the levels of inflammatory mediators TNF-α, IL-6, and IL-1ß in the cortex, enhance motor coordination, and decrease the loss of dopaminergic neurons through a neuroprotective effect.
Methods: The 6-OHDA-induced Parkinson's disease model was used to assess therapeutic efficacy in vivo, with Fraternine-10 administered intracerebroventricularly at three doses (10, 5 and 1 µg/animal). Motor coordination was evaluated using the Rotarod test. An apomorphine-induced test was conducted to assess the degree of lesion. Immunohistochemistry was employed to evaluate neuronal depletion in the Substantia Nigra, with TH-reactive cells counted on both lesioned and non-lesioned sides. Cytokine levels were measured using a capture enzyme-linked immunosorbent assay. The peptide's interaction with glutamatergic neurotransmission was tested using binding techniques with rat cerebral cortex.
Results: Fraternine-10 had a theoretical molecular mass of 1,456.71 Da and a theoretical isoelectric point of 9.70. Doses of 5 and 10 µg/animal on day 2 showed a difference compared to the Control group. In the six-hour Rotarod test, the group treated exhibited significant differences in time but not between treatments. Treated animals spent less time on the Rotarod than the SHAM group at all three doses, indicating neuromuscular toxicity. Fraternine-10 did not show a significant difference in cytokine levels or in glutamate binding.
Conclusions: Fraternine-10 improved motor coordination in 6-OHDA-lesioned animals. However, it did not reduce inflammatory mediators and exhibited toxic effects. While promising, toxicity and effectiveness remain challenges to be addressed. This work was supported by FAPDF, CNPq e CAPES.

IN VIVO EFFICACY AND TOLERABILITY OF SNP614, A LRRK2 ANTISENSE OLIGONUCLEOTIDE AS POTENTIAL THERAPEUTIC AGENT FOR PARKINSON'S DISEASE

POSTERS: C02.K. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: ASO AND RNAI

Dai-Shi Su[1], Irene Riera Tur[2], Andreas Zembrzycki[1], Yuka Martens[1], Marta Reyes Jiménez[2], Sven Michel[2], Richard Klar[2], Frank Jaschinski[2], Guojun Bu[1], Min Li[1]
[1]SciNeuro Pharmaceuticals, R&d, Rockville, United States of America, [2]Secarna Pharmaceuticals, R&d, Munich, Germany

Aims: Parkinson's disease (PD) is a progressive neurodegenerative disorder characterized by the degeneration of dopaminergic neurons in the substantia nigra and a deficiency of dopamine in the striatum. Pathogenic mutations in the Leucine-Rich Repeat Kinase 2 (LRRK2) gene are strong genetic risk factors for PD. The majority of disease-associated LRRK2 mutations lead to increased LRRK2 kinase activity that disrupts multiple aspects of normal cellular physiology. Our objective is to develop therapeutic agents capable of reducing LRRK2 mRNA to broadly lower PD-associated LRRK2 overactivation in the central nervous system (CNS).
Methods: By performing *in silico* design and cellular screening, a series of antisense oligonucleotides (ASOs) against LRRK2 have been isolated. Here, we describe *in vivo* activities and safety assessments of SNP614, one of the leading candidates.
Results: The candidate ASOs targeting different regions of *LRRK2* effectively knocked down the LRRK2 expression, reduced LRRK2 protein levels, and attenuated its downstream signaling, as demonstrated by reduced phosphorylation of a LRRK2 substrate, RAB10, in human cells. In both rodent and non-human primate (NHP), SNP614 substantially decreased LRRK2 mRNA and protein levels in broad CNS regions of therapeutic interest. Furthermore, the selected ASOs including SNP614 were well-tolerated in the tested animals.
Conclusions: We report the discovery of ASOs that reduce LRRK2 mRNA levels to broadly lower PD-associated LRRK2 overactivation in CNS. These ASOs are potent, efficacious, and well-tolerated, and have excellent potentials to be developed as therapeutic agents for PD.

EFFECTS OF COMBINED EXCITATORY THETA BURST STIMULATION AND VIDEO GAME-BASED TRAINING ON DEXTERITY IN PARKINSON'S DISEASE: A RANDOMIZED TRIAL

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Manuela Pastore-Wapp[1], Brigitte Kaufmann[1], Thomas Nyffeler[1], Cornelia Cox[1], Tobias Nef[2], Stephan Bohlhalter[1], Tim Vanbellingen[2]
[1]Luzerner Kantonsspital, Klinik Für Neurologie Und Neurorehabilitation (knn), Luzern, Switzerland, [2]University Bern, Artorg Center For Biomedical Engineering Research, Gerontechnology And Rehabilitation Group, Bern, Switzerland

Aims: Persons with Parkinson's disease (PD) are often faced with difficulties performing dexterity-related activities of daily living (ADL) (such as buttoning, writing). The present study aimed to investigate the efficacy of combined excitatory intermittent theta burst stimulation (iTBS) over supplementary motor area (SMA) with video game-based dexterity training (VBT) to improve dexterity-related ADL in PD.
Methods: This single-blinded, stratified (Hoehn & Yahr), randomized, sham-controlled trial included 30 persons with PD (mean age: 67.2 years, duration of PD: 5.4 years, range: 0.3-18.25 years). They received either iTBS (n=15) or sham (n=15) stimulation over SMA (contra-lateral to most affected hand) followed by a 45-min VBT, three times a week for three weeks. The dexterity questionnaire 24 (DextQ-24: dexterity related ADL, primary outcome), the Parkinson's Disease Questionnaire 39 (PDQ-39: quality of life), coin rotation task (CRT) and the nine-hole peg test as secondary outcomes were assessed before and immediately after the intervention.
Results: There were no drop-outs, and +-90% of the patients adhered to the training protocol. The analysis revealed some effects für dexterity-related outcome. Significant effects for quality of life were found, overall ($p = .044$).
Conclusions: This is the first randomized sham-controlled combined iTBS video game-based intervention which evaluated the effects of a short three-week training program to improve dexterity-related ADL in PD. Further larger well-powered RCT's are needed, including more severely affected persons with PD, to further explore the impact of such combined approaches.

BIOINSPIRED PEPTIDE FRATERNINE-14 EFFECTS ON 6-OHDA-INDUCED MOUSE AND RAT MODELS OF PARKINSON'S DISEASE

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Maria Clara Resende[1], Andréia Mayer[2], Henrique Amaral[2], Danilo De Oliveira[2], Adolfo Carlos De Souza[2], Gabriel Campos[2], Solange Rego[2], Raffael De Castro[2], Anamélia Bocca[2], Márcia Renata Mortari[2,3]
[1]Institute of biological sciences/ University of Brasilia, Department Of Physiological Sciences, Brasília, Brazil, [2]University of Brasilia, Institute of Biological Sciences, Department Of Physiological Sciences, Laboratory Of Neuropharmacology, Asa Norte, Brasília, Brazil, [3]Institute of Biological Science, Department Of Physiology, Brasília, Brazil

Aims: The peptide fraternine, present in the venom of the wasp *Parachatergus fraternus*, has shown neuroprotective capacities against 6-OHDA dopaminergic lesions. However, such peptide has a very low bioavailability. In light of these findings, the aim of this work is to synthesize the peptide Fraternine-14 inspired by the natural fraternine, analyzing its effects over motor coordination, levels of TH+ neurons in the substantia nigra pars compacta (SN), and inflammation mediators TNF-α, IL-6, and IL-1ß in the cortex.
Methods: Maldi TOF/TOF mass spectrometry (MS/MS) was used to determine Fraternine-14's sequence and molecular mass. The 6-OHDA Parkinsonism model was employed for *in vivo* experiments with male Swiss mice (Mus musculus) and Wistar rats in order to investigate the therapeutic efficacy of the peptide. A guide canula was used for its administration, with doses of 10, 5 and 1 µg/animal. Rotarod and apomorphine-induced rotational behavior tests were used to analyze the lesion and motor coordination. TH-reactive cells were counted comparing the 6-OHDA lesion side and non-lesion side to quantify neuronal depletion.
Results: Fraternine-14 reduced the intensity of the lesion caused by 6-OHDA. In the apomorphine rotation test, animals treated with Fraternine-14 at a dose of 5 µg/animal showed a longer stay in the equipment, which may be linked to the reduction of the severity of motor incoordination of the animals.
Conclusions: Motor coordination in 6-OHDA lesioned animals was improved by Fraternine-14. However, the peptide did not reduce inflammatory mediators. It also exhibited toxic effects when in higher doses. These results show that Fraternine-14 is a promising peptide in regards to Parkinson's Disease treatment, but further research is necessary in order to improve its effectiveness and toxicity. This work was supported by FAPDF, CAPES and CNPq.

AT1 RECEPTOR AUTOANTIBODIES MEDIATE EFFECTS OF METABOLIC SYNDROME ON DOPAMINERGIC VULNERABILITY

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Ana Isabel Rodríguez Pérez[1,2], Maria A. Pedrosa[1], Carmen M. Labandeira[3], Rita Valenzuela[1,2], Jose L Lanciego[2,4], José Luis Labandeira-Garcia[1,2]
[1]Cellular and Molecular Neurobiology of Parkinson´s disease, Research Center for Molecular Medicine and Chronic diseases (CIMUS), Idis, Santiago de Compostela, Spain, [2]CIBERNED, Networking Research Center On Neurodegenerative Diseases, Madrid, Spain, [3]University Hospital of Ourense, Neurology Service, Ourense, Spain, [4]CIMA, University of Navarra, Pamplona, Spain, Neurosciences Division, Pamplona, Spain

Aims: Metabolic syndrome (MetS) is associated with chronic peripheral inflammation and is related to Parkinson's disease (PD). Previous studies have involved the brain renin-angiotensin system (RAS) in PD progression and the angiotensin receptor type 1 (AT1) has been revealed as a major marker of dopaminergic vulnerability in humans. Tissue RAS dysregulation is a key common mechanism for all MetS components. Circulating AT1 agonistic autoantibodies (AT1-AAs) have been observed in several inflammation-related peripheral processes, and activation of AT1 of endothelial cells, dopaminergic neurons, and glial cells has been observed to disrupt blood-brain barrier and induce neurodegeneration, respectively. in this work, we studied if AT1-AAs and ACE2-AAs (antagonist Angiotensin-converting enzyme II autoantibodies) are increased in MetS and if these autoantibodies may mediate an enhancing effect of MetS on dopaminergic death and PD.
Methods: Experiments were carried out in an animal model of MetS and results were confirmed in humans.
Results: MetS causes overactivity of the nigral pro-inflammatory RAS axis, increasing oxidative stress and neuroinflammation and accelerating dopaminergic neurodegeneration. AT1 receptor blockers (ARBs) prevented the dopaminergic neurodegeneration. MetS increased the levels of 27-hydroxycholesterol, LIGHT, and major pro-inflammatory cytokines in rat serum which also showed a significant increase in levels of AT1-AAs and ACE2-AAs. AT1-AAs and ACE2-AAs were also found in CSF. Chronic infusion of AT1-AAs, which disrupted the blood-brain barrier, increased pro-inflammatory RAS activity and dopaminergic neuron death. Observations in rat models were confirmed in a cohort of Parkinsonian and non-parkinsonian patients with or without MetS.
Conclusions: The present results show that peripheral chronic inflammatory processes, such as those observed in the MetS, can induce the production of AT1 and ACE2 autoantibodies in serum and CSF, which may disrupt the blood-brain barrier and increase the progression of neuroinflammation and dopaminergic neurodegeneration.

IMMEDIATE EFFECTS OF TRANSCUTANEOUS ELECTRICAL STIMULATION ON DYSPHAGIA IN PD PATIENTS

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Nobutaka Sakae[1], George Umemoto[2], Akihiro Watanabe[1], Hajime Arahata[1], Akifumi Yamamoto[1], Naokazu Sasagasako[1]
[1]National hospital organization Omuta national hospital, Neurology, Omuta City, Japan, [2]Swallowing Disorders center, Fukuoka University Hospital, Fukuoka, Japan

Aims: We aimed to investigate if interferential current stimulation (IFS) through the skin of the neck could immediately improve dysphagia in patients with Parkinson's disease (PD).
Methods: We included patients who had a diagnosis of 14 idiopathic PD with dysphagic complaints in this study. We used a portable device to generate IFS by two different altering currents through both sides of the skin of the neck. To evaluate the effect of IFS on swallowing function, we performed the standardized videofluoroscopic swallowing examination protocol (thin and thick liquid, solid food, and liquid containing the contrast medium) in our hospital, before and immediately after electrical stimuli for 15 min, sequentially. We analyzed the video images including vallecular and pyriform sinus residue, oral transit time, pharyngeal transit time, laryngeal penetration, and aspiration to compare the swallowing function before and after the stimulation in each patient respectively, together with self-evaluation during the study.
Results: Among 14 PD patients with dysphagic complaints, 5 patients did not show swallowing dysfunction before and after IFS in this study. When compared with before IFS, patients revealed significant reduction in oral transit time after IFS. Among 9 patients with abnormal swallowing pattern detected by videofluoroscopic examination, 3 patients shortened the oral transit time for solid food after IFS. Besides, laryngeal penetration disappeared in a patient and aspiration did in another patient after IFS for 15 min.
Conclusions: Although one-third of patients in this study did not show objective swallowing dysfunction, some patients showed immediate improvement in swallowing function in the videofluoroscopic swallowing study after IFS. Our results suggest that IFS through the percutaneous neck could produce an immediate therapeutic effect on dysphagia in some PD patients.

PARKINSON'S DISEASE: A TALE OF TWO CITIES, THE GENOME AND THE EXPOSOME

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Souvarish Sarkar
University of Rochester Medical Center, Environmental Medicine, Rochester, United States of America

Aims: Epidemiological studies support the role of environmental factors in the pathogenesis of Parkinson's disease (PD). Genetic risk factors, including penetrant single-gene mutations and risk factors identified from genome-wide associated studies (GWAS), also contribute to PD risk and progression, but available model systems are limited in their ability to interrogate gene-environment crosstalk in vivo and at scale.
Methods: We developed a multiplex model in *Drosophila* in which we knocked down GWAS candidate genes in neurons or glia in a new α-synucleinopathy model and exposed the flies to environmental neurotoxicants, rotenone, and Manganese.
Results: We identified multiple interactions among various genes, α-synuclein, and environmental factors and decided to study further the interaction among LRRK2, rotenone, and α-synuclein. Expression of the disease-causing Lrrk-G2019S mutant in the presence of rotenone and α-synuclein-induced behavioral deficits and mitochondrial dysfunction. Further, super-resolution microscopy analysis revealed that the interaction of LRRK2, α-synuclein, and rotenone leads to hyperstabilization of the actin cytoskeleton. Genetic analysis from a patient cohort with previous pesticide exposure revealed that the patient's LRRK2-R1398H mutation reduces the chance of developing PD. Since global actin severing may have unwanted side effects, we used a combination of forward genetic screen and proteomics to identify potential kinases that can be druggable targets. We identified Cdc42 binding protein kinase MRCKα, an actin-binding protein, as a potential target. Genetic and pharmacological inhibition of MRCKα in Drosophila can modify the toxicity induced by the interaction among LRRK2, α-synuclein, and rotenone by inhibiting actin hyperstabilization.
Conclusions: Using our novel multiplex model, we have identified an interaction between LRRK2, α-synuclein, and rotenone, which is modulated by actin stabilization and mitochondrial dysfunction. Our findings have implications for developing a personalized approach to drug discovery and lead identification.

FOSGONIMETON PROTECTS AGAINST ALPHA-SYNUCLEIN-MEDIATED PATHOLOGY IN PRECLINICAL MODELS OF PARKINSON'S DISEASE

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Sharay Setti, Sherif Reda, Andree-Anne Berthiaume, Wei Wu, Jewel Johnston, Robert Taylor, Kevin Church
Athira Pharma, Inc., Research, Bothell, United States of America

Aims: The aggregation of α-synuclein protofibrils is a major pathological hallmark of Parkinson's disease (PD), triggering lysosomal dysfunction, oxidative stress, and dopaminergic neuron loss, ultimately resulting in motor dysfunction. Here, we assess the impact of fosgonimeton, a small molecule positive modulator of the neurotrophic and neuroprotective hepatocyte growth factor (HGF) system, on these outcomes in preclinical models of PD.
Methods: Rat primary mesencephalic neurons were challenged with α-synuclein preformed fibrils (α-syn-PFF) in the presence or absence of the active metabolite of fosgonimeton (fosgo-AM). After 96 hours, immunostaining for tyrosine-hydroxylase (TH), mitochondrial ROS, and LAMP2 was performed to interrogate key aspects of PD pathology. In vivo, 18-month-old mice received a single bilateral substantia nigral injection of α-syn-PFF followed by administration of lysosomal disruptor conduritol B epoxide (CBE) 3 times weekly for 6 weeks. The impact of daily treatment with vehicle, L-DOPA, or fosgonimeton on motor function in the ladder test was assessed.
Results: α-syn-PFF injury resulted in lysosomal dysfunction, oxidative stress, and dopaminergic neuron loss in vitro. Treatment with fosgo-AM improved dopaminergic neuron survival and preserved neurite networks, as evaluated via TH staining. Fosgo-AM also significantly decreased lysosomal burden and oxidative stress, as indicated by reduced LAMP2 expression and mitochondrial ROS, respectively. In vivo, fosgonimeton significantly attenuated α-synuclein-mediated motor dysfunction after both 3 and 6 weeks of treatment, as indicated by reduced time to cross and reduced errors in the ladder test.
Conclusions: Our data highlight the ability of fosgonimeton to address cellular dysfunction associated with α-synuclein toxicity in vitro, which was consistent with improved motor function in an α-synuclein-driven preclinical model of PD. Overall, the evidence presented here continues to support the therapeutic potential of fosgonimeton for people with PD.

PHYLLANTHIN OFFERS NEUROPROTECTION IN AN IN VITRO MODEL OF PARKINSON'S DISEASE

POSTERS: C02.M. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT: OTHER

Joshua Delport[1], Sylvester Omoruyi[2], Okobi Ekpo[3]
[1]University of the Western Cape, Medical Bioscience, Cape Town, South Africa, [2]University of the Witwatersrand, Anatomical Sciences, Johannesburg, South Africa, [3]Khalifa University, Department Of Anatomy And Cellular Biology, Khalifa University, Abu Dhabi, United Arab Emirates

Aims: Parkinson's disease (PD) is among the most common neurodegenerative conditions in the ageing population, affecting about 2% of persons older than 60 years of age. It is characterized by the loss of dopaminergic neurons in the substantia nigra pars compacta (SNpc) region of the of the midbrain, often leading to a decline in motor and cognitive functions. Levodopa is the current effective treatment for PD, however, its long-term use often leads to debilitating side effects. Therefore, research into alternative PD treatments is plausible, especially botanical phyto-compounds. The aim of this study is to investigate the potential neuroprotective effects of phyllanthin, a bioactive lignan, in an *in vitro* model of PD
Methods: An MPP^+-induced SH-SY5Y cellular model of PD was used to investigate the cytotoxic effects of phyllanthin while the optimum concentrations of phyllanthin and MPP^+ were determined using the MTT cell viability assay. Experiments to determine nitric oxide (NO), adenosine triphosphate (ATP), intracellular calcium levels, mitochondrial membrane potential (MMP), and caspase 3/7 activity were performed. Molecular docking was performed to determine phyllanthin interaction with the enzymes acetylcholinesterase (AChE), butyrylcholinesterase (BuChE) and monoamine oxidase-B (MAO-B)
Results: Overall, results show that phyllanthin could protect cells against MPP^+-induced toxicity. Specifically, phyllanthin increased cell viability in MPP^+-treated cells, attenuated mitochondrial dysfunction by increasing ATP production and prevented cell death through the inhibition of MPP^+ induced increase in caspase 3/7 activities. Results from the *in-silico* studies and enzymatic assays also showed weak binding of the enzymes AChE, BuChE and MAO-B to phyllanthin, as well as very poor enzyme inhibition.
Conclusions: The results obtained suggest that phyllanthin has neuroprotective effects, thus supporting its potential use as a neuroprotective agent. However, more experiments are needed to elucidate its mechanisms of action.

VQ-101, A SMALL MOLECULE ALLOSTERIC ACTIVATOR OF GLUCOCEREBROSIDASE, DEMONSTRATES NEUROPROTECTION IN MODELS OF GBA-PARKINSON'S DISEASE AND ROBUST IN-VIVO TARGET ENGAGEMENT

POSTERS: C03.B. DRUG DEVELOPMENT, CLINICAL TRIALS: VITAMINS, ANTIOXIDANTS, NEUROPROTECTIVE COMPOUNDS

Daniel Ysselstein, Maria Nguyen, Jianbin Zhang, Hyunkyung Jeong, Eric Zluhan, Sida Shen, Jennifer Hu, Razaul Karim, Cynthia Martinez, Jeremiah Brittin, Zhiquan Lei, Greg Sheyka, Paola Carrilo, Nikki Huynh, Kori Kirby, Jim Sullivan, Kevin Hunt
Vanqua Bio, Research And Development, Chicago, United States of America

Aims: Heterozygous mutations in the gene *GBA1*, which encodes for glucocerebrosidase (GCase), are a major risk factor for Parkinson's disease (PD) accounting for 7-13% of all PD cases. *GBA1* mutations result in reduced enzymatic activity in the lysosome and have detrimental effects on lysosomal function and neuronal health. Here we evaluate VQ-101, a novel small molecule allosteric activator of GCase, that activates lysosomal GCase in a live cell assay *in vitro*, *ex vivo* and *in vivo*, demonstrates pathway engagement and blocks the accumulation of insoluble alpha synuclein (aSyn).
Methods: VQ-101, a selective, CNS-penetrant small molecule activator of GCase, was evaluated using *in vitro* and *in vivo* models to assess target engagement and downstream effects of GCase activation. *In vitro*, dopaminergic neurons (DaNs) differentiated from GBA-PD patient-derived induced pluripotent stem cells (iPSCs) were used to assess changes in GCase activation, GCase substrates, and accumulation of insoluble aSyn. *In vivo* target engagement was directly assessed by measurement of GCase activation following oral administration of VQ-101 across preclinical species.
Results: GCase activation of 50-100% above baseline was achieved in iPSC-derived DaNs carrying *GBA1* mutations treated with nanomolar concentrations of VQ-101. Treatment at concentrations that activate GCase by 50-100% resulted in a reduction in GCase lipid substrates and significantly blocked the accumulation of insoluble aSyn. *In vivo*, dose- and time-dependent GCase activation was observed in peripheral blood across preclinical species after oral administration of VQ-101.
Conclusions: VQ-101 demonstrates significant GCase activation and neuroprotection in DaNs from GBA-PD subjects. The robust GCase target engagement observed in preclinical species is readily translatable to target engagement of GCase activators in clinical studies. These findings support the continued development of VQ-101 for GBA-PD and other synucleinopathies.

A RANDOMIZED, DOUBLE BLIND, PLACEBO-CONTROLLED STUDY WITH UB-312, AN ANTI-ALPHA-SYNUCLEIN PEPTIDE VACCINE IN PARKINSON'S DISEASE PATIENTS.

POSTERS: C03.A. DRUG DEVELOPMENT, CLINICAL TRIALS: IMMUNOTHERAPY

Pepijn Eijsvogel[1], Hui Jing Yu[2], Philip Kremer[1], Lauren Fedor[2], Igor Radanovic[1], Dario Mirski[2], Maurits Vissers[1], Marieke De Kam[1], Jean-Cosme Dodart[2], Geert Jan Groeneveld[1]
[1]CHDR, Neurology, Leiden, Netherlands, [2]Vaxxinity, Inc, Neurology, Florida, United States of America

Aims: Alpha-Synuclein (aSyn) plays a central role in Parkinson's disease (PD) and is considered a target for disease modification. UB-312 is a synthetic aSyn peptide conjugated to a T-helper peptide and is expected to induce antibodies specifically against oligomeric and fibrillar aSyn, making UB-312 a potential immunotherapeutic for synucleopathies. The aim of the trial was to investigate the safety, tolerability, and immunogenicity of UB-312 in a two-part Phase 1 clinical trial, in healthy volunteers (HVs) and PD patients.
Methods: Participants were enrolled in a 44-week, randomized, placebo-controlled, double-blind study. A total of 28 HVs and 19 PD patients were randomized to three intramuscular UB-312 or placebo injections at weeks 1, 5, and 13 at varying dose levels. Safety and tolerability were assessed by adverse events (AEs) and standard safety assessments. Immunogenicity was assessed by measuring serum and cerebrospinal fluid (CSF) anti-aSyn antibodies.
Results: In HVs, the antibodies were detectable in 100% of the HVs who received 3 doses of 300µg UB-312 and in 92% of PD patients who completed dosing with UB-312. Anti-aSyn antibodies were also detectable in CSF. Most AEs were mild and transient. UB-312 was generally well tolerated with overall adverse event profile similar across UB-312 and placebo groups. No serious adverse events (SAEs) were reported in HVs. Two patients experienced SAEs. Only one event was deemed possibly related to the trial, and all SAEs were resolved.
Conclusions: The trial met its primary objectives. UB-312 was generally safe, well tolerated, and induced anti-aSyn antibodies in serum and CSF. These data support further development of UB-312 for alpha-synucleinopathies.

Aims: Parkinson's disease dementia (PDD) and Dementia with Lewy bodies (DLB) are neurodegenerative diseases characterized by protein aggregation that is linked to synaptic dysfunction and neuronal death, with clinical features that include changes in cognition and behavior. Positive modulation of the neurotrophic hepatocyte growth factor system with fosgonimeton may offer a therapeutic approach for several neurodegenerative diseases. This exploratory phase 2 SHAPE trial sought to evaluate the safety of fosgonimeton and effects of treatment on a variety of outcomes including cognition, activities of daily living, motor function, and behavior in participants with PDD and DLB. Plasma samples were collected for biomarker analysis.
Methods: SHAPE was a 26-week, multicenter, randomized, double-blind, placebo-controlled, phase 2 trial of subcutaneous fosgonimeton (40 mg/day or 70 mg/day) versus placebo in participants with PDD or DLB. The primary end point was the effect of fosgonimeton treatment versus placebo at week 26 per change from baseline (CFB) in a composite score Global Statistical Test [GST] combining the z-scores of ADAS-Cog13 and ERP P300L. Secondary efficacy end points were CFB in validated scales for measuring cognitive function (ADAS-Cog13; MMSE), executive response/function (ERP P300L; COWAT), activities of daily living (ADCS-ADL23), motor function (MDS-UPDRS), and other holistic disease burden measures (NMSS; CGI).
Results: Twenty-eight participants (PDD: fosgonimeton n=14, placebo n=6; DLB: fosgonimeton n=5, placebo n=3) in this first-in-patient exploratory trial were randomly assigned. We will report the effects of fosgonimeton versus placebo per GST score, secondary outcomes including biomarker findings, and safety findings based on adverse events.
Conclusions: The synthesis of these data will inform the hypothesis generation for continued development of fosgonimeton as a potential therapeutic for PDD, PD, and DLB.

A PHASE 1A FIRST-IN-HUMAN CLINICAL TRIAL OF HER-096, A SUBCUTANEOUSLY ADMINISTERED CDNF-DERIVED PEPTIDOMIMETIC

POSTERS: C03.B. DRUG DEVELOPMENT, CLINICAL TRIALS: VITAMINS, ANTIOXIDANTS, NEUROPROTECTIVE COMPOUNDS

Kira Holmström[1], Katarina Jääskeläinen[1], Natalia Kulesskaya[1], Jani Koskinen[1], Päivi Vuorio[1], Antti Vuolanto[1], Marica Engström[2], Mika Scheinin[2,3], Charlotte Videbaek[1], Aleksi Tornio[2,3], Henri Huttunen[1]
[1]Herantis Pharma, Scientific Department, Espoo, Finland, [2]University of Turku, Institute Of Biomedicine, Turku, Finland, [3]CRST Oy, Clinical Development, Turku, Finland

Aims: HER-096 is a peptidomimetic compound developed from the active site of human CDNF that in preclinical studies has shown brain penetration and protection of nigrostriatal dopamine neurons. In this study we aimed to (1) assess the safety and tolerability of subcutaneously administered HER-096 in healthy volunteers (HV), and (2) assess its pharmacokinetic properties, including blood-brain barrier penetration in humans.
Methods: A randomised, double-blind, placebo-controlled, safety, tolerability and pharmacokinetic study of single ascending subcutaneous doses of HER-096 was conducted at a single site in Finland. In Part 1 of the study, 48 young (20-45 years) male HV subjects were randomised to receive single doses of HER-096 (10, 30, 60, 120, 200 or 300 mg) or placebo at a 6:2 ratio in six dosing cohorts. In Part 2, 6 older (50-64 years) and 6 elderly (65-75 years) male and female HV subjects were administered a single 200 mg dose of HER-096. The primary endpoint was safety, assessed by incidence, type and severity of treatment-emergent adverse events (AE), including injection-related events, as well as standard clinical and laboratory assessments. Secondary endpoints were pharmacokinetic properties of HER-096 (up to 24 h) in plasma and urine in the young HVs, and in plasma, urine and cerebrospinal fluid in the older and elderly subjects.
Results: All study subjects were recruited and dosed in Q2-Q3 2023. Data analysis is on-going. There were no reports of serious AEs or other dose-limiting AEs affecting progression of the clinical study.
Conclusions: Preliminary assessments suggest a good safety profile for single ascending subcutaneous doses of HER-096. Full data analysis will be completed after database lock by November 2023 and the results will be reported in the AD/PD 2024 conference presentation.

Aims: The objective of this study was to investigate the potential of novel doxycycline (DOX) derivatives as neuroprotective agents for Parkinson's disease (PD). Specifically, we aimed to design non-antibiotic tetracycline (TC) derivatives with improved efficacy against PD-related pathomechanisms while minimizing cytotoxicity.
Methods: To achieve our objectives, we designed 18 novel DOX derivatives. The design involved reducing the dimethyl-amino group at C4 to reduce antimicrobial activity and conducting multiple coupling reactions at position C9 of the aromatic D ring, known for its reactivity in introducing substituents. We assessed the effectiveness of these derivatives using the Thioflavin-T assay to inhibit α-Synuclein (α-Syn) aggregation. Additionally, we evaluated their anti-inflammatory effects in a microglial cell culture system modeling PD-related neuroinflammation. We measured membrane integrity and metabolic activity using LDH and MTT assays to assess potential cytotoxicity.
Results: Our study revealed that seven TC compounds among the derivatives were more effective than the parent compound, DOX, in inhibiting α-Syn aggregation. Notably, two of these derivatives, compounds 6 and RDOX, demonstrated superior anti-inflammatory effects compared to DOX. Furthermore, these compounds exhibited no adverse effects on membrane integrity or metabolic activity, as evidenced by the LDH and MTT assays.
Conclusions: Based on our current findings, we conclude that novel 4-des-N-dimethylaminodoxycycline derivatives functionalized at position C9 show greater efficacy in inhibiting pathological α-Syn aggregation compared to DOX. Compound 6 and RDOX emerge as promising drug candidates for the treatment of Parkinson's disease. Their non-cytotoxic nature and potent anti-inflammatory properties make them attractive candidates for further exploration in PD therapy.

Aims: Alpha-synuclein (α-Syn) aggregation is a hallmark of neurodegenerative diseases like Parkinson's. Doxycycline (DOX), a tetracycline, has shown potential in inhibiting α-Syn aggregation, but its antibiotic properties limit its therapeutic use. To address this, we developed a non-antibiotic tetracycline derivative, DDox, which aimed to mitigate α-Syn aggregation and offer a safe alternative for disease models.
Methods: DDox was synthesized through the removal of the dimethylamino substituent at position 4 on ring A and the reduction of the hydroxyl group at C12a. We assessed DDox's antibiotic activity against Gram(+) and (-) bacterial strains and evaluated its toxicity on the SHSY5Y cell line using MTT assay. The capability of DDox at interfering with α-Syn aggregation was assessed through: fluorescent spectroscopy, TEM and immunofluorescence in SHSY5Y cells. Additionally, we studied DDox effects on α-Syn seeding in SH-SY5Y-aS-RFP cells treated with α-Syn preformed fibrils (α-Syn-PFF), its impact on the uptake of fluorescently-labeled α-Syn-PFF and on α-Syn-PFF-triggered lysosomal stress by confocal microscopy.
Results: The chemical modifications that gave rise to DDox effectively diminished antibiotic activity against both Gram (+) and Gram (-) bacterial strains while reducing its toxicity on the SHSY5Y cell line. It outperformed DOX at inhibiting α-Syn amyloid aggregation. In cellular models, DDox reduced α-Syn aggregate formation induced by α-Syn-PFF. Notably, DDox exhibited previously unreported properties by inhibiting α-Syn-PFF uptake and α-Syn-PFF-triggered lysosomal stress, demonstrating its potential in PD models.
Conclusions: In summary, DDox, a novel tetracycline, is non-toxic and exhibited limited antibiotic activity. It also improved α-Syn associated phenotypes and showed anti-inflammatory abilities. These findings position DDox as a promising candidate for preclinical studies of synucleinopathies like PD, offering a potential solution to the antibiotic hurdle associated with DOX.

Aims: NAD replenishment therapy with nicotinamide riboside (NR) has shown promising results in preclinical and clinical studies on PD and other neurodegenerative disorders. However, individual neurometabolic responses vary and the optimal dose is yest to be determined. Here, we aim to determine the optimal biological dose of NR for the treatment of Parkinson's disease (PD), defined as the dose required to achieve maximal cerebral NAD increase, increase in the expression of the NR related pattern (NRRP), or proportion of MRS-responders, in the absence of unacceptable toxicity.
Methods: N-DOSE is a single-center, randomized, placebo-controlled, double-blinded trial. Participants will be randomized 1:1:2 into either placebo group (n=20), dose stable group (n=20) or a dose escalation group (n=40) for 3 months. Each participant will attend four visits during the trial. **Inclusion criteria:** clinically established diagnosis of idiopathic PD according to MDS criteria, DAT-SPECT imaging consistent with PD, age ≥ 40 at enrollment, Hoehn and Yahr score < 4, and ability to undergo MRI and lumbar puncture. **Exclusion criteria:** supplementation with high dose vitamin B_3 within 30 days of baseline or co-morbidity with another neurodegenerative disorder, neoplastic or severe and debilitating metabolic, psychiatric or physical disorder. Investigations: At all visits, participants will undergo: 31^{P}-MRS, 1^{H}-MRS, FDG-PET, drawing of blood and scoring of clinical scales; MDS-UPDRS, MDS-NMS, MoCA, GIDS-PD, EQ-5L. At baseline and final visit, participants will undergo CSF collection via lumbar puncture and a fecal sample will be collected.
Results: Currently 15 participants have completed the trial and 26 have been randomized. Three participants have dropped out.
Conclusions: Anticipated trial completion: Q4 2024. **Trial registration:** NCT05589766

ANTIPARKINSONIAN AND NEUROPROTECTIVE EFFECTS OF A WASP VENOM PEPTIDE IN A MODEL OF PARKINSON'S DISEASE

POSTERS: C03.B. DRUG DEVELOPMENT, CLINICAL TRIALS: VITAMINS, ANTIOXIDANTS, NEUROPROTECTIVE COMPOUNDS

Larissa Lima, Henrique Amaral, Gabriela Pinheiro, Márcia Renata Mortari
University of Brasilia, Institute of Biological Sciences, Department Of Physiological Sciences, Laboratory Of Neuropharmacology, Asa Norte, Brasília, Brazil

Aims: The present study aims to evaluate antiparkinsonian and neuroprotective effects of OcTx-1202, a wasp venom peptide, in a mouse model of 6-hydroxydopamine-induced hemiparkinsonism.
Methods: The experimental design consisted of a ten-day evaluation period, in which male *Swiss* mice were subjected to a stereotaxic procedure and two behavioral tests, the rotarod test and the apomorphine-induced rotational test. Then, animals were euthanized and brains were collected for quantification of dopaminergic neurons in the substantia nigra pars compacta (SNpc). Subjects were divided on five experimental groups: SHAM (infusion and treatment with vehicle solution), negative control (infusion of 6-OHDA and treatment with vehicle solution) and three experimental groups (infusion of 6-OHDA and diary treatment with OcTx-1202 in 2, 4 or 8 mg/kg).
Results: In the rotarod test, a progressive improvement of motor performance was observed with 8 mg/kg OcTx-1202 treatment, but these results were not obtained for lower doses. For the apomorphine-induced rotational test, treatment with all three doses of OcTx-1202 did not significantly reduce the number of contralateral rotations. As for the neuroprotection of dopaminergic neurons in SNpc, treatment with OcTx-1202 preserved 73%, 44% and 60,7% of dopaminergic neurons in doses of 2, 4 and 8 mg/kg, respectively. Lastly, an interesting finding was the 100% survival rate of animals treated with OcTx-1202 in 8 mg/kg, equivalent to the SHAM group. For the remaining groups, survival rate was 87,5% (OcTx-1202, 4 mg/kg), 81,8% (OcTx-1202, 2 mg/kg) and 66,7% (negative controls).
Conclusions: These findings suggest that OcTx-1202 has antiparkinsonian and neuroprotective effects, being a potential therapeutic alternative for PD. Future studies should investigate its mechanism of action and propose chemical modifications, such as PEGylation or nanoencapsulation. This work was supported by Fundação de Apoio e Pesquisa do Distrito Federal (FAPDF).

Aims: Parkinson's disease (PD) is a chronic neurodegenerative disorder that involves the loss of dopaminergic neurons and is triggered by toxic amyloid aggregates of αS, predominantly phosphorylated at Serine 129 (S129). Several tetracyclines (TCs) have shown neuroprotective effects in preclinical models, but their antibacterial activity limits their use. The study aimed to evaluate the potential of Double Reduce Chlortetracycline (DCT), a novel modified TC without antibiotic activity, at interfering with αS-driven pathological features in transgenic PD cell models.
Methods: The novel TC DCT was synthesized by eliminating the dimethylamino substituent at position 4 in ring A and reducing the hydroxyl group at C12a. Toxicity was tested in SH-SY5Y^{WT} cells by MTT assays and in SH-SY5Y-CytochromeC-GFP cells. Ability of DCT to modify αS aggregation was assessed through fluorescent spectroscopy, transmission electron microscopy, and immunofluorescence in SH-SY5Y-αS-RFP cells. The effects of DCT on αS seeding were studied *in-vitro*, and in SH-SY5Y-αS-RFP cells treated with α-Syn preformed fibrils (αS PFF). The impact of DCT on αS PFF-induced lysosomal stress was studied with Lysotracker. Antioxidant properties were revealed using CellROX. DCT influence on phosphorylation of αS^{S129} was discovered using immunostainings. All studies were performed in SH-SY5Y-αS-RFP and visualized by confocal microscopy.
Results: DCT showed no toxicity and conserved important antioxidant properties present in TCs. In addition, DCT inhibited amyloid aggregation, modified the kinetics, and altered the morphology of αS amyloid fibrils. DCT also diminished the ability of exogenous αS-PFF to seed endogenous αS-RFP. Surprisingly, DCT also inhibited the phosphorylation of αS^{S129} and lysosomal stress induced by αS-PFF.
Conclusions: These results poise DCT as an attractive drug candidate for further *in vivo* tests and uncover hidden properties of TCs that could be harnessed for further drug development.

AN OPTIMIZED NURR1 AGONIST PROVIDES DISEASE-MODIFYING EFFECTS IN PARKINSON'S DISEASE MODELS

POSTERS: C03.C. DRUG DEVELOPMENT, CLINICAL TRIALS: NEUROTRANSMITTER- AND RECEPTOR BASED MODULATORS

Woori Kim[1], Mohit Tripathi[2], Chunhyung Kim[1], Satyapavan Vardhineni[2], Young Cha[1], Shamseer Kandi[2], Melissa Feitosa[1], Rohit Kholiya[2], Eric Sah[1], Anuj Thakur[2], Yehan Kim[1], Sanghyeok Ko[1], Sunny Manohar[2], Youngbin Kong[1], Gagandeep Sindhu[2], Yoon-Seong Kim[3], Bruce Cohen[1], Diwan Rawat[2], Kwang-Soo Kim[1]
[1]McLean Hospital, Psychiatry, Belmont, United States of America, [2]University of Delhi, Chemistry, Delhi, India, [3]Rutgers University, Institute For Neurological Therapeutics, Piscataway, United States of America

Aims: This study was performed in order to develop an optimized Nurr1 agonist(s) that may provide beneficial disease modifying treatment of Parkinson's disease (PD).
Methods: Herein we carried out an extensive medicinal chemistry search in which over 570 4-amino-7-chloroquinoline (4A7C)-derivatives were generated and characterized for their ability to activate Nurr1. We performed the highthroughput analyses determining cytotoxicity, Nurr1 transcriptional activity, binding affinity to Nurr1, and brain/plasma ratio, to identify an optimized, brain-penetrant agonist(s). The final candidate, 4A7C-301 was tested in vitro models including MPP^+-treated midbrain dopaminergic (mDA) cell lines (MN9D and N27-A) and MPP+- or LPS-treated mDA neuron-glia co-cultures to validate its effects on neuroprotection and neuroinflammation. In addition, 4A7C-301 was administered in vivo models of PD including MPTP-induced mice and AAV2-mediated human α-synuclein (both wild-type and hA53T mutant)-overexpressing mice to verify the efficacy in PD-like behavioral deficits and pathophysiological symptoms.
Results: The brain-penetrant Nurr1 agonist, 4A7C-301, exhibits robust neuroprotective effects in vitro models (e.g., mDA cell lines and primary mDA neuron-glia co-cultures) with enhanced expression of mDA neuron-specific markers along with suppression of microglial activation against MPP^+- and/or LPS-induced toxicities. In addition, 4A7C-301 protects against the loss of mDA neurons in the MPTP-induced mouse models of PD and improves both motor and non-motor deficits without side effects such as dyskinesia-like behaviors. Furthermore, 4A7C-301 significantly ameliorates neuropathological abnormalities and improves motor and non-motor dysfunctions in AAV2-mediated human α-synuclein (both wild-type and hA53T mutant)-overexpressing mouse models, with reduced α-synuclein accumulation and increased dopamine production.
Conclusions: These disease-modifying properties of 4A7C-301 may warrant clinical evaluation of this or analogous compounds for the treatment of patients with PD.

REACT-PD – A RANDOMIZED, PLACEBO-CONTROLLED PHASE IIB TRIAL EVALUATING THE EFFICACY OF PIREPEMAT ON FALLS FREQUENCY IN PATIENTS WITH PARKINSON'S DISEASE

POSTERS: C03.C. DRUG DEVELOPMENT, CLINICAL TRIALS: NEUROTRANSMITTER- AND RECEPTOR BASED MODULATORS

Joakim Tedroff, Olivia Vu Van, Clas Sonesson, Nicholas Waters, Susanna Waters
IRLAB Therapeutics AB, Research & Development, Göteborg, Sweden

Aims: Advanced Parkinsons Disease (PD) is associated with auxiliary symptoms including cognitive decline, apathy, and increased frequency of falls, in great need of improved treatment. Emerging data suggests falls in PD are linked to impairment of noradrenergic pathways impinging on cortical areas involved in postural control. Pirepemat is a small molecule compound, enhancing cortical noradrenergic transmission, in clinical development for advanced PD. A phase IIa trial indicated improvement of balance and reduced falls assessed by MDS-UPDRS. REACT-PD is a Phase IIb study with the primary objective to evaluate the effect of pirepemat on falls frequency in people with PD. Secondary objectives include evaluation of safety, tolerability, and effects on apathy, cognition, and general PD symptoms.
Methods: Patients with PD, HY-stage ≥ 2.5, experiencing recurrent falls, are eligible, aiming for a total of 165 subjects. Participants are assigned randomly to 100 or 200 mg of pirepemat or placebo, administered t.i.d day for 12 weeks. Falls are monitored using a falls diary. Other efficacy assessment include MOCA, MDS-UPDRS part I-IV, Neuropsychiatric Inventory (NPI, Apathy/Indifference part), CGI. The analysis of the primary endpoint, falls frequency, will be performed using negative binomial regression.
Results: The study is currently active at 38 study sites across six European countries. A first DSMB meeting was held in July 2023. Top-line results are expected in H1 2024.
Conclusions: Recruitment is ongoing and the study is making good progress. Details on study procedures and early results, as available, will be presented during the meeting. Pirepemat has the potential to become the first treatment in a new class of drugs designed to improve balance and reduce falls and associated injuries in people with Parkinson's disease.

OPICAPONE EFFECT ON SLEEP DISORDERS IN FLUCTUATING PARKINSON'S DISEASE PATIENTS: FINDINGS FROM THE OASIS EXPLORATORY TRIAL

POSTERS: C03.E. DRUG DEVELOPMENT, CLINICAL TRIALS: ENZYME MODULATORS

Joaquim Ferreira[1], Miguel Gago[2], Raquel Costa[3], Miguel Fonseca[3], Joana Almeida[3], José Rocha[3], Joerg Holenz[3], Claudia Trenkwalder[4]
[1]University of Lisbon, Laboratory Of Clinical Pharmacology And Therapeutics, Lisbon, Portugal, [2]University of Minho, Life And Health Sciences Research Institute (icvs), Guimarães, Portugal, [3]BIAL - Portela, R&d, Trofa, Portugal, [4]Paracelsus-Elena Klinik, Neurology, Kassel, Germany

Aims: This clinical trial aimed to evaluate the effects of OPC treatment on sleep disorders in fluctuating PD patients.
Methods: Open-label, single-arm pilot trial that recruited 16 fluctuating PD patients. All received OPC-50mg once-daily during a 6-week evaluation period. L-dopa/DDCI daily dose, but not number of intakes, could have been adjusted during first 2 weeks. Primary endpoint was change from baseline in Parkinson's Disease Sleep Scale-2 (PDSS-2). Secondary endpoints included tolerability, functional motor and non-motor assessments [MDS-UPDRS, MDS-NMS, 8-item PD Questionnaire (PDQ-8), 16-item PD Fatigue Scale (PFS-16), ON/OFF home diary], and Global Impression of Change [Clinician (CGI-I) and Patient (PGI-I)].
Results: At week 6, there was a significant reduction from baseline of -7.9 points (95%CI: -13.6,-2.2; P=0.0099) in total PDSS-2 score. Similarly, there were also significant reductions in PFS-16 [-9.6 points (95%CI: -17.5,-1.7; P=0.0211), in MDS-NMS total score [-28.9 (95%CI: -44.7,-13.2; P=0.0052), in MDS-UPDRS III and IV [-6.3 (95%CI: -11.6,-0.9; P=0.0253) and -1.2 (95%CI: -2.0,-0.4; P=0.0044), respectively] and in PDQ-8 [-14.2 (95%CI: -23.2,-5.0; P=0.0051). Absolute OFF-time was also reduced (-142.1 mins), mirrored by an increase in ON-time without dyskinesia (+127.1 mins). Most patients (93.3%) and most clinicians (80.0%) reported any improvement as evaluated by the PGI-I and CGI-I, respectively. OPC-50mg was found to be well tolerated.
Conclusions: In this exploratory open single-arm trial, treatment with OPC-50mg as add-on to L-DOPA/DDCI improved PD-specific sleep disturbances and other relevant and troublesome non-motor symptoms. These results support the potential benefit of using opicapone for the treatment of motor fluctuations in patients with PD associated with sleep problems.

REDUCTIONS IN OFF TIME WITH ND0612 FOR PATIENTS WITH PARKINSON'S DISEASE EXPERIENCING MOTOR FLUCTUATIONS: RESPONDER-ANALYSIS FROM AN OPEN-LABEL STUDY

POSTERS: C03.F. DRUG DEVELOPMENT, CLINICAL TRIALS: DRUG DELIVERY SYSTEMS

Nelson Lopes[1], Werner Poewe[2], Aaron Ellenbogen[3], Stuart Isaacson[4], Nissim Sasson[1], Tami Yardeni[1], Alberto Espay[5]
[1]NeuroDerm.com, Clinical Development, Rehovot, Israel, [2]Medical University Innsbruck, 2. department Of Neurology, Innsbruck, Austria, [3]Michigan Institute for Neurological Disorders, Neurology, Farmington Hills, United States of America, [4]Parkinson's Disease & Movement Disorders Center of Boca Raton, Neurology, Boca Raton, United States of America, [5]University of Cincinnati, Neurology, Cincinnati, United States of America

Aims: We have previously reported that one year treatment with investigational ND0612 infusion was generally safe and well-tolerated. Adjusted mean daily 'Good ON' time (sum of ON time without dyskinesia + ON time with non-troublesome dyskinesia) increased from baseline by 2.3 hours at Month 3 and was maintained for at least 12 months (Poewe et al. Mov Disord 2021; 36: 2687-2692). Here we evaluate the efficacy of subcutaneous levodopa/carbidopa infusion with ND0612 in reducing OFF time in people with Parkinson's disease (PwP) experiencing motor fluctuations.
Methods: The BeyoND study is an ongoing open-label study (NCT02726386) of ND0612 treatment conducted in PD patients (n=214) with Hoehn & Yahr score of ≤3 during ON experiencing ≥2 hours daily OFF-time. In these analyses of daily OFF time (patient home diaries), a responder was conservatively defined as a patient who achieved ≥50% reduction from baseline in adjusted mean daily OFF time.
Results: Using the last observation carried forward, 44.0% patients were classified as treatment responders, and this level of response was maintained over the 12 months of follow-up. Moreover, 63.5% of patients achieved a >25% reduction in OFF time from baseline and 26.9% of patients achieved a >75% reduction in OFF time. Additionally, 12.8% of patients had their OFF time reduced by 100%. Using only observed cases (i.e., not LOCF), the percentage of ND0612 treatment responders increased from 44.0% at Month 1 (N=150) to 53.3% at Month 6 (N=107), and 56.7% at Month 12 (N=90).
Conclusions: This open-label study provides preliminary support for the 12-month efficacy of treatment with ND0612 in reducing OFF time in PwP experiencing motor fluctuations.

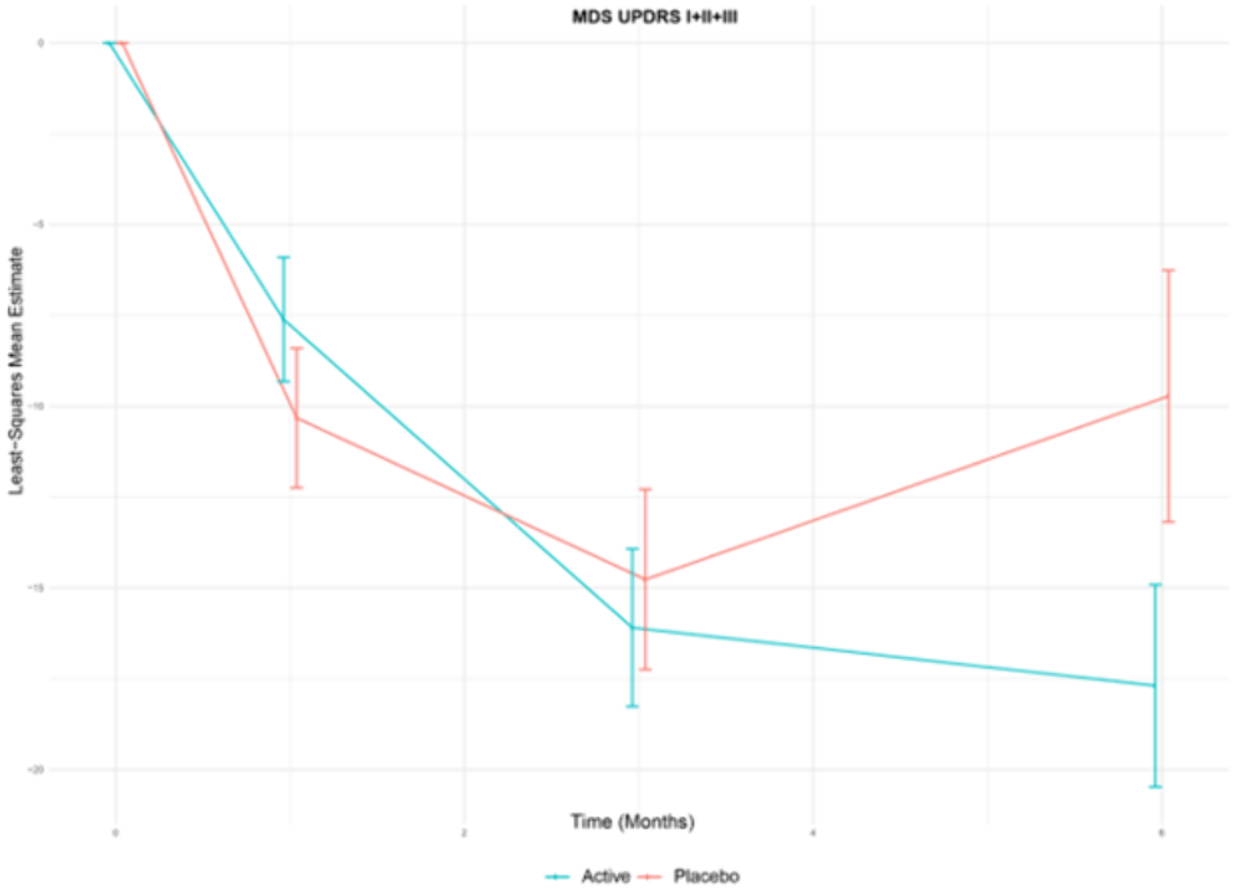
Aims: Presenting safety and efficacy results of a phase 2 study of Spectramax Light Therapy (SLT), a circadian targeted, blue+green light as adjunctive treatment in Parkinson's disease (PD) and describing the design for a currently-enrolling phase 3 trial in a similar population.
Methods: Current treatments do not adequately address many disabling features of PD, including circadian dysfunction. SLT may improve circadian rhythms affecting both motor and non-motor features of PD.[1] A 6-month, phase 2, multi-center, randomized, double-blind, controlled clinical trial of one hour/day of passive exposure to SLT in PD patients on stable dopaminergic therapy demonstrated motor and non-motor benefits. Clinical endpoints included MDS-UPDRS Parts 1-3 (assessed during the On-state), PDQ-39, CGI-I, and ESS. A phase 3 RCT is currently enrolling similar patients and is entirely remote.
Results: 92 subjects (45 active, 47 sham) were randomized. Effects were 8-points for MDS-UPDRS score (p=0.074), 5.7-points for PDQ-39 (p=0.038), 0.37-points for CGI-I (p=0.067), and 1.5-points on ESS (p=0.054) were observed. Non-motor symptoms were significantly affected (MDS-UPDRS Part 1, p=0.006). Spectramax was safe and well
tolerated.

Figure: 6-Month Comparison of Active vs. Control for MDS-UPDRS 1-3



Conclusions: Once-daily Spectramax LT improved PD symptoms, particularly non-motor symptoms and quality of life. SLT was well-tolerated. A phase 3 double-blind study is currently enrolling 300 patients in PD, with the PDQ-39 as the primary and MDS-UPDRS Parts 1-2 as key secondary efficacy outcomes, with ESS, FSS, and MDS-UPDRS Part 3 as additional outcomes. **References** [1] Videnovic A, Rutten S, Croft W, Erickson H, Groves J, Havemann C, Herrington T, Hendrix S, Kieburtz K, Van der Werf Y, Van den Heuvel O. ***Double-blind controlled trial of Spectramax™ light therapy for the treatment of Parkinson's disease patients on stable dopaminergic therapy,*** Mov Disord. 2018 Oct;33 Suppl 2:S429

Poster Topic: *Theme C: α-Synucleinopathies / C04.a. Imaging, Biomarkers, Diagnostics: Structural MRI, MR spectroscopy*

BRAIN MRI VOLUME PERCENTILES ARE ASSOCIATED WITH FUTURE MOTOR AND COGNITIVE SCORES IN PARKINSON'S DISEASE.

POSTERS: C04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Nuno Pedrosa De Barros[1], Thibo Billiet[1], Thanh Vân Phan[1], Vincenzo Anania[1], Diana Sima[1], Annemie Ribbens[1], Elnaz Ghasemi[2], Marian Shahid[2], Kathleen Poston[2]
[1]icometrix, Clinical Trials, Leuven, Belgium, [2]Stanford University, Neurology And Neurological Sciences, Stanford, United States of America

Aims: In Parkinson's disease (PD), predicting motor and cognitive decline is important for optimal treatment. Previously [1], we identified brain regions-of-interest (ROI) that correlate with future motor and cognitive scores based on voxel-based morphometry (VBM). Here, we aim to validate those findings based on brain volume percentiles calculated for those ROI.
Methods: Brain structures (Tables 1, 2) were segmented with the regulatory cleared ico**brain** software applied on baseline 3D-T1 MRI scans of 726 patients with PD from the Parkinson's Progression Markers Initiative (n=592) and Stanford (n=134) studies. Associations with cognitive and motor scores were assessed with linear mixed effect models. The worst MoCA/MDS-UPDRSIII score in the next 5 years was set as the dependent variable. Brain volume percentile scores (based on an age- and sex-matched healthy reference population) in an ROI, sex, disease duration and age were used as independent variables.
Results: MDS-UPDRSIII was significantly associated with brain volume percentiles of the caudate, putamen, frontal lobe GM, white matter and cerebellar WM. MoCA was significantly associated with the whole brain, gray matter, midbrain, cerebellar WM, temporal lobe, hippocampus and thalamus. Disease duration had a significant effect on MoCA and MDS-UPDRSIII, with longer duration associated with worse clinical scores. Older age was associated with worse MoCA scores and being male with worse MDS-UPDRSIII.

Table 1. Significant results for the model: Future MoCA ~ brain volume percentile + disease duration + age + sex

ROI	ROI vol. prctile		Disease duration		Age		Sex (male)	
	coef.	p-val	coef.	p-val	coef.	p-val	coef.	p-val
GM	0.011	0.006	0.204	<0.001	-0.113	<0.001	-0.495	0.106
WB	0.01	0.009	0.206	<0.001	-0.113	<0.001	-0.48	0.119
midbrain	0.008	0.047	0.199	<0.001	-0.115	<0.001	-0.496	0.108
thalamus	0.008	0.03	0.203	<0.001	-0.115	<0.001	-0.465	0.132
hippocampus	0.015	<0.001	0.206	<0.001	-0.115	<0.001	-0.378	0.217
cerebellar WM	0.008	0.034	0.206	<0.001	-0.117	<0.001	-0.505	0.102
CGM Temporal lobe	0.012	0.001	0.215	<0.001	-0.115	<0.001	-0.467	0.128

Table 2. Significant results for the model: Future MDS-UPDSRIII ~ brain volume percentile + disease duration + age + sex

ROI	ROI vol. prctile		Disease duration		Age		Sex (male)	
	coef.	p-val	coef.	p-val	coef.	p-val	coef.	p-val
WM	**0.038**	**0.006**	**0.449**	**0.001**	0.073	0.189	**2.307**	**0.036**
caudate	**-0.035**	**0.031**	**0.385**	**0.005**	0.069	0.214	**2.409**	**0.028**
putamen	**-0.035**	**0.03**	**0.399**	**0.004**	0.082	0.139	**2.506**	**0.023**
cerebellar WM	**0.045**	**0.004**	**0.459**	**0.001**	0.061	0.274	**2.243**	**0.041**
CGM Frontal lobe	**-0.032**	**0.038**	**0.424**	**0.002**	0.071	0.2	**2.191**	**0.045**

Conclusions: In line with our previous studies [1, 2], results indicate that brain volume percentile scores, compared to a healthy reference population, can have predictive value for future motor and cognitive decline.

COMPARISON OF NEUROANATOMICAL CHANGES IN PARKINSON'S DISEASE COHORTS FROM NORTH AMERICAN AND INDIAN POPULATIONS

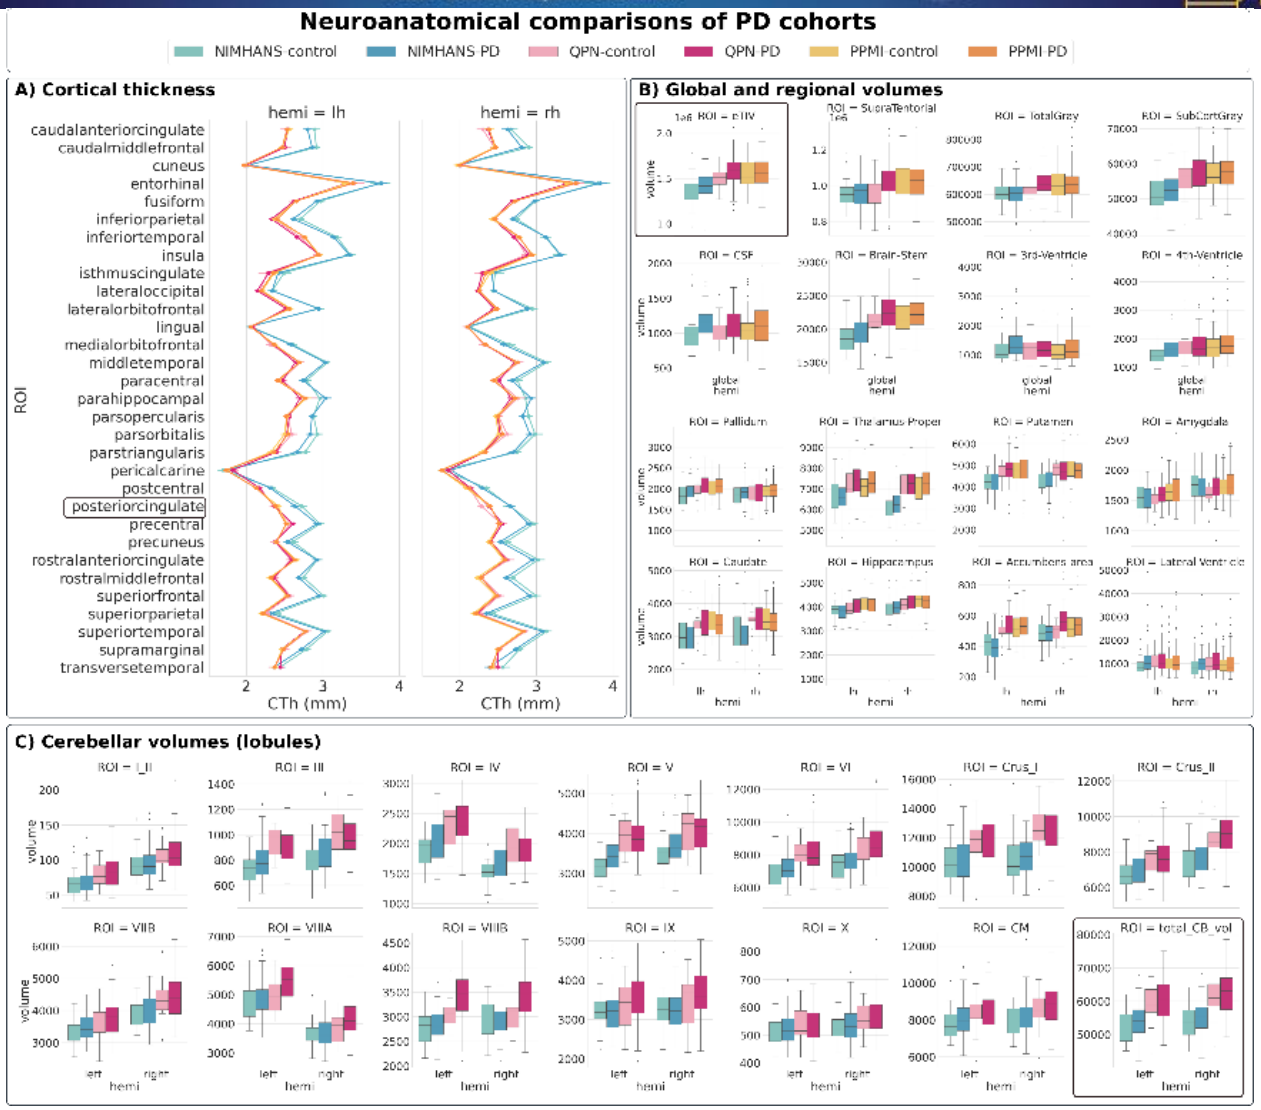
POSTERS: C04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Nikhil Bhagwat[1], Shweta Prasad[2], Jitender Saini[2], Pramod Pal[2], Ravi Yadav[2], Edward Fon[1], D Louis Collins[1], Madeleine Sharp[1], Alain Dagher[1], Jean-Baptiste Poline[1]
[1]McGill University, Montreal Neurological Institute And Hospital, Montreal, Canada, [2]National Institute of Mental Health and Neuro Sciences, Neuroimaging & Interventional Radiology, Bengaluru, India

Aims: We compare neuroanatomical signatures associated with Parkinson's disease (PD) from North-American and Indian cohorts quantified using sMRI. We aim to identify commonalities and differences in brain morphometry in PD patients - possibly resultant of genetic, demographic, and lifestyle factors.
Methods: We analyze age-matched samples from PPMI (n=294), QPN (n=162), and NIMHANS (n=138) cohorts. The MRI data are acquired on different scanners but processed with identical pipelines. We quantify cortical thickness (CTh) and subcortical volumes using FreeSurfer-6.0 (DKT parcellation), and cerebellar volumes using the MAGeT Brain pipelines. To control for site effects, we assess CTh and volumetric PD-vs-control differences separately for the three cohorts using GLM. We control for age and sex in all models and additionally for total-intracranial-volume in regional and total-cerebellar-volume in cerebellar volumetric analyses.

Cohort	N (PD|Control)	Age (mean,std)
PPMI	210 84	54.2 (5.7) 51.6 (7.9)
QPN	136 26	55.9 (5.3) 52.5 (7.6)
NIMHANS	108 30	55.4 (7.1) 52.0 (5.9)

Results: NIMHANS consistently shows lower values for total-intracranial, supra-tentorial, and cerebellar volumes, and higher values for regional CTh compared to QPN and PPMI across PD and controls. The PD-vs-control comparisons show significant differences in CTh of posterior-cingulate (right) in both QPN and NIMHANS cohorts. Significant differences in Thalamic (left&right) volume are seen in PPMI, but not in QPN or NIMHANS. In cerebellum, lobules III(right), VIII-A(left), VIII-B (left&right) show differences only in QPN.



Conclusions: The results indicate that cross-cohort differences are affected by both scanner and biological factors. The PD-vs-control comparisons suggest few regional anatomical markers, however only CTh differences in posterior-cingulate are replicated across QPN and NIMHANS. Image harmonization and analysis of clinical phenotypes are needed (ongoing) to address cohort-specific biomarker shifts and isolate reliable PD-specific neurological signatures across datasets.

EARLY PREDICTION OF NEURODEGENERATION AT BIOBANK-SCALE VIA MACHINE LEARNING AND IMAGING

POSTERS: C04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Anant Dadu[1,2], Michael Ta[1,2], Nicholas Tustison[3], Ali Daneshmand[4], Andrew Singleton[2], Roy Campbell[5], Michael Nalls[1,2], Hirotaka Iwaki[1,2], Brian Avants[3], Faraz Faghri[1,2]
[1]Data Tecnica LLC, Data Tecnica Llc, Washington, United States of America, [2]National Institutes of Health, Center For Alzheimer's And Related Dementias, Bethesda, United States of America, [3]University of Virginia, Dept Of Radiology And Medical Imaging, Charlottesville, United States of America, [4]Boston University School of Medicine, Department Of Neurology, Boston, United States of America, [5]University of Illinois Urbana Champaign, Department Of Computer Science, Champaign, United States of America

Aims: Alzheimer's disease and related dementias (ADRD) and Parkinson's disease (PD) are the most common neurodegenerative disorders. Patients with ADRD or PD have long asymptomatic phases. Hence, quantitative measures that can provide early disease indicators are necessary to improve patient stratification, clinical care, and clinical trial design. This work uses machine learning techniques to derive such a quantitative marker from T1-weighted (T1w) brain MRI.
Methods: In this retrospective study, we developed a machine learning (ML) based score of T1w brain MRI image utilizing disease-specific Parkinson's Disease Progression Marker Initiative (PPMI) and Alzheimer's Disease Neuroimaging Initiative (ADNI) cohorts. Then, we evaluated the potential of ML-based scores for early diagnosis of ADRD and PD in an independent large-scale population-based cohort, UK Biobank, using longitudinal data. In this analysis, 1,826 dementia (from 731 participants), 3,161 healthy controls images (925 participants) from the ADNI cohort, 684 PD (319 participants), 232 healthy controls (145 participants) from PPMI cohort were used to train machine learning models.
Results: The classification performance is 0.94 [95% CI: 0.93-0.96] area under the ROC Curve (AUC) for ADRD detection and 0.63 [95% CI: 0.57-0.71] for PD detection using 790 extracted structural brain features. The normalized ML model's probabilistic output (ADRD and PD imaging scores) was evaluated on 42,835 participants from UK Biobank using survival analysis. ADRD imaging score is associated with dementia free survival (hazard ratio (HR) 1.76 [95% CI: 1.50-2.05] per standard deviation), and PD imaging score shows association with PD free survival (HR 2.33 [95% CI: 1.55-3.50]) after adjusting for covariates.
Conclusions: Our study demonstrates the use of quantitative markers generated using machine learning techniques and brain structural features are useful for early detection of ADRD and PD.

Aims: Regional atrophy patterns have been observed in dementia with Lewy bodies (DLB). However, determinants of regional vulnerability to atrophy remain largely unexplored. Here, we investigated the association between regional gene expression and grey matter atrophy in probable DLB patients.
Methods: 165 DLB patients along with 165 age- and sex-matched healthy controls from three European centres and the Mayo Clinic (USA) were included. Volumetric atrophy was quantified from MRI using SPM12 in 112 cortical, subcortical, and cerebellar brain regions, and compared between groups, using *w*-scores. Regional expression data of seven genes involved in the formation and degradation of pathological protein aggregates (*APOE*, *APP*, *BIN1*, *GBA*, *MAPT*, *SNCA*, *TMEM175*) was extracted from six healthy donors from the Allen Human Brain Atlas and correlated with regional atrophy *w*-scores. Additionally, we assessed the predictive values of regional gene expression on regional atrophy using Gaussian stepwise backwards linear regression including all seven genes as predictors.
Results: Most brain regions showed atrophy in DLB patients compared to healthy controls, with atrophy being most pronounced in occipital and parietal lobes. Regional expression of *APOE* correlated negatively with regional atrophy in DLB. Conversely, regional expression of *MAPT* correlated positively with regional atrophy. Both APOE and MAPT gene expression were significant predictors of regional atrophy in the regression analysis. None of the other gene expression values was significantly associated with regional atrophy in DLB.
Conclusions: Our findings show that regional expression of genes associated with the abnormal accumulation of amyloid and tau, common co-pathologies in DLB, partially account for the brain atrophy pattern observed in DLB patients. This finding emphasises the relevance of co-pathologies in predicting atrophy progression and identifying potential targets for future disease-modifying treatments.

Aims: The choroid plexus (ChP) has emerged as a critical player in neurosecretory and neuroimmune mechanisms, with its dysfunction often linked to protein aggregation and neuroinflammation. Changes in ChP volume have been reported in aging, neuroinflammatory disease, and Alzheimer's disease. Our objectives were to investigate if similar change is observed in premanifest-synucleinopathy (e.g. isolated-rapid-eye-movement-sleep-behavior-disorder, iRBD) by evaluating changes in ChP volume and MRI signal-intensity, and to generate a ChP atlas.
Methods: In 12 iRBD patients (11 male, aged 68±5.70 years), and 12 age-sex-matched controls (11-male, aged 65.6±6.2 years), we acquired multi-contrast (0.75mm-isotropic-resolution T_1-weighted-MEMPRAGE; 1.1mm-isotropic resolution T_2*-weighted) MRI at 7 Tesla. ChP in the lateral ventricle was manually segmented on T_2*-weighted images coregistered to T_1-weighted images, using both as reference. Volume (normalized by the total intracranial-volume) and mean T_2*-weighted and T_1-weighted signal intensity of ChP were computed, and compared between cohorts using a two-sample t-test. ChP segmentations were coregistered to stereotactic space and averaged to create a probabilistic ChP atlas.
Results: Compared to controls, in iRBD we observed (Figure 1): (i) a significant decreased volume of the right ChP, with similar trend for the left ChP; (ii) trends towards longer T_2*-weighted values; (iii) no significant changes in mean T_1-weighted values. A probabilistic atlas of left/right ChP in the lateral ventricle in iRBD and controls was created in stereotactic space (Figure

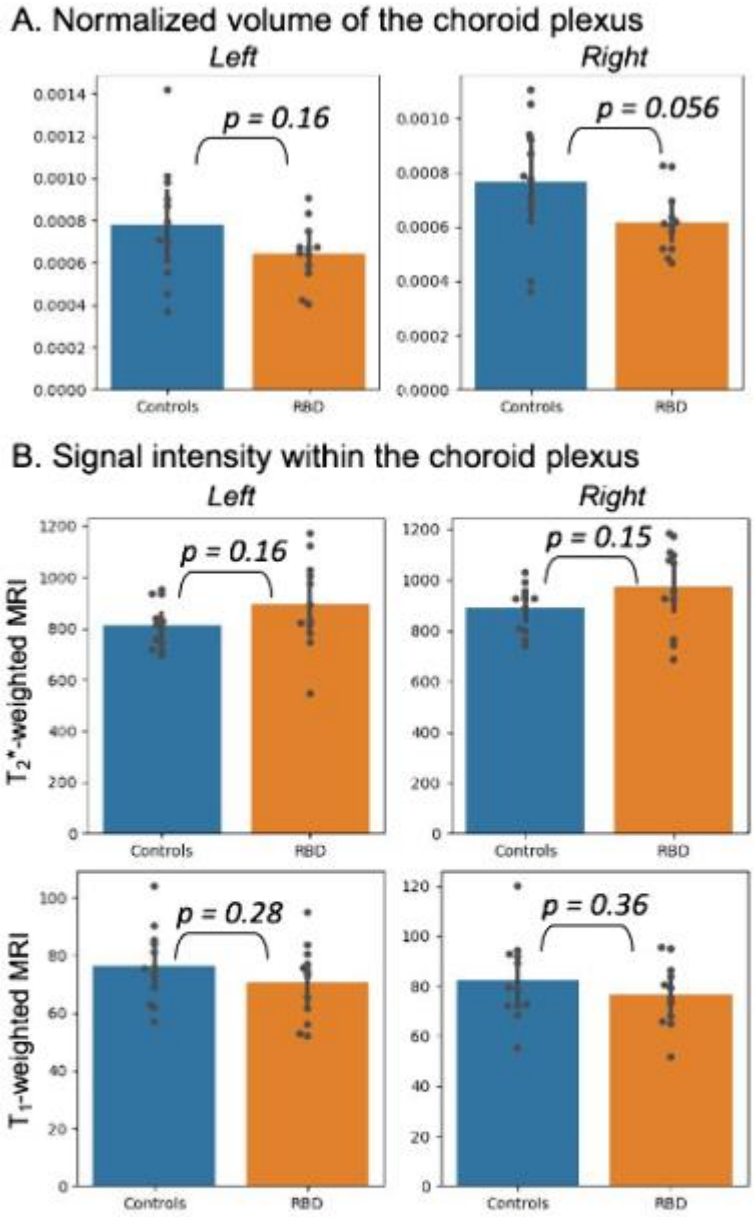

Figure 1. Changes in the volume of the choroid plexus of the lateral ventricles (A.) and in signal intensity (B.) in iRBD compared to elderly controls (n=12) using 7 Tesla multi-contrast MRI. In iRBD we observed decreased volume in right choroid plexus, trends in left choroid plexus volume and longer T_2*-weighted values, and no changes in T_1-weighted values. These results are compatible with atrophy of the choroid plexus in iRBD. We are currently analyzing multi-contrast 7 Tesla data of a larger cohort to further elucidate the choroid plexus role in the pathogenesis and progression of synucleinopathies.

2).

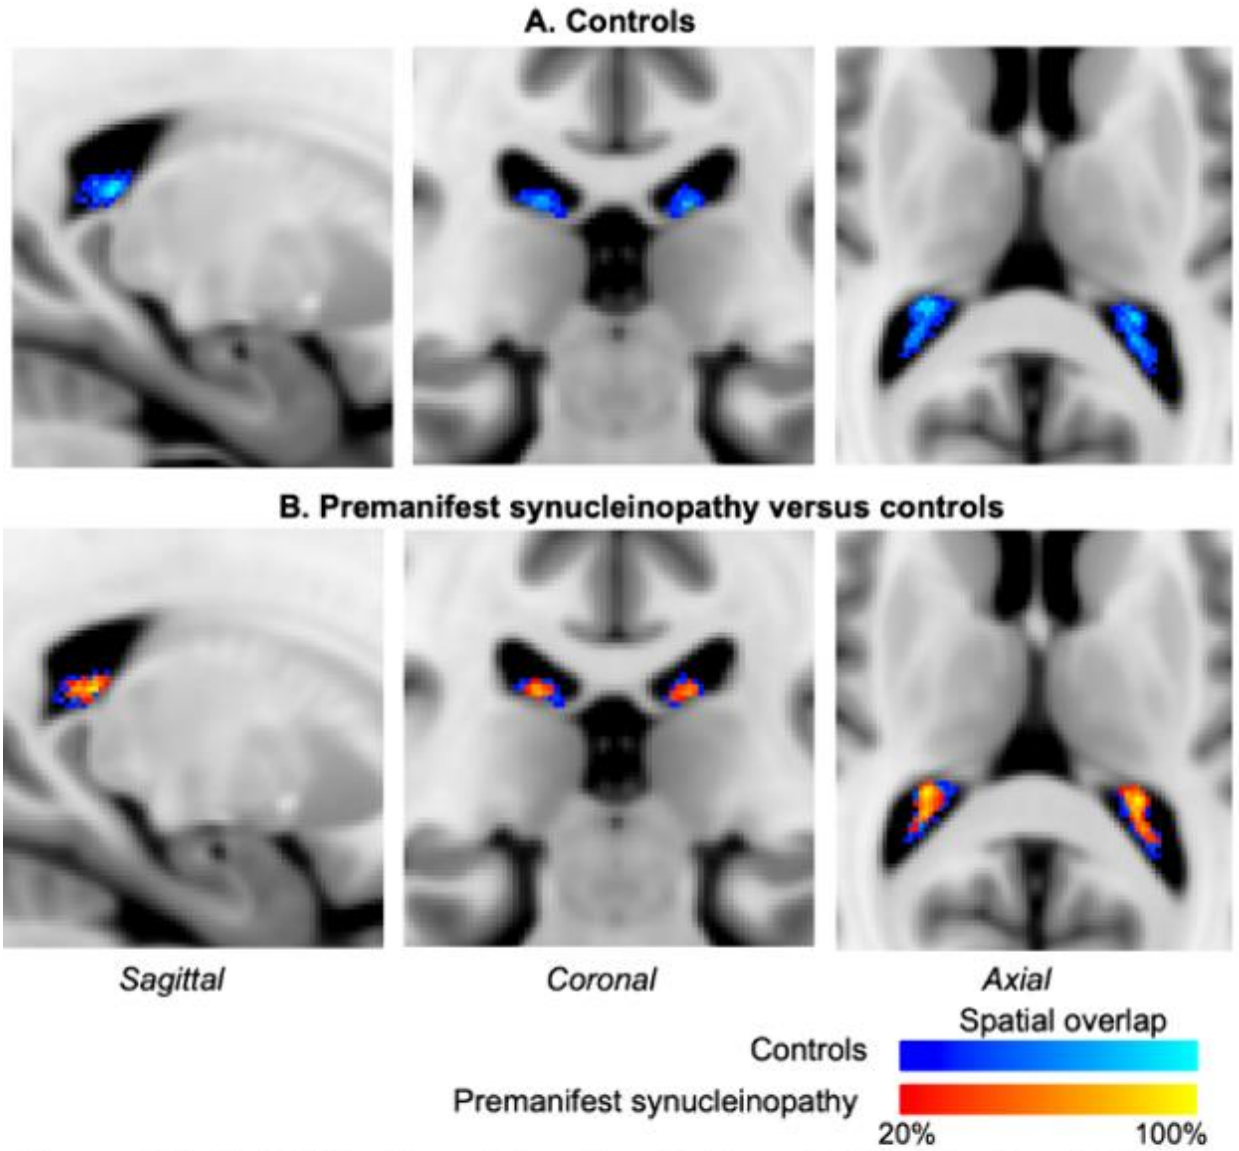

Figure 2. Probabilistic atlas of the choroid plexus in the lateral ventricles in stereotactic (Montreal Neurological Institute, MNI) space in controls (A., blue-light-blue) and in iRBD (B., red-yellow, overlapped with controls), created by computing the spatial overlap across subjects of manual segmentations. Decreased volume of the choroid plexus in iRBD is visible when compared to controls. The creation of a probabilistic atlas of the choroid plexus enhances our understanding of choroid plexus alterations in this premanifest stage, and might provide a valuable tool to automatically segment these structures in future MRI research in neurodegenerative diseases.

Conclusions: These 7 Tesla MRI-based results indicate atrophy of the ChP, which might underlie impaired neuroimmune response and neurofluid production/clearance in premanifest-synucleinopathy. This warrants further investigation to elucidate ChP role in the pathogenesis and progression of

synucleinopathies. The probabilistic atlas of ChP might be a useful tool to the community to automatically identify the location of ChP in conventional/advanced MRI.

STRUCTURAL BRAIN CHANGES IN PRODROMAL PARKINSON'S DISEASE FROM UK BIOBANK

POSTERS: C04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Mirja Kuhlencord, Andrew Vo, Alain Dagher
The Neuro (Montreal Neurological Institute and Hospital), McGill University, Neurology And Neurosurgery, Montreal, Canada

Aims: Neurodegeneration patterns of diagnosed Parkinson's disease (PD) have been successfully studied with increasingly large datasets but the same does not apply for prodromal stages. In UK Biobank, imaging participants are followed up through a linkage with their electronic health records and those who subsequently develop PD offer a unique opportunity to examine early brain changes. Here, we compared neurodegeneration patterns between unaffected controls (HC), participants with diagnosed PD (dPD) and participants with prodromal PD (pPD) at the time of their brain MRI.
Methods: From the UK Biobank imaging sample, we identified 141 participants with PD and 8,460 matched HCs based on age, sex, BMI, socioeconomic status and ethnicity. Participants with PD were either classified as diagnosed (N = 91, mean time since diagnosis: 6,2 years) if they received the diagnosis prior to the brain MRI or as prodromal (N = 50, mean time to diagnosis: 3,6 years) if they received it afterwards. We performed Kruskal-Wallis tests with FDR-correction comparing subcortical volumes, regional cortical thickness and surface area across the three groups. Significant group effects were examined with post-hoc Dunn tests.
Results: We observed significant differences between HCs and the respective PD groups for cortical thickness and between HCs and pPD patients in right hippocampal volume. Cortical thickness of both dPD and pPD patients was especially reduced in temporoparietal regions. Interestingly, there were no significant differences between the two PD groups. However, dPD patients showed a higher number of significant differences to HCs than did pPD patients. We did not find any significant differences in cortical surface area.
Conclusions: Our results show that pPD patients already display relevant neurodegeneration patterns that are mostly congruent with those observed in dPD.

WORKING MEMORY MODULATION USING A THETA-TACS OF A FRONTO-PARIETAL NETWORK

POSTERS: C03.G. DRUG DEVELOPMENT, CLINICAL TRIALS: NON-PHARMACOLOGICAL INTERVENTIONS, NEUROSURGERY

Monika Pupíková[1,2], Irena Rektorova[1,2], Adam Šimo[2], Patrik Šimko[2], Martin Lamoš[2], Martin Gajdoš[2], Kristina Mitterová[2]
[1]St. Anne's University Hospital (FNUSA), The International Clinical Research Center (icrc), Brno, Czech Republic, [2]CEITEC MU, Applied Neuroscience Group, Brno, Czech Republic

Aims: Disruption of theta oscillations within the fronto-parietal network (FPN) contributes to working memory deficits in the elderly population. The aim of this study was to test the efficacy of different unifocal and multifocal transcranial alternating current stimulation (tACS) protocols to modulate theta oscillations within the FPCN, which could compensate for working memory loss due to aging.
Methods: In a randomized, placebo-controlled trial, we tested four theta-tACS protocols with simultaneous working-memory task (Twenty seniors aged 60-80): a monofocal frontal, a monofocal parietal, and a bifocal in/out-of-phase fronto-parietal protocol. Electrodes were placed at individualized coordinates of the middle frontal gyrus (MFG) and/or the inferior parietal lobule (IPL) based on functional magnetic resonance imaging (fMRI) activations. The individual theta band stimulation frequency was based on the task-EEG recording. All participants underwent pre-post resting fMRI. Behavioral online data and rs-fmri connectivity data (pre-post stimulation changes) were analyzed using linear mixed models (LMMsfixed factors: stimulation protocol, block number, task difficulty).
Results: LMMs showed a statistically significant interaction between stimulation protocol and task difficulty ($p < 0.0001$) on performance in the N-back task. Subsequent analyses revealed the largest effect of frontal monofocal theta-tACS ($p = 0.004$, effect size $d = 0.30$). Analyses of rs-fMRI data showed a change in connectivity between the right anterior prefrontal cortex (raPFC) and the right dorsolateral prefrontal cortex (rdlPFC) compared to placebo stimulation ($p=0.022$).
Conclusions: Monofocal frontal theta stimulation resulted in small but statistically significant changes in working-memory task performance with a higher degree of difficulty, outperforming other stimulation protocols. The changes produced by tACS frontal monofocal stimulation were accompanied by changes in functional connectivity within the stimulated fronto-parietal network. Our study demonstrated the possibility of modulating working memory by externally influencing the fronto-parietal network using theta-tACS.

Aims: The spinal cord plays a critical role in processing motor and sensory information, connecting the peripheral nervous system with the brain; however, it remains unclear how its structure is affected in Parkinson's disease (PD). We studied upper (cervical) spinal cord morphometry across distinct clinical stages of PD versus controls using a state-of-the-art parcellation technique.
Methods: Spinal cord segments C1-C4 were parcellated from T1-weighted MR images of 189 individuals with PD and 131 controls, derived from two sites, using the Spinal Cord Toolbox (https://spinalcordtoolbox.com/). The PD group was stratified by Hoehn and Yahr (HY) disease stage 1 (n = 26), 2 (n = 102) and 3 and higher (n = 34) (n = 27 no HY-score available), and compared to controls on the surface area and shape of each cervical segment using a linear mixed model, including age, sex and site as covariates.
Results: HY2 and HY3 showed significantly smaller surface area of C1 (d = -0.6, p < 0.001 and d = -0.9 p < 0.001, respectively). Additionally, the surface area of C4 was significantly smaller in HY3 (d = -0.22, p = 0.037). We found no differences in HY1 for surface area and shape.
Conclusions: These results indicate the involvement of specific cervical segments in PD, dependent on disease stage. While HY1 appears normal, smaller C1 and subsequently C4 in following stages may reflect targeted neurodegeneration, in line with disease progression. Follow-up research in a larger sample is needed to confirm the robustness of these patterns and to study the relation with specific symptom domains.

G2019S-LRRK2 INDUCES NEUROVASCULAR ABNORMALITIES IN A MOUSE MODEL OF PARKINSON DISEASE

POSTERS: C04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Hannah Fuehrer[1], Bo Ning[1], Khuleshwari Kurrey[1], Lishan Lin[1], Maria Gabriela Mercado Guerra[1], Mali Jiang[1], Peter C.M. Van Zijl[2], Christopher Ross[1], Jun Hua[2], Wanli Smith[1]

Aims: Parkinson's disease (PD) is a common neurodegenerative disease characterized by motor impairments resulting from midbrain dopamine (DA) neuron loss. Mutations in LRRK2 cause genetic PD and contribute to sporadic PD. Here, we used LRRK2-G2019S transgenic mouse model to investigate abnormalities in arteriolar cerebral blood volume (CBVa) in various brain regions using the inflow-based vascular-space-occupancy (iVASO) MRI technique.
Methods: CBVa was measured in the substantia nigra (SN), olfactory cortex and prefrontal cortex. Alterations in the blood volume of small arteries and arterioles (CBVa) were detected in the G2019S-LRRK2 mouse model of PD.
Results: Compared to non-transgenic mice, G2019S-LRRK2 mice at clinical stage showed decreased CBVa in the SN, but increased CBVa in olfactory and prefrontal cortex in both male and female groups. On contrast, WT-LRRK2 mice showed no change in CBVa in the SN (male and female), the olfactory (female) and prefrontal (female) cortex, but a slight increase in CBVa in the olfactory and prefrontal cortex in the male group only. These changes in CBVa in the SN and the cortex in G2019S-LRRK2 mice was corresponding with PD pathology.
Conclusions: Our studies suggest the potential value of CBVa as a marker for clinical PD studies.

ASSOCIATION BETWEEN REGIONAL CEREBRAL PERFUSION AND MOTOR RESERVE IN EARLY PARKINSON'S DISEASE: AN EARLY-PHASE 18F-FP-CIT PET STUDY

POSTERS: C04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET

Yeo Jun Yoon[1], Su Hong Kim[2], Phil Hyu Lee[1], Yun Joong Kim[3], Young H. Sohn[1], Yong Jeong[2], Seok Jong Chung[3]
[1]Yonsei University College of Medicine, Neurology, Seoul, Korea, Republic of, [2]Korea Advanced Institute of Science and Technology, Bio And Brain Engineering, Daejeon, Korea, Republic of, [3]Yongin Severance Hospital, Neurology, Yongin, Korea, Republic of

Aims: There are individual differences in motor deficits, despite a similar degree of nigrostriatal dopamine depletion in Parkinson's disease (PD), called motor reserve. This study aimed to investigate the alterations in regional cerebral perfusion associated with motor reserve in patients with PD, using early-phase ^{18}F-FP-CIT PET images.
Methods: We enrolled 397 patients with newly diagnosed PD who underwent dual-phase ^{18}F-FP-CIT PET scans upon initial assessment. Individual motor reserve was estimated based on initial parkinsonian motor deficits and striatal dopamine depletion using a residual model. Then, patients were classified into three groups according to motor reserve estimates: the highest quartile PD group (PD-MR-H, n = 100), the intermediate (i.e., the second and third quartile) PD group (PD-MR-I, n = 197), and the lowest quartile PD group (PD-MR-L, n = 100). We explored the group differences in regional uptake in the early-phase ^{18}F-FP-CIT PET images between the three PD groups.
Results: As expected, patients in the PD-MR-H group exhibited less severe baseline motor deficits than did those in the other PD groups despite having similar levels of dopamine transporter availability in the posterior putamen. There were no significant differences in age and sex between the PD groups, while patients in the PD-MR-H group had a higher level of educational attainment and better cognitive performance in verbal memory function than those in the other groups. Quantitative analyses of early-phase ^{18}F-FP-CIT PET images demonstrated that the PD-MR-L group exhibited decreased uptake in the occipital region, including the lateral occipital, compared to the PD-MR-H group.
Conclusions: The results of the present study suggest that cerebral hypoperfusion in the occipital region on early-phase ^{18}F-FP-CIT PET images are associated with low motor reserve in patients with newly diagnosed PD.

DEEP-LEARNING BASED CLASSIFICATION OF DUAL-PHASE 18F-FP-CIT PET IMAGES FOR THE DIAGNOSIS OF PARKINSONISM

POSTERS: C04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET

Dongwoo Kim, Daesung Kim, Kyobin Choo, Hyunkyung Han, Jihye Lee, Soomin Kim, Jaekyung Park, Hyunkeong Lim, Mijin Yun
Yonsei University College of Medicine, Department Of Nuclear Medicine, -, Yonsei-Ro, Seodaemun-gu, Seoul , Republic of Korea, Korea, Republic of

Aims: This study aims to develop a deep-learning based framework that helps with the analysis of dual-phase 18F-FP-CIT PET images to detect persons with normal condition (NC), idiopathic Parkinson's disease (IPD), progressive supranuclear palsy (PSP), and multiple system atrophy (MSA).
Methods: This study analyzed 388 cases from 2015 to 2022. Labels were given by the consensus of two experts, one nuclear medicine physician and one clinician. Data was split into train, validation, and test sets by an 8:1:1 ratio to evaluate the effects of model architecture, regularization, and dual-phase imaging. Models were chosen based on F1 score and accuracy, followed by 5-fold cross validation. The top models were compared with their ensemble, and the best ensemble was tested prospectively on 76 cases for a month.
Results: DenseNet, EfficientNet, and a custom CNN were chosen as candidate architectures. The custom CNN had the highest performance (F1 score, accuracy: 0.90, 0.90) individually. Regularization improved its accuracy to 0.92. When trained on delay-phase and early-phase images, its scores dropped to 0.62, 0.77 and 0.83, 0.82. DenseNet showed best performance in 5-fold cross-validation, with an average F1 score of 0.90 (std 0.05) and an average accuracy of 0.92 (std 0.04). In ensemble, the F1 score and the accuracy improved to 0.94 and 0.95. This ensemble model yielded a F1 score of 0.71 and an accuracy of 0.92 during the prospective study.
Conclusions: Convolutional neural network has shown to be capable of classifying 18F-FP-CIT PET images at the level of a skilled nuclear medicine physician. Further research may explore the possibility of performing classification on data from different PET devices.

A NOVEL ALGORITHM TO PRODUCE POPULATION-BASED INPUT FUNCTION FOR ARTERIAL INPUT FUNCTION

POSTERS: C04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET

Daren Ma[1], Sneha Pandya[2], Ashish Raj[1], Ajay Gupta[2]
[1]University of California San Francisco, Radiology And Biomedical Imaging, San Francisco, United States of America, [2]Cornell University, Weill-cornell Medical College, New York, United States of America

Aims: The accuracy of Population-based Input Functions (PBIF) depends on scaling with at least a small number of arterial or late venous blood samples, which defeats its primary non-invasive purpose. We propose to produce the PBIF estimate using machine learning algorithms on limited current data without requiring new blood samples.
Methods: First, we collected the Time Activity Curves (TACs) from 22 subjects, and performed linear interpolation and peak alignments. Next, we divided the processed TACs by their corresponding AUCs for each subject and calculated the average to obtain the PBIF curve. Subsequently, we used demographic data as input for our Gradient Boosting model to generate AUC predictions. Afterwards, we multiplied the PBIF curve by the subject-wise predicted AUCs to form the predicted AIF curves. After obtaining the pAIF, Kinetic modelling was done to extract total V_T , derived from both empirical AIF and pAIF for 86 brain regions in D-K Atlas through the graphical Logan method. Lastly, we implemented a slope-prediction ML algorithm to improve the fit between Logan V_T from AIF and pAIF.
Results: We demonstrate excellent match with arterial blood derived V_T results, comparing favorably to prior naive PBIF techniques. Our PBIF approach doesn't rely on a priori distinguish between healthy and disease subjects. Indeed, it's equally effective on control and Parkinson's patients, and in genetically medium- versus high-affinity binders. Results are shown in Fig 1 and 2.

Fig 1: PBIF Related Curves

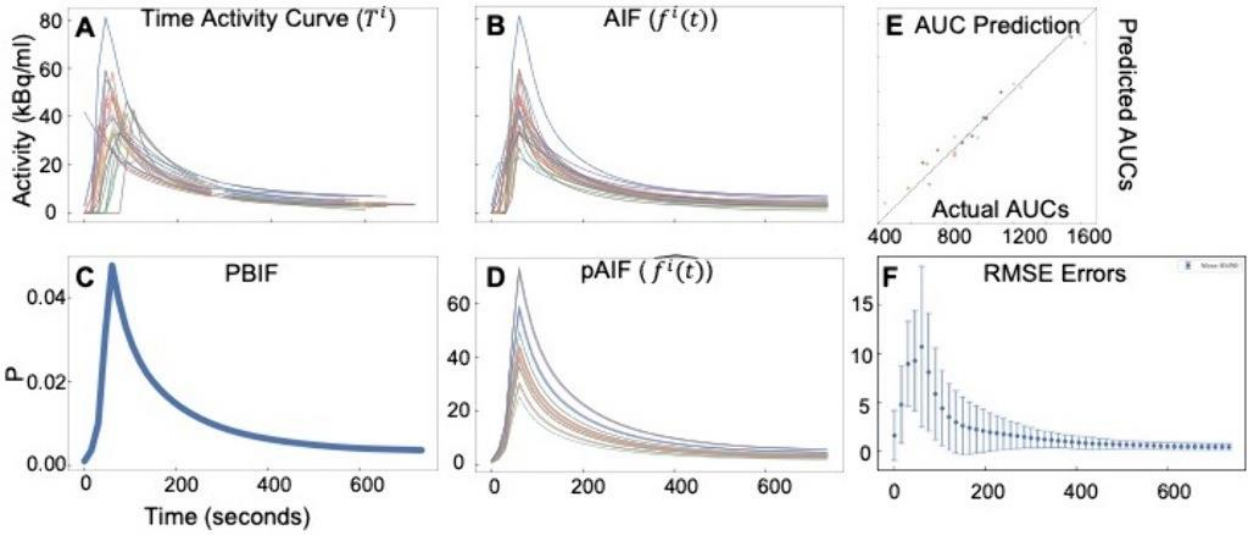

Fig 2: Logan V_T Results

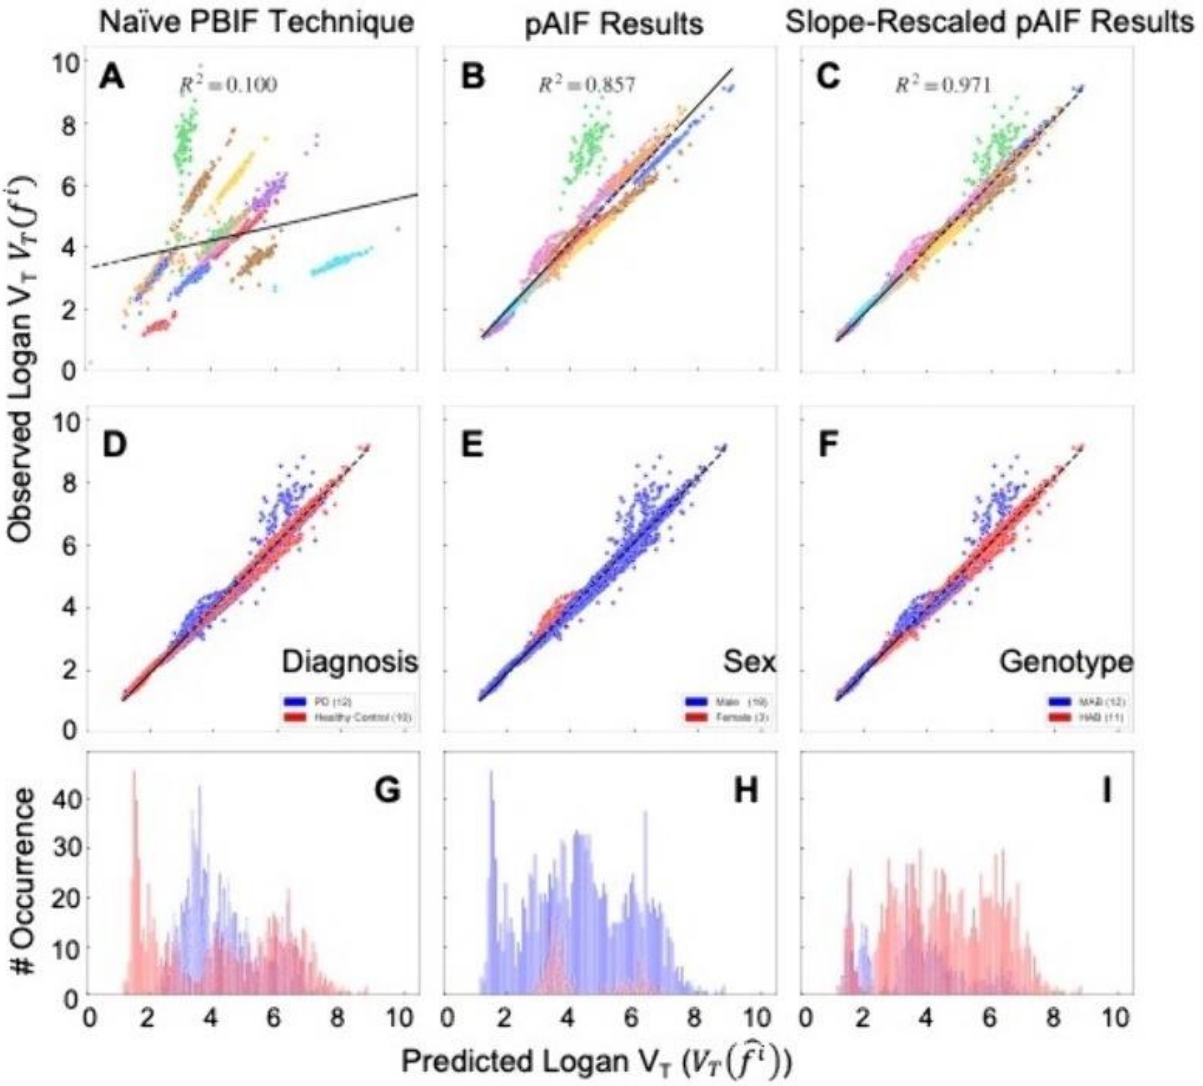

Conclusions: This study shows that [^{11}C] DPA-713 radioligand can be quantified without any arterial blood or venous blood samples, from PBIF based on previously acquired dataset on patients with A-lines, in clinical applications or scientific exploratory analyses where the primary attention is on spatial gradients or heterogeneity of microglial PET signal.

SPINOCEREBELLAR ATAXIA TYPE 3 (MJD) WITHOUT DISTINCT PARKINSONISM SHOWING PRESYNAPTIC DOPAMINE TRANSPORTER (DAT) UPTAKE LOSS

POSTERS: C04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET

Mee Young Park, Jeanseo An, Dong Sung Shin
YEUNGNAM UNIVERSITY MEDICAL CENTER, Neurology, Daegu, Korea, Republic of

Aims: We report a unusual case of SCA3 showing presynaptic DAT uptake loss without initial parkinsonism.
Methods: A 29-year-old female presented with posture imbalance and gait disturbance. Her neurologic examination showed bidirectional gaze evoked nystagmus, dysarthria, ataxia, spasticity but no parkinsonism for 2years. Her family history was usual.
Results: Brain **MRI** demonstrated ponto-cerebellar atrophy and 1**8F FP-CIT PET** imaging demonstrated definite presynaptic dopamine transporter (DAT) uptake loss. Molecular analysis revealed an expanded **SCA3 allele of 15/74 expansion**. Figure 1. Brain MRI of the patient. T2-saggital (A) and T2-FLAIR (B, C) images shows mild ponto-cerebellar atrophy (arrowheads). After 7 months, a follow-up brain MRI (D, E, F) also shows similar findings without significant change. Figure 2. FP-CIT PET of the patients. Diffuse uptake loss of presynaptic dopamine transporter (DAT) binding in Both putamen and caudate nucleus Figure 3. **Cardiac 123I-MIBG** of the patients. Cardiac meta-iodobenzylguanidine (MIBG) uptake is assessed using the heart-to-mediastinum (H/M) activity ratio. This image shows cardiac sympathetic denervation in Cardiac 123I-MIBG scan. (A) early anterior image of the patient (H/M ratio = 1.61). (B) early lateral anterior oblique image of the patient (H/M ratio = 1.86). (C) late anterior planar of the patient (H/M ratio = 1.66). (D) late lateral anterior oblique image of the patient (H/M ratio = 1.93) Table 1. , UPDRS(united PD rating scale) and SARA (Scale for the assessment and rating of ataxia) of the patients for 2 years
Conclusions: In SCA 2 and 3, parkinsonism may rarely presenting as the disease progresses, early diagnosis by DAT scan, L-dopa therapy can improve the patient's QOL. 1. Ludger Scho¨ ls, et al. No parkinsonism in SCA2 and SCA3 despite severe neurodegeneration of the dopaminergic substantia nigra. *BRAIN* 2015:138;3316–26.

EFFICACY OF 18F-DOPA PET AND SNIFFIN' STICKS TEST FOR THE DIAGNOSIS OF PARKINSON'S DISEASE

POSTERS: C04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET

Denis Pokhabov[1], Vladislav Abramov[2], Michael Sadovsky[3], Dmitrii Pokhabov[1]
[1]Krasnoyarsk state Medical University, Neurological Diseases, Krasnoyarsk, Russian Federation, [2]Federal Siberian Research Clinical Centre FMBA, Neurological Diseases, Krasnoyarsk, Russian Federation, [3]Siberian Federal University, Computational Technology Process, Krasnoyarsk, Russian Federation

Aims: Parkinson's disease(PD) is among the most common neurodegenerative diseases of the elderly. The etiology of PD is still unknown. Positron emission tomography(PET) is an up-to-date and promising method in diagnosing PD and other diseases. Our aim was to examine patients using PET for the analysis of development and degradation of dophaminergic neurons in PD and also examine their olfactory function.
Methods: 18F-DOPA is the optimal radiopharmaceutical(RP) for studying the dopaminergic system. All patients initially underwent MRI of the brain to exclude structural changes and compare the MRI and PET images. Fifty minutes after the administration of 18F-DOPA, static 3D scanning was performed for 20 minutes on a PET scanner. We analysed the max and mean(ave) values of activity, as well as ratio of the activity of the shell/visual cortex(SOR), caudate/visual cortex(COR), posterior shell/front shell(PAR) and in-shell activity to the activity in the caudate nucleus (SCR). An examination procedure of olfactory function was based on extended olfactory Sniffin' sticks test.
Results: The level of RP uptake in the rear part of the shell is the most diagnostically significant indicator among all relative indices. SOR is the most diagnostically valuable indicator. It is associated with the most significant difference in RP accumulation in the shell and the visual cortex. The diagnostic value of SCR and COR is slightly lower because of the minor difference between the accumulation in the shell and them. Two separate clusters appear in constructing elastic maps using eight selected relative. We also got a three clusters of patients by olfactory test.
Conclusions: Here we present the reference values of the indices for brain PET investigation. The informative indices are determined from the observed PET data. Also, high efficiency of PET for Parkinson's disease was approved.

EFFECTS OF DE-FACING MRI AND PET SCANS ON FDG BIOMARKERS OF DLB

POSTERS: C04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET

Christopher Schwarz[1], Walter Kremers[2], Stephen Weigand[2], Scott Przybelski[2], Timothy Lesnick[2], Bradley Boeve[3], Carl Prakaashana[1], Matthew Senjem[1], Qin Chen[1], Julie Fields[4], Jeffrey Gunter[1], Paul Min[1], Manoj Jain[5], Toji Miyagawa[3], Rodolfo Savica[3], Jonathan Graff-Radford[3], Hugo Botha[3], David Jones[3], Neill Graff-Radford[6], Tanis Ferman[7], Prashanthi Vemuri[1], David Knopman[3], Val Lowe[1], Kejal Kantarci[1], Clifford Jack[1]
[1]Mayo Clinic, Radiology, Rochester, United States of America, [2]Mayo Clinic, Quantitative Health Sciences, Rochester, United States of America, [3]Mayo Clinic, Neurology, Rochester, United States of America, [4]Mayo Clinic, Psychiatry & Psychology, Rochester, United States of America, [5]Mayo Clinic, Radiology, Jacksonville, United States of America, [6]Mayo Clinic, Neurology, Jacksonville, United States of America, [7]Mayo Clinic, Psychiatry & Psychology, Jacksonville, United States of America

Aims: Recent work has shown that de-identified brain research scans can potentially be re-identified using face recognition. Software to automatically "de-face" images (remove the face before data sharing) is increasingly used to protect participant privacy. *mri_reface*, which replaces the face with an average face, was shown to have no significant effects on AD biomarkers from MRI, amyloid PET, and tau PET. However, effects on FDG PET and biomarkers of DLB have not been measured.
Methods: We replicated a previous analysis of FDG metabolic signatures of DLB (Kantarci et al., NeuroImage: Clinical, 2021) both with and without applying *mri_reface* to all T1-weighted 3T MRI and FDG PET images. This included images from patients with MCI at the Mayo Clinic Alzheimer's Disease Research Center who underwent PET at baseline and progressed to either probable DLB (MCI-DLB, n=17) or AD dementia (MCI-AD, n=41) during follow-up, and a comparison cohort of age- and sex-frequency-matched cognitively unimpaired (CU) participants from the Mayo Clinic Study of Aging (n=100). We measured the group-discrimination ability of 3 FDG PET biomarkers (Cingulate Island Sign (CIS) Ratio, Substantia Nigra SUVR, and Medial Temporal SUVR) and voxel-wise FDG group differences. We then directly tested for statistical differences between the unmodified and de-faced image analyses.
Results: All analyses were qualitatively similar between unmodified and de-faced image measurements. Region-based analyses had AUC values that differed by ≤ 0.02, and voxel-based analyses found qualitatively identical voxel masks and statistical power. There were no statistically significant differences between any pairs of analyses with unmodified vs. de-faced images.

model	AUC.Unmodified	AUC.DeFaced	p.Original_vs_DeFaced
Group ~ CISRatio	0.79	0.79	0.777
Group ~ MedialTemporal	0.81	0.81	0.687
Group ~ SubstantiaNigra	0.79	0.80	0.717
Group ~ CISRatio + MedialTemporal	0.86	0.86	>0.999
Group ~ CISRatio + SubstantiaNigra	0.88	0.88	>0.999
Group ~ MedialTemporal + SubstantiaNigra	0.89	0.87	0.316
Group ~ CISRatio + MedialTemporal + SubstantiaNigra	0.91	0.91	0.785

Figure 1: For each logistic regression model using regional FDG PET imaging biomarkers, we measured the ability to discriminate between MCI-DLB and MCI-AD using the Area Under the Receiver Operating Characteristic Curve (AUC), first with the unmodified images, and again with the de-faced images. We directly compared these AUC values from the unmodified vs. de-faced images with roc.test(). In total, there were no significant differences between models with measurements from the original vs. the de-faced images.

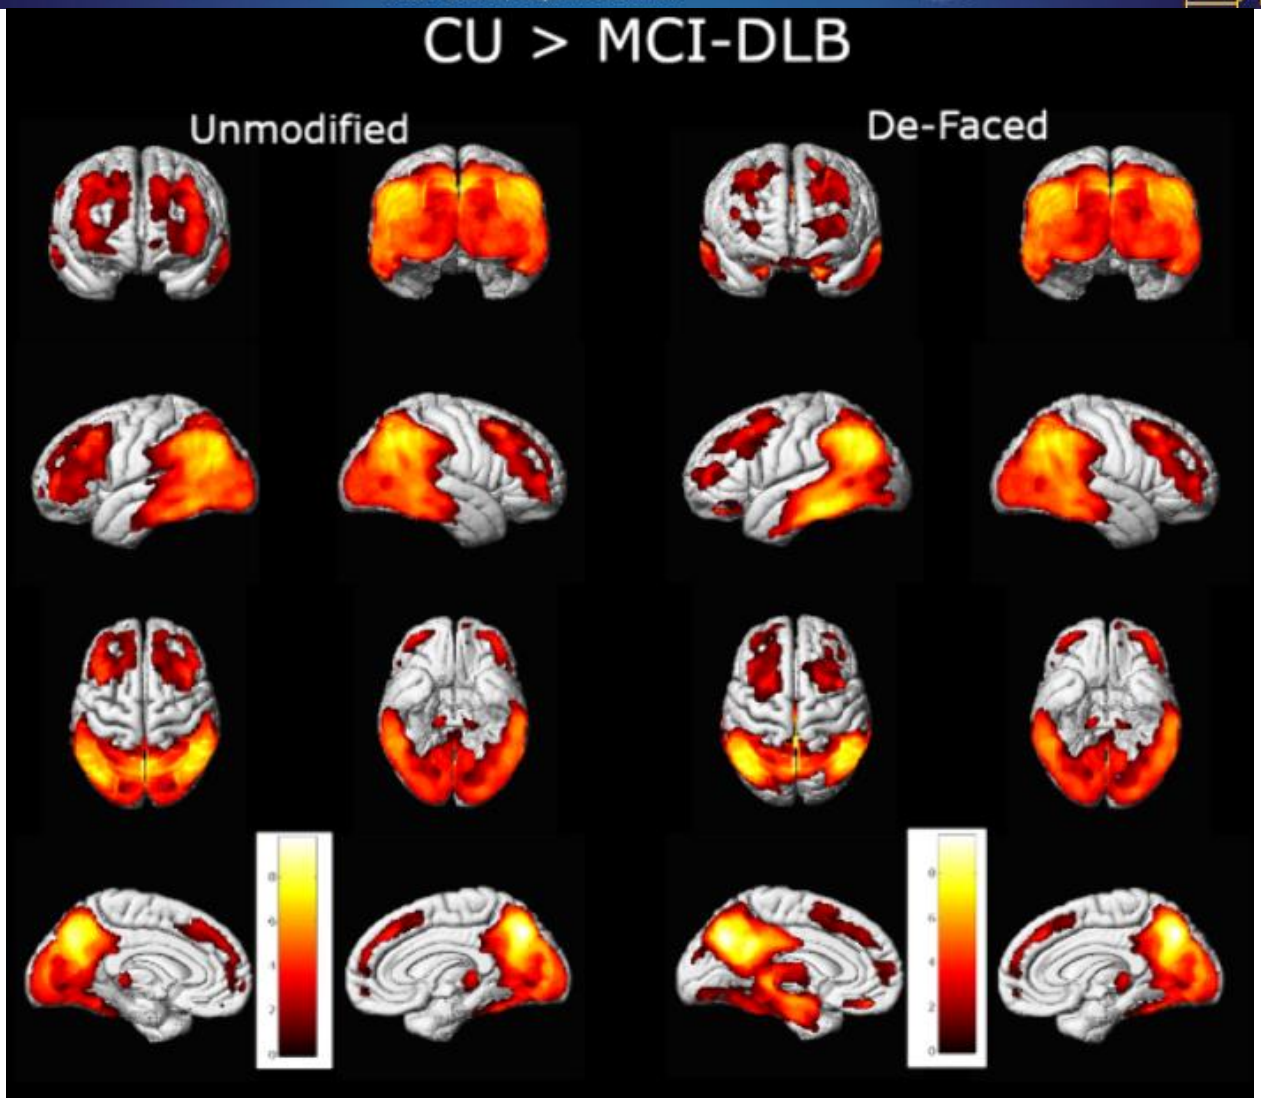

Figure 2: Voxel-based analyses (p<0.05 FWE) with unmodified images (left) vs. de-faced images (right) were qualitatively identical. A second-level analysis comparing these analyses (not shown) had zero significant differences in both directions (p<0.001 uncorrected).

Conclusions: De-facing MRI and FDG PET images with *mri_reface* had no significant effects on analyses of FDG PET biomarkers of DLB.

CHARACTERIZATION OF A PREFORMED FIBRIL SEEDING MODEL OF SYNUCLEINOPATHY WITH A NOVEL ALPHA SYNUCLEIN PET TRACER

POSTERS: C04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET

Jonathan Sugam[1], Yuchuan Wang[2], Hyking Haley[2], Mona Purcell[2], Jun Meng[2], Stefan Verhoog[2], Rob Drolet[1], Zhizhen Zeng[2], Patricia Dockery[2], Idriss Bennacef[2], Kerry Riffel[2], Mallory Stenslik[2], Lei Ma[1], Wenping Li[2], Helen Mitchell[3], Jacob Marcus[1], Sean Smith[1], Eric Hostetler[2]
[1]Merck Sharp & Dohme, Discovery Biology, Rahway, United States of America, [2]Merck Sharp & Dohme, Translational Imaging, Rahway, United States of America, [3]Merck Sharp & Dohme, Chemistry, Rahway, United States of America

Aims: The pathological spreading hypothesis of Parkinson's disease (PD) has been modeled preclinically using a preformed fibril (PFF) seeding model. Detection of this synucleinopathy has previously only been possible via post-mortem histological or biochemical evaluations. A PET tracer for alpha synuclein would further validate that the pathology induced by the PFF seeding model is similar to the pathology present in patients and provide a clinically translatable biomarker of efficacy for therapeutic targets of synucleinopathy.
Methods: Young A30P mice (9-10 weeks old) were injected unilaterally into the striatum with varying concentrations of PFF or monomeric synuclein. Animals were imaged with an [^{18}F] labeled synuclein PET tracer 15-16 days following injection. SUVR changes were determined for the striatum using cerebellum as reference, and both bilateral striatal SUVR and right/left striatal uptake ratio were measured.
Results: We observed a dose response related relationship in SUVR in the striatum of animals injected with PFF compared to monomer with higher SUVR for animals injected with higher concentrations of PFF. Further, we also observed elevated SUVR in the right (injected) striatum compared to the left (uninjected) striatum. The ratio of right/left SUVR was greater for higher concentrations of PFF compared to monomer.
Conclusions: As the PFF seeding model is widely used in the field, this data validates that the synucleinopathy induced by PFF is relevant to human PD. This model can also help accelerate the evaluation of novel PET tracers, as PFF seeding induces pathology in young mice in as short as 2 weeks rather than relying on aged transgenic models. As a whole, this platform will be critical for the evaluation of preclinical to clinical translatable biomarkers of disease progression and therapeutic efficacy.

THE POTENTIAL USEFULNESS OF SEMIQUANTITATIVE ANALYSIS OF 10-MINUTES POST-INJECTION F-18-DOPA PET FOR THE DIAGNOSIS OF PARKINSONIAN SYNDROMES

POSTERS: C04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET

Tiago Vieira[1], Facundo Diaz[2], Manuel Perez[3], José Oliveira[4]
[1]Atrys, Nuclear Medicine, porto, Portugal, [2]Atrys, Radiology, Barcelona, Spain, [3]Hospital Italiano de Buenos Aires, Radiology, Buenos Aires, Argentina, [4]Atrys, Nuclear Medicine, Porto, Portugal

Aims: F-18-DOPA is a PET agent for presynaptic dopaminergic assessment. PET can be analyzed qualitatively or semiquantitatively using standardized uptake ratio (SUR). SUR of F-18-DOPA PET showed to differentiate subjects with and without parkinsonian syndromes (PS), but 10-minutes post-injection (tenPI) ratios have not been evaluated. We studied the accuracy of semiquantitative analysis of tenPI PET in predicting the visual interpretation of 90-minutes post-injection (ninetyPI) PET in subjects with suspected PS.
Methods: PET was acquired at 2 time-points, 10 minutes and 90 minutes, post-injection of F-18-DOPA; image reconstruction using OSEM. SUVmax was recorded in each basal ganglia and in the occipital cortex, at both time-points. SUR was calculated as SUVmax of basal ganglia/SUVmax of the occipital cortex. The results of the visual analysis of ninetyPI PET, as reported by the nuclear medicine physician, were used for evaluating the accuracy of the semiquantitative analysis in predicting the visual interpretation.
Results: Sixteen subjects include; nine male, 7 female; median age: 63±10 years. As per qualitative analysis, 6 exams were considered to show decreased uptake (DU) in the basal ganglia and 10 exams were interpreted as presenting normal uptake (NU). In tenPI PET, SUR was significantly different between subjects with DU and NU ((p = 0.016); 1.2 (1.1-1.3) and 1.4 (1.3-1.5), in DU and NU, respectively). In ninetyPI PET, SUR was not significantly different between subjects with DU and NU ((p = 0.118); 3.1 (2.5-3.1) and 3.2 (2.9-3.3), in DU and NU, respectively). In tenPI PET, sensitivity, specificity, positive predictive value, and negative predictive value of SUR were 83.3%, 80%, 71.4% and 88.9%, respectively.
Conclusions: For the diagnosis of PS, SUR in tenPI F-18-DOPA PET seems to predict the visual interpretation of ninetyPI F-18-DOPA PET with good accuracy.

THE IMPACT OF AN ADVANCED BAYESIAN PENALIZED-LIKELIHOOD RECONSTRUCTION ALGORITHM ON THE SEMIQUANTITATIVE ANALYSIS OF F-18-DOPA PET FOR THE DIAGNOSIS OF PARKINSONIAN SYNDROMES

POSTERS: C04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET

Tiago Vieira[1], Facundo Diaz[2], Manuel Perez[3], José Oliveira[1]
[1]Atrys, Nuclear Medicine, Porto, Portugal, [2]Atrys, Radiology, Barcelona, Spain, [3]Hospital Italiano de Buenos Aires, Radiology, Buenos Aires, Argentina

Aims: F-18-DOPA is a PET agent for presynaptic dopaminergic assessment. PET can be analyzed visually or semiquantitatively using standardized uptake ratio (SUR). SUR showed to differentiate subjects with or without parkinsonian syndromes (PS). We aimed to study the impact of an advanced Bayesian penalized-likelihood reconstruction algorithm (BPLA) - which allows effective convergence, in contrast to ordered subset expectation maximization (OSEM) - on the semiquantitative analysis in predicting the visual interpretation of F-18-DOPA PET from subjects with suspected PS.
Methods: For semiquantitative analysis, SUVmax was recorded in the basal ganglia and in an occipital ROI, using images reconstructed with BPLA and standard OSEM. SUR was calculated as the SUVmax in the basal ganglia/SUVmax in the occipital cortex. The semiquantitative data were compared to the PET visual analysis reported by the nuclear medicine physician.
Results: Sixteen subjects included. Nine were male and 7 were female. Median age: 63±10 years; range: 43-80 years. As per visual analysis, 6 exams were considered to show decreased uptake (DU) in the basal ganglia and 10 exams were interpreted as presenting normal uptake (NU). When using BPLA, the average SUVmax of the two striata was significantly different between subjects with DU and NU ($p = 0.022$; 4.7 (4.5-6) and 6.8 (5.2-7.9), in DU and NU, respectively), and the SUR of the right striatum was significantly different between subjects with DU and NU ($p = 0.042$; 2.9 (2.5-3) and 3.3 (3-3.6), in DU and NU, respectively). When using OSEM, there were no statistically different values of SUVmax or SUR between subjects with DU and NU.
Conclusions: This study suggests that an advanced BPLA reconstruction algorithm positively impacts the ability of semiquantitative analysis to predict the visual interpretation of F-18-DOPA PET for diagnosing parkinsonian syndromes.

INTEROBSERVER VARIABILITY AND ASSERTIVENESS IN THE VISUAL INTERPRETATION OF F-18-DOPA PET FOR THE DIAGNOSIS OF EARLY-STAGE PARKINSONIAN SYNDROMES

POSTERS: C04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET

Tiago Vieira[1], Facundo Diaz[2], Adriana Pinto[1], Rui Ferreira[1], Fernando Silva[1], Manuel Perez[3], José Oliveira[1]
[1]Atrys, Nuclear Medicine, Porto, Portugal, [2]Atrys, Radiology, Barcelona, Spain, [3]Hospital Italiano de Buenos Aires, Radiology, Buenos Aires, Argentina

Aims: Interobserver variability affects the overall accuracy of imaging and less assertive interpretation generates diagnostic doubt, increases costs, delays treatment decisions, and causes anxiety to patients. We evaluated the interobserver variability of F-18-DOPA PET visual interpretation in subjects with suspected early-stage parkinsonian syndromes (EPS) and assessed how the assertiveness on imaging interpretation impacts interobserver variability.
Methods: Were included F-18-DOPA PET of subjects with clinical suspicion of EPS. Five nuclear medicine physicians interpreted qualitatively the exams and categorized it in 4 categories of striatal uptake: “definitively normal uptake”, “probably normal uptake”, “probably decreased uptake” and “definitively decreased uptake”; this categorization was considered non-assertive. For assertiveness, interpretation was further catagorized into three types: assertive interpretation balanced for sensitivity and specificity (“definitively normal uptake” and “probably normal uptake” were categorized as “normal uptake”, and “definitively decreased uptake” and “probably decreased uptake” were categorized as “decreased uptake”); assertive interpretation favoring sensitivity (only “definitively normal uptake” were categorized as “normal uptake”); assertive interpretation favoring specificity (only “definitively decreased uptake” were categorized as “decreased uptake”). Interobserver reliability (IR) was analyzed regarding the non-assertive categorization and assertive categorizations.
Results: Sixteen subjects included. Regarding the non-assertive categorization, the IR was very high (average measurements = 0.95 (95% CI 0.89-0.98), p<0.00001). Regarding the assertive categorizations, the IR was perfect when assertiveness pended for increased specificity, very high when assertiveness was balanced for sensitivity and specificity (average measurements = 0.93 (95% CI 0.86-0.97) p<0.00001), and regular when assertiveness pended for increased sensitivity (average measurements = 0.72 (95% CI 0.44-0.89), p<0.00001).
Conclusions: Interobserver variability in the visual interpretation of F-18-DOPA PET for evaluation of EPS is influenced by the type of assertiveness, with higher interobserver variability being associated with assertiveness pending for increased sensitivity.

STRUCTURAL MECHANISM FOR SPECIFIC BINDING OF CHEMICAL COMPOUNDS TO AMYLOID FIBRILS

POSTERS: C04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET

Shenqing Zhang, Jiang Bian
shanghai jiao tong university, School Of Life Sciences And Biotechnology, shanghai, China

Aims: Amyloid fibril is an important pharmaceutical target for diagnostic and therapeutic treatment of neurodegenerative diseases. However, rational design of chemical compounds that interact with amyloid fibrils is unachievable due to the lack of mechanistic understanding of the ligand–fibril interaction.
Methods: Here we used cryoelectron microscopy to survey the amyloid fibril-binding mechanism of a series of compounds including classic dyes, (pre)clinical imaging tracers and newly identified binders from high-throughput screening.
Results: We obtained clear densities of several compounds in complex with an α-synuclein fibril. These structures unveil the basic mechanism of the ligand–fibril interaction, which exhibits remarkable difference from the canonical ligand–protein interaction. In addition, we discovered a druggable pocket that is also conserved in the ex vivo α-synuclein fibrils from multiple system atrophy.
Conclusions: Collectively, these findings expand our knowledge of protein–ligand interaction in the amyloid fibril state, which will enable rational design of amyloid binders in a medicinally beneficial way.

BRAIN-AGE GAP IN IDIOPATHIC AND GENETIC VARIANTS OF PARKINSON'S DISEASE – ASSOCIATIONS WITH AMYLOID PATHOLOGY AND RATES OF COGNITIVE DECLINE

POSTERS: C04.A. IMAGING, BIOMARKERS, DIAGNOSTICS: STRUCTURAL MRI, MR SPECTROSCOPY

Stefan J. Teipel[1], Hauke Hoffmann[1], Julia Schumacher[1], Alexander Storch[2], Martin Dyrba[1]
[1]Deutsches Zentrum für Neurodegenerative Erkrankungen, Deutsches Zentrum Für Neurodegenerative Erkrankungen, Rostock, Germany, [2]University Medical Center Rostock, Department Of Neurology, Rostock, Germany

Aims: The brain-age gap, i.e. the difference between calendar and estimated brain age, has been proposed as a measure of accelerated brain aging in neurodegenerative brain diseases. Here, we studied brain-age in idiopathic PD and in preclinical and clinical stages of LRRK2 and GBA genetic variants.
Methods: We studied 1,200 cases from the Parkinson's Progression Markers Initiative (PPMI), including 149 asymptomatic GBA and 169 asymptomatic LRRK2 mutation carriers, 112 LRRK2 carriers and 60 GBA carriers with PD, 499 idiopathic PD, and 211 healthy controls. For comparison, we studied brain age in 187 patients with AD dementia and 254 healthy controls from the ADNI cohort. We used Bayesian ANCOVA to determine associations of diagnosis, amyloid and tau pathology, motor impairment, and dopamine function with brain-age gap. Using Bayesian mixed effect models, we determined associations of brain-age gap with rates of cognitive and motor decline.
Results: Brain-age was increased by 0.65 years in idiopathic PD and by 1 year in LRRK2 PD, but was unaltered in preclincial and clinical GBA mutation carriers. Interestingly, brain-age was reduced by 1.1 years in preclinical LRRK2 mutation carriers. Brain-age in AD dementia was increased by almost 6 years. Dopamine function contributed to brain-age gap across all PD diagnoses, but AD pathology contributed to brain-age gap in the idiopathic PD group. A higher brain-age gap was associated with accelerated episodic memory decline.
Conclusions: Brain age was less accelerated in PD than in AD, possibly due to more restricted involvement of cortical brain regions. Dopamine dysfunction contributed to brain-age gap in genetic PD, concomitant AD pathology in idiopathic PD. Decreased brain-age in preclinical LRRK2 mutation carriers may point to developmental changes in brain structure before the manifestation of symptoms.

IN VIVO IMAGING OF SYNUCLEINOPATHY IN A30P AND PFF-A30P MOUSE MODELS WITH [11C]MK-7337 PET

POSTERS: C04.C. IMAGING, BIOMARKERS, DIAGNOSTICS: PET

Yuchuan Wang[1], Idriss Bennacef[1], Hyking Haley[1], Jonathan Sugam[2], Rob Drolet[2], Jun Meng[1], Wenping Li[1], Helen Mitchell[3], Jacob Marcus[2], Sean Smith[2], Eric Hostetler[1]
[1]Merck Sharp & Dohme, Translational Imaging, Rahway, United States of America, [2]Merck Sharp & Dohme, Discovery Biology, Rahway, United States of America, [3]Merck Sharp & Dohme, Chemistry, Rahway, United States of America

Aims: [^{11}C]MK-7337 is a potent binder for α-synuclein, with first-in-human testing planned. To facilitate translational imaging in PD drug development, we investigate the feasibility of using [^{11}C]MK-7337 PET for imaging the synucleinopathy in both A30P and PFF-A30P mouse models. A30P is a transgenic PD mouse model and PFF-A30P is a seeding model with the pre-formed fibrils (PFF) of recombinant, human α-synuclein administered in A30P mouse brains.
Methods: Longitudinal scans are performed on ten A30P mice, including both homozygous and age-matched wild-type, from 12- to 24-month-old. Standardized uptake value ratio (SUVR) changes were determined for several brain regions-of-interest (ROIs) using cerebellum as reference. Next, four 3-month-old A30P mice are imaged 25-days after intra-striatal administration of both 133 μM α-synuclein PFFs (right-side) and monomers (left-side), with controls injected with only vehicles. Both bilateral striatal SUVR and right/left striatal uptake ratio are measured.
Results: Compared to wild-type, longitudinal imaging of A30P homozygous mice did not reveal elevated SUVR in any brain ROIs until after 16-month-old. Between 16- and 20- months, most homozygous mice showed heterogeneous brain uptake with higher SUVR in midbrain/brainstem which increased aggressively in the following months, concomitant with deteriorating health of the mice. In the young PFF-A30P mice, the PFF-injected (right) striatum, but not the monomer-injected (left) striatum showed significantly higher SUVR (average right/left ratio = 1.5) relative to control mice.
Conclusions: [^{11}C]MK-7337 PET can be used for imaging synucleinopathy in both A30P and PFF-A30P mouse models. The longitudinal changes of synucleinopathy in A30P were typically only detectable in mice aged >16 months. The PFF-induced synucleinopathy were detectable shortly after injections in younger mice, providing a more practical model for translational imaging.

DIFFERENTIAL VULNERABILITY IN DOPAMINERGIC PATHWAYS BETWEEN IDIOPATHIC PD AND GBA-PD PATIENTS

POSTERS: C04.D. IMAGING, BIOMARKERS, DIAGNOSTICS: SPECT

Silvia Paola Caminiti[1], Rachele Malito[2], Alice Galli[3], Micol Avenali[4]
[1]University of Pavia, Department Of Brain And Behavioral Sciences, Pavia, Italy, [2]Vita-Salute San Raffaele University, Faculty Of Psychology, Milano, Italy, [3]University of Brescia, Neurology Unit, Department Of Clinical And Experimental Sciences, Brescia, Italy, [4]IRCCS MONDINO FOUNDATION, Uiverisity Of Pavia, PAVIA, Italy

Aims: Parkinson's disease with GBA mutation (GBA-PD) shares common clinical features with idiopathic PD (iPD) without GBA mutation, however, GBA-PD shows more rapid motor and cognitive deterioration, in association with severe autonomic dysfunction and neuropsychiatric symptoms. We already found that GBA-PD patients show more severe striatal dopamine depletion than iPD. Dopaminergic connectivity alterations associated with GBA-mutations have never been investigated.
Methods: We enrolled a total of 87 patients, 44 GBA-PD and 43 iPD patients (matched for age, motor impairment and disease duration) with available brain [123I]FP-CIT-SPECT. We applied molecular connectivity analyses to assess possible alterations in the nigrostriatal and mesolimbic dopaminergic pathways characterizing the two groups, in comparison with a group of healthy controls.
Results: As expected, as the two clinical groups were similar in terms of motor impairment, we observed comparable connectivity alterations within the nigrostriatal motor pathway (GBA-PD: 16%; iPD: 22% altered connections). These changes predominantly affected connections originating from the dorsal putamen and extending to the caudate and premotor cortex. Instead, connectivity within the mesolimbic pathway was more profoundly disrupted in the GBA-PD group (GBA-PD: 13%; iPD: 6% altered connections). In GBA-PD, the connectivity alteration encompasses the ventral striatum, olfactory cortex, parahippocampal gyrus, amygdala, and the anterior cingulate gyrus.
Conclusions: Extensive and severe impairment of mesolimbic pathway connectivity has already been found in the literature in PD, and it was associated with neuropsychiatric symptoms. These new findings in the GBA population represent a further support of the association between mesolimbic dopaminergic connectivity alterations and neuropsychiatric symptoms in PD.

DATSCAN STRIATAL BINDING RATIO DYNAMICS IN MUTATIONS CARRIERS AT RISK FOR PARKINSON'S DISEASE: A 2-YEAR PROSPECTIVE STUDY

POSTERS: C04.D. IMAGING, BIOMARKERS, DIAGNOSTICS: SPECT

Amgad Droby[1], Daniel Atias[1], Hedva Lerman[2], R. Matthew Hutchison[3], Jesse Cedarbaum[4], Einat Even Sapir[2], Nir Giladi[1], Anat Mirelman[1], Avner Thaler[1]
[1]Tel Aviv Sourasky Medical Center, Neurology, Tel Aviv, Israel, [2]Tel Aviv Sourasky Medical Center, Nuclear Medicine, Tel Aviv, Israel, [3]Biogen Idc, Biomarkers, Cambridge, United States of America, [4]Coeruleus Medical Sciences LLC, Coeruleus Medical Sciences Llc, Woodbridge, United States of America

Aims: ***Background:*** Dopamine transporter spectral positron emission computed tomography (DaTscan) is widely used for establishing PD diagnosis and receives high importance in LR scores estimation. However, the association between DaTscan measures and LR scores over time remains unclear. ***Objectives:*** To investigate the temporal dynamics of striatal binding ratios (SBRs) among individuals with Parkinson's disease (PD)-related mutations and its' association with likelihood ratio (LR) for prodromal PD.
Methods: 52 healthy first-degree relatives (age 52.73±8.72 yrs, 22/30 F/M) were enrolled. All participants were genotyped and underwent DaTscan at baseline and on average after 2.21±0.3 years, and a comprehensive clinical assessment battery. LR scores and striatal binding ratio (SBRs) were calculated for all included participants. The relationship between DaTscan-derived measures and LR scores was investigated using hierarchical regression models accounting for age and sex.
Results: N=14 *GBA* Non-Manifesting Carriers (NMC), N= 14 *LRRK2* NMC, and N=24 age-matched Non-Manifesting Non-Carriers (NMNC) were included in each study group. No significant differences were detected in clinical measures and rates of change (ROC) in striatal SBRs among the study groups. Over time LR difference were associated with right putamen SBR, putamen asymmetry index, right putamen-caudate ratio at baseline (R^2= *0.11* p=0.035*;* R^2= *0.17* p=0.007; R^2= *0.16* p=0.009 respectively), and with SBR ROC in the right caudate (R^2=*0.1* p=0.036).
Conclusions: DaTscan-derived asymmetry metrics might serve as an early marker for LR increase over time, reflecting subclinical changes preceding symptoms onset in the prodromal phase of PD.

Aims: Growing literature is highlighting the presence of monoaminergic alterations in the insula and other extra-nigrostriatal regions in early phases of alpha-synucleinopathies, whereas no large studies on idiopathic REM sleep behaviour disorder (iRBD) are still available. Objective of this multicenter study was to evaluate clinical underpinnings and longitudinal predictive value of extrastriatal monoaminergic deficits in iRBD, contrasting them with controls and overt alpha-synucleinopathies namely Parkinson's disease (PD) and Lewy bodies dementia (DLB).
Methods: Polysomnography (PSG)-confirmed iRBD, age-matched PD, DLB, and controls underwent a standardized neurological examination, and ^{123}I-FP-CIT Brain SPECT imaging. iRBD subjects were classified according to standard visual basal ganglia inspection (DAT+ vs DAT-) and underwent clinical follow-up for phenoconversion. Between-groups differences in ^{123}I-FP-CIT binding were evaluated by voxel-wise analyses adjusted for age, sex and center of recruitment. Longitudinal analyses on iRBD evaluate the value of baseline monoaminergic deficits in predicting phenoconversion using cox-regression analysis adjusted for age, sex, and nigrostriatal deficits at baseline.
Results: One-hundred eighty-four subjects entered the study, namely 45 iRBD, 47 PD, 42 DLB, and 50 age-matched controls. Nigrostriatal standard visual assessment enables the classification of iRBD in RBD-DAT- (n=32), and RBD-DAT+ (n=13). Compared to controls, RBD-DAT- showed an early involvement of the left insula, with an increasing extent in RBD-DAT+, PD, and DLB. Longitudinal cox regression analyses revealed a higher risk of conversion to alpha-synucleinopathies, especially in iRBD subjects only with insular deficits (HR=6.264 [C.I. 95% 0.813-48.247 in RBD-DAT-).
Conclusions: Insular monoaminergic deficits are an early signature of iRBD, associated with higher risk of conversion to alpha-synucleinopathies. Longitudinal ongoing studies with serial imaging and advanced digital and biological prodromal markers are needed to confirm and extend these findings.

DIABETES IMPACT ON NIGROSTRIATAL VULNERABILITY IN PARKINSON'S DISEASE

POSTERS: C04.D. IMAGING, BIOMARKERS, DIAGNOSTICS: SPECT

Alice Galli[1], Andrea Pilotto[1], Cinzia Zatti[1], Clara Tirloni[2], Alessandro Lupini[1], Barbara Paghera[3], Alessandro Padovani[1]
[1]University of Brescia, Department Of Clinical And Experimental Sciences, Brescia, Italy, [2]ASST Spedali Civili, Neurology Unit, Brescia, Italy, [3]Spedali Civili Hospital, Nuclear Medicine Unit, Brescia, Italy

Aims: Several studies suggested a possible association between diabetes mellitus (DM) and Parkinson's disease (PD). Aim of the study was to investigate in vivo whether diabetes mellitus influences motor function via its impact on nigrostriatal dopaminergic vulnerability in two independent cohorts of drug-naïve patients with early-stage Parkinson's Disease (PD).
Methods: The study included two independent prospective cohorts of drug naïve PD patients who underwent a standardized neurological examination, and ^{123}I-FP-CIT brain SPECT imaging. Each cohort comprised two subgroups of PD patients with diabetes mellitus (PD-DM) or without diabetes mellitus (PD), which were matched 1:1 for age, sex, motor and cognitive impairment at baseline. We tested differences in striatal binding using an ANCOVA test adjusted for age, sex, and handedness. Longitudinal analysis on a subset of PD patients was conducted to evaluate annual difference in striatal binding driven by diabetes mellitus
Results: One-hundred sixty-six drug-naïve PD patients entered the study, namely 54 patients from the single-center DMA-PD cohort, and 112 patients from the PPMI dataset. Compared to PD, PD-DM showed a higher dopamine uptake in left putamen in both the considered cohorts. The longitudinal evaluation revealed that PD-DM had a faster annual decline of left putamen binding than PD (-20% vs. -9%).
Conclusions: Findings showed that diabetes mellitus may impact on compensatory mechanisms of nigrostriatal systems resulting in less dopamine deficits even with comparable degree of motor and non-motor impairment at baseline. This result was further confirmed by the follow-up evaluation showing a greater annual difference in left putamen binding. Results were confirmed in both an Italian monocentric cohort and in the multicentric PPMI cohort.

RECEPTOR DENSITY CHANGES IN MPTP MOUSE MODEL OF PARKINSON'S DISEASE – IN VIVO AND EX VIVO CHARACTERIZATION

POSTERS: C04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Jussi Rytkönen[1], Kimmo Lehtimäki[1], Pekka Poutiainen[2], Taneli Heikkinen[1], Johanna Uhari-Väänänen[1], Artem Shatillo[1], Susanne Bäck[1]
[1]Charles River, Discovery, Kuopio, Finland, [2]Kuopio University Hospital, Radiopharmacy, Kuopio, Finland

Aims: Loss of dopaminergic neurons in substantia nigra pars compacta is a cardinal feature of Parkinson's disease (PD). The subsequential loss of striatal dopamine (DA) and reduced dopamine transporter (DAT) levels trigger the characteristic movement symptoms for PD, and are important readouts in preclinical PD models. The loss of dopaminergic neurons also triggers changes in receptor density of other neurotransmitters. In this study we used various imaging tools (MRI, PET, autoradiography) to characterize changes in the mouse brain following induction of dopaminergic cell death with systemic administration of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP).
Methods: MPTP was administered intraperitoneally (i.p. 20 mg/kg) two times a day with 3h-interval on two consecutive days. Starting from 2 weeks after the MPTP administration, pathological changes in the brain were evaluated with PET imaging using tracers for DAT (^{18}F-FE-P2I) and glucose consumption (FDG-PET) and with 1H-MRS. Following endpoint sampling, receptor densities were evaluated *ex vivo* with autoradiography.
Results: MPTP administration induced changes in cellular metabolites in striatum when compared to vehicle treated mice. On week 5, a decrease in DAT receptor density was seen in MPTP mice with PET imaging of ^{18}F-FE-P2I. In support of the 1H-MRS findings, we observed that glucose consumption by FDG-PET was significantly decreased at week 6 after the MPTP challenge. *Ex vivo* analysis showed in no change in D2 receptor level in striatum, but upregulation of $GABA_A$ and CB1 in cingulate cortex and reduction in SERT density in substantia nigra. No change in TSPO (translocator protein) receptor density was observed 6 weeks after MPTP challenge.
Conclusions: *In vivo* and *ex vivo* imaging tools can be used to evaluate changes in dopaminergic and non-dopaminergic systems in the brain following MPTP lesioning in mice.

NEUROMELANIN-SENSITIVE MRI CORRELATION WITH I-123 IOFLUPANE SPECT AND MOTOR SYMPTOMS DEPENDS ON COGNITIVE STATUS IN PARKINSON'S DISEASE

POSTERS: C04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Daniel Huddleston[1], Jason Langley[2], Xiangchuan Chen[3], Kelsey Tucker[3], Amanda Lansdell[3], Xiaoping Hu[4]
[1]Emory University, Neurology - 6th Floor, Atlanta, United States of America, [2]University of California, Riverside, Center For Advanced Neuroimaging, Riverside, United States of America, [3]Emory University, Neurology, Atlanta, United States of America, [4]University of California, Riverside, Bioengineering, Riverside, United States of America

Aims: 1) To study the correlation between neuromelanin-sensitive MRI (NM-MRI) and I-123 ioflupane single photon emission computed tomography (SPECT) measures in the nigrostriatal system in Parkinson's disease (PD) with (CI) and without (NC) cognitive impairment. 2) To assess correlation between substantia nigra pars compacta (SNc) volume measured with NM-MRI and PD motor features in PD-CI and PD-NC.
Methods: PD-NC (n=11) and PD-CI (n=13) patients were recruited at the Emory Movement Disorders Clinic under an IRB approved protocol. Each patient completed a 3 T MRI scan (Siemens Prisma Fit) and an I-123 ioflupane SPECT scan (DaTScan, GE Healthcare). MRI included a magnetization-prepared 2D gradient echo NM-MRI sequence and a T1 structural sequence. Patients were clinically assessed with the Movement Disorders Society Unified Parkinson's Disease Rating Scale (MDS-UPDRS), the Montreal Cognitive Assessment (MoCA), and a neuropsychological testing battery designed to assess the Lewy body dementias (LBDs).
Results: PD-NC and PD-CI baseline demographics were compared and the groups differed in age (PD-NC=57.7+/-10.5; PD-CI=70.0+/-8.2; p=0.004), but not in sex, race, or education. Analyses were performed controlling for age. Partial correlation between SNc volume (mm3) and putamen binding ratio asymmetry ratio was significant in the combined PD group (r=0.520, p=0.022), driven by a strong correlation in the PD-NC group (r=0.784, p=0.007), while there was no correlation observed in the PD-CI group (r=0.045, p=0.916). Partial correlation between MDS-UPDRS-III and SNc volume was significant in all PD (r=-0.445, p=0.029), with a trend toward significance in the PD-CI group (r=-0.483,p=0.095) and no correlation in the PD-NC group (r=-0.361, p=0.276).
Conclusions: NM-MRI SNc volume is highly correlated with I-123 ioflupane putaminal SPECT in PD-NC, tracks motor symptoms, and has potential as a cost-efficient surrogate outcome measure in PD trials.

RADIOLOGICAL HETEROGENEITY OF TOKYO MEDICAL BIOBANK PARTICIPANTS WITH LEWY BODY DISEASES

POSTERS: C04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Masanori Kurihara[1,2], Ryosuke Shimasaki[1], Keiko Hatano[1], Kenichiro Taira[1], Ryoko Ihara[1], Mana Higashihara[1], Yasushi Nishina[1], Masashi Kameyama[3,4], Atsushi Iwata[1,2]

Aims: Although biobank samples are useful for validation of recently identified cerebrospinal (CSF) and blood-based biomarkers for Lewy body diseases (LBD), sensitivity may be affected by heterogeneity among participants. The objective of this study was to summarize the radiological heterogeneity of our biobank participants with LBD.
Methods: We recruited all patients receiving lumbar puncture as a part of assessment of neurodegenerative diseases from December 2021 to July 2023 to Tokyo Medical Biobank. Results of dopamine transporter (DAT) SPECT using ^{123}I-ioflupane and ^{123}I-MIBG cardiac scintigraphy were summarized for patients with LBD.
Results: We enrolled 157 participants and 61 were clinically suspected to have LBD. One with negative DAT SPECT finding and one with later diagnosis of progressive supranuclear palsy were excluded. Mean age was 73.3 ± 9.2 years old. Thirty-three were male and 26 were female. Clinical diagnoses were Parkinson's disease (PD) in 50, dementia with Lewy bodies (DLB) in 6, prodromal DLB in 1, pure autonomic failure in 1, and REM-sleep behavior disorder in 1. Results of both DAT SPECT and MIBG scintigraphy were available in 52. Scatter plot showed wide distribution and the correlation between averaged striatal DAT standard binding ratio (SBR) and MIBG delayed heart-to-mediastinum ratio were weak and nonsignificant. Twenty-three (44 %) showed normal MIBG scintigraphy results including 3 of 15 clinically-established and 16 of 30 clinically-probable PD according to the MDS-PD criteria. No significant difference was observed for age, sex, disease duration, and averaged DAT SBR between MIBG-positive versus MIBG-negative group.
Conclusions: We have collected paired blood and CSF samples from participants with LBD with radiological heterogeneity. Whether sensitivities of fluid biomarkers such as seed amplification assays are affected by this heterogeneity will be evaluated soon.

ESYA PD360: A MULTI-PARAMETRIC PLATFORM FOR ESTABLISHING A NOVEL LYSOSOME-BASED BIOMARKER FOR PARKINSON'S DISEASE

POSTERS: C04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Florence Young, Souvik Modi, Adam Shellard, Hernando M. Vergara
Esya Labs, R&d, London, United Kingdom

Aims: Neuronal homeostasis heavily relies on the lysosomal pathway to remove protein aggregates and damaged organelles. Although altered lysosomal acidification and perturbed autophagy have been linked to both familial and sporadic Parkinson's disease (PD), these features are not currently utilized in diagnostic approaches. Esya's objective is to develop a multiparametric biomarker platform that integrates lysosomal and autophagic function along with transcriptomic changes at the cellular level, ultimately leading to more accurate diagnosis, disease subtyping, and treatment.
Methods: Lysosomal, autophagic and transcriptomic data were acquired from peripheral cell samples across multiple cohorts including healthy and genetic or sporadic PD samples. We assessed: **a)** lysosomal dysfunction using our patented two-ion mapping probes that ratiometrically measure H^+ and Ca^{2+} concentrations with single lysosome resolution; **b)** autophagic alterations by transduction with tandem LC3-autophagy sensors, and **c)** transcriptomic changes through an RNA panel, identified through RNA-seq.
Results: Lysosomal Ca^{2+} and pH are affected in PD patients carrying an LRRK2 mutation, and Ca^{2+} levels are altered in sporadic PD. Defects in the autophagic pathway are identified in PD patients carrying GBA, LRRK2, or Vps35 mutations and sporadic PD, with autophagic dysfunction strongly correlated with lysosomal ionic status. Lastly, we identified differentially expressed gene clusters in PD patients compared to healthy controls, most of which are involved in organellar functions. Finally, integration of these features through principal component analysis allowed us to separate PD from healthy individuals and stratify PD into two distinct populations.

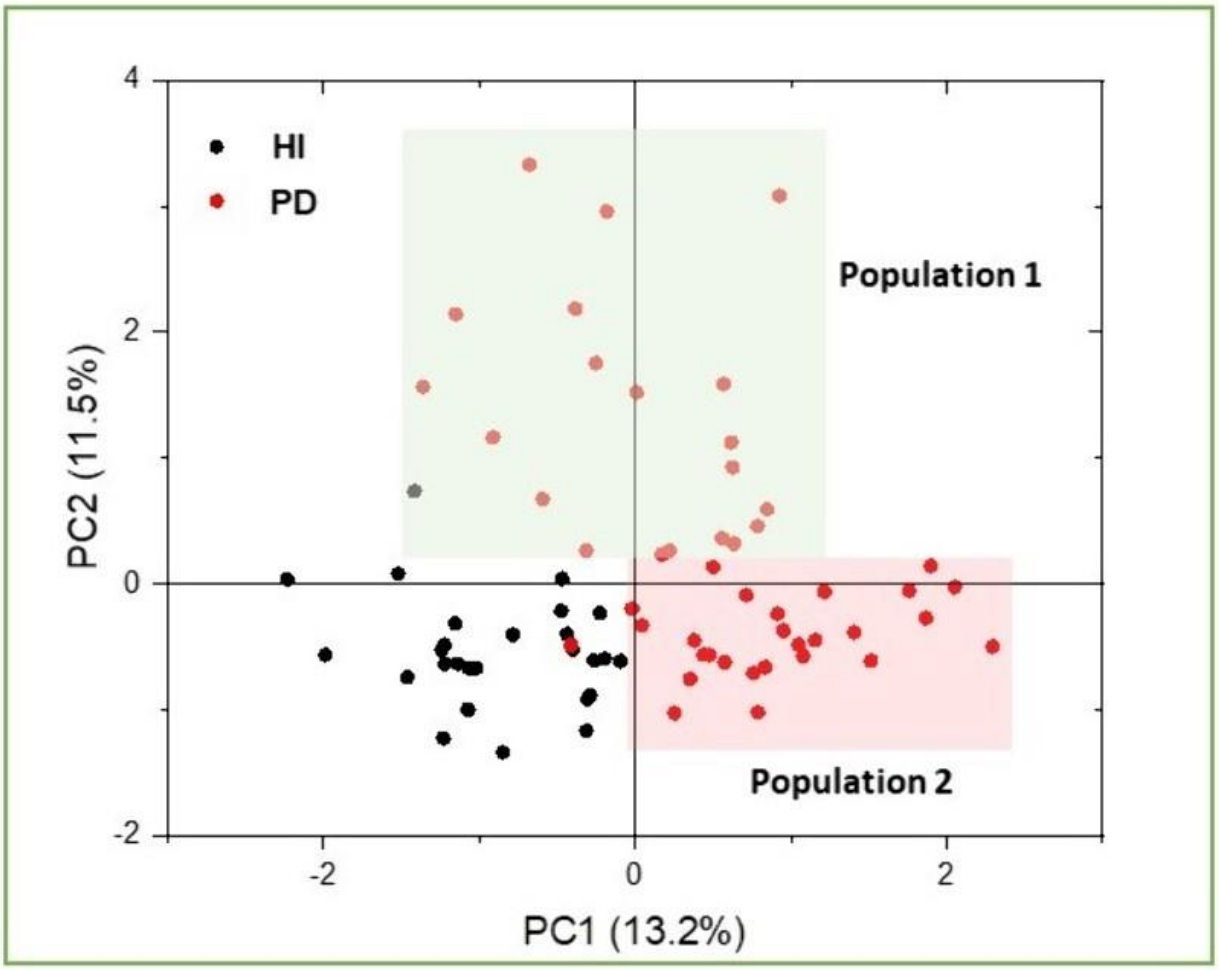

Figure 1. Principal component analysis using 12 lysosomal features and 28 differently expressed RNAs differentiates Parkinson's disease (PD) from healthy individuals (HI) and identifies two PD populations.

Conclusions: We identified disease subclass-specific transcriptomic changes that may be linked to underlying lysosomal and autophagic dysfunction. Moreover, our multiparametric approach accurately distinguishes PD from healthy individuals, and sub-classes PD into distinct populations. This innovative biomarker platform paves the way for improved PD diagnosis and personalized medicine.

NEUROIMAGING BIOMARKERS FOR DETECTING EARLY CORTICAL CHANGES ASSOCIATED WITH COGNITIVE IMPAIRMENT IN PARKINSON'S DISEASE.

POSTERS: C04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Jesús Silva-Rodríguez[1], Miguel A Labrador-Espinosa[1], Sandra Castro-Labrador[1], María Isabel Reina-Castillo[1], Laura Múñoz-Delgado[1], Pablo Franco-Rosado[1], Ana María Castellano-Guerrero[1], Daniel Macías-García[1], Silvia Jesús[1], Astrid Adarmes-Gómez[1], Fátima Carrillo[1], Juan Francisco Martín-Rodriguez[1], Florinda Roldán-Lora[2], David García-Solís[3]
[1]Institute of Biomedicine of Seville, Movement Disorders Group, Sevilla, Spain, [2]Hospital Virgen del Rocío, Radiology Department, Seville, Spain, [3]Hospital Virgen del Rocío, Nuclear Medicine Department, Seville, Spain

Aims: Imaging biomarkers of cortical neurodegeneration bear great promise for improving diagnosis and prognosis of cognitive impairment in Parkinson's disease (PD). We compared the accuracy of three commonly used neuroimaging modalities for detecting cortical changes associated with mild cognitive impairment (MCI) and dementia in PD.
Methods: 42 cognitively normal PD patients (PD-CN), 23 with MCI (PD-MCI), and 31 with dementia (PDD) underwent structural MRI (sMRI), diffusion-weighted MRI (dMRI) and FDG-PET. Grey matter volumes (GMV, sMRI), mean free water fraction (FW, dMRI), and standardized uptake value ratios (SUVR, FDG-PET) were extracted for all brain regions included in the Harvard-Oxford neuroanatomical atlas. An exhaustive cross-validated feature selection process was used to identify the regions that are most predictive of cognitive status for each modality. Modality-specific diagnostic accuracies for distinguishing PD-MCI and PDD from PD-CN were assessed using bootstrapped receiver operating characteristics (ROC) analyses.
Results: In PDD, sMRI revealed significant atrophy in medial temporal and posterior-parietal areas, while dMRI showed a brain-wide increase in FW (Figure 1). Only subtle effects were observed in PD-MCI for both modalities. FDG-PET revealed significant hypometabolism in posterior cortical regions in both PDD and PD-MCI (Figure 1). FDG-PET SUVR (area under the curve (AUC) =0.90±0.05) and dMRI FW (0.89±0.05) provided significantly higher diagnostic accuracies for distinguishing PDD vs PD-CN compared to sMRI GMV (0.77±0.08, p's<0.001). Only FDG-PET provided notable diagnostic accuracy for detecting PD-MCI (0.80±0.08), which was significantly higher compared to both sMRI (0.61±0.12, p<0.001) and dMRI (0.68±0.09, p=0.028) (Figure
2).

Conclusions: FDG-PET hypometabolism was the most sensitive imaging biomarker for detecting cortical changes associated with cognitive impairment in PD, especially at early stages. In the absence of FDG-PET, dMRI-measured FW represents a promising MRI-based alternative.

THE SYNUCLEIN ONE STUDY: CUTANEOUS ALPHA-SYNUCLEIN DEPOSITION IN PARKINSON'S DISEASE

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Roy Freeman[1], Todd Levine[2], Bailey Bellaire[3], Christopher Gibbons[1]
[1]Harvard Medical School, Beth Israel Deaconess Medical Center, Neurology, Boston, United States of America, [2]HonorHealth, Neurology, Scottsdale, United States of America, [3]CND Life Sciences, Neurology, Scottsdale, United States of America

Aims: The Synuclein-One study is an NIH-funded 30-site trial that included 96 participants with Parkinson's disease (PD), and 120 healthy controls. We report the detection and quantitation of cutaneous phosphorylated alpha-synuclein (P-SYN) in patients with PD in those with and without DaTscan imaging and compare this to the P-SYN detection in the healthy population. Ongoing challenges exist in the search for a simple, reproducible marker of synuclein pathology. Costs and patient convenience limit the use of diagnostic nuclear neuroimaging while lumbar puncture is a complicated outpatient procedure that inadequately reimburses physician time and is not endorsed by patients.
Methods: After signed consent, study participants completed neurologic examinations (MDS-UPDRS), medical history review, cognitive evaluation, orthostatic vital signs and neurodegenerative disease questionnaires. Skin biopsies at the distal leg, distal thigh and posterior cervical sites were performed on all participants with quantitation of P-SYN.
Results: In the 96 PD participants (MDS-UPDRS 49±24; Hoehn and Yahr 2.1±0.5), P-SYN was detected in 89/96 (93%) and in 4/120 (3%) of healthy controls. Cutaneous P-SYN testing performed at 92.7% sensitivity and 96.7% specificity for detection of P-SYN in PD. Seventeen participants with PD completed a DaTscan (16 positive), and 15/16 were P-SYN positive, and the 1 DaTscan negative case was P-SYN positive. There were correlations between P-SYN and UPDRS score ($R=0.43$, $P<0.01$). No serious adverse events were reported, mild bleeding from a skin biopsy site noted in 2 study participants.
Conclusions: Cutaneous P-SYN testing is sensitive and specific for detection of the phosphorylated form of alpha-synuclein in patients with PD. Although only a small proportion completed DaTscan testing, the P-SYN testing was positive in 94%. Quantitative measures of cutaneous P-SYN may offer a novel outcome in disease modifying clinical trials.

Aims: We aimed to describe the diagnostic performance of the Real-Time Quaking-Induced Conversion assay for detecting alpha-synuclein seeds (RT-QuIC aSyn assay) in cerebrospinal fluid (CSF) to diagnose LBD in a clinical cohort with cognitive impairment.
Methods: A cohort of subjects with cognitive impairment (neurodegenerative and non-neurodegenerative) with available CSF sample at the moment of first evaluation was selected by convenience sample in our database. Subjects had clinical follow-ups ranging from 6 months to 12 years and current clinical diagnosis according to established consensus criteria. The diagnostic performance of RT-QuIC aSyn for the diagnosis of LBD were evaluated.
Results: The test was evaluated in 317 subjects (age 66 years (SD 11), MMSE 25 (SD 4.5), 48% female) with the following clinical diagnoses: LBD (n=71), Alzheimer's disease (AD) (n=134) (all with compatible CSF profile), frontotemporal dementia (FTD) (n=22), non-neurodegenerative mild cognitive impairment (MCI) (n=50), other neurodegenerative diagnoses (n=8) and healthy controls (n=32). aSyn was detected in 62/71 (87%) LBD patients, 18/134 (13%) AD, 2/22 (9%) FTD patients, 0/50 MCI patients, 0/8 patients with other neurodegenerative diseases and 0/32 healthy controls. The sensitivity and specificity of the assay were 87% and 91% respectively for the diagnosis of LBD, with a PPV of 76% and a NPV of 96%.
Conclusions: Detection of αSyn seeds by RT-QuIC has a good performance in identifying patients with LBD in a clinical cohort of cognitively impaired subjects. The test also identifies aSyn co-pathology in a subgroup of subjects diagnosed with AD.

PLASMA PTAU181 AS A POTENTIAL PROGNOSTIC BIOMARKER IN LEWY BODY DISEASE

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Carla Abdelnour[1], Christina Young[1], Marian Shahid[1], Alena Smith[1], Edward Wilson[1], Hillary Vossler[1], Melanie Plastini[1], Joseph Winer[1], Lu Tian[1], Geoffrey Kerchner[2], Katrin Andreasson[1], Victor Henderson[1], Elizabeth C Mormino[1], Kathleen Poston[1]
[1]Stanford University, Department Of Neurology And Neurological Sciences, Stanford, United States of America, [2]F. Hoffmann-La Roche, Ltd., Pharma Research And Early Development, Basel, Switzerland

Aims: Lewy body disease (LBD) often co-occurs with Alzheimer's disease (AD), influencing disease progression, cognitive decline, and neurodegeneration. This study aims to determine whether plasma phosphorylated-Tau181 (pTau181) is a prognostic biomarker in LBD patients.
Methods: Among 633 Stanford research participants, 565 were selected, including 94 LBD with normal cognition (LBD-nlCog), 83 LBD with abnormal cognition (LBD-abnlCog), 114 AD, and 274 cognitively normal (CN). Plasma pTau181 levels were measured with Lumipulse G fully automated platform by Fujirebio with Lumipulse G Assays. Multiple linear regression models were used to examine the relationship between baseline plasma pTau181 levels and global cognition (MoCA), daily functioning (CDR-SOB), and neuropsychological performance. Linear mixed effects models (LMEM) assessed the impact of baseline and longitudinal changes in plasma pTau181 levels on 4-year declines in clinical outcomes.
Results: In the LBD-abnlCog group, higher baseline plasma pTau181 levels were associated with worse baseline CDR-SOB and MoCA scores. After 4 years, baseline plasma pTau181 levels predicted a more rapid decline in CDR-SOB. Additionally, a rapid increase in plasma pTau181 levels within the first 2 years predicted accelerated declines in MoCA, CDR-SOB, memory, executive function, and attention/working memory. In contrast, no significant associations were found between baseline or longitudinal plasma pTau181 levels and clinical outcomes in the LBD-nlCog group at either baseline or during the 4-year follow-up.
Conclusions: For LBD patients with MCI and dementia, baseline plasma pTau181 levels provide valuable insights into initial and long-term daily functioning. Moreover, a rapid increase in plasma pTau181 within the first 2 years correlates with accelerated declines in cognition, daily function, and neuropsychological performance. This highlights the significant potential of plasma pTau181 as a prognostic biomarker for LBD.

CAN BIOMARKERS IN EXTRACELLULAR VESICLES FROM BODILY FLUIDS ACCURATELY DIAGNOSE PARKINSON'S DISEASE OR RELATED DISORDERS? A SYSTEMATIC REVIEW AND DIAGNOSTIC META-ANALYSIS

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Hash Brown Taha[1], Aleksander Bogonwieski[2]
[1]University of Southern California, Leonard Davis School Of Gerontology, Los Angeles, United States of America, [2]University of California Los Angeles, Medical And Molecular Pharmacology, Los Angeles, United States of America

Aims: Parkinsonian disorders, including Parkinson's disease (PD), multiple system atrophy (MSA), dementia with Lewy body (DLB), corticobasal syndrome (CBS) and progressive supranuclear palsy (PSP) are often misdiagnosed due to overlapping symptoms and the absence of precise biomarkers. Furthermore, there are no current methods to ascertain the progression and conversion of prodromal conditions such as REM behavior disorder (RBD). Extracellular vesicles (EVs), containing a mixture of biomolecules, have emerged as potential sources for parkinsonian diagnostics. However, inconsistencies in previous studies have left their diagnostic potential unclear. We conducted a meta-analysis, following PRISMA guidelines, to assess the diagnostic accuracy of general EVs isolated from various bodily fluids, including cerebrospinal fluid (CSF), plasma, serum, urine or saliva, in differentiating patients with parkinsonian disorders from healthy controls (HCs).
Methods: The meta-analysis included 21 studies encompassing 1,285 patients with PD, 24 with MSA, 105 with DLB, 99 with PSP, 101 with RBD, and 783 HCs. Analyses were conducted only for patients with PD vs. HCs using bivariate and hierarchial receiver operating characteristics (HSROC) models, given the limited number for other comparisons.
Results: The meta-analysis revealed moderate diagnostic accuracy in distinguishing PD from HCs, with substantial heterogeneity and publication bias. The trim-and-fill method revealed at least two missing studies with null or low diagnostic accuracy. CSF-EVs showed better overall diagnostic accuracy, while plasma-EVs had the lowest performance. General EVs demonstrated higher diagnostic accuracy and less publication bias compared to CNS-originating EVs (estimated 2 out of 21 vs. 5 out of 16 missng studies, respectively), which are more time-consuming, labor- and cost-intensive to isolate.
Conclusions: While holding promise, utilizing biomarkers in general EVs for PD diagnosis remains unfeasible due to existing challenges. Though the diagnostic accuracy of biomarkers in EVs was superior than CNS-originating EVs, both methodologies suffered from substantial heterogeneity and publication bias.The focus should shift toward harmonizing the field through standardization, collaboration, and rigorous validation.

EFFECT OF NEFLAMAPIMOD TREATMENT ON PLASMA GLIAL FIBRIALLARY ACIDIC PROTEIN (GFAP) LEVELS IN PATIENTS WITH DEMENTIA WITH LEWY BODIES (DLB)

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

John Alam[1], Marleen Koel-Simmelink[2], Jennifer Conway[1], Amanda Gardner[1], Kelly Blackburn[1], Inge Verberk[2], Charlotte Teunissen[2]
[1]CervoMed, Inc., Clinical Development, Boston, United States of America, [2]Amsterdam UMC location Vrije Universiteit Amsterdam, Department of Laboratory Medicine, Neurochemistry Laboratory, Amsterdam, Netherlands

Aims: In the 16-week phase 2a AscenD-LB study in DLB, the oral drug neflamapimod demonstrated significant positive effects vs. placebo on CDR-SB and Timed Up and Go test, most prominently in patients with pure DLB (i.e., without Alzheimer's disease-related (AD) co-pathology, assessed by plasma ptau181). With a recent report (Hamilton *et.al. Psychological Medicine,* 2023) that plasma GFAP and neurofilament-light-chain (NfL) discriminated MCI-DLB from healthy controls, with GFAP being more discriminant, we evaluated the effects of neflamapimod in AscenD-LB on plasma GFAP and NfL, both overall and in pure DLB patients.
Methods: GFAP and NfL levels (pg/mL) in stored plasma samples from AscenD-LB were determined using the Simoa® platform. Overall design and results (Jiang et.al. Nature Communications, 2022), and analysis after stratification for baseline plasma ptau181 (Alam et.al. Neurology, 2023) are published.
Results: At baseline, GFAP was higher (p=0.02) in DLB with AD co-pathology [282(SD=120, n=29] versus in pure DLB [215(SD=91), n=28]; NfL was not. In the overall population, reduced GFAP levels were seen in neflamapimod-treated participants (n=30, -12.3+/-6.8, baseline-to-week16) and not in placebo-recipients (n=27, +3.7+/-7.8; p=0.13 for neflamapimod-placebo difference). In pure DLB participants, a significant reduction (p=0.04) in GFAP levels with neflamapimod (n=15, -10.6+/-6.4) vs. placebo (n=13, +14.1+/-10.2) was seen. For NfL, no neflamapimod-placebo differences were evident in either population.
Conclusions: Plasma GFAP has potential utility to assess drug effects in DLB, though to lessen masking effects of GFAP production related to AD co-pathology it may be best to make such evaluations in pure DLB patients. To confirm the potential effects of neflamapimod on GFAP levels and evaluate the relation to clinical outcomes, plasma GFAP will be assessed in an ongoing phase 2b clinical study of neflamapimod in early DLB.

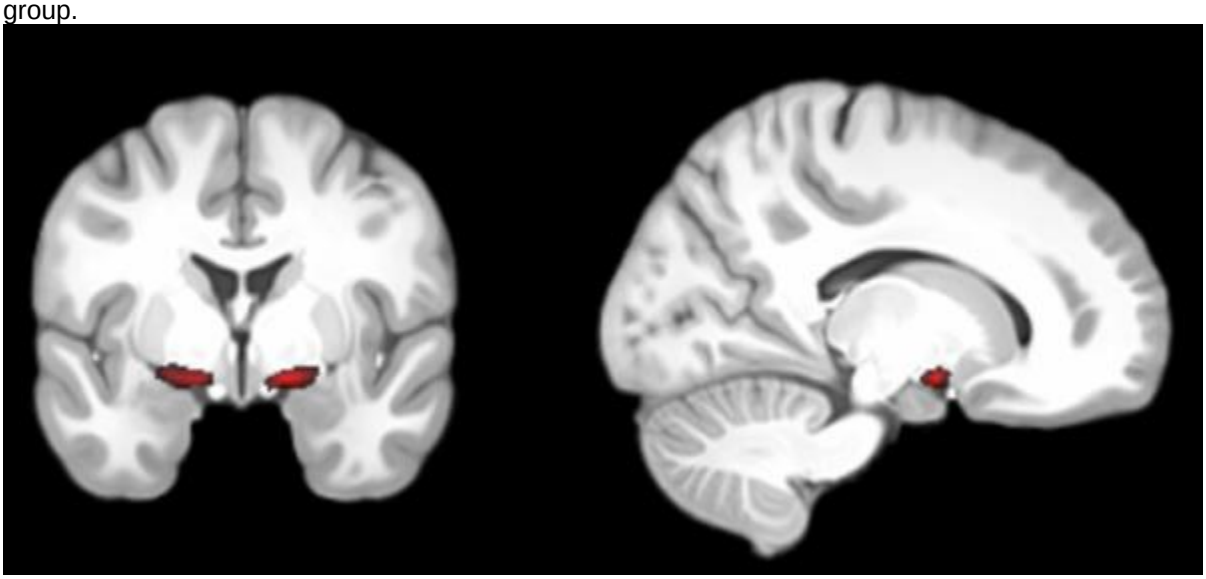
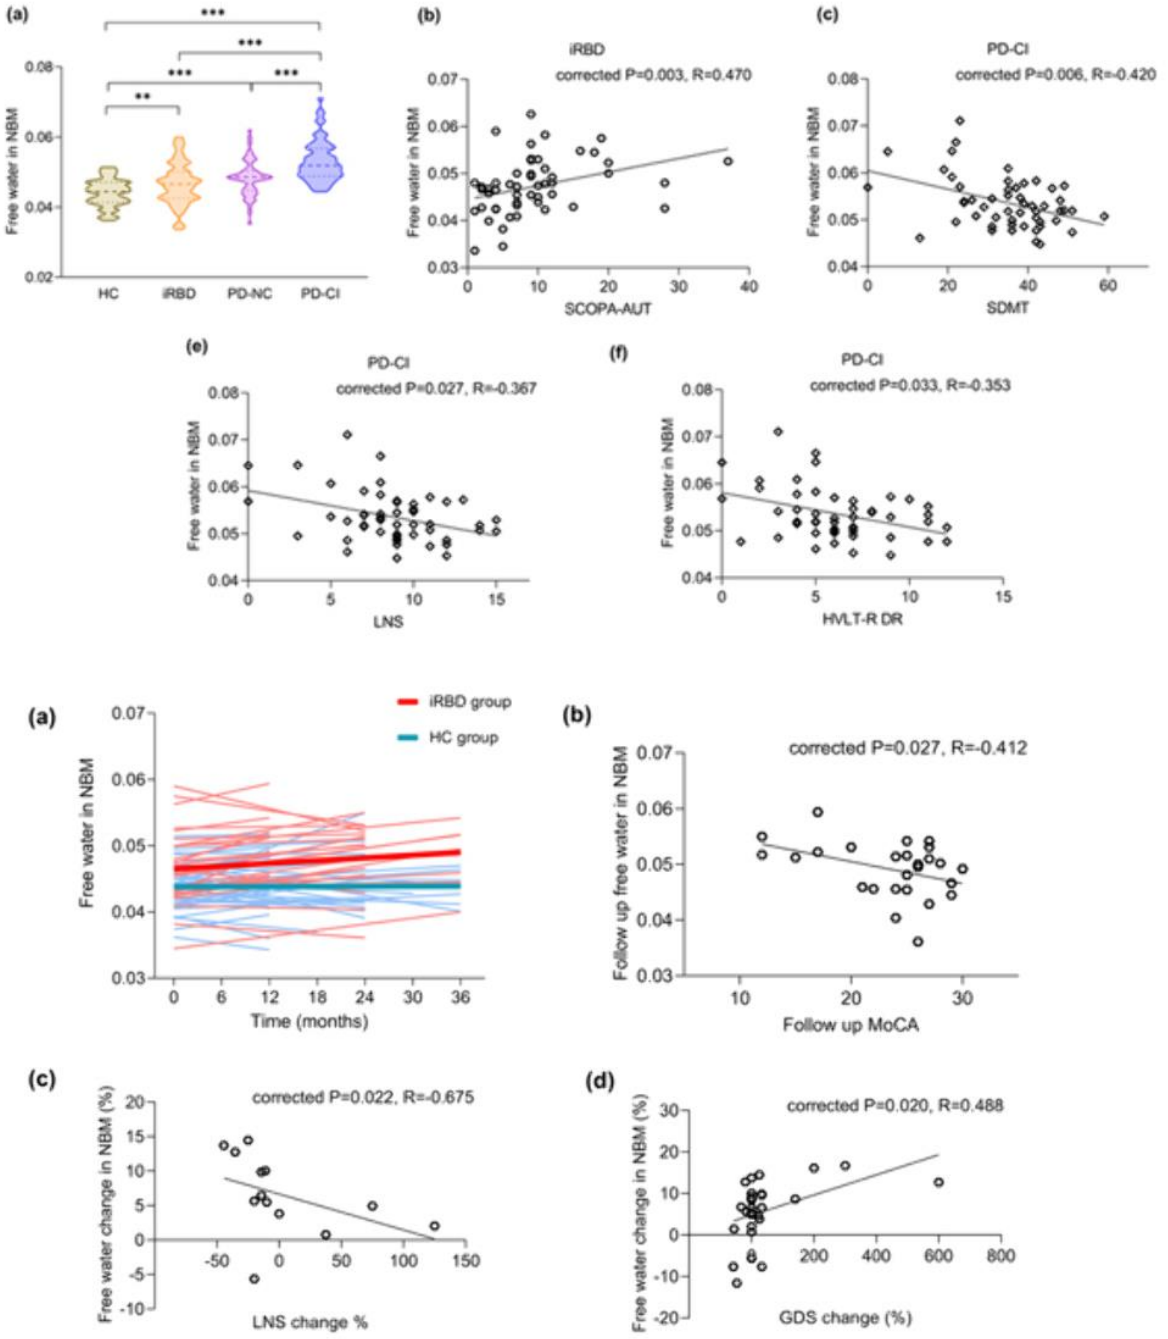
FREE-WATER IMAGING OF THE NUCLEUS BASALIS OF MEYNERT IN IDIOPATHIC REM SLEEP BEHAVIOR DISORDER

POSTERS: C04.E. IMAGING, BIOMARKERS, DIAGNOSTICS: MULTIMODAL IMAGING

Dongling Zhang[1], Liche Zhou[2], Tao Wu[1], Jun Liu[2], Tao Feng[1]
[1]Beijing Tiantan Hospital, Department Of Neurology, Beijing, China, [2]Ruijin Hospital, Department Of Neurology And Institute Of Neurology, Shanghai, China

Aims: Objectives: Cognitive impairments are common in idiopathic REM sleep behavior disorder (iRBD), in which the cholinergic degeneration of nucleus basalis of Meynert (NBM) may play an important role. However, the progressive changes of NBM remain unclear. This study aimed to investigate the cross-sectional and longitudinal microstructural alterations in the NBM of iRBD patients using free-water imaging.
Methods: Methods: We compared the baseline free water values in the NBM between 59 healthy control (HC), 57 iRBD patients, 57 Parkinson's disease (PD) patients with normal cognition (PD-NC), and 64 PD patients with cognitive impairment (PD-CI). 30 iRBD patients and 40 HC had longitudinal data. In iRBD patients, we explored the associations between baseline and longitudinal changes of free water values in the NBM and clinical characteristics and whether baseline free water values in the NBM could predict cognitive decline.
Results: Results: IRBD, PD-NC and PD-CI groups had significantly increased free water values in the NBM compared to HC, while PD-CI had higher free water values compared to iRBD and PD-NC. In iRBD patients, free water values in the NBM were progressively elevated over follow-up and correlated with the progression of cognitive performance and depression. Free water values in the NBM could predict cognitive decline in iRBD
group.





Conclusions: Conclusions: This study proves that free water values in the NBM are elevated cross-sectionally and longitudinally, and are associated with the progression of cognitive impairment and depression in iRBD patients. Moreover, the free water value in the NBM can predict cognitive decline in iRBD patients. Our results suggest that free-water imaging of the NBM has the potential to be a marker for monitoring progressive cognitive impairment and predicting the conversion to dementia in synucleinopathies.

CSF NEUROSECRETORY PROTEINS VGF AND NEUROSERPIN IN PATIENTS WITH ALZHEIMER'S AND LEWY BODY DISEASES

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Lorenzo Barba[1], Giovanni Bellomo[2], Patrick Oeckl[3], Davide Chiasserini[4], Lorenzo Gaetani[2], Edoardo Guido Torregiani[2], Federico Paolini Paoletti[2], Petra Steinacker[1], Samir Abu-Rumeileh[1], Lucilla Parnetti[2], Markus Otto[1]
[1]Martin-Luther-University Halle-Wittenberg, Department Of Neurology, Halle (Saale), Germany, [2]University of Perugia, Laboratory Of Clinical Neurochemistry, Section Of Neurology, Department Of Medicine And Surgery, Perugia, Italy, [3]Ulm University, Department Of Neurology, Ulm, Germany, [4]University of Perugia, Section Of Physiology And Biochemistry, Department Of Medicine And Surgery, Perugia, Italy

Aims: VGF (non-acronymic) and neuroserpin are neurosecretory proteins involved in the pathogenesis of neurodegenerative diseases. We aimed to evaluate their cerebrospinal fluid (CSF) concentrations in patients with Alzheimer's disease (AD) and Lewy body disease (LBD).
Methods: We measured VGF [AQEE] peptide and neuroserpin protein levels in 101 patients with LBD (Parkinson's disease, PD n=89; PD with dementia, PDD n=12; dementia with Lewy bodies, DLB n=7), 76 patients with AD and 37 control subjects, and tested associations with clinical scores and AD core biomarkers.
Results: We found increased CSF levels of VGF [AQEE] (p=0.001) and neuroserpin (p=0.009) in patients with AD compared to patients with LBD, especially in cases with dementia. Lower levels of VGF [AQEE] and neuroserpin were significantly associated with lower Mini-Mental State Examination (MMSE) scores, with CSF tau protein levels and with each other in both LBD and AD. After stratification according to the CSF AT(N) profile, VGF [AQEE] and neuroserpin CSF concentrations were significantly increased only in LBD patients with A+T+ profiles and in AD patients compared to controls and other LBD subgroups. Finally, VGF [AQEE] showed a good diagnostic accuracy in the discrimination between AD dementia and PDD/DLB (AUC=0.754) and both biomarkers could well distinguish LBD/A-T- from LBD/A+T+ cases (AUC=0.740 for VGF [AQEE], AUC=0.756 for neuroserpin).
Conclusions: CSF VGF and neuroserpin levels are elevated in patients with AD or LBD with AD copathology, thus, representing markers of AD-related pathogenetic changes of neurosecretory pathways.

Aims: Neuropathological studies indicate that synucleinopathy represents one of the most common co-pathologies in Alzheimer's disease (AD). We applied α-synuclein seed amplification assay (αS-SAA) in cerebrospinal fluid (CSF) samples of AD patients to estimate the prevalence of αS-SAA positivity, also investigating whether such positivity was associated to clinical and neuropsychological parameters and disease progression.
Methods: A highly reliable αS-SAA protocol was applied on n=430 CSF samples of AD patients encompassing the whole clinical spectrum (n=240), controls (n=85) and individuals with Lewy body disorders (n=105). Association between aS-SAA positivity and cognitive/behavioural changes over time was also evaluated.
Results: As expected, a large majority (87%) of patients affected by Lewy body disorders showed a positive CSF αS-SAA, as opposite to a very low prevalence in controls (9%). In a significant proportion of all clinical AD stages we could see a positive CSF αS-SAA (26-27% in preclinical and prodromal AD; 36% in dementia stage). Of interest, out of 12 cases with posterior presentation, 8 (67%) showed a positive CSF αS-SAA. Moreover, all AD cases with CSF αS-SAA positivity showed a more marked impairment of visuospatial skills at baseline and cognitive decline at followup, as compared to AD cases with negative CSF αS-

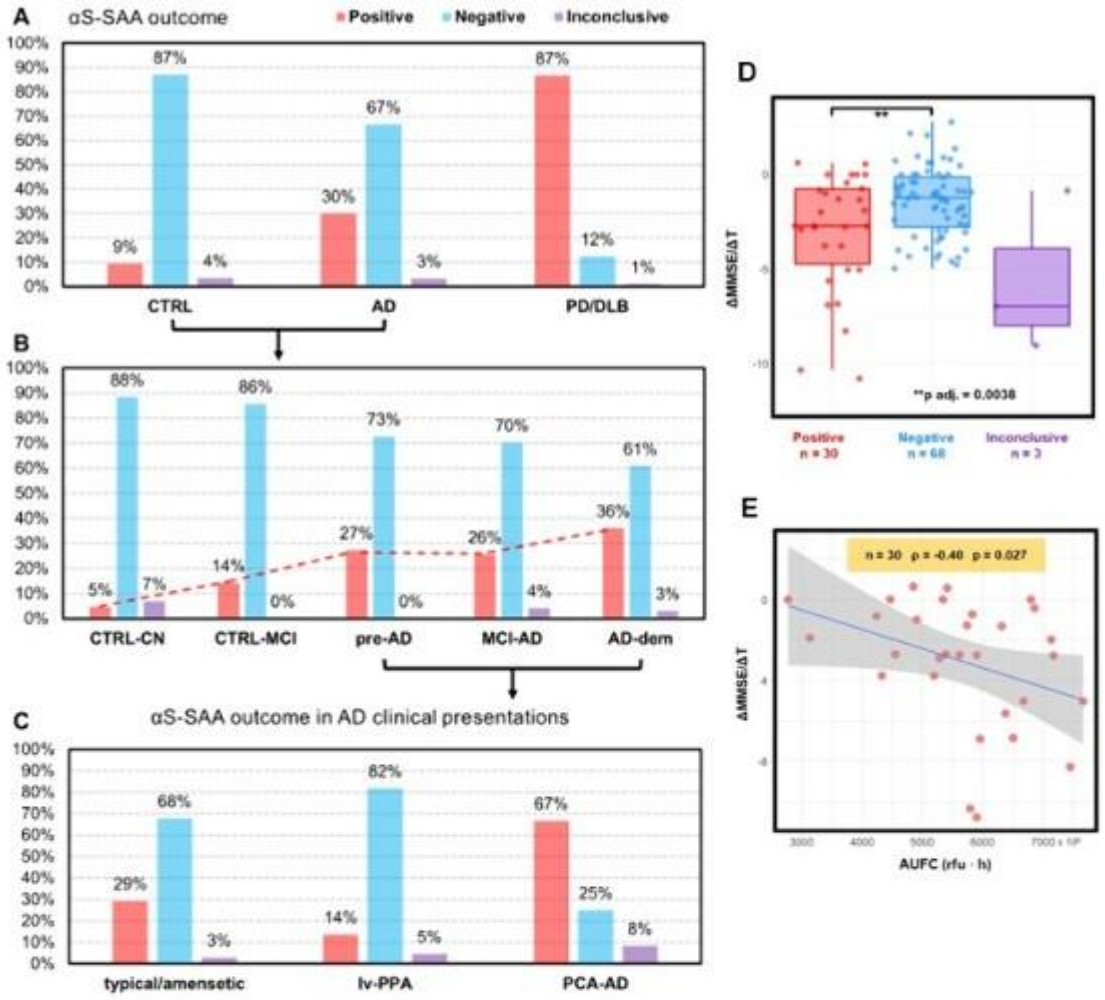

Figure 1. CSF αS-SAA outcome in the clinical groups and subgroups considered. A) Barplot representing the percentages of CSF αS-SAA positive, inconclusive, and negative subjects within CTRL, AD and PD/DLB groups. B) Barplot representing the percentages of CSF αS-SAA positive, inconclusive, and negative subjects within CTRL-CN, CTRL-MCI, pre-AD, MCI-AD, and AD-dem subgroups. C) Barplot representing the percentages of CSF αS-SAA positive, inconclusive, and negative subjects among typical/amnestic AD (n=205) and lv-PAA (n=22) and PCA AD (n=12) clinical variants. D) boxplots representing the rate of change of MMSE score over time (ΔMMSE/Δt) in CSF αS-SAA positive, negative, and inconclusive AD patients in which boxes represent the interquartile range. The horizontal lines within boxes represent the medians and whiskers reflect the first/third quartile -/+ 1.5 times the interquartile range. The p-values reported are calculated by logistic regression for pairwise comparisons and are adjusted for age and sex. E) Linear regression between ΔMMSE/ΔT and AUFC with 95% CI of the linear regression and Spearman's correlation coefficient (ρ) displayed.

SAA.

Conclusions: Our study suggests that α-synuclein-related co-pathology may influence the clinical presentation and prognosis of AD. Accordingly, an update of the A/T/N system including the letter "S" for

"synucleinopathy" should be taken into account in order to better define the molecular profile of AD patients.

Aims: The objective of this study is to validate the Seeding Amplification ImmunoAssay (SAIA) as a sensitive and specific method for the early detection of alpha-synucleinopathies, with an emphasis on its diagnostic capabilities in prodromal stages of the disease. By focusing on prodromal rapid eye movement sleep behavior disorder (RBD) and LRRK2 mutation carriers, this research seeks to establish SAIA as a pivotal tool for identifying individuals at risk of developing Parkinson's disease (PD) before clinical symptoms manifest.
Methods: This extended validation study engaged a broad cohort of CSF samples, including individuals diagnosed with synucleinopathies, tauopathies, and amyloidoses. The assay's clinical applicability was further explored in prodromal RBD cases and asymptomatic LRRK2 mutation carriers, groups at risk for developing PD.
Results: In this comprehensive analysis, SAIA achieved exceptional diagnostic accuracy, with sensitivities and specificities in the range of 80-100% and area under the curve (AUC) values consistently exceeding 0.9. Remarkably, SAIA positively identified 100% of prodromal RBD cases within the study cohort, with 94% sensitivity and 82% specificity. Unprecedently, the assay successfully detected α-synuclein seeds in 78% of LRRK2 mutation carriers who had not yet exhibited clinical symptoms of PD, demonstrating its potential in pre-symptomatic disease detection.
Conclusions: The findings confirm the potential of SAIA in the early detection of synucleinopathies during their prodromal phase, which could revolutionize the diagnostic approach for at-risk populations. The assay's high specificity and sensitivity highlight its value as a diagnostic tool and its role in future clinical trials. Further investigation is warranted to solidify SAIA's role in neurodegenerative disease management and its predictive power in prodromal synucleinopathies.

IMMUNOASSAY DEVELOPMENT FOR FCER2 – A NOVEL BIOMARKER CANDIDATE FOR DLB

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Katharina Bolsewig[1], Imane Al Idrissi[1], Afina Lemstra[2], Eline Willemse[1,3], Charlotte Teunissen[1]
[1]Amsterdam UMC, Department Of Laboratory Medicine, Neurochemistry Laboratory, Amsterdam, Netherlands, [2]Amsterdam UMC, Alzheimer Center Amsterdam, Amsterdam, Netherlands, [3]University Hospital Basel and University of Basel, Department Of Neurology, Multiple Sclerosis Center And Research Center For Clinical Neuroimmunology And Neuroscience Basel, Departments Of Biomedicine And Clinical Research, Basel, Switzerland

Aims: Diagnosing dementia with Lewy bodies (DLB) is still challenging, but could be facilitated by a DLB-specific, easily accessible biomarker. In an antibody-based proteomics study we identified Fc Epsilon Receptor 2 (FCER2) as a novel biomarker candidate, showing reduced levels in DLB compared with controls (CN), Alzheimer's disease (AD) and frontotemporal dementia (FTD). Here, we aimed to develop and validate an immunoassay for the detection of FCER2 in cerebrospinal fluid (CSF).
Methods: We developed an automated immunoassay on the Simpleplex Ella platform. The assay was optimized for antibody combination and concentration, as well as buffer conditions. Assay performance was validated by assessing sensitivity, precision, parallelism, dilution linearity, recovery and sample stability. FCER2 was measured in a pilot cohort (controls: n=29, DLB: n=28, AD: n=31, FTD: n=29) and group differences were assessed by analysis of covariance corrected for age and sex.
Results: The in-house developed FCER2 assay had a lower limit of detection of 14.13 pg/mL. Precision parameters were below a coefficient of variation of 20% (repeatability=12.2%; intermediate precision=19.8%). Mean parallelism was 114%, dilution linearity ranged from 57% to 179%, but was acceptable (85%-99%) within the working range of the assay. Recovery ranged from 93% (high spike) to 145% (low spike). Two out of three samples were stable across 7 freeze-thaw cycles. Lowest FCER2 concentrations were observed in DLB (193 pg/mL vs CN: 238 pg/mL; AD: 202 pg/mL; FTD: 243 pg/mL), but differences across groups did not reach significance ($F(3, 109)=1.411$, $p=.244$).
Conclusions: We successfully developed and analytically validated an immunoassay for the detection of FCER2 in CSF. Next, clinical utility of FCER2 for DLB to differentiate DLB from other diagnostic groups will be evaluated in a larger clinical cohort.

STRATIFICATION OF SUBJECTS WITH PARKINSON'S AND MULTIPLE SYSTEM ATROPHY BY SEMI-QUANTITATIVE ALPHA-SYNUCLEIN SEED AMPLIFICATION ASSAY.

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Luis Concha-Marambio[1], Carly Farris[1], Yihua Ma[1], John Middleton[2], Hieu Nguyen[1], Sandra Rosete-Gonzalez[1]
[1]Amprion, R&d Unit, San Diego, United States of America, [2]Amprion Inc., Amprion Inc., San Francisco, United States of America

Aims: To determine if alpha-synuclein semi-quantitative seed amplification assay (αSyn SQ-SAA) can stratify patients with synucleinopathies such as Parkinson's disease (PD) and multiple system atrophy (MSA) based on levels of seeding activity present in cerebrospinal fluid (CSF).
Methods: PD and MSA CSF samples were serially diluted in a synthetic diluent developed by Amprion that mimics human control CSF. Each of the dilutions were evaluated using Amprion R&D αSyn-SAA in triplicate. The dilution factor needed to reach 50% of the replicates positive (SD50-DF) for each of the titrated CSF samples was estimated using the Spearman-Karber method. The calculation included adjustment to account for self-aggregation and trimming when needed.
Results: SD50-DF values were different for PD and MSA, with the PD group presenting amplification at much higher dilutions than the MSA group. Seeding activity in CSF from MSA and PD subjects was diluted out (no seeds detected) at 1:17 and 1:729 dilutions, respectively. Thus, two different dilution schemes were used to analyze additional PD and MSA CSF samples. MSA subjects presented a bimodal distribution, effectively dividing the group between "low seeders" and "high seeders". The distribution for PD subjects was more complex and a larger number of samples is needed to determine if subgroups with different levels of seeding activity will emerge.
Conclusions: Our results show that semi-quantitation based on dilutions can identify two subgroups of MSA subjects. Identification of these subjects may enable better selection criteria for clinical trials as SD50-DF may correlate with sub-strain features and/or levels of αSyn-seeds. SD50-DFs for PD CSF are much lower than reported levels for brain, skin, and other tissues, suggesting that normal CSF turnover, or unknown clearance mechanisms, oppose unlimited accumulation of αSyn-seeds in CSF.

NUTRITIONAL DECLINE PREDICTS SHORT SURVIVAL IN MULTIPLE SYSTEM ATROPHY

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Yuri Asano, Toshio Shimizu, Kota Bokuda, Shinsuke Tobisawa, Kazushi Takahashi
Tokyo Metropolitan Neurological Hospital, Neurology, Fuchu, Tokyo, Japan

Aims: Multiple system atrophy (MSA) is a neurodegenerative disease that often leads to weight reduction and nutritional problems throughout its course. However, there is limited evidence regarding the relationships between nutritional issues and other clinical features of MSA, including survival length. This study aims to investigate the prognostic significance of nutritional problems in MSA through a retrospective cohort study at a single tertiary hospital.
Methods: A total of 218 patients with MSA who met the 2022 MDS-Ccriteria were enrolled in this study. We assessed onset age, motor subtype, the presence of orthostatic hypotension (OH), Unified MSA Rrating Sscale (UMSARS) Part Ⅳ, serum albumin, blood lymphocyte count, prognostic nutritional index (PNI), and body mass index (BMI) at the time of diagnosis. Additionally, we calculated the post-diagnostic decline rate of BMI per year (ΔBMI). Survival length was defined as the duration between the time of diagnosis and the time of death or tracheostomy. The relationship between each clinical marker and survival was explored using a log-rank test and a Cox proportional hazards model.
Results: The post-diagnostic survival was 2.5 years (mean, SD 2.0). Log-rank tests revealed a significant association between serum albumin, PNI, ΔBMI, and the presence of OH at diagnosis with post-diagnostic survival. Multivariate analysis using the Cox model demonstrated that PNI at diagnosis (HR 2.01; 95% CI 1.00–4.01) and ΔBMI (HR 2.51; 95% CI 1.32–4.76) were independent prognostic factors for survival ($p < 0.05$ and $p < 0.01$, respectively).
Conclusions: Nutritional decline predicts a shorter survival in MSA. Nutritional intervention may be required from the time of diagnosis to improve the survival prognosis in patients with MSA.

Aims: Objectives: Parkinson's disease is characterised by accumulation (aggregation) of not just alpha-synuclein but also other neurodegenerative proteins in the brain which are filtered into the cerebrospinal fluid and blood for removal. A combination of different protein aggregate biomarkers in serum is suggested to work as a sensitive discriminator between early-stage Parkinson's patients and healthy controls [1]. If optimised this may provide an early screening test for a high-risk population for the disease and provide the opportunity for early-stage intervention and treatment. The screening protocols are lengthy and highly labour intensive. Here we present a high throughput platform using a robotic liquid handling system to increase the speed of testing from around 50 samples to hundreds of samples per day.
Methods: Methods: The robotic liquid handling system (CyBio FeliX Robot by Analytik Jena) is used to prepare a sandwich single-molecule pulldown (SiMPull) immunoassay, using commercially available antibodies. Direct Stochastic Optical Reconstruction Microscopy (dSTORM) provides specific morphological data of the aggregates. Analysing the relative prevalence of different protein aggregates (primarily alpha-synuclein and tau) combined with the information on their size and shape gives a combination of metrics for distinguishing the patients from controls.
Results: Results: Preliminary testing indicates that this technique can be used to distinguish Parkinson's patients from controls, as well as patients who have high risk of developing early dementia.
Conclusions: Conclusions: This platform represents the first step towards large scale population screening for early diagnosis and prognosis of Parkinson's disease and provides the basis for similar deployment with other neurodegenerative diseases. **References** [1] Lobanova E. et al. Aims: Dementia with Lewy Bodies (DLB), the second most common cause of degenerative dementia, is characterized by non-motor cognitive alterations preceding parkinsonism. Currently, DLB is diagnosed using a combination of medical and neuropsychological tests. However, these methods are sometimes insufficient for a solid and sharp diagnosis. ADmit has developed a cutting-edge technology based on next-generation sequencing (NGS) that identifies differential mitochondrial DNA methylation patterns in blood samples from DLB patients against control subjects. The aim is to develop a classification model to diagnose DLB patients from blood samples.
Methods: Eighty-four subjects were recruited from Bellvitge University Hospital, AIBL Consortium, CITA-Alzheimer Foundation, and Hospital Clínic de Barcelona. The methylation levels of ND1 and D-loop loci were measured by NGS in DLB (n=42) and control (n=42, CDR=0) subjects. Ten different supervised learning methods were considered to build a prototype model. All methods were run using a 3 repeated 10-fold Cross-Validation.
Results: Significant differences in the methylation profile distribution were found when comparing control *vs* DLB blood samples in both loci (FDR < 0.05). Random Forest (RF) method yielded the best performance of the classification model with accuracy=0.83 and Kappa=0.65. The RF model exhibited an accuracy of 0.81 on the testing data, with a 95% Confidence Interval ranging from 0.54 to 0.96, and a Kappa value of 0.63. The Sensitivity and Specificity were 0.75 and 0.875, respectively. The precision of the model was 0.86, and the F1-score 0.8. The ROC curve showed an AUC of 0.891.
Conclusions: These results support the existence of a specific mitoepigenetic signature in blood samples from DLB patients. The present model performs a good classification of DLB patients, representing a promising minimal-invasive diagnostic tool to improve DLB diagnosis.

Aims: To evaluate the ability of a novel optimized alpha-synuclein seed amplification assay (aSyn-SAA) to detect alpha-synuclein (aSyn) aggregates in cerebrospinal fluid (CSF) samples and distinguishing between various movement disorders, including different synucleinopathies.
Methods: This study was performed with CSF samples from a cohort comprised of healthy controls (n=30), and patients with Parkinson's disease (PD) (n=101), corticobasal degeneration (CBD) (n=3), progressive supranuclear palsy (PSP) (n=22), or multiple system atrophy (MSA) (n=26). The detection of aSyn aggregates was evaluated using an optimized aSyn-SAA approach, which rapidly amplifies minimal aSyn aggregate amounts, making them easily detectable by thioflavin-T within just 24 hours.
Results: The optimized aSyn-SAA effectively identified aSyn aggregates in CSF samples, with most of the PD samples testing positive. Samples from MSA patients were mostly positive as well, although to a lesser extent than PD patients. In contrast, tauopathy-related movement disorders, such as PSP and CBD, had predominantly negative results. Furthermore, the majority of samples from healthy controls also tested negative. The small number of negative cases within the PD and MSA groups could indicate false negatives, misdiagnosis or, in case of the PD group, the presence of genetic variants that are not associated with Lewy body pathology, and would therefore test negative on this assay.
Conclusions: These results indicate that this optimized aSyn-SAA exhibits high sensitivity and specificity, and can accurately detect aSyn seeds in individuals with PD and MSA. Furthermore, we show that it can be a valuable tool for distinguishing PD and MSA from other movement disorders like CBD and PSP.

PREDICTION OF MOTOR AND NON-MOTOR PARKINSON'S DISEASE SYMPTOMS USING SERUM LIPIDOMICS: A TWO-YEAR STUDY

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Jasmin Galper[1], Gordon Mcdonald[2], Giorgia Mori[2], Diba Rastegar[1], Russell Pickford[3], Simon Lewis[4], Glenda Halliday[1], Woojin Kim[1], Nicolas Dzamko[1]
[1]The University of Sydney, Faculty Of Medicine And Health, Sydney, Australia, [2]University of Sydney, Sydney Informatics Hub, Sydney, Australia, [3]University of New South Wales, Bioanalytical Mass Spectrometry Facility, Sydney, Australia, [4]University of Sydney, Faculty Of Medicine And Health, Sydney, Australia

Aims: To investigate the potential for >900 serum lipids measured at baseline to predict motor and non-motor clinical scores of Parkinson's disease subjects after a two year follow up.
Methods: Untargeted high-performance liquid chromatography–tandem mass spectrometry was used to measure > 900 lipids in serum from Parkinson's disease subjects (*n* = 122). The potential for baseline lipids to predict motor and non-motor clinical scores (UPDRS III, UPSIT, Geriatric Depression Scale and The Schwab and England ADL) after a two year follow up (*n* = 67) was assessed by machine learning. The ability of baseline serum lipids to predict clinical scores was compared to 27 serum cytokines.
Results: Species of lysophosphatidylethanolamine, phosphatidylcholine, platelet-activating factor, sphingomyelin, diacylglycerol and triacylglycerol were top predictors of both motor and non-motor scores. Serum lipids were overall more important predictors of clinical outcomes than subject sex, age and mutation status of the Parkinson's disease risk gene *LRRK2*. Furthermore, lipids were found to better predict clinical scales than a panel of 27 serum cytokines previously measured in this cohort.
Conclusions: These results provide a platform for further targeted investigations into the involvement of lipids in Parkinson's disease.

FRAMEWORK FOR ISOLATING EVS FROM NEURONS AND MEASURING THEIR CARGO

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Tal Gilboa, Dima Ter-Ovanesyan, Sara Whiteman, David Walt
Harvard Medical School, Wyss Institute, Brookline, United States of America

Aims: This study aims to address two key challenges in isolating neuron-specific extracellular vesicles (EVs) from human biofluids, such as plasma. First, we aimed to identify a neuron-specific marker for immuno-isolation while ensuring its presence on EVs rather than as a soluble protein. Second, we sought to develop methods to confirm the presence of neurodegenerative disease biomarkers within EVs isolated from plasma and quantify the ratio of this cargo in EVs to the total plasma.
Methods: We developed an unbiased pipeline that combined gene expression and EV proteomics data to identify potential cell-type specific EV markers for neuron EV isolation. We also devised a methodology involving a high-yield size exclusion chromatography (SEC) protocol, an optimized protease protection assay, and Single Molecule Array (Simoa) assays for quantifying EV protein cargo. These methods allowed us to achieve ultrasensitive measurements of proteins within EVs
Results: We identified potential novel handles for isolating neuron EVs using our computational-experimental framework. We applied our EV protein cargo quantification method to analyze prominent proteins associated with neurodegenerative diseases, including α-synuclein, Tau, Aβ40, and Aβ42. We found that α-synuclein and Tau are present in plasma EVs at a fraction of the levels in total plasma, whereas Aβ40 and Aβ42 are undetectable in plasma EVs
Conclusions: Our study presents a valuable foundation for determining protein levels in both total plasma EVs and neuron-derived EVs. These findings hold promise for utilizing EVs as potential biomarkers for neurological diseases, offering an exciting avenue for understanding neuronal states and diagnosing neurological disorders non-invasively.

Aims: To evaluate lysosomal biomarkers in PBMCs and plasma from Parkinson's disease (PD) patients with and without *GBA1* or *LRRK2* mutations compared to healthy controls.
Methods: We analyzed PBMC samples (96 non-carrier PD, 51 non-carrier controls, 33 *LRRK2* PD, 18 *LRRK2* non-PD, 21 *GBA1* PD, 8 *GBA1* non-PD, 5 *LRRK2/GBA1* PD, 1 *LRRK2/GBA1* non-PD) and plasma samples (62 non-PD and 67 PD) for biomarker analysis. Immunoassays on the Meso Scale Discovery (MSD) platform to measure the lysosomal-related proteins LAMP1, Cathepsin B (CatB), glucocerebrosidase (GCase), pS935 LRRK2 and total LRRK2. GCase enzyme activity was measured using the plate-based 4-methylumebelliferone assay and its substrate glucosylsphingosine (GlcSph) by targeted LC-MS/MS based approach.
Results: We observed decreased GCase enzymatic activity and elevated GlcSph levels in PBMCs from *GBA1* mutation carriers versus non-carriers, as well as significantly lower GBA protein levels. *LRRK2* carriers had increased GCase enzymatic activity and reduced GlcSph levels with no change in overall GBA protein levels in PBMCs. LAMP1 levels were significantly, albeit slightly reduced, in PD compared to control in both PBMCs and plasma. CatB was elevated in PD plasma.
Conclusions: Reduced LAMP1 levels in PD patient supports the hypothesis that lysosomes are reduced in PD patients. Additionally, elevated CatB levels in plasma suggests dysregulation in the normal lysosomal pathway in PD patients. We confirmed prior reports of elevated GCase activity in LRRK2 carriers, which may be biologically meaningful considering reduction of GlcSph. Our findings further support loss of function in GBA1 shown by decreased PBMC GCase protein level and enzymatic activity along with elevation in GlcSph. This study provides novel biomarker data on Parkinson's disease and *LRRK2 /GBA1* genetic associations with readouts of lysosomal perturbations in plasma and PBMCs.

Aims: Amyloid-beta plays a pivotal role in cognitive decline in Parkinson's disease (PD). The prevalence of amyloid positivity evaluated by cerebrospinal fluid (CSF) of PD without dementia in their sixties is lower than that in the subjects with normal cognition without a diagnosis of PD (subjects with normal cognition) in the same age range. However, it is unclear whether this is also the case in patients with PD without dementia in their eighties. We aimed to identify the prevalence of amyloid positivity in patients with PD without dementia in their eighties using CSF amyloid-beta 42 levels.
Methods: PD patients (UKPDSBB) without dementia who had been diagnosed between 2013 and 2022, and whose duration of parkinsonism was < 5 years were retrospectively evaluated. CSF was obtained at diagnosis. Patients were divided into two groups based on the age at diagnosis (≥73 or <73); a high group and a low group, because its mean age at diagnosis was 80.2 (± 4.4) and 64.9 (± 7.3), respectively.
Results: Forty-nine and 40 patients were included in the high group and the low group, respectively. The prevalence of amyloid positivity was significantly higher in the high group (30.6%) compared to the low group (10.0%) ($p = 0.02$).
Conclusions: The prevalence of amyloid positivity in both groups was lower than that in the subjects with normal cognition in the same age range, because the prevalence of amyloid positivity has been reported to be in the 40% range and 20% range in the subjects with normal cognition in the eighties and sixties, respectively. Our findings suggested that the inhibitory effects on amyloid positivity by α- synuclein may persist regardless of aging.

QUANTITATIVE DETECTION OF ALPHA-SYNUCLEIN PATHOLOGY IN PARKINSON'S DISEASE SKIN

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

David Holzinger, Bryan Frey, Simone Giaisi, Michael O'Neill, Stefan Barghorn, Roland Heym
AbbVie Deutschland GmbH & Co. K, Neuroscience Discovery, Ludwigshafen, Germany

Aims: Biomarkers to assess progression of α-synuclein pathology and potential treatment effects in Parkinson's disease (PD) patients are currently lacking. Established α-synuclein seed amplification assays (SAA) for cerebrospinal fluid (CSF) have a binary readout and direct detection of α-synuclein pathology in CSF by ligand-binding assays (LBAs) has not been successful. The skin emerges as an attractive alternative to CSF due to presence of α-synuclein aggregates in peripheral nerves and low invasiveness of collection.
Methods: We developed a new LBA for quantification of phosphorylated (pS129) α-synuclein aggregates in skin homogenate and adapted our in-house SAA method for detection of α-synuclein seeding in skin. Using these assays, we characterized a set of 20 postmortem skin samples from control and PD cases with documented Lewy-body pathology in the brain.
Results: pS129 α-synuclein aggregates were significantly increased in PD skin and undetectable in most controls highlighting the specificity for PD. These LBA results were in concordance with the detection of α-synuclein seeding by SAA in the same samples. We observed a strong correlation between LBA and SAA readouts suggesting a relationship between pS129 α-synuclein aggregates and seeding activity in PD skin. Interestingly, the dynamic range of LBA was at least 30-fold higher than SAA highlighting the advantage of LBA for accurate quantification.
Conclusions: Here, we report the successful development of LBA and SAA for detection of pathological α-synuclein in PD skin. Due to its superior quantification LBA for PD skin offers potential for the assessment of pathology progression and treatment effects. We are currently extending our data set to a larger cohort including early Lewy-body stages to further investigate the relationship between α-synuclein pathology in skin and brain.

LONGITUDINAL MIXED MODEL ANALYSIS REVEALS ALTERATIONS IN THE TRANSCRIPTOME ASSOCIATED TO PARKINSON'S DISEASE L RESULTS FROM THE PDBP STUDY

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Santiago Sanchez, Aleksandra Beric, Laura Ibanez, Yichen Sun, Charissa Martin
Washington University School of Medicine, Psychiatry, Saint Louis, United States of America

Aims: Objectives: Our primary aim was to identify longitudinal changes in linear RNAs associated with Parkinson's Disease (PD) by leveraging one of the largest available datasets.
Methods: We utilized the Parkinson's Disease Biomarkers Program (PDBP) cohort, that includes 2,939 blood samples from individuals of European origin collected at five distinct time points, all with available transcriptomic data. Our analysis involved employing STAR for sequence mapping to the GRCh38 reference genome and Salmon for transcript quantification. We conducted mixed model differential expression analyses to account for data's longitudinal nature. Additionally, pathway and enrichment analyses were conducted, with all significance levels adjusted for multiple testing using the FDR correction.
Results: We identified 290 transcripts associated with PD progression over time: TET2 (p=4.89x10-4, effect size=0.048), B4GALT1 (p=7.51x10-4, effect size=0.045), and NCL (p=1.08x10-4, effect size=-0.050). In PD patients' substantia nigra, B4GALT1 and TET2 have been shown to exhibit increased expression, while NCL shows decreased expression. We also detected upregulated transcripts previously detected in blood samples from PD participants, including MDM4 (p=7.28x10-4, effect size=0.031) and BCL2L11 (p=4.05x10-5, effect size=0.056). Additionally, we found other PD-related transcripts, such as PARP1, OGA, OGT, NDFIP1 and NOTCH2NLC. Enrichment analyses revealed dysregulation in processes related to lysosomal membranes (p=1.90x10-2), protein folding (p=1.00x10-2), Tauopathies (p=1.30x10-2), cerebral degeneration (p=5.00x10-3), and glycosyl transferase activity (p=3.00x10-2), among other glycosylation-related pathways.
Conclusions: Conclusion: Our findings unveil several known PD-related changes in blood that have already been described in the central nervous system. These results suggest the potential of using blood-derived transcriptomic data as PD biomarkers and adds evidence to the holistic nature of central nervous system diseases.

SERUM LEUCINE-RICH A2 GLYCOPROTEIN AS A POTENTIAL BIOMARKER FOR SYSTEMIC INFLAMMATION IN PARKINSON'S DISEASE

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Takashi Kasai, Takuma Ohmichi, Fukiko Kitani-Morii, Yuzo Fujino, Makiko Shinomoto, Toshiki Mizuno
Kyoto Prefectural University of Medicine, Neurology, Kyoto, Japan

Aims: There is ample epidemiological and animal-model evidence suggesting that intestinal inflammation is associated with the development of Parkinson's disease (PD). Leucine-rich α2 glycoprotein (LRG) is a serum inflammatory biomarker used to monitor the activity of autoimmune diseases, including inflammatory bowel diseases. In this study, we aimed to investigate whether serum LRG could be used a biomarker of systemic inflammation in PD and to help distinguish disease states.
Methods: Serum LRG and C-reactive protein (CRP) levels were measured in 66 patients with PD and 31 age-matched controls.
Results: We found that serum LRG levels were statistically significantly higher in the PD group than in the control group (PD: 13.9 ± 4.2 ng/mL, control: 12.1 ± 2.7 ng/mL, $p = 0.036$). LRG levels were also correlated with Charlson comorbidity index (CCI) and CRP levels. LRG levels in the PD group were correlated with Hoehn and Yahr stages (Spearman's $r = 0.40$, $p = 0.008$). LRG levels were statistically significantly elevated in PD patients with dementia as compared to those without dementia ($p = 0.0078$). Multivariate analysis revealed a statistically significant correlation between PD and serum LRG levels after adjusting for serum CRP levels, and CCI ($p = 0.019$).
Conclusions: We conclude that serum LRG levels could be considered a potential biomarker for systemic inflammation in PD.

OVERCOMING CHALLENGES OF MEASURING SMALL EXTRACELLULAR VESICLE (SEV) BIOMARKERS IN A CLINICAL SETTING

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Christoph Kleinert[1], Hubert Aviolat[2], Michael Schulz[1], Mario Richter[1]
[1]AbbVie Deutschland GmbH & Co. KG, Qtas (dmpk), Ludwigshafen, Germany, [2]AbbVie Deutschland GmbH & Co. KG, Discovery, Ludwigshafen, Germany

Aims: The objectives of analyzing small extracellular vesicles are to simplify diagnosing or monitoring diseases by shifting from biopsy or CSF sampling to blood-based analysis. Some isolation methods lack the clinical requirements of exosomal yield, purity, reproducibility, and throughput. However, these features are essential in biomarker analysis.
Methods: We compared twelve isolation methods, including size exclusion chromatography (SEC), differential centrifugation (DC), bead-based immunoprecipitation (BBIP), polymer-based precipitation (PolyP), and membrane affinity isolation (MAI). The isolated vesicles were characterized by several methods, including: 1.) Appearance of common EV markers. 2.) Depletion of plasma contaminants. 3.) Amount and size distribution of particles. Throughput and technical requirements of each method of isolation and characterization were estimated, which allows judging the feasibility of application in a clinical setting. Further, we evaluated the reproducibility of selected EV purification methods. For the preferred method, we tested the interindividual variability.
Results: Residual protein corresponds largely to protein contaminations like albumin and IgG. SEC sEVs show an excellent depletion of high-density lipoprotein but a copurification of low-density lipoprotein, while the other isolation methods showed contrary results. We used several methods to quantify tetraspanins, like western blot, ELISA, and NanoView analysis. SEC (SmartSEC, qEVsingle35T) and DC samples showed high exosomal yield. Various particle-sizing methods allowed to represent an EV typical distribution, but the validity seems doubtful.
Conclusions: In conclusion, an adapted SEC protocol gave the highest purity with simultaneously high EV marker yield. The reproducibility matched our acceptance criteria, and it revealed the interindividual variability.

AN ALPHA-SYNUCLEIN SEED AMPLIFICATION ASSAY FOR HIGHLY SENSITIVE AND SPECIFIC DETECTION OF LEWY-FOLD ALPHA-SYNUCLEINOPATHIES

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Sebastian Longen[1,2], Alexander Bernhardt[3,4], Svenja Trossbach[2], Günter Höglinger[3,4,5], Armin Giese[2], Johannes Levin[2,3,4,5], Torsten Matthias[1,2]
[1]AESKU.Diagnostics GmbH, N/a, Wendelsheim, Germany, [2]MODAG GmbH, N/a, Wendelsheim, Germany, [3]Ludwig-Maximilians-Universität München, Department Of Neurology, Munich, Germany, [4]German Center for Neurodegenerative Diseases (DZNE), Site Munich, Munich, Germany, [5]Munich Cluster for Systems Neurology (SyNergy), N/a, Munich, Germany

Aims: Misfolded alpha-Synuclein aggregates underlie the pathology of Parkinson's Disease (PD), dementia with Lewy bodies (DLB), and multiple system atrophy (MSA), collectively known as alpha-synucleinopathies. These diseases exhibit distinct misfolded alpha-synuclein strains, with MSA characterized by two unique MSA-fold strains and PD/DLB sharing a Lewy-fold strain. Current alpha-synuclein seed amplification assays (SAAs) lack the necessary specificity to differentiate between these strains, posing a challenge for clinical diagnosis. This study aimed to develop a refined SAA with enhanced strain specificity for precise detection of Lewy-fold alpha-synucleinopathies.
Methods: We designed and implemented an improved SAA and optimized the expression and purification of alpha-Synuclein. 180 cerebrospinal fluid samples of patients with a broad spectrum of clinically diagnosed neurodegenerative diseases from the LMU Munich Department of Neurology were analysed in a blinded fashion, including alpha-Synucleinopathies (MSA, PD, DLB), mixed 3-repeat/4-repeat Tauopathies (Alzheimer disease), 4-repeat Tauopathies (progressive supranuclear palsy), frontotemporal dementia and healthy controls. To further validate strain specificity, brain homogenates from 30 neuropathologically diagnosed cases with Lewy body disease, multiple system atrophy, and progressive supranuclear palsy were employed.
Results: Blinded analysis yielded a high sensitivity and specificity for neuropathologically diagnosed Lewy-fold alpha-Synucleinopathies identifying clinically diagnosed PD and DLB samples correctly but not cases with clinically diagnosed MSA, progressive supranuclear palsy, and frontotemporal dementia. Consistent with previous research, a part of Alzheimer's disease cases showed a copathology.
Conclusions: Our refined SAA is characterized by a unique Lewy-fold specificity. It may assist with the *ante mortem* clinical-biological diagnosis of the Lewy-fold alpha-synucleinopathies PD and DLB and the differential diagnosis from multiple system atrophy as well as other parkinsonian syndromes, such as progressive supranuclear palsy.

Aims: Parkinson's disease (PD) is the most common neurodegenerative disorder characterized by motor symptoms. The deposition of fibrillary aggregated alpha-synuclein (aSyn) in Lewy bodies (LB) and Lewy neurites (LN) is considered a main neurotoxic event in the brain of patients affected by PD. Of note, several lines of evidence support that mature aSyn aggregates contain elevated levels of Ser129-phosphorylated aSyn (pSer129-aSyn), supporting that this post-translationally modified form of the protein may serve as a biormarker for PD. Recent studies showed that pSer129-aSyn is increased in the serum/plasma of PD patients and suggested that pSer129-aSyn levels correlate with motor severity and progression in patients with PD. Here, we aimed at evaluating the relative amount of pSer129-aSyn in the plasma of PD, dementia with LB (DLB) patients and age-matched healthy controls (HC).
Methods: We developed a novel enzyme-linked immunosorbent assay (ELISA) to evaluate the relative amount of pSer-aSyn in plasma, coupled with a standard ELISA protocol for the detection of total aSyn (taSyn).
Results: We found that the ratio p-Ser129-aSyn/taSyn was significantly higher in PD patients when compared with DLB and age-matched HC. While both PD and DLB patients exhibited lower levels of taSyn, only PD patients showed a significant increase of pSer129-aSyn when compared to HC. Notably, taSyn and pSer129-aSyn levels were found to correlate with UPDRS III scores only in the PD group, while no significant correlation was found in the DLB group.
Conclusions: Taken together, these results support that plasma p-Ser129-aSyn/taSyn ratio may enable to discriminate patients affected by PD and DLB and that combined plasma taSyn and pSer129-aSyn levels may serve as biomarkers of PD severity.

VALIDATION OF PROTEOMICS-DERIVED CSF BIOMARKER CANDIDATES IN PARKINSON'S DISEASE

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Fabian Maass, Katharina Obermeier, Peter Lange, Christoph Van Riesen
University Medical Center Göttingen, Germany, Dept. Of Neurology, Göttingen, Germany

Aims: Different studies concerning untargeted proteomics analysis of CSF samples of patients with PD can be found in the literature, yielding different regulated protein candidates. But only few of the reported proteins could be reproduced in other proteomics studies. This might be due to multiple factors (demographical, analytical and statistical differences). Concerning non-CNS specific proteins, simultaneous quantification of paired serum and CSF samples could give further information on the variance of CSF levels dependent on correlating serum levels / correlating individual blood brain barrier dysfunction, but this was not considered in the majority of studies. Therefore, we plan to analyze a selection of promising non-CNS specific protein candidates using paired serum and CSF samples of patients with PD, controls and atypical conditions for comparison.
Methods: Paired samples of 23 PD patients, 23 control patients and 15 atypical Parkinsonian patients (PSP, CBD) will be analyzed concerning the levels of Apolipoprotein A1, Gelsolin, Human Zinc Alpha 2 Glycoprotein and Pigment Epithelium Derived Factor (PEDF) levels, applying commercially available ELISA systems. Additionally, the CSF/serum albumin ratio (QAlb) as a marker for blood brain dysfunction is calculated.
Results: For Apolipoprotein A1, no group difference ($p > 0.05$) but a highly significant correlation ($p < 0.0001$) between CSF levels and the corresponding QAlb values could be detected. Analysis of further candidates is in progress and results will be demonstrated at the AD/PD congress.
Conclusions: The individual blood brain barrier dysfunction - as reflected by QAlb - is an important factor concerning the interpretation of CSF levels of non-CNS specific biomarker candidates and could explain some part of the variance of the results of proteomics studies as reported in the literature.

Aims: The role of neurofilament light chain (NFL) as a potential biomarker for Parkinson's disease (PD) severity and progression has yielded varying findings. This study seeks to examine serum NFL levels at the time of PD diagnosis and their correlation with disease progression during the first ten years of disease.
Methods: Serum NFL was measured in up to 172 PD patients and 194 healthy controls from the Norwegian ParkWest cohort at baseline, three years, and five years. Linear mixed-effects regression analysis was employed to assess changes in NFL levels from baseline to year 5 and the association between NFL and repeated measures of MMSE and UDPRS part III scores up to 9.6 years.
Results: PD patients exhibited higher serum NFL levels compared to controls at all time points, and NFL increased more rapidly over five years than in the control group. Elevated baseline NFL in PD correlated with accelerated cognitive and motor decline. Moreover, higher rates of change in serum NFL were linked to faster disease progression.
Conclusions: This study underscores the association of serum NFL with PD and the severity and change of cognitive and motor impairment. The findings suggest that serum NFL holds promise as a biomarker to predict and track disease progression in PD, warranting inclusion in future biomarker panels for the disease.

Aims: Objectives: The Parkinson Associated Risk syndrome (PARS) study is designed to identify a Parkinson disease (PD) biomarker/clinical marker derived cohort enriched to develop typical symptoms of PD. **Background:** PARS participants were enrolled from the community using a sequential clinical marker/biomarker strategy testing olfactory function remotely followed by dopamine transporter (DAT) imaging. About 4800 individuals returned a University of Pennsylvania Smell Identification test (UPSIT), and 203 hyposmic (<15% UPSIT by age and sex) and 100 normosmic participants were evaluated with extensive clinical evaluation and DAT imaging. Individuals with hyposmia were enriched for DAT deficit and were likely to develop symptoms of PD within four years.
Methods: Methods: PARS participants in clinic were followed longitudinally for up to six years with DAT imaging every two years. 99 of the 303 participants (27 normosmic, 72 hyposmic) underwent lumbar puncture during the 6-year follow-up. CSF were blindly analyzed using Amprion's α-synuclein seed amplification assay **(**αS-SAA).
Results: Results: Among the hyposmic participants 34/72 (47.2%) are αS-SAA positive, 36/72 (50%) are αS-SAA negative and 2 are inconclusive. Among normosmic participants 1/25 (4%) are αS-SAA positive. The majority of both α-syn SAA positive (74%) and α-syn SAA negative (92%) hyposmics had no DAT deficit at the baseline visit. During the study, there was a strong trend for α-syn SAA positive hyposmics to be more likely have a DAT deficit compared to α-syn SAA negative hyposmics (12/34 (35%) vs. 4/36 (11%). Among DAT deficit hyposmic SAA positive 8/11 participants developed PD symptoms compared to 0/3 DAT deficit hyposmic SAA negative.
Conclusions: Conclusion: Hyposmics in the PARS cohort demonstrate widespread synuclein pathology that precedes DAT deficit. These data may enable therapeutic PD studies to prevent the onset of clinical PD syndromes.

Aims: Parkinson's disease (PD) is a neurodegenerative disorder characterized by the loss of dopaminergic neurons of substantia nigra pars compacta due to the formation of alpha-synuclein aggregates. Currently, only symptomatic therapies are available, and long-term treatments are associated with adverse effects. It is demonstrated that circulating lipids may mirror the alteration of cellular pathways. In this study, we explored whether long-term treatment of PD patients induced altered lipid metabolism.
Methods: Untargeted lipidomics strategy using ultra performance liquid chromatography was performed to obtain lipidomic signature. We also used multiplex ELISA assay to measure circulating biomarkers such as leptin, ghrelin, FABP3, FABP7, TNF-alpha, Gro-alpha, BDNF and GFAP. The study cohort included three groups of PD patients: the first treated with standard L-Dopa-based therapy, the second with deep brain stimulation (DBS) and L-Dopa-based maintenance therapy, and the last of untreated patients in the early stage of PD. A group of matched controls was also investigated.
Results: We found an extensive dysregulation of lipid profile in PD patients compared to controls. Specifically, we found elevated triglycerides (TG) levels in all PD patients, increased phosphatidylcholine (PC-O) only in untreated patients and lower levels of sphingomyelin (SM) in two treated groups compared to healthy subjects. Interestingly, we also observed a downregulation of Ether-linked Lyso-phosphatidyl-ethanolamine (LPE-O) and fatty acid (FA) in DBS compared to L-Dopa-treated patients. Furthermore, untreated patients showed a decreased level of FABP3 and FABP7 markers of lipid mobilization and catabolism, while only DBS patients showed an increase in TNF-α, marker of neuroinflammation.
Conclusions: These data, although preliminary, may be encouraging to extent this analysis to a larger cohort of patients to discover new biomarkers for therapeutic drug monitoring and identify novel targets that will improve long-term treatments for PD.

PERFORMANCE OF A SEED AMPLIFICATION ASSAY FOR MISFOLDED ALPHA-SYNUCLEIN IN CEREBROSPINAL FLUID AND BRAIN TISSUE IN RELATION TO LEWY BODY DISEASE STAGE AND PATHOLOGY BURDEN

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Piero Parchi[1,2], Giuseppe Mario Bentivenga[1], Angela Mammana[2], Simone Baiardi[1], Marcello Rossi[2], Alice Ticca[1], Franco Magliocchetti[2], Andrea Mastrangelo[1], Sabina Capellari[1]
[1]University of Bologna, Department Of Biomedical And Neuromotor Sciences, Bologna, Italy, [2]IRCCS, Instituto Delle Scienze Neurologiche Di Bologna, Bologna, Italy

Aims: 1) To evaluate the diagnostic performance of a seed amplification assay for misfolded alpha-synuclein (αSyn SAA) in antemortem CSF of patients with a neuropathological diagnosis. 2) To study the relationship between SAA kinetic parameters, the number of αSyn brain seeds and the LBD burden assessed by immunohistochemistry.
Methods: We tested 269 antemortem CSF samples and 138 serially diluted brain homogenates from patients with LBD in different stages by the αSyn Real-Time Quaking-Induced Conversion (RT-QuIC) SAA. Moreover, we looked for LB pathology by αSyn immunohistochemistry in a consecutive series of 604 Creutzfedt-Jakob disease (CJD)-affected brains.
Results: CSF αSyn RT-QuIC showed 100% sensitivity in detecting LBD in limbic and neocortical stages. The assay sensitivity was significantly lower in early stages (37.5% in Braak 1 and 2, 73.3% in Braak 3) or focal pathology (50% in amygdala-predominant). The number of CSF αSyn RT-QuIC positive quadruplicate fluorescence curves significantly correlated with the LBD stage. Brain αSyn RT-QuIC showed higher sensitivity than immunohistochemistry for detecting misfolded αSyn. In the latter, the kinetic parameter lag phase (time to threshold) strongly correlated with the αSyn seed concentration. Finally, incidental LBD prevalence was 8% in the CJD cohort.
Conclusions: The present results indicate that (a) CSF αSyn RT-QuIC has high specificity and enough sensitivity to detect all patients with LB pathology at Braak stages >3 and most of those at stage 3; (b) Brain deposition of misfolded αSyn precedes the formation of LB and Lewy neurites; (c) αSyn RT-QuIC provides "quantitative" information regarding the LB pathology burden, with the lag phase and the number of positive replicates being the most promising variables to be used in the clinical setting.

MIRO1 AS A NOVEL PERIPHERAL DRUG-RESPONSIVE BIOMARKER FOR PD PATIENT IDENTIFICATION AND SEGMENTATION

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Sean Pintchovski, Atossa Shaltouki, Eric Beattie, Chung-Han Hsieh, Wesley Sun, Bill Shrader
Acurex Biosciences, Biology, San Carlos, United States of America

Aims: Defects in mitophagy, the process for recycling damaged mitochondria, are a major pathological driver of Parkinson's disease (PD) and other neurodegenerative disorders. The protein Miro1 must be released from mitochondria for normal mitophagy to proceed. Interestingly, Miro1 retention was discovered in post-mortem PD brain tissues and PD patient iPSC dopaminergic neurons. Additionally, Miro1 retention was observed in PD patient fibroblasts, serving as a novel peripheral biomarker to distinguish healthy from PD subjects. This study has two objectives: 1. Determine whether the Miro1 biomarker is detectable in more clinically tractable peripheral blood mononuclear cells (PBMCs) from PD subjects. 2. Evaluate the efficacy of Acurex's therapeutic compound CU-00048 to trigger Miro1 release from damaged mitochondria in PBMCs from PD subjects.
Methods: Establish a robust *ex vivo* mitophagy assay to quantify Miro1 protein levels in PBMCs obtained from PD patients and age- / sex-matched healthy controls.
Results: The Miro1 biomarker was observed in PBMCs collected from both sporadic and genetically defined (G2019S LRRK2) PD subjects. Treatment with Acurex's best-in-class Ca_V3 calcium channel antagonist, CU-00048, effectively rescued Miro1 levels in both PD subgroups.
Conclusions: Preliminary findings suggest that the PBMC Miro1 assay is a high-fidelity clinical biomarker, enabling the rapid identification and segmentation of PD subjects. Miro1 rescue by CU-00048 could identify potential clinical responders and determine their optimal drug dosage, thereby significantly reducing risk in early clinical trials. Through larger longitudinal studies, the Miro1 biomarker will improve our understanding of disease progression in pre-symptomatic PD subjects, enabling targeted treatment at the earliest disease stages. The innovative PBMC Miro1 biomarker test is poised to advance a new era of precision medicine, significantly boosting the likelihood of therapeutic efficacy and improving the quality of life for PD patients.

[1]BIAL - Portela & C[a], S.A., Research & Development, Coronado, Portugal, [2]BIAL - R&D Investments, S.A., Research & Development, Coronado, Portugal, [3]CHDR, Neurology, Leiden, Netherlands

Aims: Heterozygous glucocerebrosidase 1 (*GBA1*) pathogenic variants are the most common genetic risk factor for Parkinson's disease (PD). The aim of this study was to assess whether glucocerebrosidase (GCase) enzyme activity and glucosylsphingosine (GlcSph) levels (enzyme substrate) differs between GBA-PD and idiopathic PD patients compared to healthy volunteers (Toetsing Online number: NL79102.100.21).
Methods: GCase activity in dried blood spots (DBS) and GlcSph levels in plasma were analyzed from healthy volunteers (n=8), idiopathic PD patients (n=8) and GBA-PD patients (n=8).
Results: No statistically significant intra- and inter-day variability in GCase activity in DBS was observed. GCase activity in DBS was statistically significantly lower in GBA-PD compared with idiopathic PD patients and healthy volunteers [-2.30 (0.67) and -2.70 (0.67) µmol/L mean (SE) difference, p=0.003 and 0.001 respectively], whilst plasma GlcSph levels were statistically higher in GBA-PD patients compared with idiopathic PD patients and healthy volunteers [0.45 (0.15) and 0.54 (0.15) pmol/mL mean (SE) difference, p=0.007 and 0.002 respectively]. No statistically significant differences for GCase activity and plasma GlcSph levels between idiopathic PD patients and healthy volunteers were detected.
Conclusions: Heterozygous *GBA1* mutations had a relevant functional impact on GCase activity in DBS and on GlcSph in plasma. Further studies are being conducted to refine their use as biomarkers in clinical trials targeting GBA-PD.

ASSOCIATION OF PLASMA NEUROFILAMENT LIGHT CHAIN WITH CLINICAL MANIFESTATIONS IN DEMENTIA WITH LEWY BODIES

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Íñigo Rodríguez-Baz[1], Javier Arranz[1], Nuole Zhu[1,2], Sara Rubio[1,2], Elena Vera[1,2], Isabel Sala[1,2], Juan Fortea[1,2], Alberto Lleó[1,2], Daniel Alcolea[1,2]
[1]Sant Pau Biomedical Research Institute, Universitat Autònoma de Barcelona, Sant Pau Memory Unit, Department Of Neurology, Barcelona, Spain, [2]Biomedical Research Network Center for Neurodegenerative Diseases, CIBERNED, Spain, Memory Unit, Barcelona, Spain

Aims: Our aim was to investigate plasma neurofilament light chain (NfL) level variations in patients with Dementia with Lewy Bodies (DLB) and their correlation with manifested symptoms.
Methods: We assessed NfL levels in plasma samples from patients at prodromal (pDLB) and dementia (dDLB) stages of DLB, along with healthy controls (HC) assessed between 2017 and 2022 at the Sant Pau Memory Unit in Barcelona. Considering the association between NfL concentrations and age in HC, we adjusted NfL by age in DLB patients. We compared concentrations between groups and evaluated their association with the presence of Alzheimer's co-pathology (identified via cerebrospinal fluid biomarkers), core clinical symptoms (cognitive fluctuations, hallucinations, REM sleep behaviour disorder, parkinsonism), and disease severity.
Results: We included 312 participants, comprising 56 with pDLB, 70 with dDLB, and 186 HC. The mean age in our cohort was 63.7±13.6 years, 57.7% female. NfL concentrations were higher in DLB patients (+0.41SD, p=0.002) compared to HC (+0.36SD in pDLB and +0.44SD in dDLB). Having co-existing Alzheimer's pathology had no significant effect on NfL concentration. Likewise, we found no differences based on core symptom presence (neither number nor duration). dDLB patients in the highest quartile of NfL concentrations exhibited poorer cognitive performance on the MMSE, compared to those in the lowest quartile ($\bar{x}$25.7±2.8 Vs $\bar{x}$21.3±5.7;
p=0.013).

ASSOCIATION BETWEEN PLASMA AMYLOID-B BIOMARKER AND NEUROPSYCHOLOGICAL SYMPTOMS IN PATIENTS WITH PARKINSON'S DISEASE

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Yuji Saitoh[1,2], Kotaro Hattori[3], Yuji Takahashi[1]
[1]National Center of Neurology and Psychiatry, Neurology, Kodaira, Tokyo, Japan, [2]Tokyo Metropolitan Neurological Hospital, Neurology, Fuchu, Japan, [3]National Center of Neurology and Psychiatry, Medical Genome Center, Kodaira, Tokyo, Japan

Aims: Amyloid-β (Aβ) is a major neuropathological hallmark in Alzheimer's disease (AD) and commonly co-exist in Lewy body disease (LBD). Aβ may play an important role in developing neuropsychological symptoms such as a cognitive decline in patients with LBD. As a non-invasive technique, the development of a reliable plasma biomarker detecting Aβ allows us to predict the brain Aβ burden in patients with AD. However, it is not well evaluated whether the plasma Aβ biomarker is associated with neuropsychological symptoms of LBD. The purpose of our study was to investigate the relationship between plasma Aβ biomarker and neuropsychological symptoms in patients with Parkinson's disease (PD).
Methods: Plasma Aβ biomarker composite score, calculated from plasma Aβ precursor protein $(APP)_{669-711}$/ $Aβ_{1-42}$ and $Aβ_{1-40}$/ $Aβ_{1-42}$, originally reported by Nakamura et al. in 2018, were measured in 32 patients with PD. A retrospective review of medical records was performed to identify the comorbidity of the major neuropsychological symptoms in PD, including cognitive decline, delusion, and hallucination, of these patients in the clinical course. We conducted a Chi-squared test to evaluate the association between the plasma Aβ biomarker and neuropsychological symptoms.
Results: Among 32 patients with PD, 10 patients showed the abnormal plasma Aβ biomarker composite score. Chi-squared test with Yates' continuity correction revealed that abnormal composite plasma Aβ biomarker score was significantly associated with the development of both dementia ($\chi^2(1)=7.13$, $p=0.0076$) and hallucinations ($\chi^2(1)=3.85$, $p=0.0498$) in the clinical course, but delusion was not ($\chi^2(1)=0.0831$, $p=0.773$).
Conclusions: In our cohort, abnormal plasma Aβ biomarker composite score predicts the development of cognitive decline and hallucination in patients with PD. Further validation studies are required to confirm these findings.

BIOMARKERS IN PARKINSON'S DISEASE: PAST, PRESENT, AND FUTURE

POSTERS: C04.F. IMAGING, BIOMARKERS, DIAGNOSTICS: CSF, BLOOD, BODY FLUID BIOMARKERS

Pratibha Sharma[1], Rajinder Dhamija[2]
[1]Institute of Human Behaviour and Allied Sciences, Human Behaviour Department, Delhi, India, [2]Institute of Human Behaviour and Allied Sciences, Director And Professor Neurology, Delhi, India

Aims: Background: Parkinson's disease (PD) is a neurodegenerative disease that affects millions of people worldwide. The diagnosis of PD can be challenging due to the lack of specific biomarkers and the reliance on clinical symptoms and medical history.
Methods: This study sheds light on the past, present, and future of biomarkers in PD research.
Results: In the past, researchers have identified several potential biomarkers, including dopamine transporter imaging, CSF biomarkers, and genetic markers. However, these biomarkers lacked the sensitivity and specificity required for accurate diagnosis and monitoring of PD. Currently, significant progress has been made in the field of PD biomarkers, and biomarkers such as alpha-synuclein have shown promise as potential diagnostic and prognostic markers. Imaging techniques, such as PET scans, utilizing ligands that bind to alpha-synuclein aggregates may be useful in diagnosis. CSF biomarkers, including alpha-synuclein, tau, and DJ-1, have shown some potential in detecting PD pathology. However, further validation and standardization are required for their use in clinical practice.
Conclusions: Recent advancements in genomics, proteomics technologies and bioinformatics, may lead to the identification of genetic markers that can predict an individual's risk of developing PD or their disease progression. While the field of PD biomarkers has made significant progress, several challenges need to be addressed. The role of biomarkers in PD diagnosis, risk, and progression has been discussed. The future of PD biomarkers holds great potential, with the development of novel imaging techniques, genetic, and protein biomarkers.

Aims: Heterozygous loss-of-function mutations in the gene *GBA1*, which encodes for glucocerebrosidase (GCase), are a major risk factor for the development of Parkinson's disease (PD). Vanqua Bio has developed novel, small-molecule allosteric activators that significantly increase GCase activity. Current methods to assess GCase activity fail to evaluate GCase activity within the lysosomal environment, where an allosteric activator functions. We aimed to develop and test a novel assay to assess lysosomal GCase activity in fresh blood samples, in order to measure target engagement by the Vanqua GCase activator, VQ-101, in Phase 1 clinical studies.
Methods: An assay to assess lysosomal GCase activity was developed and transferred to two independent labs. Intra-day, before and after food, and inter-day assessment of GCase activity was measured to determine natural fluctuations in GCase activity and to understand potential food effects in a Phase 0 study of healthy volunteers (HV) and GBA-PD patients. Activation of GCase by VQ-101 in peripheral blood from HV, iPD, and GBA-PD subjects was assessed by spiking VQ-101 into blood samples and assessing GCase activity. Finally, non-human primates (NHPs) were dosed with VQ-101 and GCase activity was assessed longitudinally.
Results: The GCase activity assay was successfully transferred to independent labs with consistent measurements obtained across both sites. Minimal intra- and inter-day fluctuations in GCase activity was observed with no evidence of a food effect. Concentration-dependent activation of GCase was observed after spike of VQ-101 into fresh blood samples from HV, iPD, and GBA-PD subjects. Lastly, NHPs dosed with VQ-101 demonstrated robust activation of GCase over 24 hours.
Conclusions: We have developed a robust assay to measure live-cell GCase activity in humans that will enable assessment of target engagement by GCase activators in early clinical development.

Aims: Cerebrospinal fluid (CSF) concentrations of homovanillic acid (HVA) and 5-hydroxyindole acetic acid (5-HIAA), the dopamine and serotonin metabolites, had been shown to decrease in Parkinson's disease (PD). The aim of this study was to evaluate the relationships between these CSF biomarkers and imaging biomarkers, striatal dopamine transporter (DAT) SPECT using ^{123}I-ioflupane and cardiac scintigraphy using ^{123}I-MIBG (MIBG), in PD patients.
Methods: We retrospectively reviewed 58 patients with drug-naïve PD receiving DAT SPECT, MIBG, and lumbar puncture from September 2021 to August 2023. The Z-score of the bilateral averaged striatal DAT standard binding ratio (averaged-SBR Z-score) was measured with DAT SPECT, and MIBG was judged as positive or negative results by expert readings.
Results: Mean age was 75.5 ± 8.7 years old. Thirty-one were male and 27 were female. Thirty-four were MIBG-positive and 24 were MIBG-negative. Averaged-SBR Z-score was -3.41±1.01. HVA was 25.2±12.5 ng/ml and 5-HIAA was 14.2±5.3 ng/ml. Significant difference was observed in 5-HIAA ($t=3.80$, $p<0.001$) between MIBG-positive and MIBG-negative groups. Logistic regression analysis with MIBG-negative or MIBG-positive as the dependent variable and age, sex, HVA and 5-HIAA as independent variables showed no significant difference in age, sex and HVA, but a significant difference in 5-HIAA (odds ratio=0.747, $p=0.005$). Averaged-SBR Z-score correlated with HVA ($r=0.484$, $p<0.001$) and 5-HIAA ($r=0.365$, $p=0.005$). Multiple regression analysis with averaged-SBR Z-score as the dependent variable and age, sex, HVA and 5-HIAA as independent variables showed no correlation in age, sex and 5-HIAA, but a correlation in HVA ($t=3.539$, $p<0.001$).
Conclusions: Our study showed that striatal DAT binding associated with HVA and cardiac MIBG associated with 5-HIAA. These results suggest some pathophysiological links between serotonin concentration in the central nervous system and degeneration of the cardiac sympathetic systems.

Aims: The detection of alpha-synuclein phosphorylated at serine129 (pS129Syn) in human biofluids remains challenging considering its low abundance and the complexity of alpha-synuclein diversity in the pathology of synucleinopathies. However, the potential of pS129Syn as a biomarker of synucleinopathy is established in tissues. Our work describes a novel Simoa Homebrew immunoassay for detection of pS129Syn in human cerebrospinal fluid (CSF) using a monoclonal antibody (mAb) pair with documented specificity.
Methods: Specificity of the pS129Syn mAb (code#RD-091) and pan alpha-synuclein mAb (code#RD-006) was assessed by mapping the epitopes using (phosphorylated) synthetic peptides. For the novel assay, a number of analytical performance parameters were evaluated, i.e.: measuring range, precision, LLOQ and specificity, using commercially sourced non-clinical CSF.
Results: The pS129syn antibody was mapped in the region aa128-138 (not containing tyrosine125), suggesting a different (phospho-)specificity when compared to reference mAb MJF-R13 that maps in the aa125-131 region. Pan alpha-synuclein mAb RD-006 has an epitope in the aa 99-110 region. The Simoa Homebrew assay displayed an average intra- and inter-assay variability of 1.3%CV and 12.9%CV, respectively, for a 3-member CSF QC-panel. For all samples measured (CSF: n=21; plasma: n=19), the pS129syn concentrations were within the measuring range of the assay (0.25 to 25 pg/mL). The assay was specific for pS129Syn up to 10.000 pg/mL of spiked recombinant alpha-synuclein in remnant CSF.
Conclusions: A prototype Simoa Homebrew pS129Syn assay was established, based on an antibody pair characterized for pS129Syn specificity. Our results suggest that this novel pS129Syn prototype assay may detect pathological pS129Syn species. Further clinical exploration of this assay is warranted, e.g., by testing a cohort of paired CSF-plasma samples characterized by an alpha-synuclein seed amplification assay.

Aims: Parkinson's disease (PD) is characterized by prodromal gastrointestinal (GI) inflammatory symptoms. Acumulating evidence points to a gut-to-brain spread of PD associated mediators. Analyzing patient stool offers a unique, non-invasive approach to uncover GI-tract changes. This study delved into whether gut content affects the brain through investigating the response of astrocytes to PD stool extracts. Moreover, we explored alterations in PD stool samples by focusing on i) the quantity of eukaryotic and prokaryotic cells, ii) calprotectin levels as a GI inflammation marker, iii) protein acetylation (PA) linked to gut inflammation, and iv) microbiota composition.
Methods: To assess astrocytic responses, primary mouse astrocytes were exposed to stool extracts, and glutamate transporter 1 (GLT1) expression was assessed via RT-PCR. Cell composition in the stool was analyzed by estimating prokaryotic and eukaryotic cells using PCR for 16S and 18S rRNA genes, respectively. Calprotectin and PA levels were measured through immunoblotting. Microbiome analysis was performed using 16S rRNA sequencing.
Results: Astrocytes exposed to PD stool extracts exhibited significantly reduced GLT1 expression compared to controls. PD stool samples showed an increase of prokaryotic cells and a significant decrease in eukaryotic cells. Elevated calprotectin levels and reduced PA levels were observed in PD stool. Altered microbiota in PD stool were observed, with *Faecalibacterium* consistently decreased.
Conclusions: Our findings suggest that PD stool contains mediators affecting astrocytes differently compared to control stool extracts. We also observed significant changes in stool cell composition, protein patterns, and microbiota in PD-derived stool. While stool composition may not fully reflect GI alterations, our data supports the potential of stool analysis as a surrogate and stratification method for PD patients.

Aims: The lack of sensitive and specific biomarkers for α-synucleinopathies, such as Parkinson's disease (PD), multiple system atrophy (MSA), and dementia with Lewy bodies (DLB), presents a significant challenge in diagnostics and disease monitoring. We aimed to develop and characterize a novel diagnostic assay, Seeding Amplification ImmunoAssay (SAIA), for its quantitative, highly sensitive, and disease-specific detection of alpha-synuclein seeds in synucleinopathies
Methods: SAIA was assessed for its analytical performance in a pilot study using brain homogenates from PD, MSA, DLB cases, and age-matched controls. Additionally, SAIA's application was explored in cerebrospinal fluid (CSF) samples from discovery cohort of PD subject and controls.
Results: SAIA demonstrated remarkable performance in amplifying and detecting α-synuclein seeds in brain homogenates, with dilutions up to 6,400-fold and detection thresholds as low as 0.5 attogram. The assay effectively distinguished synucleinopathies from non-synucleinopathies and controls, achieving sensitivities and specificities between 80-100%, as evidenced by area under the curve values exceeding 0.9. Notably, SAIA also revealed a positive correlation between CSF α-synuclein seed levels and disease severity in PD patients, as measured by the Unified Parkinson's Disease Rating Scale.
Conclusions: The development of SAIA marks a significant step forward in the field of synucleinopathy research. Its ability to quantitatively and specifically detect α-synuclein seeds in both brain homogenates and CSF demonstrates its potential as a reliable diagnostic and disease monitoring tool.

SLEEP PHENOTYPES OF SYNUCLEINOPATHY AND TAUOPATHY IN PARKINSONISM

POSTERS: C04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: EEG, BRAIN MAPPING, MEG

Nils Briel[1,2], Céline Marti[1], Heide Baumann-Vogel[1,3], Rositsa Neumann Poryazova[1,4], Philipp Valko[1,5,6], Esther Werth[1,4,6], Christian Baumann[1,6,7], Simon Schreiner[1,6,7]
[1]University Hospital Zurich, Department Of Neurology, Zurich, Switzerland, [2]Ludwig-Maximilians-University, Center For Neuropathology And Prion Research, Munich, Germany, [3]Clienia Schlössli, Privatklinik Für Psychiatrie Und Psychotherapie, Oetwil am See, Switzerland, [4]Bellevue Medical Group, Neurozentrum Oerlikon, Zurich, Switzerland, [5]Klinik Hirslanden, Klinik Für Neurologie, Zurich, Switzerland, [6]University of Zurich, Center Of Competence Sleep & Health Zurich, Zurich, Switzerland, [7]*, Contributed Equally, Zurich, Switzerland

Aims: Neurodegenerative parkinsonism is mainly caused by neuropathologically defined alpha-synucleinopathy (Syn) or tauopathy (Tau). To date non-invasive and easily accessible antemortem biomarkers of underlying pathology are a major unmet need. Sleep-wake disturbances are highly prevalent in neurodegenerative disorders and attract growing interest. In fact, rapid-eye-movement (REM) sleep behavior disorder (RBD) is a strong predictor of underlying alpha-synucleinopathy. However, little is known about non-REM (NREM) sleep features across different types of parkinsonism. Here, we explored whether sleep features from polysomnography differentiate suspected tauopathy or synucleinopathy in patients with neurodegenerative parkinsonism.
Methods: We performed a retrospective single-center analysis of polysomnography recordings from 198 patients with a clinical diagnose of neurodegenerative parkinsonism with suspected Syn (20 DLB, 100 PD, 45 MSA) or Tau (27 PSP, 6 CBS). Sleep features were compared across groups and used in unsupervised clustering.
Results: Tau patients showed less REM sleep, less NREM stage 2, more wake after sleep onset and less sleep efficiency than Syn patients (all $p<0.001$). We also found differences in sleep parameters between diagnostic groups, showing a gradient towards worse sleep from Lewy body disorders (DLB+PD) to atypical parkinsonism (MSA+PSP+CBS). Clustering allowed differentiation of Syn vs. Tau patients based on polysomnography features.
Conclusions: NREM sleep features differ between neurodegenerative parkinsonism with suspected Syn or Tau. These findings suggest that neurodegeneration of sleep-wake regulatory brain regions might differ according to proteinopathy, in addition to RBD-related brainstem involvement as a feature of Syn. Sleep phenotypes derived from polysomnography could be of value as antemortem biomarkers for proteinopathy and clinical diagnosis in neurodegenerative disorders.

BRAIN-FIRST VS. BODY-FIRST SUBTYPES OF PARKINSON'S DISEASE: EEG-BASED FUNCTIONAL FEATURES AND THEIR PATHOPHYSIOLOGICAL CONSEQUENCES

POSTERS: C04.G. IMAGING, BIOMARKERS, DIAGNOSTICS: EEG, BRAIN MAPPING, MEG

Matteo Conti[1], Andrea Guerra[2], Roberta Bovenzi[1], Mariangela Pierantozzi[1], Alessandro Stefani[1]
[1]University of Rome "Tor Vergata", Department Of Systems Medicine, Rome, Italy, [2]University of Padua, Department Of Neuroscience, Padova, Italy

Aims: Recent research suggests that isolated REM sleep behavior disorder prior to parkinsonism (pRBD) is a sign of the body-first subtype of Parkinson's disease, in which synucleinopathy starts in the peripheral autonomic nervous system. Instead, in the brain-first subtype, synucleinopathy would initially arise in limbic areas. Functional connectivity (FC) could improve the understanding of pathophysiological features of these subtypes. The aim of this study is to analyze changes in FC between PD patients with and without pRBD, by means of high-density EEG (HD-EEG).
Methods: We enrolled 74 subjects, including 28 early-stage PD patients without pRBD (PD^{pRDB-}), 20 with pRBD (PD^{pRBD+}) and 24 healthy controls (HC). HD-EEG was recorded using a 64-channels system, and a source-reconstruction method was used to identify brain regions activity. Cortical FC in theta, alpha and beta bands was analyzed based on weighted phase-lag index. Potential FC changes between HC, PD^{pRDB-} and PD^{pRBD+} were assessed using network-based statistics.
Results: With respect to HC, PD patients showed hypoconnected networks in theta and alpha band, involving prefronto-limbic-temporal and fronto-parietal areas, respectively. When comparing the PD^{pRDB-} and PD^{pRBD+} subgroups, we found a lower FC in alpha frequency band in PD^{pRBD-}, which involved a network composed by temporo-parietal, frontal and sensorimotor areas (t=2.5, p=0.025).
Conclusions: Reduced FC in alpha band we found in PD^{pRBD+} patients may be linked to an early alteration of brainstem cholinergic pathway, which projects widely to the cortex, in patients with the body-first PD subtype. Furthermore, given that alpha rhythm abnormalities play a role in PD dementia, our data of an early alpha FC impairment in frontal and temporo-parietal areas in PD^{pRBD+} support the hypothesis that patients with the body-first subtype are more likely to progress to dementia than brain-first PD.

Aims: Parkinson's disease (PD) is a prevalent neurodegenerative disorder characterized by the degeneration of dopaminergic nigrostriatal neurons. It has been observed that electroencephalography (EEG) can detect abnormalities in dopaminergic subcortical-cortical networks in PD. However, it remains inconclusive whether EEG abnormalities can serve as sensitive indicators for PD. This study developed an EEG recording platform to investigate whether abnormal quantitative EEG parameters can be monitored in a rat model of PD induced by 6-hydroxydopamine (6-OHDA).
Methods: To induce Parkinsonian rat model, we injected 6-OHDA into the left medial forebrain bundle (MFB) to selectively eliminate dopaminergic neurons. Four electrodes were concurrently implanted to collect signals from the frontal and parietal lobes. EEG recordings, combined with wireless data transmission, were monitored two weeks after the 6-OHDA injection, followed by the analysis of differences in power spectral density across various frequency bands (delta, theta, alpha, beta, gamma, and high frequency).
Results: The results of quantitative EEG demonstrate that, compared to rats with sham PD lesion, PD rat exhibited lower power in frequencies of low gamma (30~48 Hz) and high gamma (52~95 Hz), while no obvious differences were observed among the delta (0.5~4 Hz), theta (4~8 Hz), alpha (8~13 Hz), and beta (13~30 Hz) bands.
Conclusions: Our preliminary findings suggest that 6-OHDA-induced neurodegeneration leads to a decrease in gamma power in EEG profiles, implying that it could serve as a potential indicator for monitoring disease progression and assessing the efficacy of intervention protocols in PD.

IMPACT OF RATER CHANGE ON DATA VARIABILITY IN MDS-UPDRS PART III TOTAL SCORE IN PARKINSON'S DISEASE TRIALS

POSTERS: C04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC, BEHAVIORAL AND MOTOR TESTS

Barbara Echevarria[1], Matthew Welch[2], Selam Negash[2], Catarina Cunha[1], Christopher Randolph[3]
[1]WCG Clinical Research Solutions, Clinical Science, Munich, Germany, [2]WCG Clinical Research Solutions, Clinical Data Analytics, Princeton, United States of America, [3]WCG Clinical Research Solutions, Chief Scientific Officer, Princeton, United States of America

Aims: The MDS-UPDRS part III is the most widely used tool to measure changes in motor function over time in clinical trials of Parkinsons Disease (PD). This study evaluates the impact of rater change in visit-to-visit score variability on the MDS-UPDRS part III total score in PD clinical trials.
Methods: Data from six multinational clinical trials of early PD (H&Y I-III) were analyzed. MDS-UPDRS part III motor assessments conducted by site raters were arranged according to visit sequence and divided into two groups: Rater Change (different raters administered subject's consecutive visits) and No Rater Change (same rater administered consecutive visits). The two groups were matched on mean interval times between visits using random sampling. Visit-to-visit absolute score changes for Part III total score were calculated, and frequency distributions were evaluated.
Results: Welch corrected, two sample t-tests were conducted to compare score changes between rater change groups. For MDS-UPDRS part III, the Rater Change group showed a higher mean visit-to-visit score change (N = 2,523, mean = 6.7, SD = 5.53) compared to the No Rater Change (N = 7,553, mean = 4.1, SD = 3.74) group. This group difference reached statistical significance (t = 22.31, *df* = 3325.45 , $p < 0.0001$). Rater Change and No Rater Change groups did not differ significantly on mean interval times (t = 1.80, df = 3891.41, p = .07).
Conclusions: Findings from the study indicate significantly higher score changes when there is a rater change between visits than not for MDS-UPDRS motor assessments. These results highlight the importance of rater consistency in reducing variability in an effort to improve data quality in PD trials.

USING WEARABLE DEVICES TO ASSESS RESPONSE TO MEDICATION IN DE NOVO PARKINSON'S DISEASE

POSTERS: C04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC, BEHAVIORAL AND MOTOR TESTS

Maksymilian Brzezicki[1], Niall Conway[2], Charalampos Sotirakis[1], James Fitzgerald[1], Chrystalina Antoniades[1]
[1]University of Oxford, Ndcn, John Radcliffe Hospital, Level 6, Oxford, United Kingdom, [2]University of Oxford, Ndcn, Oxford, United Kingdom

Aims: Patients not yet receiving medication provide insight to drug-naïve early physiology of Parkinson's Disease (PD). Decisions to start medication and assessment of response to its initiation can be challenging for physicians and patients alike. To identify objective, sensor-derived features of upper limb bradykinesia, postural stability, and gait that can inform decision-making in a movement disorder clinic.
Methods: We used a single finger sensor to identify upper limb features and an array of six body-worn sensors to measure postural stability and gait. Patients were tested over nine visits, at three-monthly intervals, as part of a standard neurological examination.
Results: Three upper limb bradykinetic features (finger tapping speed, pronation supination speed, and pronation supination amplitude) and three gait features (gait speed, arm range of motion, duration of stance phase) were found to progress in unmedicated early-stage PD patients. In all features, progression was masked after the start of medication. There was no change in Montreal Cognitive Score and Mini Mental State Examination scores.
Conclusions: Commencing antiparkinsonian medication is known to lead to masking of progression signals in clinical measures in de novo PD patients. In this study, we show how this effect can be measured using digital devices. The testing kit can be used in movement disorder clinics to inform decision-making and progression monitoring in early PD.

Aims: Parkinson's disease (PD) patients treated with dopaminergic agonists (DAs) often develop impulse control disorders (ICDs). This study investigated the role of oscillatory brain activity in PD patients with and without ICDs.
Methods: Thirty-six participants were divided into three groups: healthy controls (HCs), PD patients with ICDs (PD+ICDs), and PD patients without ICDs (PD-ICDs). Resting state EEG was recorded from all participants, and PD patients underwent two recording sessions, one during regular DA treatment (ON) and another after an overnight washout of DA replacement therapy (OFF)
Results: PD+ICDs patients in the OFF condition showed increased theta (θ) power in the central region compared to HCs. These patients also showed decreased central θ activity and θ/β ratio, as well as increased central-parietal beta (β) activity in the ON condition. Trait impulsivity correlated with frontal θ/β ratio in the ON condition in PD+ICDs patients, and with frontal and parietal θ/β in the OFF condition in PD-ICDs patients. Differences in central θ were detected between PD+ICDs in the OFF condition and HCs in frontal regions, and between PD+ICDs in the ON and OFF conditions. Additionally, parietal sources of β oscillations showed a treatment effect in the PD+ICD group, with increased β activity in the ON condition.
Conclusions: These findings suggest that PD+ICDs patients have a distinctive neurophysiological profile characterized by altered θ and β oscillations. This profile is sensitive to dopaminergic treatment and shares similarities with other disorders characterized by high trait impulsivity.

IDENTIFYING PARKINSONISM IN MILD COGNITIVE IMPAIRMENT

POSTERS: C04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC, BEHAVIORAL AND MOTOR TESTS

Paul Donaghy[1], Rishira Fernando[1], Calum Hamilton[1], Rory Durcan[1], Sarah Lawley[1], Sally Barker[1], Joanna Ciafone[1], Nicola Barnett[1], Kirsty Olsen[1], Michael Firbank[1], Gemma Roberts[2], Jim Lloyd[2], George Petrides[2], Sean Colloby[1], Louise Allan[3], Ian Mckeith[1], John O'Brien[4], John-Paul Taylor[1], Alan Thomas[1]
[1]Newcastle University, Translational And Clinical Research Institute, Newcastle upon Tyne, United Kingdom, [2]Newcastle Hospitals NHS Foundation Trust, Nuclear Medicine, Newcastle upon Tyne, United Kingdom, [3]University of Exeter, Centre For Research In Ageing And Cognitive Health, Exeter, United Kingdom, [4]University of Cambridge, Department Of Psychiatry, Cambridge, United Kingdom

Aims: Clinical parkinsonism is a core diagnostic feature for mild cognitive impairment with Lewy bodies (MCI-LB) but can be challenging to identify. A five-item scale[1] derived from the UPDRS has been recommended for the assessment of parkinsonism in dementia.[2] This study aimed to determine whether the five-item scale is effective in identifying parkinsonism in people with MCI.
Methods: Participants with MCI from two cohorts (n=146) had a physical examination including the Unified Parkinson's Disease Rating Scale and [123I]-FP-CIT SPECT striatal dopaminergic imaging. Participants were classified as having parkinsonism (P+) or no parkinsonism (P-) based on a consensus of three clinicians, and with abnormal striatal dopaminergic imaging (D+) or normal imaging (D-). The five-item scale was the sum of tremor at rest, bradykinesia, action tremor, facial expression, and rigidity scores from the UPDRS. The ability of the scale to differentiate participants with clinically identified parkinsonism and abnormal striatal dopaminergic imaging (P+D+) and no parkinsonism with normal imaging (P-D-) was examined.
Results: The five-item scale had an AUROC of 0.92 in Cohort 1, but the 7/8 cut-off defined for dementia had low sensitivity to identify P+D+ participants (sensitivity 25%, specificity 100%). Optimal sensitivity and specificity was obtained at a 3/4 cut-off (sensitivity 83%, specificity 88%). In Cohort 2, the five-item scale had an AUROC of 0.97, and the 3/4 cut-off derived from Cohort 1 showed sensitivity of 100% and a specificity of 82% to differentiate P+D+ from P-D- participants.
Conclusions: The five-item scale is effective to identify parkinsonism in MCI, but a lower threshold must be used in MCI compared with dementia. **References** Ballard et al. *Acta Neurol Scand* 1997;**96**:366-71. Thomas et al. *Int J Geriatr Psychiatry* 2018;**33:**1293-1304.

RESTING-STATE FUNCTIONAL CONNECTIVITY ASSOCIATED WITH SOCIO-COGNITIVE DYSFUNCTION IN NON-DEMENTED PARKINSON'S DISEASE

POSTERS: C04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC, BEHAVIORAL AND MOTOR TESTS

Giulia Funghi, Giuseppe Rabini, Claudia Meli, Luca Turella, Jorge Jovicich, Costanza Papagno, Alessandra Dodich
University of Trento, Center For Mind/brain Sciences (cimec), Rovereto, Italy

Aims: Social cognition (SC) deficits have been reported in Parkinson's disease (PD), but the characterization of these deficits and their underlying neural correlates remains limited. The aim of this study is to evaluate alterations in the recognition of complex mental states from faces in this population using a novel task and to explore their neural correlates.
Methods: Twenty-two PD patients (M:11; age in years: 66.9±7.2, education in years: 11.0±3.9, MOCA: 23.4±4.2) were enrolled. All patients underwent a basic clinical and neuropsychological assessment and performed the Facial Complex Expressions (FACE) test. Patients were classified as impaired (PD-SOC, n=7) or unimpaired (PD-CON, n=15) according to their performance on the FACE test, based on Italian normative data. Resting-state functional magnetic resonance imaging (rs-fMRI) was used to investigate functional connectivity (FC) within the emotion understanding network using both ROI-to-ROI and seed-based connectivity analyses, both across the entire PD sample and comparing PD-SOC vs. PD-CON.
Results: ROI-to-ROI connectivity analyses revealed a positive association between FACE test performance and BOLD co-activation of the right and left amygdala (p-FDR=0.003). Similarly, seed-based correlation analyses revealed significant clusters of FC between the left amygdala and the right temporal pole (peak p-FDR=0.025), the left insular cortex (peak p-FDR=0.025) and the right amygdala (peak p-FDR=0.015). The same regions showed a lower FC in PD-SOC compared to PD-CON.
Conclusions: This study demonstrated clinically relevant complex mental state recognition deficits in PD patients, associated with functional changes in emotion-related brain regions. FC results highlight the critical role of the bilateral amygdala in PD patients' FACE test performance and extend the neural network for complex mental state recognition to include the left insular cortex and the right anterior temporal pole.

EFFECT OF DOPAMINERGIC TREATMENT ON COGNITIVE CONTROL MEASURED BY OCULOMOTOR BEHAVIOR AND STROOP TASK IN PARKINSON'S DISEASE: A PILOT STUDY

POSTERS: C04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC, BEHAVIORAL AND MOTOR TESTS

Comenius University Faculty of Medicine University Hospital Bratislava, 2nd Department Of Neurology, Bratislava, Slovak Republic

Aims: To study how dopaminergic treatments, affect cognitive control in Parkinson's disease (PD) over three visits with escalating dosages.
Methods: Ten drug-naive patients diagnosed with PD (median age = 59.5, IQR = 7.25 years) without dementia (mean MoCA = 25.5, IQR = 5.5) were enrolled. All patients initiated dopaminergic treatment, with Levodopa (n=4) and Pramipexol (n=6), administered during three visits (baseline, one-month, and three-month follow-up) with incremental dosages. The protocol for each visit involved eye-tracking, assessing latencies of prosaccades and antisaccades, express saccades (<130ms), errors, gain, and speed. A screening neuropsychological battery was employed, which included a tablet-based Numeric Stroop test with congruent and incongruent conditions. We analyzed statistical differences among the 3 measurements using rank-transformed data and analysis of variance.
Results: Significant measurement effect was observed for express prosaccades index ($F = 3.76$, $p < 0.05$), and numeric Stroop both in congruent and incongruent conditions ($F = 5.2$, $p < 0.05$), ($F = 4.77$, $p < 0.05$). The express prosaccade index significantly decreased from the second (median = 16.75, IQR = 15.9) to the third (median = 3.36, IQR = 5.68) measurement, $p < 0.05$. Numeric Stroop tasks showed reduced reaction times between the second (median = 1408.4, IQR = 327) and third (median = 1175.5, IQR = 459.9) measurements for congruent, and between the second (median = 1275.13, IQR = 389.27) and third (median = 954.03.5, IQR = 372.86) measurement for incongruent condition.
Conclusions: Initially impaired cognitive control showed improvement with dopaminergic treatment in the third assessment, seen in reduced express prosaccades and Stroop reaction times. Eye tracking demonstrated its potential as a sensitive clinical tool compared to other neuropsychological tests which did not exhibit significant differences.

Aims: To determine long-term, cumulative dementia prevalence rates in PD using data from two large, ongoing, prospective observational studies.
Methods: The Parkinson's Progression Markers Initiative (PPMI) and a longstanding PD research clinical core at the University of Pennsylvania (Penn) were observed. PPMI enrolls *de novo*, untreated PD participants at baseline, and Penn enrolls a convenience cohort from a large clinical center. For PPMI a cognitive battery and MDS-UPDRS Part I are administered annually, and the site investigator assigns a cognitive diagnosis annually. At Penn a comprehensive cognitive battery is administered either annually or biennially, and a cognitive diagnosis is made by consensus. Kaplan-Meier (KM) survival curves were fit for time from PD diagnosis to stable dementia diagnosis for each cohort, using assigned cognitive diagnosis of dementia as the primary endpoint, and MoCA score <21 and MDS-UPDRS Part I cognition score ≥3 as secondary endpoints (for PPMI). Cumulative dementia prevalence by PD disease duration was tabulated for each study and endpoint.
Results: For the PPMI cohort, 417 PD participants were seen at baseline; estimated cumulative probability of dementia at year 10 disease duration were: 7% (site investigator diagnosis), 9% (MoCA) or 7.4% (MDS-UPDRS Part I cognition). For the Penn cohort, 389 PD participants were followed over time, with 184 participants (47% of cohort) eventually diagnosed with dementia. The KM curve for the Penn cohort had median time to dementia diagnosis =15 years (95% CI: 13-15) disease duration; the estimated cumulative probability of dementia was 27% at year 10, 50% at year 15, and 74% at year 20.

Conclusions: Results from two large, prospective studies suggest that dementia in Parkinson disease occurs less frequently, or later in the disease course, than often-cited previous research studies have reported.

EXPANDING THE RESOURCES FOR PARKINSON'S DISEASE DRUG DISCOVERY: ACCELERATING MEDICINES PARTNERSHIP IN PARKINSON'S DISEASE

POSTERS: C04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Sri Ramulu Pullagura[1], Christine Swanson-Fischer[2], Debra Babcock[2], Alessio Travaglia[1]
[1]Foundation for the National Institutes of Health, Neuroscience, North Bethesda, United States of America, [2]National Institute of Neurological Disorders and Stroke/NIH, Division Of Neuroscience, Bethesda, United States of America

Aims: The Accelerating Medicines Partnership® (AMP®) program for Parkinson's Disease (PD), launched in 2018, fosters collaboration among government, industry, and non-profits to enhance our understanding of PD. Its key goals include identifying disease mechanisms, discovering diagnostic and prognostic biomarkers, and validating targets for PD treatment.
Methods: AMP PD's research plan involves comprehensive molecular and clinical profiling of patient data and biosamples to find and validate PD biomarkers. This includes sharing harmonized molecular and clinical data, such as genome sequencing, transcriptomics, and proteomics to identify new targets, disease subtypes, and predictive markers for PD progression. AMP PD uses eight well-characterized cohorts and collaborates with the Global Parkinson's Genetics Program (GP2).
Results: Currently, AMP PD has collected extensive data from 10,807 participants across eight cohorts by September 2023. This includes 3,537 PD subjects (1,469 with known mutations), 4,337 healthy controls (1,615 with known mutations), and 2,933 subjects with other diagnoses. Longitudinal blood-based transcriptomics data is available for 3,277 participants, while whole genome sequencing data covers 10,418 subjects, and targeted proteomics involves 413 participants. Additional data, such as single-cell sequencing in post-mortem tissue, blood-based transcriptomics, and unbiased proteomics from blood and CSF, will be accessible in late 2023/early 2024.
Conclusions: AMP PD's platform, hosted on Google Cloud, promotes data sharing, supports efficient analysis, reduces costs, and encourages collaboration, facilitating the discovery of PD biomarkers for clinical trials and therapy development. This presentation highlights scientific breakthroughs made possible by AMP PD, emphasizing genomics, proteomics, and post-mortem tissue sequencing research for biomarker discovery. It also underscores the potential of AMP PD data for broader scientific exploration now and as the program moves into its next phase

AUTONOMIC FUNCTIONS AND DOPAMINERGIC CORRELATES IN DEMENTIA WITH LEWY BODY: A PRELIMINARY STUDY

POSTERS: C04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Chiara Giuseppina Bonomi[1], Camilla Rocchi[2], Caterina Motta[1], Chiara Serafini[1], Agostino Chiaravalloti[3], Alessandro Martorana[1]
[1]University of Rome Tor Vergata, Memory Clinic, Rome, Italy, [2]University of Rome Tor Vergata, Neurology Unit, Rome, Italy, [3]University of Rome Tor Vergata, Nuclear Medicine Unit, Rome, Italy

Aims: Both autonomic failure and nigrostriatal denervation are well-known features of Dementia with Lewy Body (DLB). However, the relationship between the two has been poorly investigated. We aimed to assess cardiovascular and sudomotor autonomic function tests (AFTs) in DLB and to evaluate the relationship between AFTs and ^{123}I-ioflupane dopamine transporter uptake at single photo-emission computed tomography (DAT-SPECT).
Methods: 15 DLB patients and 20 healthy controls (HC) underwent head-up tilt-test (HUTT), Valsalva Maneuver, deep-breathing, cold-face, hand-grip test (HG), electrochemical skin conductance (ESC). DLB patients also underwent DAT-SPECT, we used the DaTQUANT software for semi-quantitative analysis.
Results: DLB patients showed lower delta heart rate at 3rd minute of HUTT (p=0.016), Valsalva Ratio (p<.001) and Overshoot (p=0.004), lower delta systolic (ΔSBP, p=0.002) and diastolic blood pressure (ΔDBP, p<.001) at HG, lower inspiration-espiration difference at deep-breathing (p=0.004), and lower hands-feet ESC than HC (both p=0.003). Of all the AFTs, only HG responses correlated with striatal DaTQUANT measures: HG ΔDBP strongly inversely correlated with bilateral uptake of ^{123}I-FP in the anterior (Right: rho -0.691, p 0.004; Left: rho -0.676, p 0.006) and posterior putamen (Right: rho -0.769, p<.001; Left: rho -0.663, p 0.007).
Conclusions: Despite the absence of overt orthostatic hypotension, DLB patients showed covert dysautonomia encompassing adrenergic and parasympathetic dysfunction. Moreover, the functioning of sympathetic peripheral efferent pathways to vessels, reflected by HG ΔDBP, was inversely associated with nigrostriatal denervation. This could suggest the presence of different profiles of peripheral-predominant vs central-predominant impairment in DLB patients

OPTIMAL DIGITAL ENDPOINT SELECTIONS OF MOVEMENT IN PARKINSON'S DISEASE

POSTERS: C04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Kristen Sowalsky, Vrutangkumar Shah, Fay Horak
Clario, Medical & Scientific Affairs, Portland, United States of America

Aims: Wearable sensors enable precise, sensitive, and reliable digital endpoint capture of movement impairment in Parkinson's disease (PD). As there are thousands of digital movement endpoints available for use in clinical trials, selecting those most optimal per each unique study can be challenging. We offer guidelines, aligned with regulatory guidance, and supported by the latest scientific evidence.
Methods: An approach to selecting the best digital movement outcome for a clinical trial is outlined considering the following criteria: 1) meaningfulness to participants 2) sensitivity/specificity to disease 3) related to the conventional stage of disease/progression and patient-reported scales 4) reflective of pathophysiology and 5) sensitivity to change. A review of the literature on gait and balance digital outcomes for newly diagnosed PD was performed.
Results: Digital endpoints of gait captured with inertial sensors on the feet, lower back, and wrists have the most scientific supported. The majority of evidence is available from short walking and standing tasks performed in a controlled setting, while evidence for passive, real-world data is growing. Specifically, measures including foot strike angle, turn velocity, arm swing reduction/asymmetry, gait variability, and sway jerkiness reflect the outlined criteria for early PD. Measures of bradykinesia and tremor, while having more limited evidence, are also promising. However, the hypothesized effect of the therapy under investigation must also be considered, as the sensitivity of specific gait and balance endpoints to change differ by treatment due to the underlying pathophysiology.
Conclusions: Digital endpoints of movement impairment specific to early PD are meaningful to patients, more sensitive to disease progression than conventional clinical scales, and a critical tool in the future success of clinical trials to provide effective treatments for PD patients.

REDUCED VARIABILITY IN CARDIAC R-R INTERVAL AS A PREDICTOR OF PARKINSON'S DISEASE

POSTERS: C04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Laura Vacca[1], Daniele Bravi[2], Margherita Torti[1], Stefania Proietti[1], Maria Francesca De Pandis[3], Rossella Rotondo[3], Fabiana Radicati[1], Miriam Casali[1], Giuseppe Rosano[4], Fabrizio Stocchi[2]
[1]IRCSS HSR La Pisana, Ctc, Rome, Italy, [2]IRCSS HSR La Pisana, Ctc, Rome, Italy, [3]San Raffaele Cassino, Neurology, Cassino, Italy, [4]IRCSS HSR La Pisana, Cardiology, Rome, Italy

Aims: Non Motor Symptoms in Parkinson's disease are resulting from neurodegerative processes that also involves the peripheral autonomic nervous system. Cardiovascular changes have been recognised to affect all stage of ethe disease plus suggested as potential prodromal sign. The aim of the present study was to evaluate the changes in the heart rate variability as predictor of disease onset
Methods: Fisrt Degree relatives, with age between 50 to 75 years, of individuals with established diagnosis of Parkinson's disease underwent a 10 min electrocardiogram and followed up over 10 years by phone check to report any changes in their health status Primary objective was to evaluate Heart rate variability . Subjects were also clinically investigated about the presence of depression, constipation, hyposmia and RBD like sleep disorders
Results: 324 subjects have been enrolled. 204 subjects eligible for analyss (44 screening failure, 76 excluded to to poor ECG output) . Outcome data did not reveal any significant abnormalities in heart rate variability in such population. A subgroup of 31 participants with heart rate variability papameter below the 5th percentile was identified, however no-one from this subgroud expereinced the occurence of parkinsons's disease symptoms. Study confirmes previous data showing a reduction of heart rate variability with increasing age.
Conclusions: The Heart rate Variability of first degree relatievs of parkinson's disease patients did not differ from the reference ranges of healthy population, therefore such parameter does not seem to represent a reliable biomarker for prodromal Parkinson's disease. However , given the heterogeneicity of teh disease, lack of clinical and imaging biomarkers , additional studies involving more accurate and sensitive EEg methdologies associated to confirmatory imaging and or biofluid markers are needed

ARTIFICIAL INTELLIGENCE OPPORTUNITIES FOR VOICE DIAGNOSTICS OF PARKINSON'S DISEASE (BRAINPHONE PROJECT)

POSTERS: C04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Zuleykha Zalyalova[1], Diana Khasanova[2], Ildar Khasanov[3], Guzal Ilina[2]
[1]Kazan State Medical University, Department Of Neurology, Kazan, Russian Federation, [2]Republican Centre for Movement Disorders, -, Kazan, Russian Federation, [3]LLC Brainphone, -, Kazan, Russian Federation

Aims: The work was carried out within the framework of BRAINPHONE project for voice diagnostics of Parkinson's disease (PD) with artificial intelligence (AI) method. The method used is convolutional neural network (CNN), trained with 1000 unique audiorecords of voices of PD patients vs healthy volunteers (50/50%). The aim of the study was the assessment of quality metrics of AI method in comparison with MDS clinical criteria of PD.
Methods: For validation test 10% from training sample was selected: balanced sample with 50 PD patients (25 early and 25 advanced stages) and 50 healthy volunteers. From the sample were excluded patients with atypical and other types of parkinsonism and with disorders associated with speech disturbances. Data was collected in June-July 2023 in the Republican Centre for Movement Disorders (Kazan, Tatarstan Republic, Russia). All patients were assessed at first by 2 experienced parkinsonologists and then with the trained CNN. The specialist's diagnosis was made on the MDS clinical criteria of PD with output "PD" or "non-PD". The trained CNN output was "possible PD" (counted probability of 0.5 and higher) and "non-PD" (counted probability less than 0.5).
Results: The sensitivity of trained CNN was 80.1%, the specificity – 92.3%. According to literature for MDS clinical criteria of PD the sensitivity is 82,6-94,5% and the specificity is 57,8-88,5% [1,2].
Conclusions: Compared with clinical criteria voice diagnostics via trained CNN shows comparable results in sensitivity and better results in specificity. Potentially, diagnostics using trained CNN can be applied as a screening tool. The limitations of the study are balanced testing sample (50/50% vs 99,5-98/0.5-2% of PD and healthy persons in real-life depending on age and area); people with speech disturbances and other types of parkinsonism were excluded.

Aims: To examine region- and substrate-specific autoradiographic patterns of alpha-synuclein radioligands targeting Sites 2 and 9, and to determine whether there is off-target binding to other amyloid/non-amyloid proteins.
Methods: We applied [^{3}H]Tg1-90B (Site 2), [^{3}H]M503-1619 (Site 9) and [^{3}H]HY-2-15 (Site 9) *in vitro* real-time autoradiography and immunohistochemistry studies to postmortem samples from patients with a definite pathological diagnosis of Parkinson disease, dementia with Lewy Bodies, Multiple system atrophy, Alzheimer disease, frontotemporal lobar degeneration-tau (progressive supranuclear palsy and corticobasal degeneration) and elderly controls free of pathologic changes of neurodegenerative disease. Brain tissue sections were stained for a-syn, Aβ, tau and compared to [^{3}H]Tg1-90B, [^{3}H]M503-1619 and [^{3}H]HY-2-15 autoradiography on adjacent sections.
Results: Our data indicate that [^{3}H]Tg1-90B displayed specific binding in PD, DLB and MSA tissue. [^{3}H]M503-1619 binds to a-syn inclusions found in PD, DLB brain but not in MSA; conversely [^{3}H]HY-2-15 autoradiography showed the opposite pattern. However, specific binding of the radioligands was also observed in tissue from AD, PSP, CBD cases indicating binding to tau pathology, that was confirmed by tau immunostaining.
Conclusions: Our observations derived from combined autoradiography and immunohistochemistry, indicate that the Site 2 ligand Tg1-90B is able to detect α-syn inclusions present both in PD and MSA patient. M503-1619 preferentially recognize α-syn aggregates in PD, and DLB brain tissue over α-syn lesions in MSA patients. In contrast, HY-215 autoradiography support its potential use for imaging α-syn in MSA patients. Our results suggest that compounds targeting Site 2 ligands may be a “pan-a-syn” radiotracer (i.e., targeting both PD and MSA), whereas radiotracers targeting Site 9 show specificity for PD or MSA. The reason for the disease specificity of Site 9 ligands is not clear at this time

CHARACTERIZING PARKINSON'S MOTOR FLUCTUATIONS USING WEARABLE DEVICES

POSTERS: C04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Witney Chen, Tiffany Jansen, Aiden Arnold, Ro'Ee Gilron
Rune Labs, Neuroscience, San Francisco, United States of America

Aims: Generate algorithmic approaches to detect and characterize motor fluctuations in Parkinson's disease using wearable device data.
Methods: Wearable data from 900+ subjects with Parkinson's disease were analyzed to characterize the prevalence and dynamics of medication-induced motor fluctuations. Subjects wore an Apple Watch and carried an iPhone to continuously monitor tremor, dyskinesia, gait and mobility, vitals, and sleep. We filtered for subjects with data for at least 10 days and >8 hours per day. We quantified periodicity using frequency decomposition methods, identifying spectral peaks above statistical chance thresholds. The periods of the identified cycles were validated against patient-reported medication schedules. We generated statistical features of the periodicity, which were used to cluster subjects as fluctuators versus non-fluctuators and to assess cycle dynamics over time.
Results: Periodic fluctuations in tremor and dyskinesia were successfully identified in unevenly sampled time series data from tremor-dominant subjects. The prevalence, cadence, and magnitude of motor fluctuations varied across subjects, and we found fluctuators and non-fluctuators in our cohort (Figures 1, 2). The algorithm was affected by patient phenotype, consistency in medication times, complexity of medication regimen, and data quantity per subject.

Figure 1

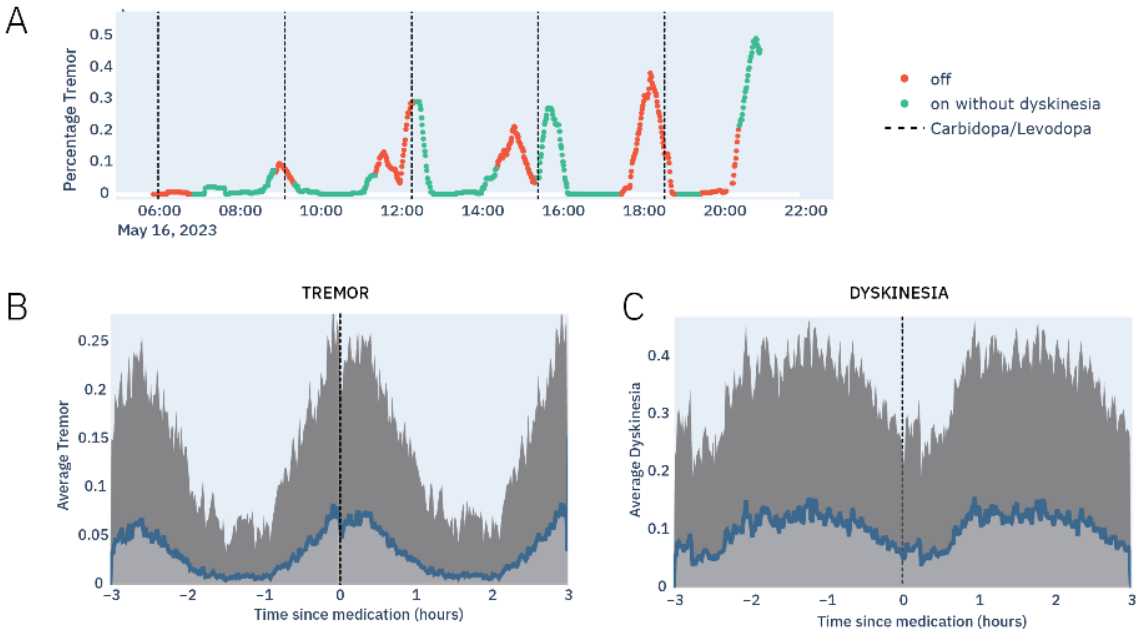

Figure 1. Wearable data from a single subject example *with* medication-induced motor fluctuations. Percent of recorded time with resting tremor fluctuates throughout a representative day, corresponding with medication times and the subject's motor diary responses (A). Dose response curves of tremor (B) and dyskinesia (C) in response to carbidopa/levodopa, indicating a 3 hour fluctuation cycle.

Figure 2

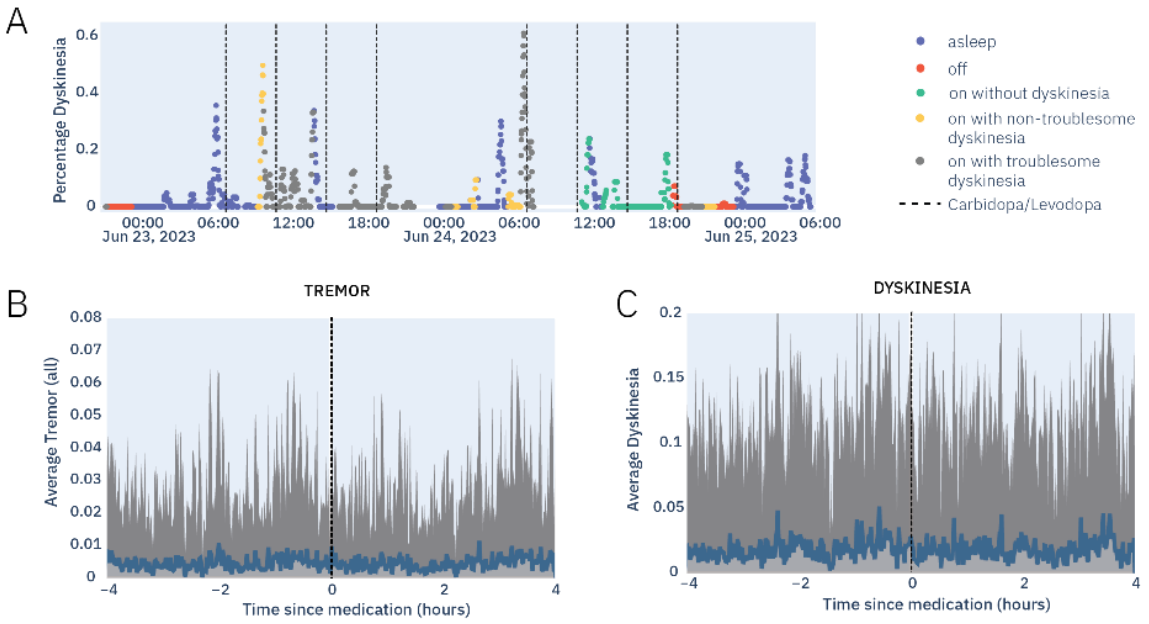

Figure 2. Wearable data from a single patient example *without* medication-induced motor fluctuations. Percent of recorded time with dyskinesia fluctuates throughout a representative day, but these do not consistently correspond with medication times and patient's motor diary responses (A). Dose response curves of tremor (B) and dyskinesia (C) do not indicate clear fluctuations in response to carbidopa/levodopa.

Conclusions: Data-driven approaches successfully identify motor fluctuators using wearable devices. Continuous monitoring can be used to quantify the cadence and magnitude of fluctuations, assess the change over time, and assess responses to therapeutic interventions.

DEVELOPMENT OF THE JAPANESE VERSION OF GASTROINTESTINAL DYSFUNCTION SCALE FOR PARKINSON'S DISEASE (GIDS-PD)

POSTERS: C04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Fukiko Kitani-Morii[1], Takuma Ohmichi[1], Etsuro Nakanishi[2], Ryosuke Takahashi[2], Yuzo Fujino[1], Shoko Ohtomo[1], Toshiki Mizuno[1], Takashi Kasai[1]
[1]Kyoto Prefectural University of Medicine, Neurology, Kyoto, Japan, [2]Kyoto University Graduate School of Medicine, Neurology, Kyoto, Japan

Aims: Patients with Parkinson's disease (PD) exhibit a wide range of gastrointestinal dysfunctions, but until now, there has been no disease-specific scale to assess their severity. The Gastrointestinal Dysfunction Scale for Parkinson's Disease (GIDS-PD) was introduced in 2021 as a self-administered questionnaire comprising 12 items to evaluate constipation, bowel irritability, and upper gastrointestinal symptoms in PD patients, with scores ranging from a minimum of 1 point to a maximum of 108 points.
Methods: With permission from the Movement Disorder Society, our team initiated the development of the Japanese version of GIDS-PD in August 2022.
Results: Initially, we created the Japanese version from the English version of the original paper (Mov Disord. 2021;36:2358-2366). An independent team then conducted a back-translation of this Japanese version into English, and the Translation Review Subcommittee of the MDS confirmed the equivalence between the original and back-translated versions. In a pre-cognitive test involving 10 PD patients and 10 assessors whose native language is Japanese, the comprehensibility of all items in the Japanese version exceeded an average score of 5 out of 6 points (with 6 points indicating very good understanding and 1 point indicating very poor understanding). Following another round of review by the MDS, the provisional Japanese version of GIDS-PD was posted on the MDS website, making it available for general clinical use.
Conclusions: The provisional use of the Japanese version of GIDS-PD is now possible. Currently, we are conducting field tests with 100 PD patients and 30 healthy individuals using the provisional Japanese version of GIDS-PD. This will allow us to compare its similarity to the original article.

COMPARISON BETWEEN P2X7R, MAO-B AND TSPO IMAGING BIOMARKER IN ALZHEIMER'S DISEASE AND TAUOPATHY BRAINS

POSTERS: C04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Yanyan Kong[1], Cinzia Maschio[2], Fang Xie[1], Uwe Konietzko[2], Hongjun Jin[3], Yihui Guan[1], Roger Nitsch[2], Ruiqing Ni[2]
[1]Fudan University, Pet Center, shanghai, China, [2]University of Zurich, Institute For Regenerative Medicine, Zurich, Switzerland, [3]Sun Yat-Sen University, Guangdong Provincial Engineering Research Center Of Molecular Imaging, Zhuhai, China

Aims: Neuroinflammation plays an important role in Alzheimer's disease and primary tauopathies include progressive supranuclear palsy (PSP), corticobasal degeneration (CBD). The aim of the current study is to compare the patterns of purinergic P2X7R tracer [^{18}F]GSK1482160 with monoamine-oxidase B (MAO-B) tracer [^{18}F]SMBT-1 and translocator protein (TSPO) tracer [^{18}F]DPA-714 in the brain of disease models.
Methods: MicroPET scans were performed using [^{18}F]GSK1482160, [^{18}F]SMBT-1, [^{18}F]DPA-714, as well as [^{18}F]flobetapir (amyloid-beta) and [^{18}F]PM-PBB3 (tau) in widely used mouse models of Alzheimer's disease (including APP/PS1, 5×FAD and 3×Tg mice), 4-repeat tauopathy mice (rTg4510), and age-matched wild-type mice at young and middle ages. Immunofluorescence staining was performed on the postmortem brain tissues from non-demented controls, patients with AD, PSP and CBD, as well as from the aforementioned mouse models.
Results: We found increased P2X7R levels by [^{18}F]GSK1482160 in the cortex, basal forbrain, amygdala of 7-month-old rTg4510 mice compared to wild-type mice, but not in the other models (APP/PS1, 5XFAD, 3XTg mice) at both young and middle ages. In comparison, increased regional MAO-B levels indicated by [^{18}F]SMBT-1 was observed in the middle aged rTg4510, APP/PS1, 5XFAD mice compared to wild-type mice but not in 3xTg mice, Increased regional TSPO levels indicated by [^{18}F]DPA-714 was observed n the middle aged rTg4510 and 5XFAD mice compared to wild-type mice, but not in APP/PS1 and 3xTg mice. Postmortem studies showed increased levels of P2X7R, glial fibrillary acidic protein (GFAP) and Iba1 in the brain tissues from the hippocampus from AD, striatum from PSP and CBD.
Conclusions: The findings provide in vivo imaging evidence for diverse patterns of P2X7R using [^{18}F] GSK1482160 compared to MAO-B and TSPO imaging in the brain of Alzheimer's disease and tauopathy models.

LOW-BURDEN DIGITAL SPEECH BIOMARKERS FOR EARLY DIAGNOSIS AND PROGNOSIS IN PARKINSON'S DISEASE: STUDY DESIGN AND PROTOCOL

POSTERS: C04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Alexander Jäck[1,2], Ebru Baykara[3], Mira Fischer[1,2], Urban Fietzek[1], Alexander Bernhardt[1,2], Alexandra König[3], Johannes Tröger[3], Günter Höglinger[1,2], Johannes Levin[1,2]
[1]German Center for Neurodegenerative Diseases, Dzne, Munich, Germany, [2]LMU University Hospital, Department Of Neurology, Munich, Germany, [3]ki:elements GmbH, Clinical Research, Saarbrücken, Germany

Aims: In collaboration with ki:elements, this study seeks to identify and validate digital speech biomarkers for Parkinson's Disease (PD) through AI empowered remote assessments. Building on ki:elements' prior work, the focus is on detecting early-stage Parkinson's, tracking progression, and assessing levodopa responsiveness. A subproject will further validate digital speech biomarkers against established molecular biomarkers including Tau, Amyloid and Lewy-Type Synuclein.
Methods: The study will commence as a 12-month observational research, aiming to include 100 patients and 100 healthy controls, building on established cohorts with multiparametric deep phenotyping established at LMU Munich. In addition to extensive clinical phenotyping, this study will collect comprehensive speech data remotely through ki:element's Mili mobile app. Combined with gold standard measures and advanced speech analysis using AI, this data will help to investigate speech and language based phenotypes for PD patients, capturing motor, cognitive, and mood symptoms.
Results: Study Design, no results yet. Possible preliminary data by March
Conclusions: The intricate diagnostic landscape of PD is riddled with challenges due to its reliance on clinical motor-function criteria and poor prognostic assessments. The emergence of non-motor symptoms as precursors to motor impairments showcases the complexity of PD's clinical manifestation. Considering the precursory and progressive nature of speech alterations AI and machine learning also offer immense promise in establishing reliable digital biomarkers. By delving into both speech alterations and molecular biomarkers in an exploratory subproject we seek to shed light on the underlying pathomechanisms of speech and linguistic changes in PD.

THE SYNUCLEIN ONE STUDY: CUTANEOUS ALPHA-SYNUCLEIN DEPOSITION IN DEMENTIA WITH LEWY BODIES AND MILD COGNITIVE IMPAIRMENT

POSTERS: C04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Christopher Gibbons[1], Todd Levine[2], Bailey Bellaire[3], Roy Freeman[1]
[1]Harvard Medical School, Beth Israel Deaconess Medical Center, Neurology, Boston, United States of America, [2]HonorHealth, Neurology, Scottsdale, United States of America, [3]CND Life Sciences, Neurology, Scottsdale, United States of America

Aims: The Synuclein-One study is an NIH-funded 30-site multicenter trial that included 50 patients with dementia with Lewy bodies (DLB) and 27 with mild cognitive impairment. Here we report the detection of cutaneous phosphorylated alpha-synuclein (P-SYN) in patients with DLB and MCI. An unmet need exists for a validated, well-characterized, simple, reproducible biomarker of synuclein pathology. The number of individuals with neurodegenerative diseases continues to grow and misdiagnosis within and among synuclein and non-synuclein dementias continues to occur, resulting in incorrect medication choices, iatrogenic complications, inaccurate prognostication and patient frustration.
Methods: After signed consent, study participants completed neurologic examinations (MDS-UPDRS, Hoehn and Yahr scale), medical history review, cognitive evaluation (MOCA), orthostatic vital signs and neurodegenerative disease questionnaires. DLB was defined using consensus criteria. MCI was defined as MOCA score of 18-25. Skin biopsies at the distal leg, distal thigh and posterior cervical sites were performed on all participants with quantitation of P-SYN and intra-epidermal nerve fiber density (IENFD).
Results: In the 50 DLB participants (MDS-UPDRS 68±28, Hoehn and Yahr 2.4±1.0, MOCA 16±5.4), P-SYN was detected in 48/50 (96%). Of 27 participants with MCI (MDS-UPDRS 3.5±6.0, Hoehn and Yahr 0.1±0.4, MOCA 23±2.8), P-SYN was detected in 8/27 (30%). Detection of P-SYN in healthy controls is 3.3%.
Conclusions: Cutaneous P-SYN testing is a sensitive and specific test for phosphorylated alpha-synuclein in patients with DLB. The detection of P-SYN in individuals with MCI is 10-times that of the healthy population. Longitudinal follow up of MCI participants is needed to understand the long-term implications of these results and the risk of co-pathology associated with other conditions such as Alzheimer's disease.

GAIT ALTERATIONS FROM PRODROMAL TO EARLY-STAGES OF PARKINSON'DISEASE: A MOBILE HEALTH TECHNOLOGY SUPERVISED MULTICENTER STUDY

POSTERS: C04.H. IMAGING, BIOMARKERS, DIAGNOSTICS: COGNITIVE, PSYCHOMETRIC, BEHAVIORAL AND MOTOR TESTS

Cinzia Zatti[1], Andrea Pilotto[1], Clint Hansen[2], Andrea Rizzardi[1], Marcello Catania[1], Robbin Romijnders[2], Leandro Purin[1], Maria Pasolini[3], Eva Schaeffer[2], Andrea Galbiati[4], Luigi Ferini-Strambi[4], Daniela Berg[2], Maria Rizzetti[5], Walter Maetzler[2], Alessandro Padovani[1]
[1]University of Brescia, Department Of Clinical And Experimental Sciences, Brescia, Italy, [2]Christian-Albrechts University, Neurology, Kiel, Germany, [3]ASST Spedali Civili, Neurophysiology Unit, Brescia, Italy, [4]IRCCS San Raffaele Scientific Institute, Clinical Neurosciences, Neurology-sleep Disorders Centre, Milan, Italy, [5]FERB Onlus, Parkinson's Disease Rehabilitation Center, Trescore Balneario, Italy

Aims: Gait alterations are prominent features of Parkinson's disease (PD), whereas their onset and progression is still theme of debate. Idiopathic REM sleep behavioral Disorder (iRBD) is the condition with the highest risk of conversion into PD and other alpha-synucleinopathies, and might present with subtle gait alterations. Aim of the study was to analyze gait temporal and spatial parameters in PD spectrum from the prodromal to the overt phase and to compare these to treated PD and healthy controls.
Methods: The prospective multicenter study included consecutively individuals with PSG-confirmed iRBD without parkinsonism, drug-naïve PD patients (nPD), early-stage treated PD (tPD) patients and healthy controls (HC). Each individual underwent assessment of motor and non-motor symptoms and cognitive status. All individuals underwent supervised gait assessment using mobile health technology (MHT) at normal, fast pace and during dual-task performances.
Results: The study included 208 subjects, namely 23 iRBDs, 60 nPD, 60 tPD and 65 HC. In normal gait, nPD and iRBD, but not tPD showed increased step time compared to HC. In gait at fast speed, nPD and tPD, but not iRBD exhibited increased step time compared to HC. In dual task gait, iRBD, nPD and tPD showed increased step time in comparison to HC. In all gait tasks, both nPD and tPD, but not iRBDs exhibited shorter step length compared to HC.
Conclusions: This study showed that gait temporal parameters are more sensitive to change especially in dual-task conditions in prodromal phases of the disease. Conversely, step length is a good parameter in detecting the overt phase. The findings also suggest an impact of treatment on parameters in normal gait with less impact on fast and dual task gait. Further studies are warranted to confirm these findings.

CAMPTOCORMIA FOLLOWING PRAMIPEXOLE IN A PARKINSON'S DISEASE PATIENT

POSTERS: C04.I. IMAGING, BIOMARKERS, DIAGNOSTICS: OTHER

Debi Das[1], Amit Shankar Singh[2], Jeenendra Singhvi[3], Jaslovleen Kaur[3]
[1]Fortis Hospital, Emergency And Critical Care, Mohali, India, [2]Forits Hospital, Neurology, Mohali, India, [3]Fortis Hospital, Neurology, Mohali, India

Aims: To report a case of severe and reversible camptocormia following oral pramipexole therapy in a Parkinson's disease patient.
Methods: A 79-year-old male, with a known case of Parkinson's disease presented in the clinic with 3-year complaints of progressive stooped posture on standing, with anterior bending on walking, without any history of backache or fall. This bending improves when he stands with back support or lies down suggesting camptocormia. For Parkinson's disease, the patient was on oral syndopa plus (levodopa plus carbidopa) 125 mg three times a day, pramipexole 0.25 mg three times a day, amantadine 100 mg two times a day, and his tremors, bradykinesia and rigidity were significantly controlled. There was no history of any psychiatric drug intake or any symptoms suggesting atypical parkinsonism in the past. On examination, the patient walks with significant anterior bending, with left-hand dystonic posturing while walking. On lying down posture improves, and no spinal deformity or tenderness over the back is present.
Results: On evaluation, blood tests and imaging of the brain and spine were normal. In view of camptocormia developing in Parkinson's disease patients without the use of any neuroleptic agent, the patient's pramipexole is withdrawn, and his anterior bending improved significantly following this. Syndopa CR 250 mg at night was added and amantadine was further increased to control his Parkinson's disease symptoms.
Conclusions: Dopamine agonists can cause induce or aggravate camptocormia but the exact pathophysiology is unknown. Truncal dystonia, rigidity, and/or proprioceptive disintegration are the possible central mechanisms of camptocormia. How pramipexole, a dopamine agonist causing camptocormia is debatable, but identification of this rare, but important cause of camptocormia should always be considered if other causes are ruled out.

GENOMIC INSIGHTS INTO PARKINSON'S DISEASE OF A LARGE ITALIAN COHORT

POSTERS: C05.A. GENETICS, EPIDEMIOLOGY: WHOLE GENOME SEQUENCING

Agata Fant[1], Francesco Musacchia[1], Sara Trova[1], Andrea Gaudio[2], Lucia Trevisan[3], Fabio Landuzzi[1], Luca Pandolfini[4], Andrea Cavalli[1], Edoardo Monfrini[5], Alessio Di Fonzo[6], Manuela Vecchi[1], Paola Mandich[2], Stefano Gustincich[1]
[1]Istituto Italiano di Tecnologia, Cmp3vda, Aosta, Italy, [2]IRCCS Ospedale Policlinico San Martino, Uoc Genetica Medica, Genova, Italy, [3]University of Genoa, Department Of Neuroscience, Rehabilitation, Ophthalmology, Genetics And Maternal And Child Health, Genova, Italy, [4]Istituto Italiano di Tecnologia, Center For Human Technologies (cht), Genova, Italy, [5]Dino Ferrari Center, Neuroscience Section, Department Of Pathophysiology And Transplantation University Of Milan, Milano, Italy, [6]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Neurology Unit, Milano, Italy

Aims: Parkinson's disease (PD) is heterogeneous both clinically and genetically with complex phenotypes and different progressive course. Despite recent advancements in the identification of both rare and common variants contributing to disease onset and risk, a comprehensive evaluation of the whole genome landscape in subjects with PD will improve our knowledge of this condition. The study aims at deciphering the genetic impact of coding and non-coding regions of the genome on Parkinson's disease in Northern Italy. Therefore, we are actively recruiting patients diagnosed with Parkinson's disease and expect to collect hundreds of cases in the next years. The overall goal of the study is to integrate genome sequencing into clinical practice.
Methods: Whole genome sequencing is performed on PD subjects with short-read (Illumina) and/or long-read (Oxford Nanopore) technologies. Bioinformatic analysis is performed using the NVIDIA Clara™ Parabricks® pipeline with BWA-Mem automatized and parallelized on GPUs. We also developed a consensus pipeline for SV analyses.
Results: We sequenced hundreds of subjects on the Illumina platform and we are performing long-read sequencing on a selected group of subjects. In a subset of cases, we identified pathogenic and risk variants in known causative genes, and candidate variants in non-coding regions of the genome.
Conclusions: We are sequencing the genome of a large Italian cohort of subjects with Parkinson's disease. The integration of short- and long-read sequencing will allow the identification of novel mutations and mechanisms/pathways in unsolved clinical cases with Parkinson's disease. Additionally, the characterization of causative repeat expansions, structural variants, and epigenetic modifications on native DNA with Nanopore technology will further expand our understanding of Parkinson's disease. Overall, this study will facilitate the integration of genome sequencing in clinical practice.

Aims: BLAAC PD is a multi-center study recruiting Black and African American individuals with Parkinson's Disease (PD) and healthy controls. BLAAC PD aims to provide a platform for replication studies to explore the relevance of genetic findings reported in other populations and investigate genotype-phenotype correlations. The ultimate goal is to create a foundational cohort to assess diverse aspects of PD in this historically excluded population and serve as a model for diversity and equity in research.
Methods: BLAAC PD collects samples from six sites across the United States. A total of 167 cases and 220 controls have been collected. Following DNA extraction, samples are genotyped and imputed, followed by ancestry assessment through a pre-trained machine learning model based on reference sample series. A comprehensive assessment was conducted to investigate known and novel genetic contributors
Results: Our analyses showed consistent differences in variant frequencies, magnitude of effects and

risk alleles for disease-causing mutations in PD known genes including SNCA, VPS35, LRRK2, PRKN, PINK1, DJ1 and GBA. Additionally, we screened genetic risk loci known to be associated with PD in multiple ancestral populations including over 100 loci. We also assessed structural variants in early-onset and familial PD cases.

Conclusions: These findings highlight the need for diverse representation in genetic research. Insufficiently diverse genetic data may exacerbate health disparities once translated to the clinic. BLAAC PD will help resolve the cross-ancestry applicability of drug targets, treatments and preventative measures by elucidating the genetic architecture of disease in African and African admixed ancestries and also providing a platform for replication studies of previous work in other populations. Looking ahead, BLAAC PD plans to continue recruiting and genotyping participants to serve as a foundational cohort for diverse genetic studies.

Aims: *PRKN* is the most frequent genetic cause of young-onset Parkinson's disease (YOPD). Approximately 3% of the YOPD is carrier of two damaging *PRKN* alleles. Many patients with YOPD are still genetically unresolved and some have only heterozygous variants in *PRKN* identified by conventional sequencing methods such as multiplex ligation-dependent probe amplification (MLPA) and short-read sequencing. Our previous study identified a 7.4 Mbp inversion in *PRKN* using long-read sequencing. We hypothesized that some YOPD patients with heterozygous variants of *PRKN* gene will likely have complex structural variants like inversions in the *PRKN* gene as an unrevealed second damaging variant which is difficult to identify using short-read sequencing. Thus, we aimed to elucidate the role of complex *PRKN* structural variants using long-read sequencing.
Methods: Parkinson's disease (PD) patients with age at onset younger than 50 were screened genetically by short-read amplicon sequencing and MLPA to identify potential causal variants in the causative genes for PD. Oxford Nanopore long-read sequencing was performed to patients who only have one heterozygous variants in *PRKN*.
Results: 37 PD patients were identified to have heterozygous *PRKN* variants (Female: Male = 23:14, Age at onset = 34.5 ± 9.34) including 14 patients with point mutations and 23 with exon deletion or duplication. Oxford Nanopore long-read DNA sequencing has been performed on all 37 patients and we have got enough data so far for the analysis (Overall output; 95.2 ± 21.73 Gb, N50 20.9 ± 4.55 kb).
Conclusions: Complex structural variants may exist as a second hit in heterozygous *PRKN* carriers with YOPD. Long-read sequencing can be an effective tool to identify complex structural variants in genetically unresolved patients with PD and will expand the role of *PRKN* in YOPD.

IDENTIFICATION OF NOVEL CANDIDATE GENES FOR LATE ONSET PARKINSON'S DISEASE: POLYGENIC MODEL OF INHERITANCE AND PARKINSON'S DISEASE RISK

POSTERS: C05.B. GENETICS, EPIDEMIOLOGY: DISEASE-CAUSING MUTATIONS

Teresa Esposito[1,2], Federica Carrillo[2], Giorgio Fortunato[2], Laura Ianiro[1], Nicola Modugno[1], Sara Pietracupa[1], Luigi Pavone[1], Teresa Nutile[2], Danilo Licastro[3], Nicole Piera Palomba[1]
[1]IRCCS Neuromed, Neurology, Pozzilli (IS), Italy, [2]Institute of Genetics and Biophysics CNR, Biomedicine, Napoli, Italy, [3]AREA Science Park, Argo Open Lab Platform For Genome Sequencing, Trieste, Italy

Aims: We have recently reported the identification of new rare gene variants in Parkinson's disease (PD) patients that support polygenic contribution to the disease. Here we aimed at extending the analysis to new families to identify novel genes that could increse the power of this diagnostic test.
Methods: Whole exome sequencing was performed in a cohort of 1150 Italian individuals including 850 PD patients (23 families and 804 independent patients) and 300 healthy subjects.
Results: Family-based approach of 23 PD families identified polygenic inheritance of rare (MAF<0.01) and deleterius (CADD>20) variants in 22 PD candidate genes including: *ATP10B, ACMSD, ANKK1, ANKRD50, DBH, DNAJC13, EIF4EBP1, GIGYF2, GRK5, HTRA2, LRRK2, MAN2C1, PACSIN1, PINK1, RHOT2, SH3GL2, SLC6A3, SMPD1, SNCAIP, SPG11, SYNJ1, TMEM175*. All these genes are expressed in human dopaminergic neurons and are involved in pathways potentially deregulated in PD. The co-inheritance of multiple rare variants (≥ 2) in a panel of 36 PD genes, selected combining data from this study with our published work, may predict PD occurrence in about 50% of patients, both familial and sporadic cases, with high significance (PD *sv* cnt, $p = 1.6 \times 10^{-6}$; familial PD *vs* cnt, $p = 3.9 \times 10^{-8}$; sporadic PD *vs* cnt, p = 0.0002). Furthermore, patients carrying ≥ 2 variants showed higher risk of manifesting cognitive decline (p=0.0008) and an erlier age at onset of the disease (p=0.01). LRRK2 mutation carriers showed higher risk of manifesting levodopa induced dyskinesia (p=0.009). MRI volumetric analysis in a subset of patients carrying ≥ 2 variants showed significant increase of red nucleous (p=0.007), coudate (p=0.01) and cortical thickness (p=0.01) volumes.
Conclusions: Our data underline the importance of rare variants in the genetics of PD and may be relevant for its prediction, diagnosis and treatment.

RARE VARIANT PATHWAYS: ANALYZING GENE SET BURDEN OF BIOLOGICAL PATHWAYS ASSOCIATED WITH RARE VARIANTS IN PARKINSON'S DISEASE.

POSTERS: C05.B. GENETICS, EPIDEMIOLOGY: DISEASE-CAUSING MUTATIONS

Vanessa Pitz[1], Allen Fu[2], Sara Bandres Ciga[3], Andrew Singleton[4], Mary Makarious[5], Cornelis Blauwendraat[6]
[1]National Institutes of Health, Integrative Neurogenomics Unit, Laboratory Of Neurogenetics, Bethesda, United States of America, [2]National Institutes of Health, Molecular Genetics Unit, Laboratory Of Neurogenetics, Bethesda, United States of America, [3]National Institutes of Health, Center For Alzheimer's And Related Dementias, Bethesda, United States of America, [4]National Institutes of Health, Molecular Genetics Unit, Laboratory Of Neurogenetics, Center For Alzheimer's And Related Dementias, Bethesda, United States of America, [5]National Institute on Aging, Laboratory Of Neurogenetics, Bethesda, United States of America, [6]National Institutes of Health, Integrative Neurogenomics Units, Laboratory Of Neurogenetics, Center For Alzheimer's And Related Dementias, Bethesda, United States of America

Aims: This study aims to elucidate the biological pathways associated with Parkinson's disease (PD) by analyzing rare genetic variant classes and their cumulative burden within gene sets. Exploring rare genetic variants (frequency <1%) as potential causes or significant risk factors for PD has been challenging. Burden tests assess the combined burden of rare and protein-altering variants in specific gene sets, shedding light on crucial biological pathways related to PD.
Methods: Using data from AMP-PD and the UK Biobank, we categorized variant classes based on SnpEff and LOFTEE predictions regarding impact and prediction scores. Statistical analyses utilized burden test algorithms, with adjustments specific to each dataset. Variant classes were defined based on SnpEff and LOFTEE predictions, including missense, moderate or high impact, high confidence loss of function, and Combined Annotation Dependent Depletion (CADD) PHRED score>20 variants. We used gene-sets from the Molecular Signatures Database (MSigDB) and applied custom burden test scripts (SKAT-O and CMC WALD) to each variant class and MAFs <1% and <0.01%.
Results: We conducted rare and ultra-rare variant pathway analyses on 3,090 canonical pathway gene sets: UKB contributed most gene sets with all 3,090 being present, 2,679 of which were found in AMP-PD. We report pathways significantly associated with PD, based on: passing multiple test correction at P<1.6e-05, generating robust statistical outputs, and remaining significant in a meta-analysis of both data sets.
Conclusions: Despite numerous gene associations with PD, our understanding of biological processes and networks remains incomplete. This extensive rare variant burden pathway analysis provides a valuable tool for identifying crucial biological pathways in PD. The results hold potential for guiding functional prioritization and discovering potential therapeutic targets for PD.

Aims: To investigate the potential interaction of sex and GBA mutations on the phenotype of patients with Parkinson Disease (PD).
Methods: GBA-relatedPD and nonGBA-PD underwent a comprehensive clinical characterization (MDS-UPDRS-I-IV, MOCA, SCOPAUT, UPSIT, RBDSQ, BDI and HADS-A). Clinical scores were compared between PD groups. Clustering analysis based on genetic status, demographic and clinical measures was applied to delineate new subgroups. Subgroup analysis according to GBA mutations severity was also performed.
Results: 53 GBA-PD (56% males) and 83 nonGBA-PD (64% males) were enrolled. Within GBA-PD, 10 subjects carried mild, 18 severe, 15 risk and 10 unknown variants. GBA-PD were similar to nonGBA-PD expect for significantly younger age at disease onset and higher BDI and HADS-A scores. Comparison analysis stratified by sex showed that GBA-PD males diverged significantly from nonGBA-PD males in terms of depressive symptoms, while females were comparable in the two groups. Cluster analysis based on combined clinical parameters allowed splitting the entire sample into 2 clusters, which discriminated mainly nonGBA-PD males (Cluster1), from the remaining groups (all females and GBA-PD males - Cluster 2). Dysautonomia, mood and sleep disorders were the most relevant features influencing the clustering process. Interestingly, a significantly higher proportion of mild and severe GBA mutations belonged to Cluster 1, while most of risk variants fell in Cluster 2.
Conclusions: This study highlights the intricate interplay between sex, genetic status, and non-motor features of PD. In this cohort, GBA status was associated with distinct non-motor features (particularly mood disorders), with overt sex-related differences. While these data warrant replication in independent cohort, they emphasize that the interplay of sex and genetic status need to be considered when stratifying PD patients, for improving more accurate precision medicine approaches.

Aims: We present preliminary results of an ongoing large cross-sectional cohort study on patients with Parkinson's disease (PD) to assess the role of single nucleotide polymorphisms (SNPs) in the Aquaporin 4 (AQP4) gene, an essential gene for the function of the glymphatic system, in determining clinical phenotypes of PD.
Methods: 176 PD patients consecutively enrolled across three sites in southern England performed a thorough in-person and online assessment of motor and non-motor symptoms, with particular focus on the sleep – Parkinson's disease Sleep Scale (PDSS); Epworth Sleepiness Scale (ESS); Insomnia Severity Index (ISI); and cognitive performance – Montreal Cognitive Assessment (MoCA) and Cambridge Neuropsychological Test Automated Battery (CANTAB). Venous blood was collected and analysed for detection of variants on SNPs of the AQP4 gene.
Results: Carriers of the rs162007 and rs162009 SNPs presented higher scores on the ESS (p=0.01 and p=0.02, respectively) and worse performance on the One-Touch Stockings of Cambridge test (OTS) assessing executive function (z-score p=0.016 and p=0.02, respectively). Homozygosity for the rs3875089 SNPs associated with worse sleep performance as assessed with the ISI (p=0.024), and PDSS (p=0.04). Carriers of the rs9951304 SNP displayed worse executive function on the OTS (p=0.009). Conversely, homozygosity for the rs3763040 SNP yielded better sleep scores on the ESS scale (p=0.045). and carriers of the rs72878787 SNP, better cognitive performance on the MoCA (p=0.026). This latter SNP was also associated with worse depressive symptoms as assessed with the Beck Depression Inventory II scale (BDI-II, p=0.015). Homozygous rs3875089 SNP carriers showed significantly higher total scores on NMSS (p=0.017).
Conclusions: These preliminary results provide evidence of a role of AQP4 SNPs in determining PD phenotypes mainly associated with altered sleep and cognition.

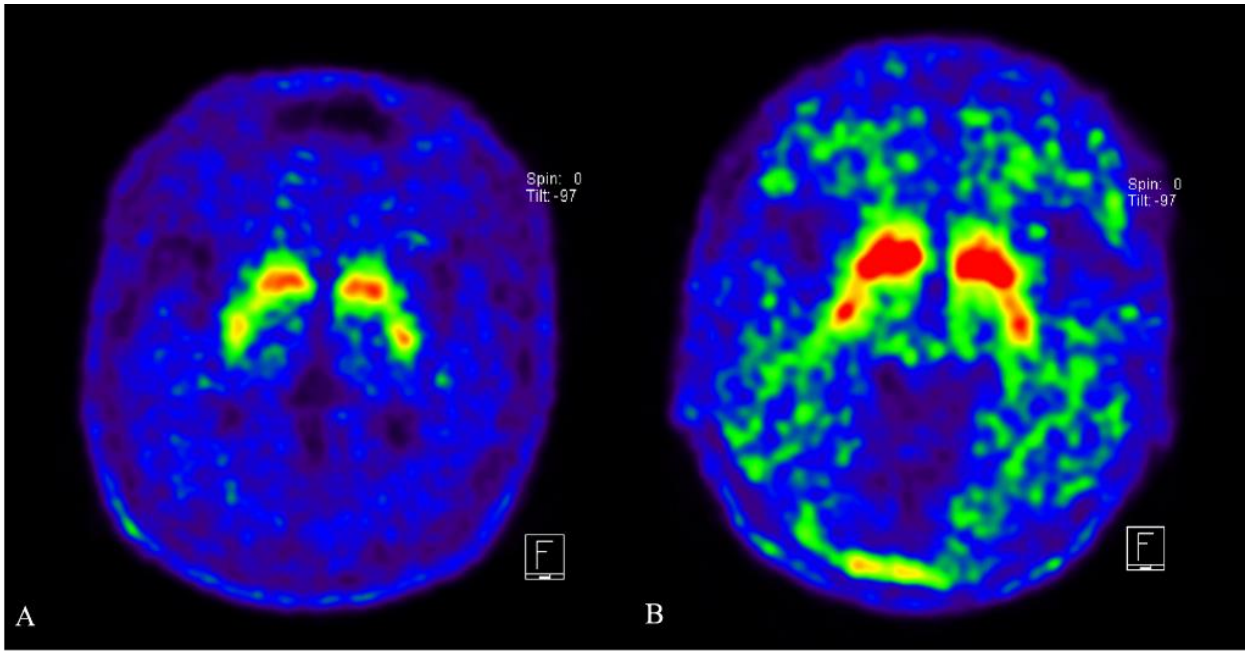
NOVEL COMPOUND HETEROZYGOUS ATP10B MUTATIONS IN A FAMILY WITH EARLY ONSET PARKINSON'S DISEASE

POSTERS: C05.C. GENETICS, EPIDEMIOLOGY: GWAS, GENETIC ASSOCIATIONS, SUSCEPTIBILITY & PROTECTIVE GENES

Da Eun Jeong[1], Min Ju Kang[1], Kyuhwan Shim[2]
[1]Central Veterans Hospital, Neurology, Seou, Korea, Republic of, [2]Gachon University, Department Of Bionano Technology, Seongnam-si, Korea, Republic of

Aims: Novel pathogenic gene, ATPase phospholipid transporting 10B (ATP10B) mutations are established casuse of autosomal recessive early onset Parkinson's Disease(EOPD) or dementia with Lewy bodies (DLB). ATP10B mutations participate in contribute to loss-of-function mechanism resulting in a dysregulated lipids glucosylceramide(GluCer) and phosphatidylcholine(PC) homeostasis. That induces lysosomal degradation, which contributes to the aggregation of alpha-synuclein.
Methods:



(A. Son and B. Mother) 18F-FP-CIT PET imaging shows bilateral posterior putamen with relative sparing of the ventral putamen decreased uptake with relative sparing of the ventral putamen. In genetic analysis, identical novel ATP10B mutation were revealed. This is the first report of familial PD with ATP10B mutation in south Korea.
Results: The mutation could affect the structural changes by the alternation of the intra-molecular interactions with other amino acids. 3D structure and interactions between amino acids were predicted from wild-type and mutant protein sequences (Figure 3). The 3D structure of wild-type protein was obtained from the AlphaFold database. Wild-type and mutant amino acids are presented, and the predicted interaction with other structura ladjacent amino acid was indicated and connected by the dashed line. The substitution from Arg303 to Trp303 led to the contraction of cavity volume of the protein.

In addition, the interaction between Arg303 and Arg1043 was disappeared when mutant Trp303 was replaced. On the other hand, ATP10B protein is a transmembrane protein in the lysosome, which may be caused by membrane instability by mutation.

Conclusions: To our knowledge, this is the korean report of ATP10B variant in parkinson's disease family. We suggest that genetic screening panel for should be provided in Korean PD patients with strong family history, including ATP10B mutation, for appropriate genetic counselling and improve the diagnostic accuracy.

UNCOVERING GENOMIC ASSOCIATIONS WITH DATA-DRIVEN PAIN TRAJECTORIES IN PERSONS WITH PARKINSON'S DISEASE

POSTERS: C05.C. GENETICS, EPIDEMIOLOGY: GWAS, GENETIC ASSOCIATIONS, SUSCEPTIBILITY & PROTECTIVE GENES

Shiying Liu[1], Douglas Gunzler[1,2], Steven Gunzler[3], Dana Crawford[1,4], Farren Briggs[5]
[1]Case Western Reserve University, Population And Quantitative Health Sciences, Cleveland, United States of America, [2]Case Western Reserve University School of Medicine, Center For Health Care Research And Policy, Cleveland, United States of America, [3]University Hospitals Cleveland Medical Center and Case Western Reserve University School of Medicine, Neurological Institute, Cleveland, United States of America, [4]Case Western Reserve University, Cleveland Institute For Computational Biology, Cleveland, United States of America, [5]University of Miami Miller School of Medicine, Department Of Public Health Sciences, Miami, United States of America

Aims: As a prevalent and complex non-motor symptom, pain is experienced by a majority of people with Parkinson's disease (PWP). Our understanding of its genetic underpinnings remains limited, challenging advancements in this area. This study aims to identify the genetic determinants associated with longitudinal pain trajectories in PWP in the early stages of their disease.
Methods: We utilized five clusters previously identified from longitudinal pain trajectories of patient-reported pain with a data-driven approach. Two genome-wide association studies (GWAS) were conducted on 4,159 PWP with European genetic ancestry. The extreme GWAS targeted PWP exhibiting a severe pain trajectory, while the multinomial GWAS encompassed all four trajectories with increasing pain. Both studies drew comparisons with PWP without significant pain over time. We also employed gene-based and pathway-enrichment analytical techniques for holistic insight.
Results: While no variant reached genome-wide significance, suggestive associations warrant further attention in both GWAS. The top hit in the extreme GWAS is rs117108018 (OR=9; $p=2.5x10^{-7}$), a brain tissue eQTL, along with other genic SNP associations, such as *MAPK8*-rs72794357 (OR=4.6; $p=1x10^{-6}$) and *VLDLR*-rs4741753 (OR=2.2; $p=1.5x10^{-6}$), implicating the role in brain development and opioid dependence. For multinomial GWAS, we identified the most significant genetic variant as rs61881484 ($p=2x10^{-7}$) that intersects with a transcription factor peak that targets *CREB1*, a critical element in synaptic plasticity within sensory neurons and is involved in the modulation of neuropathic pain. We also observed genes associated with neurotransmitter regulation and opioid dependence enriched in our findings.
Conclusions: Our findings are consistent with known neuropathic mechanisms and suggest the role of neuropathic pain in contributing to pain severity. Additionally, we observed potential associations for opioid-related pathways in PWP, highlighting potential therapeutic avenues for future investigations.

[1]VIB Center for Brain & Disease Research - KU Leuven, Department Of Neurosciences, Leuven, Belgium, [2]KU Leuven, Neuroscience, Leuven, Belgium

Aims: Genetic risk constitutes complex interactions among numerous genomic loci to affect disease susceptibility. Given the simultaneous involvement of numerous genetic factors, and the difficulty to identify the relevant genes affected by genome-wide association studies (GWAS), it has been notoriously difficult to define the most critical pathways for further functional testing. In this project I will use novel technology to define, in a high throughput and unbiased manner, which GWAS associated genes cause risk in Parkinson's disease (PD) and how their functional and complex genetic interactions are shaped.
Methods: The most recent GWAS of PD identified 90 risk variants across 78 genomic loci. I will use to a novel dual CRISPR inhibition/activation tool that we recently developed to up- and downregulate combinations of genes associated with these GWAS signals in human dopaminergic neurons, the preferentially affected cell type in PD.
Results: We have generated a stable iPSC line that successfully express our CRISPRi/a system in hiPSC- derived neurons The CRISPRi/a system succesfully increase and decrease the expression of genes in hiPSC-derived neurons.
Conclusions: This project takes a conceptual new approach and brings functional insight into GWAS and complex human genetic interactions in a major neurodegenerative disease.

BAYESIAN ESTIMATION OF REM SLEEP BEHAVIOURAL DISORDER PREVALENCE AT THE CANTON LEVEL IN LUXEMBOURG

POSTERS: C05.E. GENETICS, EPIDEMIOLOGY: OTHER

Eduardo Jubal[1], Anna Schritz[1], Gloria Aguayo[2], Olena Tsurkalenko[2], Tainá Marques[3], Clarissa Gomes[4], Magali Perquin[2], Claire Pauly[3], Lukas Pavelka[3], Rajesh Rawal[4], Soumyabrata Ghosh[4], Venkata Satagopam[4], Rejko Krüger[3], Michel Vaillant[1]
[1]Luxembourg Institute of Health, Competence Centre For Methodology And Statistics, Strassen, Luxembourg, [2]Luxembourg Institute of Health, Department Of Precision Health, Strassen, Luxembourg, [3]Luxembourg Institute of Health, Transversal Translational Medicine, Strassen, Luxembourg, [4]University of Luxembourg, Luxembourg Centre For Systems Biomedicine, Belvaux, Luxembourg

Aims: The primary aim is to estimate the true prevalence of REM sleep behavioural disorder (RBD) in Luxembourg. RBD affects an estimated 0.5 to 1.25 percent of the general population and approximately 2 percent in older adults, translating to 40 to 100 million expected patients worldwide. RBD is a known risk factor for Parkinson's disease (PD), and its global prevalence varies due to genetic and environmental factors.
Methods: The Luxembourg national RBD study invited over 300,000 citizens to participate and succeeded in collecting data from 17,000 respondents. However, this raw data likely contains sampling biases. To refine these estimates, we applied a Bayesian Statistics approach using latent class analysis. Specifically, prior information was shaped by a beta density and combined with the data observed by the Luxembourgish study to provide a more robust estimation of the underlying prevalence.
Results: We were able to approximate the latent prevalence of RBD in Luxembourg. Our analysis produced a mean estimated prevalence of 8.2%, with a median of 8.7%. The 95% credible interval for the prevalence ranged from 1.0% to 13.3%. Additionally, test sensitivity and specificity were estimated at a mean of 98.0% and 94.6%, respectively.
Conclusions: The descriptive analysis from the Luxembourg national RBD study provides valuable initial insights but might be limited by potential sampling biases. This Bayesian analysis provides the first canton-level estimation of RBD prevalence in Luxembourg, supported by a robust measure of statistical uncertainty. The model can be updated with new data at both EU and national levels, serving as a robust instrument for current and future epidemiological research.

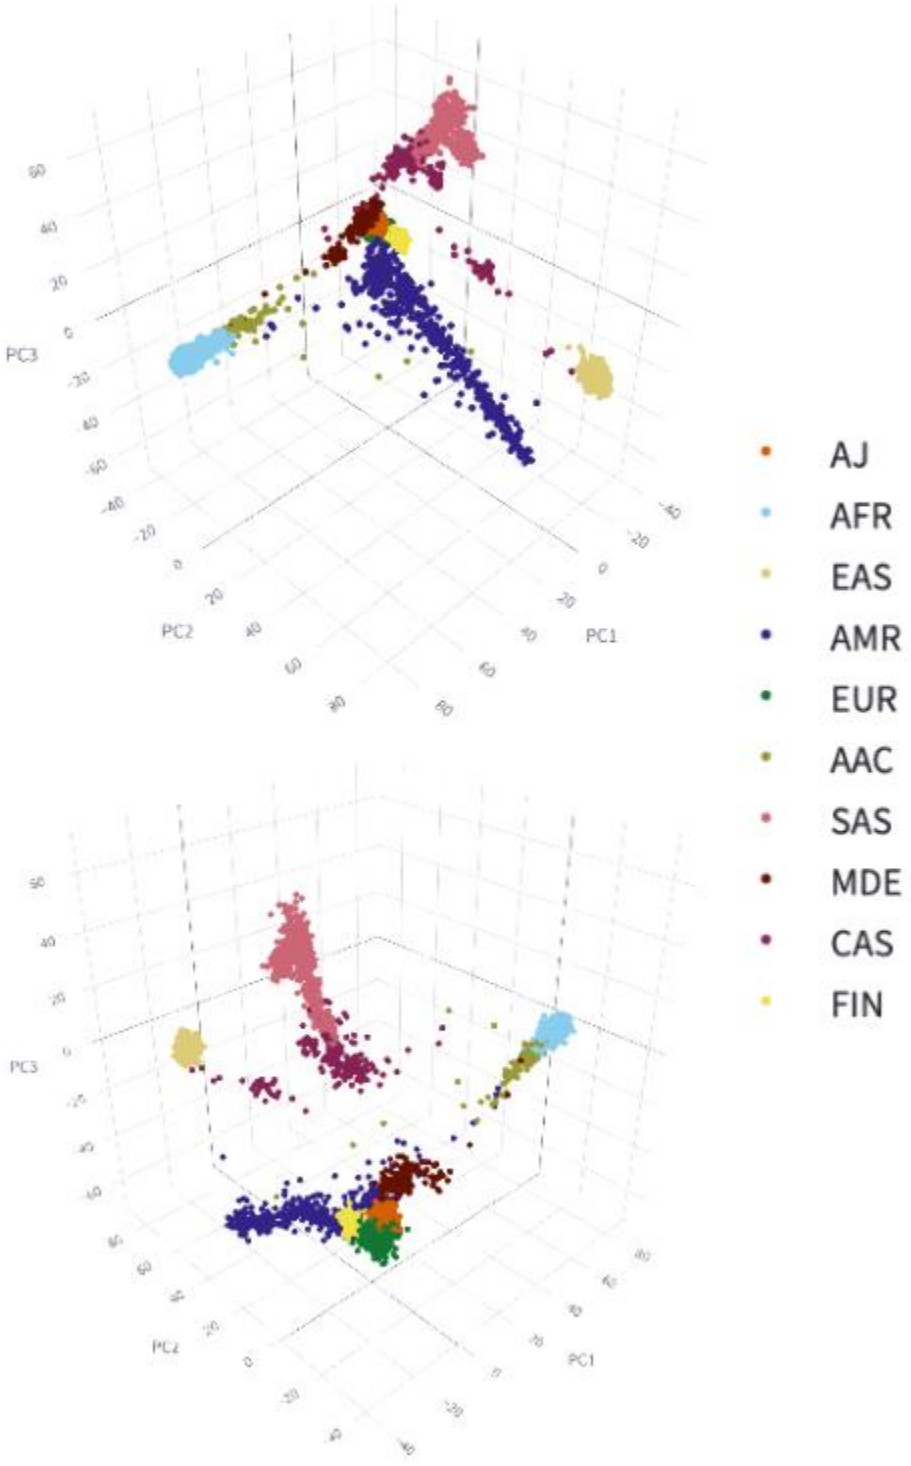
ACCURATE AND DEPLOYABLE GENETIC ANCESTRY PREDICTION FOR NEUROLOGICAL DISORDERS

POSTERS: C05.E. GENETICS, EPIDEMIOLOGY: OTHER

Mathew Koretsky[1], Nicole Kuznetsov[1], Mary Makarious[1,2,3], Hampton Leonard[1,2,4,5], Michael Nalls[1,2,4], Daniel Vitale[1,4]
[1]Center for Alzheimer's and Related Dementias, National Institutes Of Health, Bethesda, United States of America, [2]Laboratory of Neurogenetics, National Institute on Aging, National Institutes Of Health, Bethesda, United States of America, [3]University College London, Ucl Movement Disorders Centre, London, United Kingdom, [4]DataTecnica LLC, Datatecnica Llc, Washington, United States of America, [5]DZNE, Dnze, Tuebingen, Germany

Aims: The genetic architecture of diseases varies across populations. Emphasis has been placed on collecting diverse individual-level data to run genome-wide association studies (GWAS) for different ancestries. Here, we present an accessible machine learning-based approach for genetic ancestry prediction for the NeuroChip and NeuroBooster arrays, which were designed for screening neurological disorders across diverse populations.
Methods: Reference samples from 1000 Genomes Project, Human Genome Diversity Project and an Ashkenazi Jewish population defined ten ancestry groups (Supplementary Figure 1). Common variants were identified between the reference panel and samples genotyped on each array. Principal components fit on these variants were used to train XGBoost classifiers from the reference samples that render predictions on the genotypes. The models are deployed on Docker Hub for researchers to download and use on their own computing infrastructures while staying within GDPR requirements.



Results: Models trained on 24,354 and 39,340 overlapping variants achieved test accuracies of 97.3% for NeuroChip and 98.4% for Neurobooster, respectively. A GWAS performed on African and African admixed individuals that identified a population-specific Parkinson's risk variant in *GBA1* used the NeuroChip model to confirm ancestry for 589 African samples, and the NeuroBooster model for 1,722

African and 1,334 African admixed samples. The NeuroBooster model was also used to predict ancestry for 12,728 Parkinson's cases, 1,674 Alzheimer's and related dementia cases, and 10,533 controls for the Global Parkinson's Genetics Program (GP2).

Conclusions: These models serve as a foundational workflow for studies of Parkinson's and related dementias at GP2 to quantify the impact of diverse genetic datasets in precision medicine studies of neurodegeneration. Future directions include deploying models for accurate prediction on more genotyping chips for researchers to leverage.

GENOTOOLS: AUTOMATED GENOTYPE DATA PROCESSING AND GENOME-WIDE ASSOCIATION STUDIES

POSTERS: C05.E. GENETICS, EPIDEMIOLOGY: OTHER

Nicole Kuznetsov[1], Mathew Koretsky[2], Daniel Vitale[1,3], Kristin Levine[1,4], Hampton Leonard[1,5,6], Michael Nalls[1,7]
[1]Center for Alzheimer's and Related Dementias, National Institutes Of Health, Bethesda, United States of America, [2]National Institutes of Health, Center For Alzheimers And Related Dementias, Bethesda, United States of America, [3]DataTecnica LLC, Datatecnica, Washington, DC, United States of America, [4]Data Tecnica International, Data Tecnica International, Washington, United States of America, [5]DZNE, Dzne, Tuebingen, Germany, [6]DataTecnica LLC, Datatecnica Llc, Washington, United States of America, [7]Data Tecnica LLC, Data Tecnica Llc, Washington, United States of America

Aims: *GenoTools* is a Python package for automating and scaling genotype quality-control (QC) and genome-wide association study (GWAS) workflows. As larger, more diverse genotype sample sizes are produced, GWAS continues to be standard for nominating variant-trait associations. GenoTools simplifies large-scale, population genetics to produce clean genotypes, summary statistics, and ancestry-specific GWAS.
Methods: GenoTools uses PLINK2, with modifiable values, for missingness, genetic sex, relatedness, heterozygosity, Hardy-Weinberg, and non-random missingness QC. Ancestry is based on reference panels from 1000 Genomes Project, Human Genome Diversity Project, and an Ashkenazi Jewish population. Ancestry prediction incorporates PCA, UMAP, and linear classifiers to assign per-sample ancestry labels. Ancestry-specific GWAS is run, yielding population-specific summary statistics for meta-analysis.
Results: The Global Parkinson's Genetics Program performs data processing using GenoTools. To date, 24,935 samples across ten ancestry groups have passed QC, including 12,728 Parkinson's disease cases, 1,674 Alzheimer's disease and related dementia cases, and 10,533 controls. We developed an accompanying interactive web-application for scientists to examine these results regardless of computational skill. These processed data were also used in a GWAS of African and African-admixed ancestry which identified a novel Parkinson's risk variant in *GBA1*. GenoTools refined GWAS signals for *APOE*, *GBA1*, *SNCA*, and *LRRK2* while leveraging complex ancestry models, as these GWAS signals are enriched within broadly-European, Ashkenazi, and Finnish populations (Table 1).

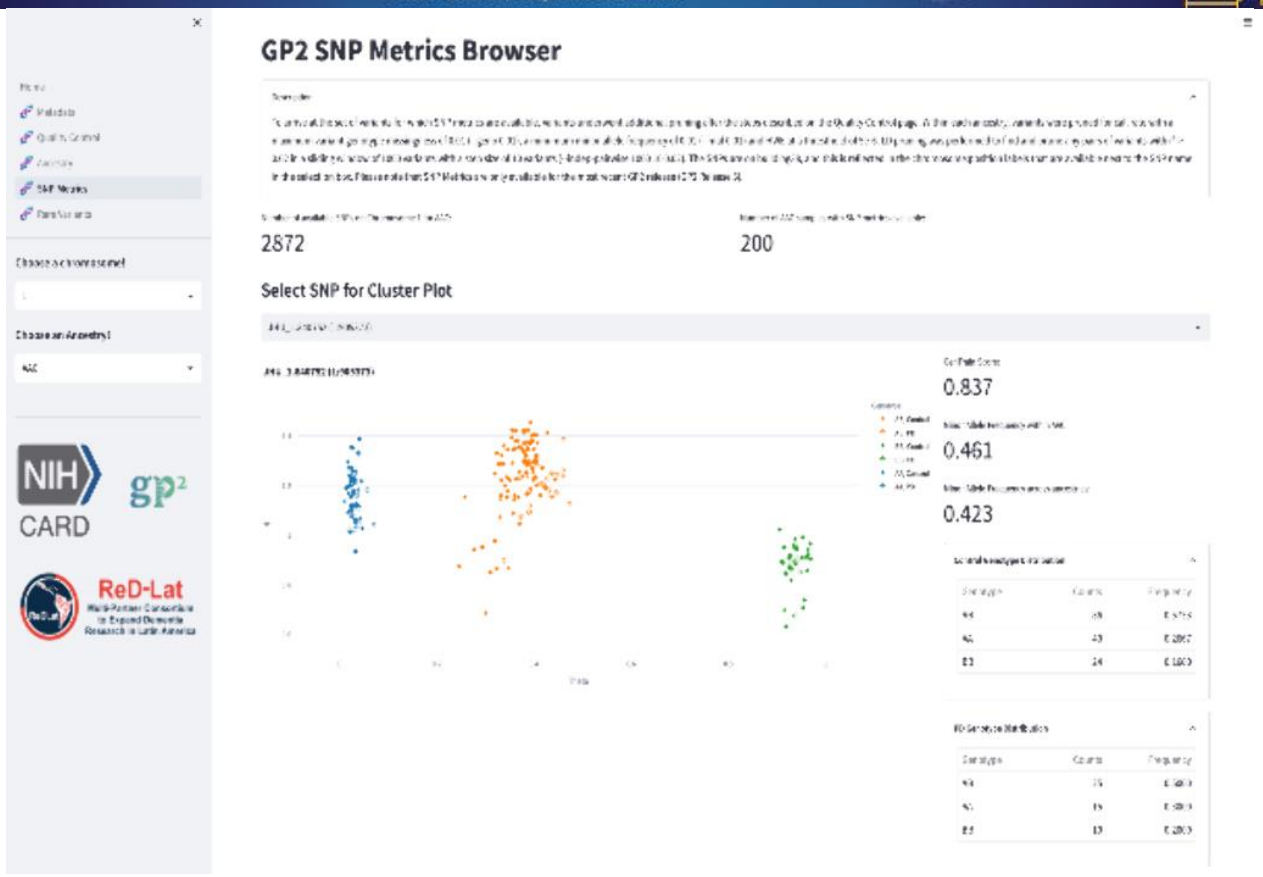
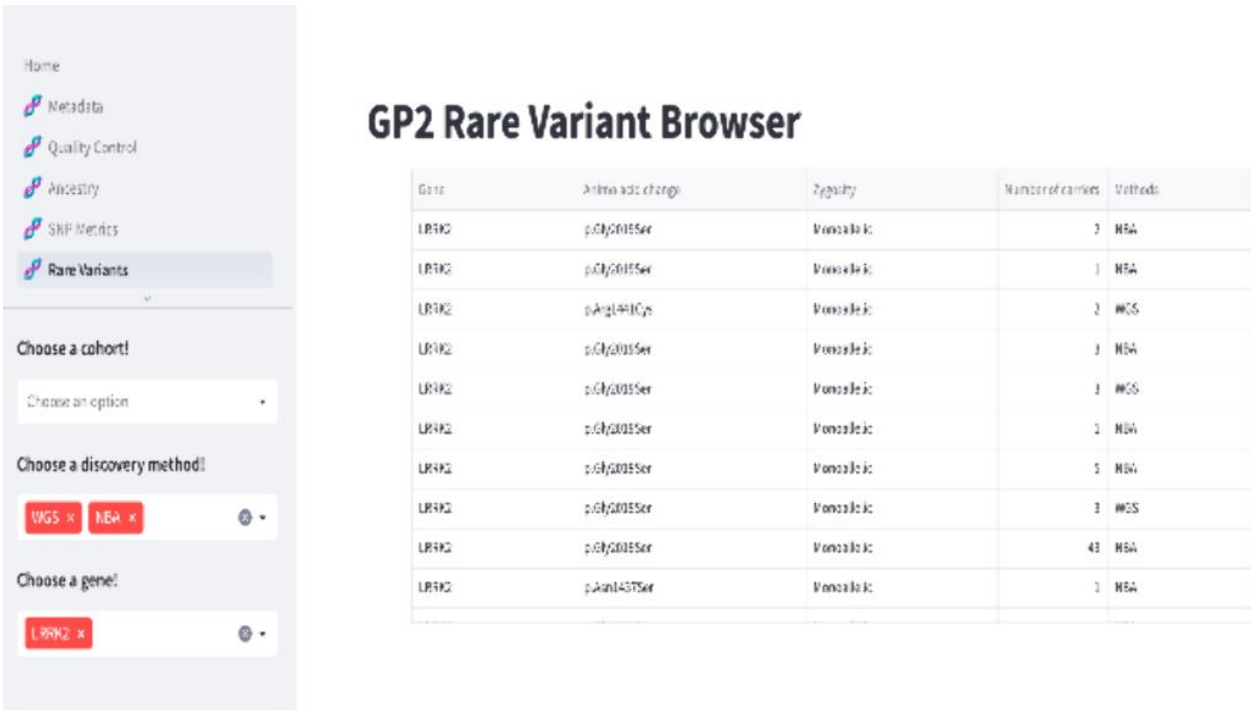
Description





Conclusions: GenoTools has shown success in producing high-quality calls at a level

deeper than commonly used in GWAS, with strong computational efficiency leading to discoveries in Parkinson's disease genetics. GenoTools will be broadly used in expediting neurodegenerative disease research and beyond.

POTENTIAL DIRECT ROLE OF SYNUCLEIN IN DOPAMINE TRANSPORT AND ITS IMPLICATIONS FOR PARKINSON'S DISEASE PATHOGENESIS

POSTERS: C06.A. CELL, MOLECULAR AND SYSTEMS BIOLOGY: A-SYNUCLEIN

Meewhi Kim[1], Ilya Bezprozvanny[1,2]
[1]UT Southwestern Medical Center, Dept Of Physiology, Dallas, United States of America, [2]Peter the Great St. Petersburg Polytechnic University, Laboratory Of Molecular Neurodegeneration, St Petersburg, Russian Federation

Aims: Parkinson Disease (PD) is a progressive neurodegenerative disorder that is caused by dysfunction and death of dopaminergic neurons. Mutations in the gene encoding α-synuclein (ASYN) have been linked with familial PD (FPD). Despite important role of ASYN in PD pathology, its normal biological function has not been clarified, although direct action of ASYN in synaptic transmission and dopamine (DA^+) release have been proposed. In the present report we propose a novel hypothesis that ASYN functions as DA^+/H^+ exchanger that can facilitate transport of dopamine across synaptic vesicle (SV) membrane by taking advantage of proton gradient between SV lumen and cytoplasm
Methods: To test this hypothesis we performed analysis of alpha-synuclein domain structure and performed computational modeling of interactions between alpha-synuclein and biological membranes.
Results: By bioinformtics anlaysis we discovered close similarity in domain structure of ASYN and pHILP, a designed peptide developed to mediate loading of lipid nanoparticles with cargo molecules. We reasoned that carboxy-terminal acidic loop D2b domain in both proteins binds cargo molecules. By mimicking DA^+ association with E/D residues in D2b domain of ASYN using Tyrosine replacement approach (TR) we have been able to estimate that ASYN is able to transfer 8-12 molecules of dopamine across SV membrane on each DA^+/H^+ exchange cycle. Our results suggest that familial PD mutations (A30P, E46K, H50Q, G51D, A53T and A53D) will interfere with different steps of the exchange cycle. We also predicted that similar impairment in ASYN DA^+/H^+ exchange function also occurs as a result on neuronal aging due to changes in SV lipid composition and size and dissipation of SV pH gradient.
Conclusions: Proposed novel functional role of ASYN provides novel insights into its biological role and its role in PD pathogenesis.

POPULATION FRACTION OF PARKINSON'S DISEASE ATTRIBUTED TO AVOIDABLE RISK FACTORS

POSTERS: C05.E. GENETICS, EPIDEMIOLOGY: OTHER

Charles Murchison[1], Timothy Sampson[2], David Standaert[1], Haydeh Payami[1]
[1]University of Alabama at Birmingham, Department Of Neurology, Birmingham, United States of America, [2]Emory University, Department Of Cell Biology, Atlanta, United States of America

Aims: Parkinson's disease (PD) is the fastest growing neurological disease with seemingly no means for prevention. While intrinsic risk factors (age, sex, genetics) are inescapable, environmental risk factors are not. This study sought to estimate the fraction of PD which could be reduced if modifiable risk factors were eliminated.
Methods: Several potentially avoidable PD risk factors were simultaneously assessed in a large cohort of persons with PD (N=808) and neurologically healthy controls (N=415). Associations between risk factors and PD were calculated in the presence of, and adjusting for, other risk factors using multivariable logistic regression. Using the adjusted odds ratio, population attributable fraction (PAF) quantified the excess proportion of PD which could have been potentially eliminated if these preventable risk factors had not been present.
Results: Several evaluated risk factors were found to be operative and independently associated with PD, including pesticide/herbicide exposure, repeated blows to the head, and military-related chemical exposure. In addition to identifying repeated blows to the head in sports or military as a potential new risk factor, PAF estimated that 23% of cases of PD in females and 30% in males were attributable to these modifiable risk factors.
Conclusions: Roughly 1/3 of PD cases in men and 1/4 of cases in women were attributed to preventable risk factors and therefore could have been potentially avoided. Critically, sex stratification showed women had no exposure to repeated blows to the head and military-related chemicals when this cohort was growing up. This is no longer the case today and these estimates will change, for better or worse, unless actions are taken to improve environmental and safety standards.

INVESTIGATION OF COMPOUNDS IDENTIFIED IN A HIGH-THROUGHPUT SCREENING IN A PARKINSON'S DISEASE CELL MODEL

POSTERS: C06.A. CELL, MOLECULAR AND SYSTEMS BIOLOGY: A-SYNUCLEIN

Svenja Bothe[1], Matthias Höllerhage[1], Claudia Moebius[2], Marc Bickle[3], Günter Höglinger[4]
[1]Hannover Medical School, Department Of Neurology, Hanover, Germany, [2]Max Planck Institute of Molecular Cell Biology and Genetics, Ht-technology Development Studio, Dresden, Germany, [3]Roche Pharma Research & Early Development, Institute Of Human Biology (ihb), Basel, Switzerland, [4]Ludwig Maximilian University, Department Of Neurology, Munich, Germany

Aims: The impact of alpha synuclein (aSyn) in Parkinson's disease (PD) has been long known. However, neither its physiological role nor its pathophysiological mechanism is fully understood and there is no aSyn-specific therapy available yet. Therefore, our goal was to perform a high-throughput screening with 50,000 small chemical compounds to find compound that protected from aSyn-induced toxicity and investigate the mechanism of action of the most potent compounds.
Methods: We used a PD cell model, in which a moderate overexpression of wild-type aSyn in postmitotic dopaminergic neurons (LUHMES) leads to 50% cell death. In this model, we performed a high-throughput screening and identified 25 compounds as potential leads for further drug development. To confirm the findings from the primary screening and to study the aSyn-specifity of the compounds, we performed LDH cell viability assays and cell stainings for apoptosis and neuronal markers. To study the mechanism of action of the compounds we used a cell-free aggregation assay and performed Western blot analyses with different marker proteins of the cellular degradation machinery.
Results: We identified 8 compounds that led to specific protection from aSyn-induced toxicity and selected them to further dissect their mechanism of action. Preliminary results from the aggregation assay showed a reduction in fluorescence intensity signal for 2 compounds, suggesting them to be inhibitors of aSyn aggregation. Western Blot analyses revealed that cells treated with 2 of the compounds had a significant increase on autophagic flux, suggesting a protective mechanism via stimulation of the intracellular degradation of aSyn.
Conclusions: In conclusion, our data suggest that 8 of our initial 25 compound hits lead to aSyn-specific protection in our PD cell model and possibly act by inhibiting the aSyn aggregation or promoting aSyn degradation.

INVESTIGATION OF THE ROLE OF NIPSNAP3A AND NIPSNAP3B IN A PARKINSON'S DISEASE CELL MODEL

POSTERS: C06.A. CELL, MOLECULAR AND SYSTEMS BIOLOGY: A-SYNUCLEIN

Kristina Losse[1], Matthias Höllerhage[1], Claudia Moebius[2], Marc Bickle[3], Günter Höglinger[4]
[1]Hannover Medical School, Neurology, Hanover, Germany, [2]Max Planck Institute of Molecular Cell Biology and Genetics, Ht-technology Development Studio (tds), Dresden, Germany, [3]Institute of Human Biology (IHB), Roche, Research & Early Development, Basel, Switzerland, [4]Ludwig-Maximilian-University, Neurology, munich, Germany

Aims: In recent years, several risk genes for Parkinson's disease (PD) have been reported to directly or indirectly influence alpha synuclein (aSyn) pathology. In order to discover novel potential genes that modulate aSyn-mediated-neuronal toxicity, we performed a genome-wide siRNA screening in a PD cell model based on aSyn-induced toxicity in human dopaminergic neurons. We found that knockdown of *NIPSNAP3A* and *NIPSNAP3B* protected in this model. Using RNAi and a CRISPR/Cas9 mediated knockout approach, we aimed to confirm the findings from the primary screening, and to explore the protective mechanisms involved.
Methods: For studying the protective efficacy, we performed LDH measurements of medium from the cells as well as Caspase3/7 staining after *NIPSNAP3A* and *NIPSNAP3B* knockdown. For investigating, the intra- and extracellular distribution of aSyn and its aggregation propensity, Western blot analyses were performed. To elucidate possible interactions between aSyn and the identified genes, we investigated the subcellular localisation of NIPSNAP3A and NIPSNAP3B by biochemical fractionation.
Results: LDH measurements and Caspase 3/7 stainings confirmed the protective efficacy of *NIPSNAP3A* and *NIPSNAP3B* downregulation. Western blot analyses indicated higher expression of total and aberrantly phosphorylated aSyn (pS129) after *NIPSNAP3A* and *NIPSNAP3B* knockdown, but no changes of the quantity of aSyn high molecular weight species. One possible explanation for the observed increases in cell viability would be that the intracellular accumulation of pathogenic aSyn prevents spreading of toxic aSyn species to neighbouring cells. Results from biochemical fractionation, revealed a NIPSNAP3A and NIPSNAP3B enrichment in the mitochondrial, nuclear, and membrane fractions.
Conclusions: In conclusion, our results indicate a protective effect against aSyn toxicity of *NIPSNAP3A* and *NIPSNAP3B* downregulation in our PD cell model, and provide preliminary data about the location of NIPSNAP3A and NIPSNAP3B protein in human dopaminergic neurons.

DISTINGUISHING PHYSIOLOGICAL AND PATHOLOGICAL A-SYNUCLEIN SERINE 129 PHOSPHORYLATION

POSTERS: C06.A. CELL, MOLECULAR AND SYSTEMS BIOLOGY: A-SYNUCLEIN

Nagendran Ramalingam, Lisa Brontesi, Shan-Xue Jin, Dennis Selkoe, Ulf Dettmer
Brigham and Women's Hospital/Harvard Medical School, Neurology, Boston, United States of America

Aims: α-synuclein phosphorylation at serine-129 (pS129) is a widely used surrogate marker of pathology in Parkinson's disease and other synucleinopathies. However, we recently demonstrated that pS129 is also a physiological activator of synaptic transmission. In a feed-forward fashion, neuronal activity triggers pS129 that accumulates at synapsin-containing presynaptic boutons but is readily reversible: blocking stimulation normalizes pS129 levels within two hours. Here, we tested whether one can distinguish physiological pS129 from abnormal pS129 observed in α-synuclein dyshomeostasis models.
Methods: Models - *in vitro* (rodent primary neurons from wildtype and *SNCA*$^{-/-}$ rats); Lentiviral transduction; Biochemistry - western blots, subcellular fractionation, and reversible phosphorylation dynamics.
Results: We show that Parkinson's-linked missense mutations in SNCA impact activity-dependent pS129. Under basal conditions, cytosol enriched A30P, H50Q, and G51D exhibited reduced pS129 levels. A53T pS129 levels were similar to wild-type, and E46K pS129 levels were higher. Interestingly, both A30P and E46K pS129 reversibility after stimulation were impaired. For the membrane-enriched amplification of E46K, '3K', dephosphorylation was virtually absent after blocking stimulation, implying reversible pS129 is severely compromised. Importantly, pS129 excess resulting from proteasome inhibition was also associated with reduced reversibility - by neuronal inhibition, kinase inhibition, or phosphatase activation. The impaired reversible pS129 dynamics we report here are likely to be one of the early changes associated with αS dyshomeostasis, potentially preceding pS129 aggregates.
Conclusions: Our findings suggest that perturbed activity-dependent pS129 dynamics are probably a shared characteristic of pathology-associated αS, with possible implications for synucleinopathy treatment and diagnosis.

OVEREXPRESSION-INDUCED NUCLEAR ALPHA-SYNUCLEIN ACCUMULATION

POSTERS: C06.A. CELL, MOLECULAR AND SYSTEMS BIOLOGY: A-SYNUCLEIN

Angela Rollar, Eva Szegö, Shirley Lee, Ayse Ulusoy, Donato Di Monte
DZNE (German Center for Neurodegenerative Diseases), Neurodegeneration And Neuroprotection In Parkinson's Disease, Bonn, Germany

Aims: Pathological accumulation of alpha-synuclein (αSyn)-containing inclusions is a hallmark of Parkinson's disease. αSyn is a synaptic protein and, under normal conditions, is predominantly detected in the form of immunoreactive puncta corresponding to synaptic boutons. The purpose of this study was to assess changes in αSyn localization triggered by increased neuronal αSyn expression. In particular, overexpression-induced changes were investigated within neuronal perikarya as well within neuronal nuclei; the latter analysis was facilitated by a newly developed assay that detected interactions between αSyn and histones.
Methods: Experiments and analyses were carried out in the substantia nigra pars compacta of rats in which αSyn overexpression was triggered by a unilateral intranigral injection of adeno-associated viral vectors delivering human αSyn DNA. Midbrain tissue sections were stained with anti-human-αSyn to detect neuronal protein accumulation. Nuclear αSyn localization was evaluated *in situ* using a proximity ligation assay (PLA). Immunoprecipitation was carried out to detect αSyn-histone interactions in nuclear preparations from rat midbrain tissue.
Results: Neither cytosolic nor nuclear αSyn was detected in non-injected control animals. Quite in contrast, overexpression of human αSyn was associated with robust neuronal accumulation of the exogenous protein. Under this condition, human αSyn could be detected in both neuronal perikarya and nuclei by immunohistochemistry. PLA confirmed this overexpression-induced nuclear accumulation and also indicated interactions of human αSyn with histones. These interactions were confirmed by immunoprecipitation using midbrain nuclei.
Conclusions: Our results provide clear evidence of a relationship between increased αSyn expression, cytosolic protein accumulation and αSyn access into neuronal nuclei. Data also reveal that, once in the nucleus, αSyn closely interacts with histones, indicating a mechanism for potential long-lasting deleterious transcriptional consequences.

Aims: The aim of the present pilot study was to assess variant of uncertain significance (VUS), and pathogenic mutations in *SNCA, PINK1, PARK7, PRKN*, and *LRRK2* genes and to analyze their possible association with mtDNA variants in Parkinson's disease (PD) patients
Methods: Fifteen PD patients were enrolled for this analysis. Blood samples were obtained from the institutional database of the IRCCS INRCA. *SNCA, PINK1, PARK7, PRKN*, and *LRRK2* specific gene mutations were assessed through an NGS-based custom panel and classified by the Parkinson's disease mutation database (PDmutDB). mtDNA was sequenced using a chip-based resequencing system which detects both homoplasmic and heteroplasmic mtDNA variants (40-60% heteroplasmy), and allows the assessment of low-level heteroplasmy (<10% heteroplasmy) by the REA (ratio of expected alleles) index.
Results: The mutations identified by PDmutDB in the specific genes were classified as benign (44.8%), benign VUS (37.1%), VUS (14.3%), likely benign VUS (2.85%) and pathogenic (0.95%). Mean homoplasmic and heteroplasmic mtDNA variants per PD patient were 22.2±5.1 and 6.5±3.5, respectively. Correlation analysis showed that total number of VUS in our cohort strongly correlated with total mtDNA homoplasmic variants (r=0.8452), and moderately with total (r=0.6002) and D-loop heteroplasmic variants (r=0.6093). Total benign VUS mutations negatively correlated with REA index in *ND4* gene indicating that high values of this kind of mutations were associated with low-level heteroplasmy (r=-0.6667). *PINK1* and *LRRK2* total mutations negatively correlated with REA, *PINK1* with total and with most mitochondrial gene REA, while *LRRK2* only with *ND4* gene REA values.
Conclusions: Our preliminary data suggest that mutations in genes associated with PD might influence mtDNA homo-and heteroplasmic variant burden, thereby supporting the role of mitochondrial dysfunction in PD pathogenesis. Further studies will be necessary to confirm these findings.

IDENTIFYING THE BINDING INTERFACES BETWEEN LRRK2 AND ITS PHOSPHATASES

POSTERS: C06.B. CELL, MOLECULAR AND SYSTEMS BIOLOGY: LRKK2, PARKIN, PINK1, DJ-1 AND OTHER PD REALTED GENES

Antonio Jesús Lara Ordóñez, Chloé Annicotte, Liesel Goveas, Marie Stoup, Marie-Christine Chartier-Harlin, Nicolas Lebègue, Maxime Liberelle, Jean-Marc Taymans
Univ. Lille, Inserm, CHU Lille, Umr-s 1172-lilncog-lille Neuroscience & Cognition, Lille, France

Aims: Mutations in LRRK2 (Leucine-Rich Repeat Kinase 2) are the most common cause of familial Parkinson´s disease (PD), and variants in this gene increase risk for the sporadic form of the disease.. LRRK2 is phosphorylated by other kinases at a cluster of serines between its ANK and LRR domains, and the phosphorylation status of LRRK2 is related to disease. Studies from our lab have identified subunits of Ser/Thr Protein Phosphatase 1 and 2A (PP1 and PP2A) as phosphatases of LRRK2. However, the binding interface of these phosphatases with LRRK2 is currently unknown.
Methods: Characterization of the binding interface of LRRK2 with its phosphatases using truncated constructs encoding LRRK2 domains with protein-protein interaction techniques such as coimmunoprecipitation, proximity ligation assay and microscale thermophoresis. Site-directed mutagenesis is performed in the domains of LRRK2 interacting with phosphatases to identify the residues that are important for their interaction.
Results: Here we confirm that PPP1CA, PPP2CA and PPP2R2A bind full length LRRK2 and have differential binding preferences towards the different domains of LRRK2.
Conclusions: Our research has identified the regions of binding between LRRK2 and its phosphatases, establishing the groundwork needed to understand the mechanisms of LRRK2 phosphoregulation at the structural level and to modulate LRRK2 complexes with its phosphatases as a strategy to manipulate the phosphorylation status of LRRK2.

IDENTIFYING INSTRINSIC DYSFUNCTION IN IPSC-DERIVED MEDIUM SPINY NEURONS FROM PARKINSON'S PATIENTS HARBOURING GBA N370S

POSTERS: C06.B. CELL, MOLECULAR AND SYSTEMS BIOLOGY: LRKK2, PARKIN, PINK1, DJ-1 AND OTHER PD REALTED GENES

Humaira Noor[1,2], Kaitlyn Cramb[1,3], Lahiru Handunnetthi[2], Richard Wade-Martins[1,3]
[1]Aligning Science Across Parkinson's (ASAP) Collaborative Research Network, (asap), Washington D.C., United States of America, [2]University of Oxford, Nufflied Department Of Medicine, Oxford, United Kingdom, [3]University of Oxford, Department Of Physiology, Anatomy & Genetics, Oxford Parkinson's Disease Centre, Oxford, United Kingdom

Aims: Parkinson's disease (PD) is a movement disorder caused by age-related progressive neurodegeneration. The cardinal motor symptoms are caused by striatal dysfunction and are attributed to the loss of dopamine release by Substantia Nigra pars compacta dopaminergic neurons which heavily innervate the striatum. The medium spiny neurons (MSNs) representing about 90-95% of the striatum are the main postsynaptic afferents of dopaminergic neurons. Despite representing an integral component of the network responsible for movement modulation that is compromised in PD, our understanding of the role of MSN in PD pathophysiology and network dysfunction remains limited. Use of iPSC-derived human MSNs from patients provides a unique opportunity to investigate these human striatal neurons in monoculture and detect early intrinsic dysfunction in PD.
Methods: iPSCs from patients harbouring PD-associated N370S mutation in the GBA gene (n=3) and healthy controls (n=3) have been differentiated into GABAergic MSNs using a 70-day protocol and characterised using immunocytochemistry and RT-qPCR. With the aid of functional analyses like ratiometric fluorescent dye Fura-2 for calcium imaging, seahorse assay for mitochondrial health and multi-electrode array for extracellular electrical activity, we will identify the impact of PD on the health and activity of iPSC-derived MSNs.
Results: iPSC-derived MSNs express specific markers, DARPP32 and GAD67, as early as Day 40, as observed from qPCR and immunocytochemistry data which persisted throughout the maturation period. Preliminary results point to an intrinsic dysregulation in iPSC-derived MSN from PD patients insinuating GBA N370S affects health and function of MSNs.
Conclusions: The highly efficient differentiation protocol results in functional iPSC-derived GABAergic MSN. Preliminary data suggests intrinsic dysregulation in iPSC-derived MSNs from patients that may contribute to PD pathology. Further studies will explore the mechanisms underlying the cell-autonomous dysfunction in these striatal neurons in the context of PD.

NetraMark, Biotechnology, Toronto, Canada

Aims: Parkinson's disease (PD) and Alzheimer's disease (AD) are two major neurodegenerative disorders with complex and poorly understood etiology. To address the clinical variability of PD and elucidate its underlying mechanisms, we leverage the power of NetraAI, a novel machine learning (ML) system. Our primary objective is to identify genetic drivers within specific PD patient subpopulations and uncover pivotal disease pathways, ultimately enhancing our understanding and treatment strategies.
Methods: Using a transcriptomic dataset consisting of 191 controls and 397 PD patients obtained and assembled from the Michael J. Fox Foundation, we employed NetraAI, powered by its unique Attractor AI algorithms, to identify causal clusters, or variables termed hypotheses explaining specific subpopulations. Cross-hypothesis integration revealed significant variables and pathways linked to PD.
Results: We report on several different hypotheses about the disease, linking mitochondrial function, the microbiome, and the immune response to PD. Importantly, we identify three key genes: *GPATCH2L*, *CLEC1B*, and *IRAK3. Protein-protein interaction networks were used to derive novel proteins of interest, all cl*osely linked to immune-mediated functions. This underscores the pivotal role of the immune system and the immune response in PD pathogenesis, showcasing NetraAI's ability to uncover key variables in disease pathogenesis.
Conclusions: This study highlights the potential of ML to untangle the intricate web of factors contributing to PD, offering insights applicable to other neurodegenerative disorders, including AD. By identifying causal clusters and significant genes in disease pathogenesis, we open new avenues for the diagnosis and treatment of these debilitating conditions. This research not only advances our understanding of the disease but also offers a scientific foundation for future investigations into the role of immune-related factors in neurodegenerative disorders, promising new opportunities for therapeutic interventions.

Aims: Alzheimer's disease (AD) exhibits substantial molecular heterogeneity, influenced by a complex interplay of environmental and genetic factors. The study aims to unravel the cell-type specific and spatial transcriptomic changes in AD, with a special focus on a subset of Down Syndrome (DS) patients suffering from AD (AD in DS). We intend to explore the congruencies and divergences between sporadic AD (sAD) and AD in DS, thereby providing insights that may bridge current gaps between mouse models and human conditions.
Methods: This investigation employed spatial transcriptomics (ST, 10x genomics visium) along with single-nucleus RNA sequencing (snRNA-seq) to examine cortical tissue samples from early-stage AD, late-stage AD, and AD in DS donors. Concurrently, amyloid plaque and fibril imaging were conducted on the same tissue samples to directly correlate gene expression alterations with pathological features.
Results: Our comprehensive analysis reveals pronounced spatial and cell-type specific changes in gene expression across the spectrum of AD pathology. Notably, the transcriptomic signatures shared remarkable similarities between sAD and AD in DS, indicating potential commonality in disease pathways. Furthermore, integration of amyloid imaging data with ST permitted the establishment of direct associations between shifts in gene expression and the spatial distribution of pathological aggregates.
Conclusions: The findings illuminate the utility of spatial transcriptomics in elucidating the intricate molecular mechanisms underlying AD. Importantly, the study uncovers converging molecular pathways between sAD and AD in DS, reinforcing the utility of AD in DS as an informative model for advancing our understanding of AD pathogenesis at the molecular level.

Aims: Parkinson's disease (PD) is a common neurodegenerative disease (NDD) characterised by abnormal protein accumulation leading to neuronal death. Research shows that NDDs share a common pathophysiology, including inflammatory responses, reactive gliosis and oxidative stress. Identifying genes that regulate these cellular responses in NDD may aid in diagnosis, understanding the disease environment, predicting disease progression and evaluating therapeutic efficacy.
Methods: We performed single-nucleus RNA sequencing on the substantia nigra of four brains each from sporadic PD and primary age-related tauopathy (PART) to serve as a more appropriate control group from a pathological standpoint. We obtained a total of 32,000 nuclei, integrated these data and used a variety of computational analyses including Seurat DEG, RNA velocity, GSEA, GO, SCENIC and TENET to understand the characteristics of PD. For histological validation in post-mortem tissue, we used single-molecule in situ hybridisation (smISH).
Results: We identified seven major cell types and their specific markers. For neurons, we observed proportional changes in dopaminergic, glutamatergic and GABAergic neurons and identified the disease-associated subpopulation of each neuronal subtype. DEG analysis revealed more pronounced changes in non-neuronal cells such as astrocytes and microglia than in neurons themselves. These changes were associated with reactive glial characteristics and inflammatory responses. For astrocytes and microglia, we performed Monocle-based pseudotime analysis and obtained the two disease-associated trajectories for each. Along with the trajectory, we were able to identify many genes involved in the cellular events of neurodegenerative disease. We constructed the networks for each related cellular process and identified representative transcription factors and their target genes.
Conclusions: We discovered multiple genes that exhibited cell-type-specific expression and underwent disease-associated expression changes, enhancing their potential as pathological markers. These genes have undergone histological validation in postmortem tissues using smISH.

DIFFERENTIAL METASTATES OF DIRECT PATHWAY STRIATAL OUTPUT NEURONS ACROSS THE DEVELOPMENT OF L-DOPA-INDUCED DYSKINESIA: A ROLE FOR ACTIVIN SIGNALING

POSTERS: C06.D. CELL, MOLECULAR AND SYSTEMS BIOLOGY: METABOLOMICS, TRANSCRIPTOMICS, LIPIDOMICS, PROTEOMICS

Henrique De Oliveira Amaral, David Figge, David Standaert, Karen Eskow Jaunarajs
University of Alabama at Birmingham, Department Of Neurology, Birmingham, United States of America

Aims: L-DOPA-induced dyskinesia (LID) is a debilitating, motor side effect arising from chronic dopamine replacement therapy with L-DOPA for the treatment of Parkinson disease (PD). The heterogeneous composition of the striatum, including diverse subpopulations of medium spiny output neurons (MSNs), interneurons, and supporting cells, has complicated the precise identification of the cell(s) underlying LID development and persistence. To elucidate the cellular and molecular mechanisms of LID, we used single nucleus RNA-sequencing (snRNA-seq) to establish a comprehensive striatal transcriptional profile during the development and maintenance of LID.
Methods: Hemiparkinsonian mice were treated with vehicle or L-DOPA for varying durations (1, 5, or 10 d) and nuclei from the striata were processed for snRNA-seq.
Results: Our analysis found that a limited population of dopamine D1 receptor-expressing MSNs (D1-MSNs) arising from both the
patch and matrix compartments were found in three activated metastates. These activated D1-MSN subpopulations displayed a majority of the transcriptional changes previously associated with LID; however, the prevalence and transcriptional behavior of each activated D1-MSN
metastate was directly correlated to the number of L-DOPA administrations. The differentially expressed genes found in these D1-MSNs indicated acute L-DOPA induced multiple plasticity-related transcription factors and regulators of MAPK signaling, while repeated L-DOPA exposure
induced numerous genes associated with synaptic remodeling, learning and memory, and transforming growth factor-ß (TGFß) signaling. Notably, repeated L-DOPA led to a sensitization in the expression of Inhba, a member of the activin/TGFß superfamily, in activated D1-MSNs and
the pharmacological inhibition of its receptor, ALK4, impaired LID development.
Conclusions: Collectively, these data suggest that a distinct subset of D1-MSNs become differentially responsive to L-DOPA. Our data further suggests that TGFß signaling plays an essential role in LID development.

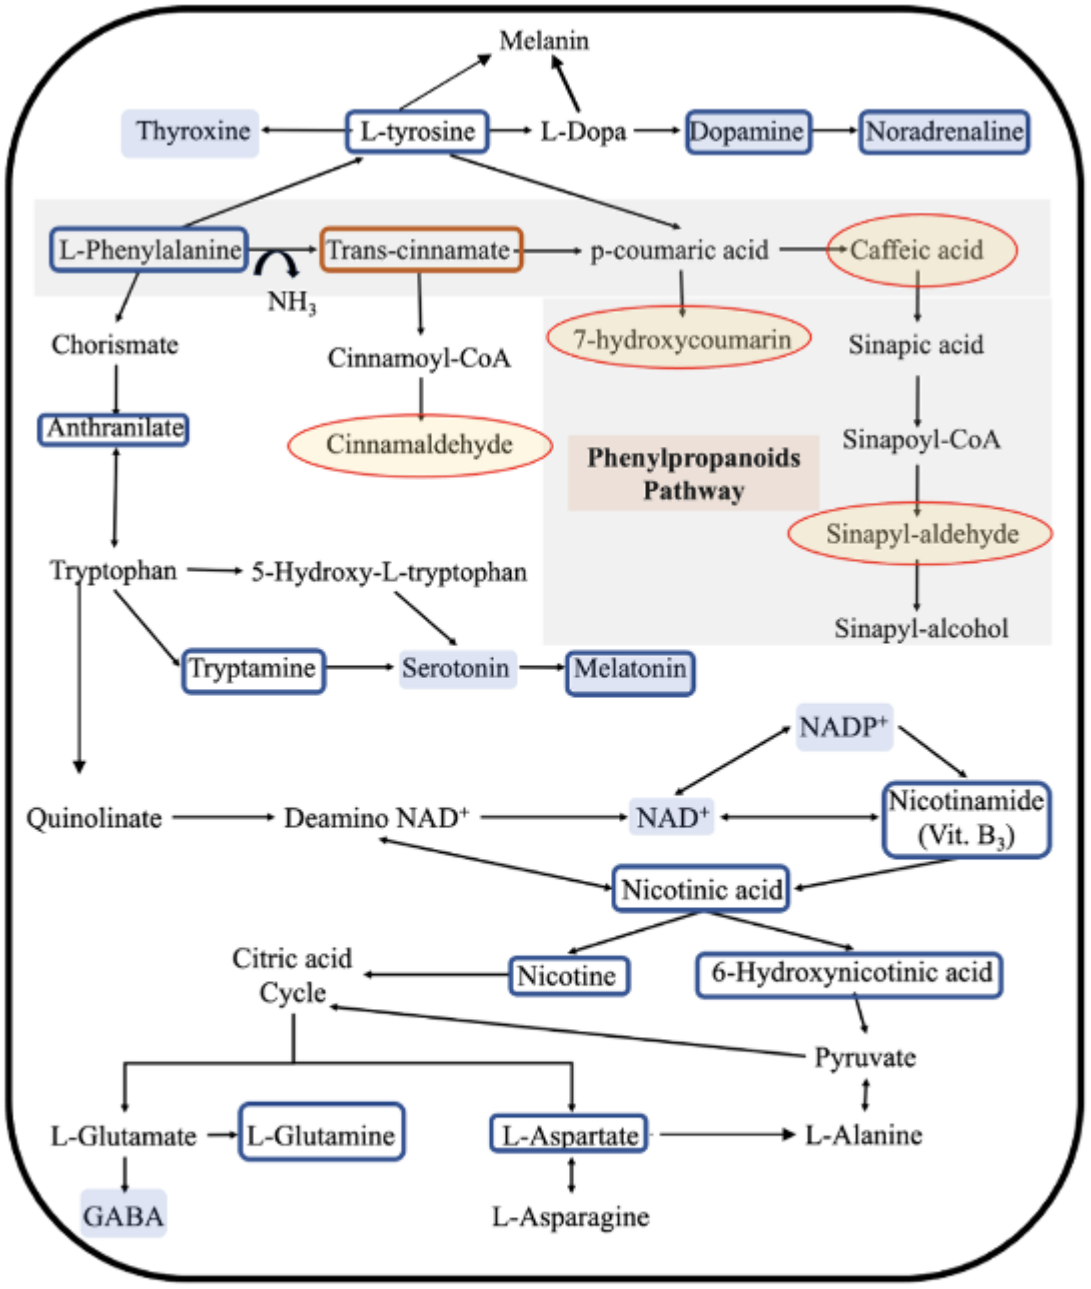
METABOLOMIC PROFILING REVEALS ALTERED PHENYLALANINE METABOLISM AND A POSSIBLE ROLE OF TRANS-CINNAMATE IN PARKINSON'S DISEASE: A METABOLOMICS STUDY OF AN EGYPTIAN COHORT

POSTERS: C06.D. CELL, MOLECULAR AND SYSTEMS BIOLOGY: METABOLOMICS, TRANSCRIPTOMICS, LIPIDOMICS, PROTEOMICS

Nourhan Shebl[1], Shaimaa El-Jaafary[2], Ayman Saeed[3], Samir Shamma[1], Jaidaa Mekky[4], Lobna Mohamed[4], Hassan El-Fawal[1], Mie Rizig[5], Mohamed Salama[1]
[1]The American University in Cairo, Institute Of Global Health And Human Ecology, Cairo, Egypt, [2]Faculty of Medicine, Cairo University, Neurology, Cairo, Egypt, [3]Research Institute, National Research Centre (NRC), Organic Chemistry, Cairo, Egypt, [4]Faculty of Medicine, Alexandria University, Neurology, Cairo, Egypt, [5]University College London, Institute Of Neurology Queen Square, London, Egypt

Aims: We investigated the metabolic alterations associated with Parkinson's disease (PD) by performing a comprehensive metabolic analysis. Our main objectives were to identify possible changes in the phenylalanine (dopamine precursor) metabolism and its impact on the dopaminergic, adrenergic, serotonergic, and melatonergic pathways; in addition, we tested the hypothesis that phenylalanine metabolism in PD may be shifted toward trans-cinnamate (phenylalanine metabolite) production, affecting the levels of critical neurotransmitters and related metabolites such as tyrosine.
Methods: Plasma samples were collected from 27 PD patients, 18 reference controls, and 8 high-risk controls to perform a non-targeted metabolomics analysis (LC-MS). The analysis focused on assessing the intensities of various metabolites, including trans-cinnamate, phenylalanine, tyrosine, dopamine (DA), norepinephrine (NE), 3-hydroxyanthranilic acid, a metabolite that connects phenylalanine metabolism to that of tryptophan. ANOVA test was performed to assess the significant differences in the metabolites' intensities between the recruited groups.
Results: Our findings revealed significantly higher intensities of trans-cinnamate in PD patients compared to controls. In addition, it also showed significantly lower intensities of phenylalanine, tyrosine, DA, NE, 3-hydroxyanthranilic acid, tryptamine, melatonin, and nicotinamide in PD patients. On the contrary, we did not find any significant difference in the levels of tryptophan among the recruited



This Figure shows the detected alterations in the metabolic pathways for the tackled metabolites. Compared to reference controls, the blue boxes show the metabolites that are significantly lower in patients, while the orange box shows the metabolite that is significantly higher in patients. On the other hand, the yellow shaded circles represent the metabolites that appear in patients only and not in controls, while the blue shaded metabolites are some molecules that may have a role in developing the clinical symptoms of PD.

groups.

Conclusions: Our study provides insights into the metabolic changes associated with PD, particularly in phenylalanine metabolism. The higher levels of trans-cinnamate in PD patients suggest a potential shift in phenylalanine metabolism towards the production of trans-cinnamate, possibly via L-phenylalanine

ammonia lyase (PAL), as opposed to the production of tyrosine. Moreover, Altered phenylalanine metabolism may have downstream effects on neurotransmitter production, including DA, NE, tryptamine, melatonin, and nicotinamide, and may contribute to the neurodegenerative processes seen in PD.

PROBING IRON AND LIPID CHANGES IN NEURODEGENERATIVE DISEASES USING METABOLOMICS ON HUMAN POST-MORTEM TISSUE

POSTERS: C06.D. CELL, MOLECULAR AND SYSTEMS BIOLOGY: METABOLOMICS, TRANSCRIPTOMICS, LIPIDOMICS, PROTEOMICS

Holly Spence, Fiona Read, Fergal Waldron, Jenna Gregory
Institute of Medical Sciences, University of Aberdeen, Institute Of Medical Sciences, Aberdeen, United Kingdom

Aims: Disruption of inflammation, iron and lipid metabolism pathways have all been implicated to have a role in neurodegenerative diseases including Alzheimer's disease and Parkinson's disease. We therefore hypothesise that iron-mediated lipid peroxidation may act as a cross cutting mechanism underpinning protein misfolding, where those with multi-morbidity proteinopathy may exhibit more generalised iron-mediated lipid peroxidation disruption compared to more specific triggers of single proteinopathies.
Methods: Here, 10 patients with pure AD pathology, 10 patients with pure PD pathology and 10 patients with pure ALS pathology were assessed alongside 10 patients with multi-morbidity proteinopathy (at least 2 of ALS, AD or PD) and 20 age and sex matched controls without any neurological disease. Over 2000 metabolites were assessed in central white matter and motor cortex (BA4) post-mortem tissue.
Results: This large-scale metabolomics study of AD, PD and ALS characterises cross-cutting metabolic dysregulation underpinning neurodegenerative disease.
Conclusions: This could be used as therapeutic targets as well as identifying pathways which could be used for differential diagnosis.

SINGLE NUCLEUS MULTIOME OPTIMIZATIONS FOR POSTMORTEM HUMAN BRAIN AND LARGE SCALE MULTIOME PROFILING OF PARKINSON'S DISEASE PROGRESSION REVEAL NOVEL GENE REGULATORY MECHANISMS

POSTERS: C06.D. CELL, MOLECULAR AND SYSTEMS BIOLOGY: METABOLOMICS, TRANSCRIPTOMICS, LIPIDOMICS, PROTEOMICS

Adam Turner, Shreya Menon, Ryan Corces
Gladstone Institutes, University of California, San Francisco, Gladstone Institute Of Neurological Diseases, San Francisco, United States of America

Aims: Parkinson's disease (PD) pathogenesis involves changes to cellular state across many cell types and brain regions. However, the cell-type specific molecular mechanisms involved in PD pathogenesis remain elusive. To enable characterization of these cell type-specific disease alterations, we must develop methods to profile the transcriptomic and gene regulatory landscapes in primary human tissues. Here, we optimized the isolation of nuclei from frozen postmortem brain tissue and the generation of corresponding single-nucleus multi-omic data sets. We highlight key advances on the experimental and computational aspects of large-scale single-nucleus data generation.
Methods: We benchmarked different nuclear isolation protocols and single-nucleus methodologies. We considered standard QC metrics as well as often overlooked metrics such as levels of ambient RNA that confound scRNA-seq analysis. We generated a large multi-omic single-nucleus atlas from 101 individuals (80 PD, 21 control) and 5 brain regions (including the substantia nigra) progressively involved in PD pathogenesis.
Results: Through protocol optimizations, we (1) reduced the presence of ambient RNA in single-nucleus RNA-seq data and (2) reduced the percentage of nuclei corresponding to oligodendrocytes and increased the percentage of nuclei corresponding to neurons. To mitigate batch effects, we implemented an experimental strategy that allows for profiling of multiple individuals simultaneously, leveraging the genotype of each donor to deconvolve donor identity in silico, and benchmarked computational tools to perform this deconvolution. We have also systematically compared data sets generated from freshly isolated nuclei (from frozen brain tissue) and cryopreserved nuclei, finding that cryopreservation substantially reduces data quality.
Conclusions: We have made key optimizations to improve single-nucleus multi-omic data quality from postmortem frozen human brain and applied these optimizations to the generation of a massive-scale dataset with more than 3.5 million nuclei.

SPATIAL LIPID PROFILING OF THE HUMAN BRAIN REVEALS CHANGES RELATED TO AGEING AND PARKINSON'S DISEASE

POSTERS: C06.D. CELL, MOLECULAR AND SYSTEMS BIOLOGY: METABOLOMICS, TRANSCRIPTOMICS, LIPIDOMICS, PROTEOMICS

Wendy Heywood[1], Jenny Hallqvist[1], Christina Toomey[2], Simon Eaton[1], Mesfer Al Shahrani[1], Simon Heales[3], Kevin Mills[1], Sonia Gandhi[2]

Aims: Dysregulation of the glycosphingolipid degradation pathway is a known risk factor for developing Parkinson's Disease (PD) as illustrated by the increased risk of PD in GBA heterozygotes. Brain lipid changes are also observed in the brains of sporadic PD patients but to a lesser extent than GBA-PD. Knowledge of how brain lipids change across the human brain anatomically, with age and disease have been relatively poorly studied. We have addressed this by spatially profiling the lipidome across 8 different brain regions and explored how lipids change across regions, with age and in response to PD. Using a multi-omic approach we also identify lipids that are associated with changes of the PD brain proteome.
Methods: We have used high precision tissue sampling with targeted LC-MS/MS lipid panels along a spatio-temporal pathology gradient of early, mid and late stage disease.
Results: All regions demonstrated a specific lipid profile with ceramide showing the least variation. Age affected the profile in the controls and was driven by increased hexosylceramide and ceramides. The parietal and frontal cortices and putamen were most affected by PD with between 18-24% of total lipids showing changes. Lipids driving these changes were mostly gangliosides, hexosylceramide and medium chain ceramides. Early PD changes were observed only in the cerebellum and frontal cortex with increased ceramides, lyso-sphingomyelin and plasmalogens. Multi-omic analysis revealed sphingomyelin C34 and C36 species (which are known to bind to a-synuclein fibrils) correlated significantly with proteins that were altered in early PD. Correlation with mitochondrial complex I activity indicated medium chain ceramides, lyso-phosphocholine and plasmalogens are associated with mitochondrial function in early PD.
Conclusions: The brain lipid profile changes with PD and early lipid changes are associated with ROS production and mitophagy.

DNA METHYLATION PROFILING IN DIFFERENT BRAIN CELL TYPES IN PARKINSON'S DISEASE

POSTERS: C06.E. CELL, MOLECULAR AND SYSTEMS BIOLOGY: EPIGENETICS, HISTONE MODIFICATION, DNA METHYLATION

Anthony Klokkaris, Jonathan Mill, Anna Migdalska-Richards
University of Exeter, Department Of Clinical And Biomedical Sciences, Exeter, United Kingdom

Aims: Much is still unknown about the aetiology of Parkinson's disease (PD). While several risk genes have been identified, there is also growing evidence of epigenetic dysregulation, with a number of recent studies identifying DNA methylation changes in PD brains. However, nearly all research has used bulk brain tissue which masks any cell-type specific epigenetic signatures. We aim to investigate genome-wide DNA methylation alterations in distinct cell types isolated from PD post-mortem brain tissue, and additionally whether DNA methylation varies according to *GBA1* mutation status (the most common PD genetic risk factor).
Methods: Fluorescence-activated nuclei sorting was used to isolate neuronal, oligodendrocyte and other glial cell nuclei from the prefrontal cortex of 129 individuals (36 PD-*GBA1*, 35 PD-non-*GBA1,* 10 control-*GBA1* and 48 control-non-*GBA1*). Nuclear DNA was extracted and bisulfite converted and genome-wide DNA methylation was measured using the Infinium MethylationEPIC BeadChip. Following a quality control pipeline, differential methylation was analysed using linear regression. Individuals were also genotyped using the Infinium Global Screening Array.
Results: Cell-type isolation was largely accurate with the vast majority of samples passing quality control. DNA methylation was analysed, comparing PD and control samples as well as PD-*GBA1* and PD-non-*GBA1*, and cell-type specific differentially methylated positions were identified.
Conclusions: This is one of the first studies to investigate genome-wide DNA methylation alterations across distinct brain cell populations in PD. Additionally, it starts to stratify individuals by *GBA1* status. Future work will involve targeted validation of the top changes and integrating DNA methylation, genetic and microRNA expression data (generated for several of these samples). The findings will shed new insights into genes and biological mechanisms involved in the disease and how these might vary according to cell type and disease subtype.

INTERACTION OF GENETIC VARIANTS AND DNA METHYLATION IN ALZHEIMER'S DISEASE

POSTERS: C06.E. CELL, MOLECULAR AND SYSTEMS BIOLOGY: EPIGENETICS, HISTONE MODIFICATION, DNA METHYLATION

Younghee Lee[1], Seonggyun Han[2], Soo-Ah Cho[1], Wongyung Cho[1], Karen Eilbeck[2], Hillary Coon[2], Kwangsik Nho[3]
[1]Seoul National University, Veterinary Medicine, Seoul, Korea, Republic of, [2]University of Utah, Biomedical Informatics, Salt Lake City, United States of America, [3]Indiana University School of Medicine, Radiology And Imaging Sciences, Indianapolis, United States of America

Aims: Alzheimer's disease (AD) is a major cause of dementia and among the most complex diseases, featuring various heterogeneous molecular mechanisms. Not only germline genetic but also epigenetic factors (i.e., DNA methylation) contribute to its progression in the human brain; in particular, dysregulation of gene expression by single nucleotide polymorphisms (SNPs) and altered DNA methylation is often observed in AD patients. Although genetic and epigenetic regulators have each independently received intensive study for their roles in AD progression, their interactive contributions are not yet fully understood. In this study, we aimed to elucidate the interplay of genetic loci (i.e., SNPs) and DNA methylation in determining transcript-level expression status in AD.
Methods: We performed an integrative analysis of whole-genome sequencing, RNA-seq, and methylation data from the dorsolateral prefrontal cortex in AD patients (n=361), generated from the Religious Orders Study/Memory and Aging Project. Likelihood ratio tests (LRTs) were performed to determine the statistical significance of differences in transcript expression between linear models with and without the SNP-methylation interaction term.
Results: We identified 179 SNP-methylation pairs as having interactions with statistically significant impacts on the expression of 67 transcripts (63 unique genes) belonging to functional gene sets, including immune-related and post-synaptic assembly pathways. In particular, a number of HLA family genes (*HLA-A*, *HLA-B*, *HLA-C*, *HLA-DRB1*, *HLA-DRB5*, *HLA-DPA1*, *HLA-K*, *HLA-DQB1*, and *HLA-DMA*) were observed to have changes associated with this SNP-methylation interplay.
Conclusions: Our study provides a new molecular insight into the crosstalk between genetic and epigenetic elements, in that it concerns transcript expression status in AD. Our findings especially implicate immune-related pathways as targets of these regulatory interactions. SNP-methylation interactions may thus contribute to the molecular complexity underlying immune-related pathogenies in AD patients.

Aims: Parkinson's disease (PD) is marked by the degeneration of midbrain dopaminergic neurons (mDANs) situated in the substantia nigra. PD risk has been linked to common single nucleotide polymorphisms (SNPs) through genome-wide association studies (GWAS), but the underlying mechanisms remain largely undiscovered. SNPs associated with various traits and diseases are enriched within gene regulatory regions. Alterations in transcription factor binding sites (TFBS), caused by variants located within accessible TFBS, can induce changes in gene expression, contributing to *cis*-regulatory variation.
Methods: To better understand how PD-associated SNPs might impact mDANs, we generated time-series transcriptome and chromatin accessibility profiles of purified mDNAs and astrocytes differentiated from human iPSC-derived neural precursor cells. We integrated these epigenomic profiles with 17 million PD-associated SNPs from PD GWAS repository, employing our novel approach to predict SNPs affecting TF binding in a cell type-specific manner.
Results: An intriguing finding involved a PD-associated SNP that introduced a proximal TFBS for NR2C2 at the promoter of lysosomal membrane protein 2 (SCARB2) in mDANs. SCARB2 is a transporter for glucosylceramidase (GBA), a gene frequently associated with PD. Luciferase assays in human neurons confirmed a reduction in transcriptional activity in the presence of the PD-associated SCARB2 allele that also exhibited reduced chromatin accessibility in mDNAs. Moreover, eQTL analysis of human brain regions revealed a lower expression of SCARB2 in the presence of the PD-associated allele, especially in substantia nigra. Consistently, a knockdown of NR2C2 resulted in increased SCARB2 expression that was accompanied by an increase in the number of mDANs within the neuronal population.
Conclusions: In summary, these findings suggest that NR2C2 may function as a repressor of mDAN differentiation, targeting SCARB2 in the presence of a PD-associated regulatory variant.

Aims: Parkinson's disease (PD) presents the selective loss of A9 dopaminergic (DA) neurons of Substantia Nigra pars compacta (SNpc) and the presence of intracellular aggregates called Lewy bodies. α-synuclein (α-syn) species truncated at the carboxy-terminal (C-terminal) accumulate in pathological inclusions and promote α-syn aggregation and toxicity. Hemoglobin (Hb) is the major oxygen carrier protein in erythrocytes. In addition, Hb is expressed in A9 DA neurons where it influences mitochondrial activity. Hb overexpression increases cells' vulnerability in a neurochemical model of PD in vitro and forms cytoplasmic and nucleolar aggregates upon short-term overexpression in mouse SNpc. In this context, our objective was to study the effects of Hb expression in DA neurons *in vivo*.
Methods: α and β-globin chains were co-expressed in DA cells of SNpc *in vivo* upon stereotaxic injections of an Adeno-Associated Virus isotype 9 (AAV9) and in DA iMN9D cells *in vitro*.
Results: Long-term Hb over-expression in SNpc induced the loss of about 50% of DA neurons, a mild motor impairment and deficits in recognition and spatial working memory. Hb triggered the formation of endogenous α-syn C-terminal truncated species. Similar α-syn fragments were found *in vitro* in DA iMN9D cells over-expressing α and β- globins when treated with pre-formed α-syn fibrils.
Conclusions: Our study positions Hb as a relevant player in PD pathogenesis for its ability to trigger DA cells' loss in vivo and the formation of C-terminal α-syn fragments.

EXERCISE REVEALS POTENTIAL AS AN EARLY DISEASE-MODIFYING TREATMENT IN A MOUSE MODEL OF PARKINSON'S DISEASE

POSTERS: C07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Malte Feja[1], Leonie Baldauf[1], Milos Stanojlovic[1], Julia Hankel[2], Christian Visscher[2], Eva Schäffer[3], Daniela Berg[3], Franziska Richter[1]
[1]University of Veterinary Medicine Hannover, Department Of Pharmacology, Toxicology, And Pharmacy, Hannover, Germany, [2]University of Veterinary Medicine, Institute For Animal Nutrition, Hannover, Germany, [3]University Hospital Schleswig-Holstein, Christian-Albrechts University, Department Of Neurology, Kiel, Germany

Aims: Subtle motor and non-motor dysfunctions indicative of beginning Parkinson's disease (PD) are evident before clinical disease diagnosis. Persons of risk developing PD would be willing to determine their risk and change their lifestyle in case of a concrete beneficial approach. Growing evidence indicates the potential of exercise in reducing components of PD-related pathology. We hypothesized that early intervention by exercise has a disease-modifying effect during prodromal phase in our PD mouse model.
Methods: Two-month-old transgenic mice overexpressing human wild-type alpha-synuclein (Thy1-aSyn) and wildtypes were assigned to three groups receiving different intensity levels of exercise on a treadmill. We assessed motor performance and activity, and took fecal and brain samples for analysis of microbiota and PD-related pathology.
Results: Transgenic mice showed motor impairment on challenging beam and vertical pole, reflecting the expected progression of aSyn pathology at this age. Improved vertical pole performance under exercise in wildtypes suggests symptomatic effects, while slightly improved beam performance of transgenics might indicate a disease-modifying potential of exercise. Levels of phosphorylated alpha-synuclein at serine 129, a key feature of PD, were increased in the substantia nigra pars compacta in untrained, but not in trained, Thy1-aSyn mice, indicating a neuroprotective potential of exercise. Intensive training did not induce inflammation, since reactive microglia were not affected. Genotypes did not differ in locomotor open field activity, but untrained transgenics exhibited an anxiety-like phenotype. Intriguingly, intensive training reduced anxiety-like behavior in transgenics to wild-type level.
Conclusions: These results suggest that exercise alleviates early sensorimotor and even non-motor deficits in Thy1-aSyn mice and demonstrate its potential as an early PD-modifying treatment. Increased fecal microbiota diversity in intensively-exercised mice supports a potential role of the gut-brain axis in the underlying pathological mechanisms of PD.

Aims: Parkinson´s disease (PD) is a multicentric neurodegenerative disorder characterized by the accumulation and aggregation of α-synuclein (α-syn). Mutations in the SNCA gene encoding for α-syn are reported to accelerate α-syn oligomerization and aggregation. Recently, it has been recognized that the brain-gut-axis may play a critical role in PD onset and disease progression. Also, an excessive stimulation of the innate immune system may induce inflammation and contribute to the initiation of α-syn misfolding. Hence, in the current study, we histologically characterized colon samples of transgenic mice expressing human α-syn with A53T mutation.
Methods: Colon tissue of 5.5-month old transgenic hA53Ttg mice and age- and sex-matched non-transgenic littermates was histologically evaluated. Briefly, swiss rolls of colon tissues were prepared, and cryosections immunofluorescently labeled for human alpha-synuclein (ha-syn) as well as inflammation markers, such as CD45, CD68 and Iba1. Also, PGP 9.5 and vimentin were labeled to visualize nervous and connective tissue, respectively. Finally, tissue sections were qualitatively evaluated. Analysis of additional markers is still ongoing.
Results: Qualitative analysis revealed presence of hα-syn in hA53Ttg mice in connective tissue but not nervous tissue. Also, as indicated by positive signals for CD45, CD68, and Iba1, hA53Ttg mouse colon showed elevated inflammation compared to non-transgenic littermates.
Conclusions: In conclusion, this study reveals the impact of hα-syn with A53T mutation in murine colon pathology and emphasizes the importance of enteric inflammatory processes of this PD mouse model. Subsequently, the data indicate a potential use of the A53Ttg mouse model for efficacy studies targeting the observed pathologies.

Aims: The human gut microbiome is a complex ecosystem that profoundly impacts the immune, metabolic and neural systems. In diseases with inflammatory signatures such as Parkinson's disease (PD), these can be influenced by numerous factors, including host genetics, lifestyle and diet. A study with a cross-sectional and a longitudinal arm was designed. The cross-sectional arm sets out to leverage multi-omic strategies to understand the relationship between the gut microbiome and the immune system in the context of neuroinflammation. The longitudinal arm investigates the impact of up to 7 days of fasting (maximum 400 kcal/day) followed by 12 months of time-restricted eating on PD patients.
Methods: For the cross-sectional arm, a total of 120 stool samples were collected from individuals with PD (n=60) and concomitant healthy controls (n=60). The longitudinal arm involved stool samples collected from 30 PD patients at regular intervals throughout the course of one year. The flash-frozen stool samples were cryomilled and the extraction of the biomolecular fractions was performed for the different multi-omics analyses.
Results: Using microbiome multi-omics data and contextualized prior knowledge in the Expobiome Map (https://expobiome.lcsb.uni.lu/), we identified several molecules of interest in PD. These include, but are not limited to, β-glutamate, ceramides and flagella-related proteins. Moreover, we are currently tracking the signatures of the identified microbiome-derived molecules in the longitudinal arm to make disease-related predictions and assess the effect of the treatment to alleviate PD-related symptoms.
Conclusions: Our study has identified relevant microbiome-derived molecules that could be of interest as biomarkers for PD and for evaluating the treatment's efficacy. The insights generated through this study will not only expand the knowledge on the PD-associated microbiome but also broaden the number of available therapeutic targets against the disease.

PFF AND/OR VIRAL VECTOR BASED MODELS FOR PRECLINICAL PROOF OF CONCEPT STUDIES TARGETING ALPHA-SYNUCLEIN PATHOLOGY

POSTERS: C07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Sofie Carmans[1], Eline Vonck[2], Wannes Dejonckheere[1], Veerle Baekelandt[2], Tom Cornelissen[1]
[1]reMYND, Cro, Leuven, Belgium, [2]KULeuven, Neuroscience, Leuven, Belgium

Aims: Parkinson's disease (PD) is the most common neurodegenerative movement disorder and is characterized by the accumulation of alpha-synuclein protein aggregates in the brain. Currently a lot of effort is put into studying the involvement of different forms of alpha-synuclein, i.e. monomeric, oligomeric, fibrillar and aggregated forms or different post translational modifications of the protein, and their contribution to disease progression. Targeting alpha-synuclein thus has an important therapeutic value. Since the research field lacks good and consistent animal models for preclinical assessment, we are developing mouse models based on the administration of sonicated preformed fibrils (PFF), either alone or in combination with viral vectors. To increase translatability for treatments which target human alpha-synuclein specifically, the development of models combining **human** PFF's and expression of **human** alpha synuclein via viral vectors is initiated.
Methods: Young wild-type mice are treated with combinations of AAV vectors and recombinant mouse or human PFF's (Stressmarq) via different administration routes. Motor performance is assessed followed by pathologic characterization.
Results: Unilateral and bilateral stereotactic injections in the dorsal striatum of young wild type mice with sonicated **mouse** PFF's showed clear pathology and robust neurodegeneration at varying time points (4-13 weeks) after PFF administration. Modeling **human** PFF spreading in mice is more difficult to acquire, due to the species barrier. Therefore hPPF's were administered via striatal injections after local overexpression of human alpha-synuclein by nigral AAV2/7-human-aSyn viral vector injection in young wild-type mice. Motor performance will be assessed followed by pathologic characterization of the model.
Conclusions: These alpha-synuclein based models can be of great importance to the research field to assess in vivo therapeutic interventions directed against alpha-synuclein pathology and more specifically human alpha-synuclein pathology.

ON THE WAY TO A NEW MODEL OF NEURODEGENERATION? FIRST EVIDENCE OF THE EXPRESSION OF GATA1 IN THE BRAIN

POSTERS: C07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Francesco Emanuele Bellomi[1], Claudia Caturano[1], Martyna Podgajna[1,2], Aleksandra Kaczyńska[1,2], Livia La Barbera[3], Paola Verachi[4], Maria Zingariello[1], Mario Falchi[1,4], Michal Wegrzynowicz[2], Simone Carotti[1], Marcello D'Amelio[3], Giorgio Vivacqua[1]
[1]Campus Bio-medico University of Rome, Microscopic And Ultrastructural Anatomy Laboratory, Rome, Italy, [2]Mossakowski medical research Centre Polish Academy of Sciences, Laboratory Of Molecular Basis Of Neurodegeneration, Warsaw, Poland, [3]Università Campus Bio-Medico di Roma, Laboratory Of Molecular Neurosciences, Rome, Italy, [4]Italian National Istitute of Health (ISS), Laboratory Of Confocal Microscopy, Rome, Italy

Aims: GATA1 is a transcription factor belonging to GATA family and involved in the development and the maturation of the hematopoietic lineage, while there are no clear evidence about the expression of GATA1 in neuronal lineage. A potential role for GATA1 in synucleinopathies has been suggested, since GATA1 regulates the transcription of SNCA gene, encoding for alpha-synuclein (a-syn) in red blood cells. In the present study, we aimed at deciphering the effects of GATA1 knocking down on the expression of a-syn and on the survival of different neuronal subtypes.
Methods: The study was performed using control mice with CD1 background and a mice model of GATA1 knock down (STOCK GATA1tm2Sho/J). Immunohistochemistry, immunofluorescence and RNAscope were used to analyze the expression of GATA1. Stereological count for different neuronal subtypes was performed in the olfactory bulbs and in the midbrain. Finally, the expression levels of a-syn were analysed by ELISA and the morphological features of GATA1 expressing neurons were visualized by Transmission Electron Microscopy (T.E.M.).
Results: The brains of CD1 mice were 21% larger in size than those of GATA1low mice. GATA1 is expressed in discrete brain-stem and telencephalic regions and predominantly in the olfactory bulbs. As expected, expression of GATA1 was reduced in GATA1low mice, where GATA1 expressing neurons appeared shrinker and morphologically altered. Stereological count and ELISA analysis demonstrate that the number of DA neurons and the expression of a-syn were altered in GATA1low mice.
Conclusions: Our results prove, for the first time, that GATA1 is expressed in the central nervous system. Regulation of SNCA gene and contribution to maturation and survival of DA neurons request detailed exploration to decipher the role of GATA1 in neurodegeneration.

OPTIMISATION OF A MOUSE MODEL FOR PARKINSON'S DISEASE BASED ON THE COMBINATION OF ASYN OVEREXPRESSION WITH ASYN FIBRIL SEEDS

POSTERS: C07.A. ANIMAL MODELS: TRANSGENIC RODENTS

Eline Vonck[1], Chris Van Den Haute[2], Tom Cornelissen[3], Veerle Baekelandt[1]

Aims: A-synuclein (αSyn) has been identified as a key protein in the pathophysiology of Parkinson's disease (PD). Since, this protein has gained a lot of interest as a possible biomarker and therapeutic target. Multiple αSyn-based rodent models have been developed, each reproducing specific features of the disease. However a more encompassing model mimicking the full spectrum of pathological and behavioural changes is needed. Therefore, we aim to create an αSyn-based model with increased construct validity by combining two established approaches to model PD, namely AAV-mediated overexpression of human αSyn with addition of human αSyn preformed fibrils (hPFFs).
Methods: Our first combination strategy is based on our established vector model where AAV2/7-CMVeSynapsin-hαSyn is injected in the substantia nigra of wild type mice. We build upon this by either co-injecting or sequentially injecting hPFFs in the striatum four weeks post-injection when stable transgene expression is achieved. Secondly, we are creating a peripheral model by administering vector and hPFFs either intracerebroventricularly (ICV) or intravenously (IV) via tail vein injections. To obtain robust transgene expression in the entire CNS we performed a study comparing different vector capsids using both administration routes.
Results: In our experimental design, local co-administration of hPFFs with vector did not lead to enhanced Lewy-like αSyn pathology or neurodegeneration. Therefore we administered striatal hPFFs when local overexpression is established. Behavioural changes and PD-like pathology will be assessed. In addition, IV administration of self-complementary vector PHP.eB-CMVeSynapsin-GFP was identified as most robust and efficient for targeting the entire CNS including spinal cord.
Conclusions: As current treatment options for PD are symptomatic and cannot halt disease progression or cure it, these αSyn-based models can be valuable in identifying novel therapeutic strategies intervening with human αSyn pathology in PD.

Aims: An important limitation in the development of therapies for Parkinson's disease treatment is the requirement for relevant pre-clinical disease models. A successful cell-based model for drug discovery would facilitate identification of relevant therapeutic targets and compounds to modulate those targets. We propose to develop a new *in vitro* model for Parkinson's disease based on the recently established human induced pluripotent stem cells (hiPSCs)-derived BrainSphere (BS) cell culture system.
Methods: BS were prepared from hiPSCs. After differentiation, BS were treated with alpha-synuclein monomers (20 ng), alpha-synuclein pre-formed fibrills (PFFs) (20 ng) or PBS during 72 h. Medium was removed and fresh medium without alpha-synuclein was added. BS were analysed 14 days after treatment.
Results: Exposure to alpha-synuclein PFF led to a significant increase of total alpha-synuclein, insoluble pSer129 alpha-synuclein and the presence of alpha-synuclein aggregates. The presence of alpha-synuclein aggregates was associated with a decrease in TH dopaminergic neurons. Moreover, LAMP-2A protein level was decreased in BS treated with alpha-synuclein PFF. Treatment with alpha-synuclein monomer did not result in the presence of alpha-synuclein aggregation or dopaminergic cell death.
Conclusions: Our results demonstrate that human BS exposed to alpha-synuclein PFFs mimic pathological mechanisms previously identified in Parkinson's disease human brain samples and animal models, and therefore constitute a new promising and versatile *in vitro* model for this disease.

Aims: Growing evidence suggest that type 2 diabetes is a risk factor for Parkinson's disease (PD). The aim of this project is to examine whether direct application of streptozotocin (STZ; used for generation of diabetes in animals) to brain region affected in PD (striatum) can induce characteristic PD symptoms.
Methods: Adult male Wistar rats were given intrastriatally STZ unilaterally or bilaterally (0.75 or 1.5 mg/kg per striatum) or vehicle and one month after, cognitive, behavioural, metabolic and motoric functions were tested by RotaRod, Novel Object Recognition, Passive Avoidance, Morris Water Maze, Elevated Plus Maze, CatWalk and PET scan. Levels of tyrosine hydroxylase (TH), insulin receptor (IR), D1, AMPAR and ChAT were measured in hippocampus and striatum.
Results: STZ rats showed deficits in motoric functions, spatial learning and memory, fear conditioned and recognition memory, and anxiety-like behaviour. Deficit was found more pronounced after bilateral administration in comparison to unilateral and with higher bilateral STZ dose. Brain glucose uptake was found increased after lower STZ dose and decreased after higher one in comparison to vehicle. Only higher STZ dose induced acute weight loss in comparison to vehicle. STZ decreased levels of TH and IR in stratum independently on the administration method and a dose, while TH levels remained unchanged in hippocampus.
Conclusions: The results demonstrate the development of PD hallmark symptoms after instrastriatal STZ administration, indicating its possible use as a new PD model. This work was funded by University of Zagreb project (10106-23-2439) and the Scientific Centre of Excellence for Basic, Clinical and Translational Neuroscience (project "Experimental and clinical research of hypoxic-ischemic damage in perinatal and adult brain"; GA KK01.1.1.01.0007 funded by the European Union through the European Regional Development Fund).

GUT MICROBIOTA-MEDIATED MODULATION OF PARKINSON'S DISEASE-LIKE PHENOTYPES IN C. ELEGANS BY ΔHNS E. COLI: INSIGHTS INTO THE ROLE OF MICROBIAL GENES IN NEURODEGENERATION

POSTERS: C07.C. ANIMAL MODELS: NON-MAMMALIAN MODELS ,OTHER

Eun Jeong Lee
Ajou University School of Medicine, Department Of Brain Science, Suwon, Korea, Republic of

Aims: Parkinson's disease (PD) patients often exhibit elevated levels of methylglyoxal (MG), a reactive carbonyl compound linked to the formation of advanced glycation end products and various pathologies, including neurodegenerative diseases. Drawing from prior research that demonstrated the lifespan-extending effects of low MG-producing *Δhns Escherichia coli (E. coli)* on *Caenorhabditis elegans (C. elegans)* (Shin et al., 2020, PNAS), we hypothesized that this *E. coli* strain might alleviate PD-like symptoms, particularly dopaminergic neuron neurodegeneration.
Methods: 1. *Δhns E. coli*-fed *C. elegans* with 6-OHDA treatment 2. Analysis of single cell RNA-seq data from the substantia nigra of PD patients 3. The expression of H-NS in the fecal samples from PD patients 4. The expression of human genes affected by methylglyoxal
Results: *Δhns E. coli* effectively mitigated the degeneration of dopaminergic neurons induced by 6-OHDA (6-hydroxydopamine) in *C. elegans*. Furthermore, we discovered that synapse-related genes, upregulated in *Δhns E. coli*-fed *C. elegans*, continued to exhibit increased expression even under 6-OHDA treatment. Remarkably, the expression levels of these genes were found to be reduced in the substantia nigra of PD patients, based on publicly available single-cell RNA-seq data. What's even more striking, our investigation of fecal samples from PD patients revealed an upregulation of the H-NS protein compared to a healthy control group. Consequently, we explored whether the human genes corresponding to those restored in *Δhns E. coli*-fed *C. elegans* could be influenced by MG levels. Indeed, the expression of these genes was reduced by MG but restored by MG scavengers.
Conclusions: These findings suggest the possibility of utilizing gene modifications in microbiota to reverse neurodegenerative phenotypes in the host, offering a potential therapeutic avenue for intervening in PD by targeting the gut microbiota.

TOXIC INTERPLAY BETWEEN SMALL DIPEPTIDE PROTEIN REPEATS AND TAU IN TAUOPATHIES

POSTERS: D01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Nemil Bhatt[1], Nicha Puangmalai[1], Cynthia Jerez[1], Mauro Montalbano[2], Shailee Gandhi[1], Rakez Kayed[2]
[1]University of Texas Medical Branch, Neurology, Galveston, United States of America, [2]The University Of Texas Medical Branch, Neurology, Galveston, United States of America

Aims: Tauopathies, including Alzheimer's Disease and Frontotemporal Dementia, are characterized as intracellular lesions composed of aggregated tau proteins. Soluble tau oligomers are shown to be one of the most toxic species and are responsible for the spread of tau pathology. Recent studies have found that several proteins such as amyloid b, a-synuclein, and TDP-43 can aggregate tau. In this study, we investigated the ability of small metabolites like *C9orf72* associated dipeptide protein repeats (DPRs) to interact with and aggregate tau to form toxic soluble tau oligomers.
Methods: We have developed various models which express dipeptide protein repeats to understand the interaction between short peptides and tau. The dipeptide protein repeat induced tau aggregates were characterized using biophysical, as well as biochemical assays in vitro and in cellular models. Furthermore, we evaluated their toxicity, and seeding potency to understand the biological effects of this interaction.
Results: Our results suggest the propensity for DPRs, especially glycine-arginine and proline-arginine repeats to form oligomeric structures which interact and seed tau in a prion like fashion. This interaction leads to the production of tau oligomers, which trigger subsequent neurodengeration. Tau oligomers also trigger alterations in the microtubule dynamics in cell lines as well as primary neuronal culture systems.
Conclusions: Many studies have investigated the toxicity of small protein repeats, however, the role of DPR oligomers in inducing tau aggregation is still unclear. Thus, the ability to understand the toxic interplay between small peptide repeats and tau oligomers has great potential to further the understanding of tau progression and aid in the development of targeted therapeutics.

THE GUT-BRAIN AXIS IN ALS: A SYSTEMATIC REVIEW AND META-ANALYSIS ASSESSING THE ROLE OF THE GUT AND ITS MICROBIOME IN AMYOTROPHIC LATERAL SCLEROSIS

POSTERS: D01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Fergal Waldron, Alexander Jackson, Rollo Press, Holly Spence, Jenna Gregory
University of Aberdeen, Institute Of Medical Sciences, Aberdeen, United Kingdom

Aims: To investigate the role of the gut and it's microbiome in amyotrophic lateral sclerosis by carrying out a systematic review and meta-analysis of relevant studies from the clinical and pre-clinical literature.
Methods: Here we present a systematic review and meta-analysis assessing the role of the gut-brain axis in ALS including preclinical and clinical studies examining both the microbiome, and non-microbial related pathological pathways. Database searches of Medline, PubMed, and Embase were performed using pre-determined search terms, and both qualitative and quantitate data were extracted for systematic literature review and meta-analysis respectively.
Results: Studies examining differences in the microbiome constituents between (i) people with ALS and healthy controls, and (ii) animals of preclinical models of ALS and controls, largely show no significant differences, noting relatively small sample sizes and both inter- and intra-study heterogeneity. However, interventions targeting the gut microenvironment and/or gut-resident pathologies demonstrate a significant improvement in disease outcomes, such as motor function and survival.
Conclusions: Our findings suggest that interventions either targeting the gut microenvironment or alleviating gut pathology offer a promising therapeutic route for treatment of ALS.

INVESTIGATING MICROGLIA MEDIATED NEUROINFLAMMATION IN STEM CELL DERIVED MODELS OF C9ORF72 AMYOTROPHIC LATERAL SCLEROSIS

POSTERS: D01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Yujing Gao[1], Harpreet Saini[2], Greg O'Sullivan[1], Elena Di Daniel[1], Carla F. Bento[1], Lizzie Glennon[1], Daniel Tams[1], Brent Graham[1]
[1]Astex Therapeutics Ltd, Translational Bioscience, Cambridge, United Kingdom, [2]Astex Therapeutics Ltd, Informatics, Cambridge, United Kingdom

Aims: Amyotrophic Lateral Sclerosis (ALS) or Motor Neurone Disease (MND) is a neurodegenerative disorder caused by the progressive loss of motor neurons. The mechanisms underlying ALS are unclear, although neuroinflammation is a major factor contributing to disease pathology. In ALS patients and animal models, brain resident macrophages called microglia demonstrate altered function, which can be detrimental to neuronal health. To investigate changes in microglia in ALS and their impact on motor neurons, we assessed monocultures and cocultures of microglia and motor neurons derived from human induced pluripotent stem cells (iPSC) carrying the hexanucleotide repeat expansion (HRE) in C9ORF72, a common genetic cause of ALS.
Methods: Human iPSCs were differentiated into microglia and motor neurons using established small molecule differentiation protocols. Generation of microglia and motor neurons were verified by expression of established cell lineage markers. The inflammatory profiles of microglia upon lipopolysaccharide (LPS) stimulation were assessed using enzyme-linked immunosorbent assays, dot blots and real time PCR. The transcriptomic profiles of microglia/motor neuron cocultures were assessed using single cell RNA sequencing.
Results: Microglia with loss of function (LOF) of C9ORF72 (HRE or knockout) showed reduced capacity for cytokine production compared to isogenic and non-isogenic controls. Specifically, the LPS-induced expression and secretion of IL-6 were reduced in C9ORF72 LOF microglia. In coculture models, we performed single cell RNA sequencing and investigated the transcriptomes of microglia and motor neuron populations independently, identifying genes of interest.
Conclusions: C9ORF72 LOF attenuated the inflammatory capacity of stimulated microglia by reducing the levels of cytokine secretion and altering gene expression. Microglia mediated neuroinflammation plays an important role in the progression of ALS, and the impact on neuronal health and function is currently under investigation.

INVESTIGATING ALTERATIONS IN THE HNRNP NETWORK IN FRONTOTEMPORAL DEMENTIA.

POSTERS: D01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Ariana Gatt, Katherine Fodder, Yaz Buhidma, Christina Toomey, Conceicao Bettencourt, Tammaryn Lashley
University College London, Neurodegenerative Disease, LONDON, United Kingdom

Aims: Heterogenous Nuclear Ribonucleoproteins (HnRNPs) are a family of RNA-binding proteins which are widely expressed in the brain. TDP-43, a well known HnRNP is present in pathological inclusions in FTLD (frontotemporal lobar degeneration) and FTLD cases are now classified into subtypes based on the pattern of TDP-43 pathology observed. We hypothesized that other HnRNPs might be playing a role in the pathogenesis of FTLD. We aimed to elucidate how the HnRNP network is altered in the presence of TDP-43 pathology.
Methods: This study encompassed a multi-omic approach to investigate changes occurring in the HnRNP network in FTLD. Different FTLD subtypes (FTLD-TDP A (C9orf72 negative / positive), FTLD-TDP C) and controls were analysed. A semi-quantitative pathological assessment was carried out for TDP-43 pathology and other HnRNPs by immunohistochemistry. Transcriptomic analysis was undertaken on bulk tissue and via single-cell RNA sequencing. DNA methylation data was analysed to observe whether methylation of HnRNPs was up or downregulated in different FTLD subtypes. Lastly, proteomic analysis was carried out to identify changes at the protein level.
Results: Pathological assessment revealed that multiple HnRNPs are mislocalised in FTLD, irrespective of TDP-43 pathological subtype. HnRNPs which showed upregulation at the bulk RNA-sequencing, methylation and proteomics level, did not, however, necessarily show overt changes in terms of pathology (e.g. HnRNP F). Overall, changes in the HnRNP network interactome were observed in the different pathological subtypes of FTLD.
Conclusions: Currently, TDP-43 pathology serves at the hallmark for post-mortem diagnosis of FTLD. We find that other RNA-binding proteins belonging to the same HnRNP family also exhibit pathological changes in FTLD and are also likely to have an effect on neuronal health and should therefore be studied in conjunction with TDP-43 in FTLD.

THE INTERPLAY BETWEEN ELECTROSTATIC AND HYDROPHOBIC FORCES IN TDP-43 PHASE SEPARATION

POSTERS: D01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Raza Haider[1], Brandon Shipley[2], Krystyna Surewicz[1], Michael Hinczewski[2], Witold Surewicz[1]
[1]Case Western Reserve University, Physiology And Biophysics, Cleveland, United States of America, [2]Case Western Reserve University, Physics, Cleveland, United States of America

Aims: 1. Ascertain the effect of C-terminal phosphomimetic substitution on TDP-43 liquid-liquid phase separation (LLPS) C-terminal phosphorylation of TDP-43 is a biomarker of proteinopathy, but few studies have investigated its effect on LLPS. We purified variants of the low complexity domain (LCD), which drives TDP-43 LLPS, with phosphomimetic substitutions at 2-to-4 pathologically-relevant sites (S403, S404, S409, S410), and explored how LLPS of these variants differed from that of WT protein. 2. Analyze forces driving C-terminal phosphomimetic TDP-43 LLPS via coarse-grained simulations Coarse-grained modeling probed the electrostatic and hydrophobic interactions contributing to TDP-43 LLPS. These simulations quantified total intermolecular electrostatic and hydrophobic forces present during LLPS, as well as pairwise/residue-residue intermolecular electrostatic and hydrophobic forces between different regions of the protein.
Methods: 1. Turbidimetic and microscopic studies Turbidity (optical density at 280 nm) and microscopy were used to ascertain droplet formation. 2. Circular dichroism spectroscopy CD profiles were used to evaluate α-helical content of proteins. 3. Coarse-grained molecular modeling Coarse-grained simulations were used to model LLPS and evaluate the intermolecular hydrophobic and electrostatic forces involved.
Results: While WT protein LLPS is enhanced by increasing salt concentration, phosphomimetic TDP-43 LLPS displayed a bi-phasic salt dependence; NaCl initially inhibited LLPS, until a point beyond which increasing NaCl further increased LLPS propensity. Coarse-grained simulations revealed hydrophobic forces drove LLPS for phosphomimetic proteins, but electrostatic interactions modulated these hydrophobic forces by causing the phosphomimetic proteins to pack differently than WT protein within droplets. The transiently α-helical region was still present in the phosphomimetic variants and remained important for their LLPS.
Conclusions: C-terminal phosphomimetic substitution of TDP-43 LCD at pathologically-relevant sites confers a bi-phasic dependence on NaCl concentration as a result of electrostatic interactions tuning the hydrophobic forces that drive LLPS.

CELL CYCLE DYSREGULATION IN NEURONS FROM C9ORF72 CARRIERS

POSTERS: D01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Rodrigo Lopez Gonzalez, Imran Ali
Cleveland Clinic Lerner research Institute, Neurosciences, Cleveland, United States of America

Aims: The GGGGCC (G4C2) repeat expansion in C9ORF72 is the most common genetic cause of amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). Previous data shows an increase in DNA damage and the generation of reactive oxygen species (ROS) in iPS derived neurons from C9ORF72 carriers. Dysregulation of cell cycle suppression in post-mitotic neurons caused by DNA instability and chronic insults including oxidative stress, may lead to cell cycle re-entry and neuronal death. Cyclin and CDK over expression have been observed in several neurodegenerative disorders including Alzheimer's disease (AD), Parkinson's disease (PD), and ALS. Here, we analyzed cell cycle markers in post-mitotic iPSC-derived neurons from C9ORF72 carriers.
Methods: We differentiated induced pluripotent cells (iPSs) from *C9ORF72* carriers and controls into high-yield post-mitotic neurons. All the iPS lines were previuosly fully characterized. We differentiated 3 controls and *3 C9ORF72* iPS-lines and analyzed cell cycle markers by qPCR and western blot at different time points: 1, 1.5 and 2-month-old iPS derived neurons.
Results: We found a significant age dependent increase in Ki67 and Geminin (GMNN), in 2- month-old iPS-derived neurons from *C9ORF72* carriers as compared to controls, but no significant differences on 1-month and 1.5-month-old MN cultures. We further analyzed the expression of several cyclins and CDKs by qPCR. We found that cyclin A2 (CCNA2), cyclin B1 (CCNB1), cyclin B2 (CCNB2), CDK1, CDK2 and CDK4 are significantly upregulated in 1.5-month-old, and 2-month-old *C9ORF72 neurons* as compared to controls. we found a similar increase in the blot cyclin A2 and cyclin B2 proteins by western blot in 2-month-old *C9ORF72 neurons.*
Conclusions: Age-dependent increase in cell division markers, cyclins and CDKs in iPSC derived post-mitotic neurons from C9ORF72 carriers as compared to controls in gene expression and protein levels.

TDP-43 CONDENSATION DYNAMICS BEHAVIOUR INFLUENCES PATHOLOGY-RELATED TDP-43 PHOSPHORYLATION

POSTERS: D01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Simone Mosna[1,2], Yelyzaveta Zadorozhna[1,2], Dorothee Dormann[1,3]
[1]Johannes Gutenberg University Mainz, Institute Of Molecular Physiology, Mainz, Germany, [2]IPP, International Phd Program, Mainz, Germany, [3]Institute of Molecular Biology gGmbH, Imb, Mainz, Germany

Aims: TDP-43 is the major aggregating protein in ALS and FTD, as well as 50% of AD patients. The deposited TDP-43 aggregates are hyperphosphorylated, and C-terminal S409/S410-phosphorylation is considered to be a pathological hallmark of these disorders. Our previous work showed that C-terminal TDP-43 phosphorylation, as seen in patients, causes a more liquid-like behaviour of TDP-43 condensates and renders TDP-43 less prone to aggregation. Based on these findings, we proposed that C-terminal TDP-43 phosphorylation could be a protective mechanism against TDP-43 aggregation. Therefore, we now aim to understand what triggers C-terminal TDP-43 phosphorylation in cells and how the TDP-43 condensation/aggregation status influences this pathology-related modification.
Methods: We use rationally designed mutations to tune TDP-43 phase separation and aggregation. In a cellular model system with stable expression of the different GFP- or MYC-tagged TDP-43 variants with different condensation properties, we quantify TDP-43 S409/S410-phosphorylation induced by cellular stress. Additionally, we use phosphoproteomics to identify the induced phosphorylation sites. In an in vitro kinase assay with recombinant TDP-43 and CK1d, we determine how the efficiency of TDP-43 phosphorylation is influenced by TDP-43 condensation status.
Results: In the cellular model system, aggregation-prone TDP-43 variants show slightly reduced S409/S410 phosphorylation levels in comparison to TDP-43 wild-type (WT), whereas liquid-like variants show a stronger decrease in S409/S410 phosphorylation. In vitro, CK1d-mediated hyperphosphorylation of TDP-43 is strongly accelerated upon phase separation of TDP-43. In line with the cellular data, aggregation-prone TDP-43 variants showed slower TDP-43 phosphorylation kinetics, and liquid-like or monomeric variants showed little to no hyperphosphorylation.
Conclusions: C-terminal TDP-43 phosphorylation can be induced by specific cellular stressors. TDP-43 hyperphosphorylation is favoured by the formation of physiological TDP-43 condensates, whereas condensates with altered dynamics reduce kinase efficiency.

DIFFERENTIAL NEURONAL VULNERABILITY TO C9ORF72 REPEAT EXPANSION DRIVEN BY XBP1 TRANSCRIPTION SIGNATURE.

POSTERS: D01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Dunxin Shen[1], Alec Vincent[1], Evan Udine[2], Yaz Buhidma[3], Carlo Frigerio[4], Marka Van Blitterswijk[5], Tammaryn Lashley[3], Teresa Niccoli[1]
[1]UCL, Iha, London, United Kingdom, [2]Mayo Clinic, Department Of Neuroscience, Jacksonville, United States of America, [3]Queen Square Brain Bank for Neurological Disorders, Department Of Clinical And Movement Neuroscience, London, United Kingdom, [4]UCL, Dri, London, United Kingdom, [5]Mayo Clinic, Neuroscience, Jacksonville, United States of America

Aims: C9orf72 repeat expansion mutation (C9) is the most common genetic cause of sporadic and familial Amyotrophic Lateral Sclerosis(ALS) and Frontotemporal Dementia (FTD). The aim of this study was to determine why cell death is triggered only in specific neuronal populations, while others remain 'protected' or are less susceptible to disease is still an open question. In particular, whether it's the way neurons respond to the accumulation of toxic insults or the initial neuronal transcriptional state that determines their vulnerability is still unknown.
Methods: We have carried out a large scale profiling of single cell transcription signature throughout disease development in a *Drosophila* model of C9 toxicity.
Results: We followed transcriptional changes across the development of disease and tracked cell populations during disease progression. We have identified cell populations which are depleted in response to C9 repeat expression, and therefore vulnerable to toxicity. On the other hand, other populations are resistant to toxicity, and maintain their cell number during disease progression. We find that a major determinant of vulnerability is the transcriptional state of the cell before it's exposed to C9 repeat expression and that this resistant transcriptional state is conserved. We identify Xbp1 as a key transcription factor in regulating the trascriptional state of a resistant population and we show that upregulating Xbp1 can rescue C9 toxicity in our fly models.
Conclusions: We find that a major determinant of vulnerability is the transcriptional state of the cell before it's exposed to C9 repeat expression and that this resistant transcriptional state is conserved, we also show that cells resistant to disease have a higher expression of pathways involved in maintenance of proteostasis.

PROGRANULIN MUTATIONS IN MICROGLIA AND ITS IMPACT IN NEURODEGENERATION

POSTERS: D01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Paula Polanco Miquel[1,2], Laura Fumagalli[1,2], Jessie Premereur[1], Diede Van Den Biggelaar[1,2], Maxim Van Hoek[1,2], Tim Meese[1,2], Bob Asselbergh[2], Renzo Mancuso[1,2]
[1]VIB Center for Molecular Neurology, Microglia And Inflammation In Neurological Disorders (mind) Lab, Antwerpen, Belgium, [2]University of Antwerp, Biomedical Sciences, Antwerpen, Belgium

Aims: Loss of function mutations in the progranulin gene (GRN), are the second most common genetic cause of frontotemporal lobar degeneration (FTLD), a disorder that accounts for 10-20% of all young-onset dementias. GRN, as other risk genes associated with dementia, is primarily expressed in microglia, the immune cells of the brain. However, the functional consequences of granulin deficiency on human microglia biology remain unknown.
Methods: Using CRISPR/Cas9 genome editing technology, we generated a *GRN* knockout (KO) induced pluripotent stem cell (iPSC) line. We confirmed the knockout using sanger sequencing and immunoblot. We have differentiated the *GRN*-KO line into microglia using our MIGRATE protocol. We have performed a series of *in vitro* experiments exploring whether GRN deficiency leads to functional alterations.
Results: We found that GRN-deficient microglia show altered transcriptomic and functional features associated with phagocytosis and lysosomal dysfunction. To better understand the effect of microglial GRN deficiency *in vivo*, we xenotransplanted the iPSC-derived microglia progenitors into the mice brain and performed histological assessment of the mouse brain.
Conclusions: Overall, our results reveal an essential role of *GRN* in regulating microglial physiology and potentially highlighting disease mechanisms contributing to *GRN*-FTLD.

Aims: Around 10% of all frontotemporal lobar degeneration patients display neuronal inclusions containing the fused in sarcoma protein (FTLD-FUS). Atypical FTLD-U (aFTLD-U) is the most common FTLD-FUS subgroup and is associated with a uniform presentation of a very early-onset, severe behavioral FTD phenotype, often without a family history. The etiology of FTLD-FUS is still largely unknown, hampering the development of effective therapies. To unravel the molecular mechanisms driving the disease and enable translational studies, we aim to generate and characterize human induced pluripotent stem cell (iPSC)-derived models from patients diagnosed with FTLD-FUS.
Methods: Initially, we reprogrammed four independent lymphoblastic lines (3 aFTLD-U, 1 healthy control) originating from the International Consortium on FTLD-FUS. Subsequently, we guided their differentiation into neuronal progenitor cells and eventually into cortical neurons. One line containing a genetically engineered mutation in FUS (p.Arg495X) that leads to amyotrophic lateral sclerosis (ALS) with FUS pathology and the corresponding isogenic control line were also included to compare and contrast pathological hallmarks in FTLD-FUS with ALS-FUS.
Results: We confirmed the expression of distinct pluripotency markers in all iPSC lines. To validate the success of neural induction and establish the cortical identity of the neural tissue, we characterized these lines using well-established markers. Our next steps will focus on exploring whether cortical neurons derived from aFTLD-U patients manifest pathological features associated with FTLD. Specifically, we will investigate FUS mislocalization or aggregation, as well as the deposition of other proteins known to co-accumulate with FUS in FTLD-FUS patients, including EWS, TAF15 and TNPO1.
Conclusions: By developing a human iPSC model of FTLD-FUS using patient-derived cells, we expect to initiate efforts for targeted therapies to be developed, ultimately leading to clinical trials and new treatment options for patients.

UNDERSTANDING THE NEUROPATHOLOGICAL CONSEQUENCES OF NEK1 MUTATIONS IN ALS

POSTERS: D01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Olivia Rifai[1], Danielle Leighton[2], Judi O'Shaughnessy[1], Fergal Waldron[3], Jenna Gregory[3]
[1]University of Edinburgh, Centre For Clinical Brain Sciences, Edinburgh, United Kingdom, [2]University of Glasgow, School Of Psychology & Neuroscience, Glasgow, United Kingdom, [3]University of Aberdeen, Institute Of Medical Sciences, Aberdeen, United Kingdom

Aims: NEK1, or (never in mitosis gene-A)-related kinase 1, is a serine/threonine kinase with loss-of-function and missense variants that have recently been associated with an increased risk of ALS. However, the cellular consequences of NEK1 mutation, as well as the clinical and pathological phenotypes related to specific NEK1 variants, remain undescribed, as no study thus far has pathologically examined *post-mortem* tissue from these rare cases. Here we set out to undertake the first characterisation of neuropathological phenotypes associated with NEK1 mutations in ALS, in a case series.
Methods: Our study characterises *post-mortem* tissue from three Scottish patients with a NEK1 mutation who went on to develop ALS. Using immunohistochemistry, we evaluated the expression and distribution of NEK1 as well as phosphorylated TDP-43 (pTDP-43) aggregates, a pathological hallmark of ALS, in the motor cortex and amygdala. We additionally examined the abundance and distribution of *NEK1* mRNA molecules using *BaseScope™ in situ* hybridisation.
Results: For one case with a p.Arg261His missense mutation, we observed increased *NEK1* mRNA expression and abundant NEK1-positive cytoplasmic aggregates, with the same morphology and distribution as the pTDP-43 aggregates. By contrast, the other two NEK1-ALS cases exhibited reduced *NEK1* mRNA expression and an absence of NEK1-positive cytoplasmic aggregates, indicating loss of NEK1 function.
Conclusions: Our findings suggest a spectrum of clinical and neuropathological consequences for NEK1 variants in ALS.

FUNCTIONAL PHENOTYPIC DISEASE MODELS WITH HUMAN IPSC-DERIVED SPINAL MOTOR NEURON CULTURES FOR AMYOTROPHIC LATERAL SCLEROSIS

POSTERS: D01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Olaf Schroeder
NeuroProof Systems GmbH, R&d, Rostock, Germany

Aims: Amyotrophic lateral sclerosis, ALS, is a fatal disease with not fully understood disease mechanisms. Therefore, phenotypic disease models are needed for the development of new therapies. The disease occurs in familial and sporadic forms, fALS and sALS. Although only about 10% of cases are familial with a known hereditary origin, they are important for disease modeling. Known fALS forms have mutations in the SOD1, C9orf72, TDP-43, FUS, and other genes.
Methods: Human induced pluripotent stem cells with fALS mutations can be differentiated toward spinal motor neurons. They are canonical disease models that reflect phenotypic disease symptoms. In our hands, iPSC-derived spinal motor neurons with SOD1 D90A, SOD1 A4V, three C9orf72 mutations, TDP43 G298S, and TDP43 A384V mutation could be cultivated on microelectrode array plates for 14 to 28 days.
Results: First electrophysiological activity can be observed after 7 days and lasts more than 5 weeks. After 14 days in vitro, a reliable hyperexcitation of the disease motor neurons compared to the wild-type neurons can be observed for C9orf72 and SOD1 mutated forms but not for the TDP43 mutated forms. Measurement of NF-L and an MTT assay delivered complementary results. We tested riluzole, TUDCA, and spermidine in these assays. Riluzole demonstrated in all assays a robust effect.
Conclusions: Observation of cells from 14 to 28 div delivers significant information on compound action profiles.

DECIPHERING THE HYPE OF EIF5A: MECHANISMS THAT DRIVE TDP-43 NEUROPATHOGENESIS IN ALZHEIMER DISEASE AND RELATED DEMENTIA.

POSTERS: D01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Christopher Saunders[1,2], Patricia Rocha-Rangel[2], Jerry Hunt[2,3], Peter Nelson[4], Ramon Sun[5], Mathew Gentry[5], Daniel Lee[2,3], Maj-Linda Selenica[1,2]
[1]University of Kentucky, Molecular And Cellular Biochemistry, Lexington, United States of America, [2]University of Kentucky, Sanders-brown Center On Aging, Lexington, United States of America, [3]University of Kentucky, Neuroscience, Lexington, United States of America, [4]University of Kentucky, Department Of Pathology & Laboratory Medicine, Lexington, United States of America, [5]University of Florida, Biochemistry And Molecular Biology, Gainsville, United States of America

Aims: TAR DNA-binding protein 43 (TDP-43) pathology is associated with clinical dementia in Alzheimer's disease (AD) patients and limbic-predominant TDP-43 encephalopathy (LATE). Regional decline in glucose metabolic rate linked to tau and amyloid-beta pathologies suggest that impaired brain metabolism is one of the earliest and most consistent features of AD. Despite decade-long efforts, the impact of TDP-43 pathology on neurometabolic dysregulation remain poorly understood. eIF5A is the only protein undergoing hypusination (eIF5A^{Hyp}) via deoxyhypusine synthase (DHS) and deoxyhypusine hydroxylase (DOHH) activity converting a single lysine to a *hypusine moiety*. Considering the role of eIF5A^{Hyp} in mitochondrial function, we investigated how exacerbated hypusination affects brain metabolic profile in a TDP-43 animal model.
Methods: Heterozygous wtTDP-43 mice (TAR^{het}) expressed rAAV-DHS/DOHH or rAAV-eIF5A for 2 months. We applied biochemical and immunohistochemical analysis to assess cerebral TDP-43 pathology and neuronal loss. Comprehensive metabolome coverage via GCMS was performed to measure cerebral metabolite levels. RNAseq and NanoString analysis were applied to identify transcriptomic profiles.
Results: Biochemical analysis demonstrated increased phosphorylated TDP-43 levels following DHS/DOHH expression. Interestingly, metabolome analysis revealed significant reduction of cortical pyruvate, lactate and several other metabolite levels following induced neuronal eIF5A^{Hyp}. In agreement, bulk RNAseq and the NanoString analyses identified upregulation of genes in mitochondrial OXPHOS pathway, carbohydrate metabolism, and oxidative stress uniquely pertinent to DHS/DOHH. Notably, DHS and hypusine levels are increased in AD and AD+LATE-NC brain, also corroborated in TDP-43 brain tissue.
Conclusions: Our study suggests that hypusination drives the cerebral metabolic dysregulation observed in rAAV-DHS/DOHH expressing mice, suggesting eIF5A^{Hyp} as a metabolic switch in controling pyruvate supply and ATP production. Our findings provide pioneering evidence for eIF5A^{Hyp} regulation of brain glucose hemostasis and mitochondrial impairment under energy-demanding TDP-43 proteinopathy state in ADRD.

RECOGNITION OF CYTOSOLIC TDP-43 CONDENSATES BY THE SELECTIVE AUTOPHAGY MACHINERY

POSTERS: D01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Yongwon Suk[1,2], Simone Mosna[1,2], Dorothee Dormann[1,3]
[1]JGU Mainz, Institute Of Molecular Physiology, Mainz, Germany, [2]IPP, International Phd Program, Mainz, Germany, [3]Institute of Molecular Biology gGmbH, Imb, Mainz, Germany

Aims: Cytoplasmic TDP-43 inclusions are a hallmark of ALS/FTD pathology. Here, we aim to investigate the molecular mechanisms underlying the recognition of aberrant TDP-43 condensates/aggregates by the cellular degradation machinery. A further aim is to check whether the biophysical state of TDP-43 condensates influences TDP-43 degradation and recognition by the degradation machinery.
Methods: In doxycycline-inducible stable cell lines expressing GFP-tagged C-terminal fragments (CTFs) of 25 kDa (TDP-43$_{220-414}$) or mutant variants (more liquid-like or more aggregation-prone), we examine TDP-43 CTF condensates upon inhibition of the proteasome or autophagy. Using an unbiased proteomics approach, we identify differential interactors of more liquid-like versus more solid-like TDP-43 CTF condensates. Furthermore, we examine colocalization of autophagy-related factors with TDP-43 CTF condensates.
Results: We demonstrate that TDP-43 CTFs form large cytosolic condensates upon inhibition of the proteasome, e.g. with MG132 or Bortezomib. TDP-43 CTF condensates do not colocalize with stress granule marker proteins, e.g. G3BP1 or ATXN2, demonstrating that they are distinct from stress granules. TDP-43 CTF condensates exhibit distinct dynamic behavior at different timepoints after inhibitor treatment and show distinct degradation kinetics. TDP-43 CTF condensates colocalize with autophagy-related factors, such as p62/SQSTM1, UBQLN2, and NBR1. These and other factors were also found to associate with TDP-43 CTF condensates in an unbiased proteomics experiment.
Conclusions: Our study suggests that TDP-43 CTFs are degraded by the proteasome, but upon proteasome inhibition accumulate to high levels and then form cytosolic condensates that are distinct from stress granules. The formed TDP-43 CTF condensates co-localize with autophagy-related factors, suggesting that they are recognized by specific autophagy receptors and cleared by autophagy. Future studies will test the hypothesis that the biophysical state of TDP-43 condensates governs their degradation mechanism.

Aims: In the last decade, numerous studies have highlighted the importance of DNA methylation in the functioning of the central nervous system, yet the genome-wide contribution of epigenetic changes to the development of FTLD remains largely unexplored and constitutes the aim of the present study.
Methods: We performed the largest FTLD methylation study to date, focused on patients with TDP-43 pathology (FTLD-TDP), where we included 192 matched pairs of frozen post-mortem tissue samples from frontal cortex (FCX) and cerebellum (CER) regions (N=394; Mayo Clinic Brain Bank). Samples were divided into 6 groups: FTLD-TDP types A, B and C, *GRN* mutation carriers, *C9ORF72* repeat expansion carriers (N=25 per group); and neurologically normal controls (N=42). For each sample, DNA methylation was profiled using reduced representation bisulfite sequencing. MethylKit, DMRFinder and EdgeR tools were employed to compare patient groups *versus* controls at the CpG level as well as differentially methylated regions, either including all genomic locations or focusing specifically on promoters.
Results: We identified differentially methylated CpGs both unique and shared between patient groups and/or brain regions. Importantly, we found multiple CpGs within *NFATC1* across all patients, possibly impacting gene transcription and neuroinflammation. At the DMR level, we identified 93 loci in FCX (FDR<0.05; 53 hypomethylated; 40 hypermethylated *versus* controls) and 138 loci in CER (79 hypomethylated; 59 hypermethylated *versus* controls). Results were prioritized for functional follow-up using an in-house built scoring system, which highlighted an important role for the hexosamine biosynthetic pathway in FTLD-TDP. Integration of the methylome data with already existing genome, transcriptome and proteome data is currently ongoing.
Conclusions: Overall, our results suggest that epigenetics plays a role in FTLD-TDP pathophysiology and highlights the need for further studies to profile additional epigenetic layers.

UNC13A TARGETING SPLICE SWITCHING ASOS AMELIORATE TDP-43 DEPENDENT MIS-SPLICING PHENOTYPES IN FTD AND ALS

POSTERS: D02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Marisa Kamelgarn, Nicholas Fiore, Jayce Brown-Culbertson, Yasmin Hamwi, Maria Banuelos, James Chow, Sandy Hinckley
QurAlis, Discovery, Cambridge, United States of America

Aims: Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disease characterized by the loss of neurons in the spinal cord, brainstem, and brain. A defining feature of both sporadic and familial disease is the cytoplasmic mis-localization of TAR DNA Binding Protein- 43 (TDP-43), resulting in defects in numerous cellular processes, including splicing of pre-mRNA transcripts. One of these transcripts is *UNC13A/MUNC13-1*, which encodes a synaptic protein required for normal priming and release of excitatory neurotransmitter containing synaptic vesicles. At QurAlis, we hypothesize that ameliorating *UNC13A* mis-splicing using a splice-switching ASO can alleviate symptoms of ALS, FTD, and ALS/FTD spectrum disorder associated with synaptic dysfunction that underlies clinical manifestation and disease progression.
Methods: We have developed an in-house iPSC motor and cortical neuron model to screen ASOs for mRNA and protein potency. Selected ASOs were assessed for restoration of synaptic function using biochemical and live-cell imaging methods.
Results: Splice-switching ASOs targeting *UNC13A* were screened via qPCR and a small subset demonstrating correction of splicing moved onto protein rescue validation studies. From those rescue experiments, ASOs were selected for functional assay testing. To assess synaptic vesicle priming and fusion, we optimized a SNAP-25/ VAMP-2 co-immunoprecipitation assay and synaptopHluorin, respectively. These assays demonstrated a restoration of UNC13A function after ASO treatment.
Conclusions: Using in-house models of iPSC motor and cortical neurons, we have established a phenotype to demonstrate the cellular consequences of *UNC13A* mis-splicing due to TDP-43 loss of function. Using these models, we were able to establish that restoring *UNC13A* splicing through treatment with a splice-switching ASOs lead to the amelioration of defects in synaptic activity.

OVEREXPRESSION OF HEAT SHOCK PROTEIN 27 MODULATES HIPPOCAMPAL APOLIPOPROTEIN E AND REDUCES AGGREGATION OF TRANSACTIVE RESPONSE DNA BINDING PROTEIN 43

POSTERS: D02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Muhammad Abeer[1], Amina Gauff[2], Justin Sherad[2], Isaiah Brooks[2], Michael Gitcho[2]
[1]Delaware State University, Biological Sciences, Dover, United States of America, [2]Delaware State university, Biological Sciences, Dover, United States of America

Aims: Aggregation of transactive response DNA binding protein 43 (TDP-43) has been recently discovered in up to 50% of Alzheimer's disease (AD) cases. Several studies reported that TDP-43 binds to heat shock protein family B (small) member 1 (HSPB1 or HSP27) but no functional evaluation of this interaction has been explored. Inducing expression of HSP27 has been shown to reduce aggregation of amyloid in AD. In general, the goal is to utilize both primary neuronal cultures and mice that are selectively expressing pathogenic TDP-43, HSP27, and apolipoprotein E (APOE) in the brain to characterize the effect of HSP27 overexpression on TDP-43 and APOE. In the present study, we hypothesize that increased expression of HSP27 may reduce TDP-43 aggregation and alter mitochondrial morphology.
Methods: A new transgenic mouse model was developed to selectively drive human HSP27 and pathological TDP-43 with a defective nuclear localization signal (DNLS) in the hippocampus and neocortex using the Ca^{2+}/calmodulin protein kinase (Camk2a) tetracycline-inducible system. The following genotypes have been evaluated for immunohistochemistry, biochemistry (solubility fractionation), and Western blot: wild-type, Camk2a/DNLS, Camk2a/HSP27 and Camk2a/HSP27/TDP43DNLS at 4 months of age. Immunohistochemical and bioenergetic experiments are currently being carried out to evaluate the brain and mitochondrial morphology upon HSP27 overexpression.
Results: Preliminary *in vitro* results show that cells overexpressing HSP27 reduce aggregation and protein levels of TDP43. However, mice overexpressing HSP27 in a TDP43DNLS background in the hippocampus and cortex does not show any reduction in the soluble fraction. Interestingly, increased expression of HSP27 in the hippocampus of Camk2a/HSP27 mice showed a significant reduction of endogenous APOE expression.
Conclusions: Our initial data suggests that modifying HSP27 expression modulates endogenous hippocampal APOE levels and may reduce TDP-43 aggregation.

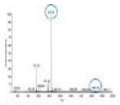
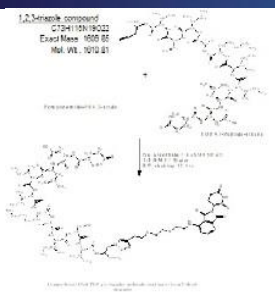
CLICK-BASED PROTEIN DEGRADERS FOR TDP 43 DEGRADATION IN NEURONAL CELL LINE

POSTERS: D02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Krishna Bhavsar, Sharad Gupta
Indian Institute of Technology Gandhinagar, Department Of Biological Science And Engineering, Gandhinagar, India

Aims: Neurodegenerative diseases such as AD, ALS, etc., are among the incurable diseases for which pertinent causes and appropriate treatments are lacking. The newly developed field of targeted protein degradation rapidly expands with significant potential for treating undruggable protein targets. We have developed the Hybrid degrader molecule CLiPD (click-based protein degrader) library targeting TDP 43 with the following objectives: Objective 1: Development of CLiPD library against cytoplasmic TDP 43. Objective 2: Establishment of mammalian and recombinant expression of full-length TDP 43. Objective 3: Neuronal cell-based TDP 43 degradation assays. CLiPD is a hybrid bi-functional molecule that hijacks the UPS and delivers the target protein to the degradation. It has three components: The E3 ubiquitin ligase sequence binds to the E3 ubiquitin ligase enzyme. Target protein sequence: binds the target protein; A linker sequence that provides flexibility to the molecule and allows the target protein to be in proximity to the E3 ligase.
Methods: CLiPD synthesis: Fmoc-based solid-phase peptide synthesis, Cu-click chemistry, RP-HPLC, UPLC-MS, and MALDI-TOF/TOF. Recombinant protein: Plasmid containing TDP 43 (pJ4M) was used for expression in *E. Coli* BL21 (DE3) —purification using Ni-NTA and characterized by MALDI-TOF. Mammalian cell culture, cellular permeability: HEK293t and SH-SY5Y were grown per ATCC's protocol. Addgene WT plasmid (wtTDP43tdTOMATOHA) and Mutant (EGFP construct 3). Viability using MTT. UPS-dependent Degradation cell-based assay using MG 132 proteasome inhibitor.
Results: The cell-permeable and non-toxic CLiPD molecules were synthesized using fmoc-SPPS and ligated by Cu-click chemistry, characterized using
LCMS.





Conclusions: The designed CLiPD molecule can potentially degrade the cytoplasmic TDP 43 involved in neurodegeneration. The CLiPD library will provide the targeted protein degradation therapy with minimized toxicity and high specificity with different targets against various mutations and isoforms of the TDP 43.

EZEPROGIND (AZP2006) IS ABLE TO PROTECT MOTONEURONS AND NEUROMUSCULAR JUNCTIONS FROM GLUTAMATE INJURY. IN VITRO EVIDENCES

POSTERS: D02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Noëlle Callizot[1], Cécilia Estrella[2], Alexandre Henriques[3], Philippe Verwaerde[2]
[1]Neuro-sys SAS, Neuropharmacology Dpt, Gardanne, France, [2]Alzprotect, Clinical Research, Loos, France, [3]Neuro-Sys, -, Gardanne, France

Aims: Amyotrophic lateral sclerosis (ALS) is a fatal disorder characterized by subtle onset of focal weakness, typically in the limbs but sometimes in bulbar muscles, which progresses to paralysis of almost all skeletal muscles. Death of motoneurons (MN) occurs in conjunction with deposition of aggregated proteins in motoneurons and oligodendrocytes, and neuroinflammation. Progranulin (PGRN), is a secreted protein that plays key roles in the brain and spinal cord regulating anti-inflammatory responses and neuron survival. PGRN reduced levels of insoluble TDP-43 and axon fibers loss in the lateral horn. PGRN overexpression significantly slowed down disease progression in TDP-43(A315T) mice. AZP2006 is a small molecule displaying neuroprotective properties currently under clinical development for Progressive Supranuclear Palsy. Its effect was shown to involve PGRN/PSAP complex and was able to help lysosomal function and homeostasis.
Methods: In this study, we investigated AZP2006 in *in vitro* ALS models. Using primary cultures of transgenic SOD1 motoneurons or spinal cord-muscle cocultures injured both with glutamate, AZP2006 effects of on MN survival and neuromuscular junctions (NMJ) integrity were studied.
Results: After Glutamate stress, AZP2006 was shown to reduce SOD1 MN death and cytoplasmic TDP43 accumulation. In nerve muscle coculture AZP2006 was able to protect loss of NMJs after glutamate injury. AZP2006 was associated with an increase of NMJ subunits clustering associated with an increased area of innervation. AZP2006 neuroprotective effect were associated with PGRN release and lysosomal stress reduction. AZP2006 displayed protective effects at nanomolar range and on a dose-dependent manner
Conclusions: AZP2006 is under clinical development (Phase2a in PSP completed) and under preclinical development for the treatment of AD and related disorders, in light of our last results, AZP2006 seems to be serious candidate for ALS indication.

NEURONAL VULNERABILITY TO HNRNP K MISLOCALISATION: MAPPING DIFFERENT BRAIN REGIONS

POSTERS: D01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Xinwa Jiang[1], Ariana Gatt[2], Tammaryn Lashley[3]
[1]Department of Neurodegenerative Disease, UCL Queen Square Institute of Neurology, London, UK, Ucl Institute Of Neurology - Neurodegenerative Diseases, London, United Kingdom, [2]University College London, Neurodegenerative Disease, LONDON, United Kingdom, [3]UCL Queen Square Institute of Neurology, Department Of Neurodegenerative Disease, London, United Kingdom

Aims: Heterogeneous nuclear ribonucleoprotein K (hnRNP K) is an RNA-binding protein. It is abundant and widely expressed in the brain, playing a crucial role in transcriptional regulation. HnRNP K predominantly resides in the nucleus. However, our group discovered that in pyramidal cells from patients with frontotemporal lobar degeneration (FTLD), hnRNP K is abnormally localized and aggregated into the cytoplasm, resulting in aberrant downstream splicing events. We investigated whether other neuronal cells in other brain regions were also vulnerable to mislocalisation, and whether it correlated with disease pathology.
Methods: We examined 13 different brain regions across different neurodegenerative diseases. HnRNP K immunohistochemistry (IHC) and hematoxylin & eosin (HE) and cresyl violet staining were performed. Staining was analysed by QuPath and ImageJ.
Results: The map reveals that mislocalisation of hnRNP K is prevalent in multiple brain regions. These regions include the cerebral cortex, CA4 neurons in the hippocampus, red nucleus in the midbrain, dorsal accessory olivary nucleus (DAO) in the medulla, thalamus, and other subregions of the brainstem. Particularly, high mislocalisation was observed in the thalamus, putamen and medulla. Moreover, we also observed that hnRNP K distribution varies among different brain regions and neuronal cell types depending on the disease context.
Conclusions: We have created a comprehensive brain map illustrating the mislocalisation of hnRNP K in different neuronal populations. The brain map serves as a valuable tool for future studies on hnRNP K mislocalisation to investigate the association between the neuronal variability of hnRNP K localisation and the clinical manifestations of the different neurodegenerative diseases. Furthermore, determining whether hnRNP K plays a causative role in the pathogenesis of neurodegenerative diseases is a question that warrants further exploration.

IDENTIFICATION OF HUMAN GENETIC MODIFIERS OF TDP-43-MEDIATED TOXICITY AND AGGREGATION

POSTERS: D02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Matisse Jacobs, Rebecca San Gil, Adam Walker
University of Queensland, Queensland Brain Institute, Brisbane, Australia

Aims: To identify potential therapeutic strategies for motor neuron disease (MND) by identifying human genes that modulate TAR DNA-binding protein 43 (TDP-43) -mediated aggregation and toxicity.
Methods: We conducted a pooled human genome-wide CRISPR activation screen in HEK293T cells expressing cytoplasmic-targeted TDP-43 protein mimicking pathology found in disease. This assessed the capability of over 18,000 genes to, when activated, modulate protein aggregation and confer cytoprotection in HEK293T cells with TDP-43 pathology. The established ranking system Model-based Analysis of Genome-wide CRISPR/Cas9 Knockout pipeline was employed, assigning a rank to genes by assessing their effect on toxicity and TDP-43 aggregation. Gene ontology (Metascape) analysis of the top 200 ranked genes from each category assessed enriched biological pathways. To identify genes involved in proteostasis pathways, these top ranked genes were also compared to a curated library of 3541 human proteostasis genes.
Results: Subsets of genes were identified that when activated significantly protected from, or sensitised cells to, toxicity (601 'Protect' genes; 733 'Sensitise' genes. LFC > 1) and inhibited or enhanced TDP-43 aggregation (832 'Inhibit' genes; 37 'Enhance' genes. LFC > 1). A subset of genes significantly influenced both toxicity and aggregation. Gene ontology analysis revealed that the top ranked genes that protected cells from toxicity when activated are involved in protein degradation pathways, and top ranked genes that inhibited TDP-43 aggregation were associated with regulation of apoptotic signalling. Many of the top 200 ranked genes in each category appeared in a library of proteostasis genes (87 'Protect' genes; 88 'Sensitise' genes; 114 'Inhibit' genes; 3 'Enhance' genes).
Conclusions: This CRISPR activation screen identified targets that may promote clearance or refolding of pathological TDP-43, supporting development of therapies for those living with MND.

SORTILIN INHIBITION WITH VES001 AND ELEVATION OF PROGRANULIN AS A NOVEL THERAPEUTIC APPROACH IN FTD-GRN AND OTHER NEURODEGENERATIVE DISEASES

POSTERS: D02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Louise Klem, Ove Pedersen, Paul Little, Anders Nykjaer, Mads Kjolby
Vesper Bio, Research And Development, Copenhagen, Denmark

Aims: Progranulin deficiency is associated with different neurodegenerative diseases, including GRN-related frontotemporal dementia (FTD-GRN). Heterozygote carriers of null GRN mutations have 50% progranulin levels relative to healthy controls. Reduced progranulin levels are associated with distinct and overlapping pathological processes, including gliosis, complement activation, TDP-43 accumulation, and neurodegeneration. Sortilin inhibition elevates extracellular progranulin and reduces the apoptotic signalling stemming from the sortilin-$P75^{NTR}$ complex. Vesper Bio has developed novel small molecule sortilin inhibitors for oral administration and is investigating the therapeutic potential within different neurodegenerative diseases. Vesper Bio aims to develop the first sortilin inhibitor for oral administration to treat FTD-GRN, and lead candidate, VES001, will enter Phase 1 clinical trials Q4 of 2023.
Methods: Characterization of VES001 included quantification of target affinity by Grating-Coupled Interferometry, competition binding with progranulin by flow cytometry, and PK/PD studies in different species. The PK/PD studies included multiple rodent studies that quantified the levels of compound and progranulin in a) plasma following a VES001 dose range, and b) in plasma, CSF, and brain interstitial fluid following repeated administration of VES001 in a microdialysis experiment. Pharmacodynamic changes in progranulin were quantified in both absolute terms and relative to baseline levels.
Results: VES001 shows a high affinity for sortilin across multiple species and inhibits progranulin binding. VES001 was measured in all compartments. Single-dose VES001 administration increased plasma progranulin up to ~1.5-fold, and repeated dosing increased progranulin in plasma, CSF, and brain ~2-fold with the selected dose-range. The vehicle groups did not show changes in progranulin.
Conclusions: Sortilin inhibition with oral small molecule VES001 increases progranulin in different compartments and holds promise as a novel therapeutic approach to attenuate neuroinflammation and neurodegeneration for different neurodegenerative diseases, including FTD-GRN.

Healey & Amg Center For Als, Boston, United States of America, [3]University of Southern California, Eli And Edythe Broad Cirm Center For Regenerative Medicine And Stem Cell Research, Los Angeles, United States of America, [4]Inoviv, Research And Development, London, United Kingdom, [5]Tel Aviv University, Faculty Of Medicine, Tel Aviv, Israel

Aims: ALS's complex pathophysiology necessitates a multifactorial therapeutic strategy targeting various pathways. PrimeC, a novel formulation combining ciprofloxacin and celecoxib, synergistically targets key pathologies to impede ALS progression. The synergistic effect between ciprofloxacin, a Dicer gene regulator, and celecoxib, a neuroinflammation regulator was demonstrated preclinically. Rodent studies demonstrated improved pharmacokinetics when the two were combined, with significant beneficial effects for the combination utilizing synaptoneurosomes and iPSC ALS models. PrimeC was evaluated clinically in a 12-month, open-label, Phase 2a study. 15 patients with ALS treated with PrimeC were compared to propensity-matched, untreated ALS patients. Significant changes in ALS-related biomarkers following treatment (TDP43 p=0.002, PGJ2 p<0.001, CATD p=0.015, LC3 p=0.05) indicated PrimeC's biological activity. Clinical outcomes demonstrated an 18% and 30% improvement, as measured by ALSFRS-R and FVC, respectively. NeuroSense's PARADIGM trial reflects a pioneering approach to spotlighting blood-based biomarkers. Primary outcomes include analyzing TDP-43 and PGJ2. Exploratory endpoints include additional biomarker-driven assays, potentially elucidating PrimeC's biological activity and target engagement.
Methods: PARADIGM is a prospective, randomized, double-blind, placebo-controlled Phase 2b study evaluating PrimeC. A multicenter trial on 69 patients was commenced. A large battery of biomarkers will be screened using mass spectrometry-based Proteomics Discovery and validated via Targeted Proteomics Assay. Additionally, miRNA profiling in PrimeC-treated patients' blood will map differentially expressed miRNAs. PrimeC's ability to alter NfL elevation, a promising biomarker for neuronal degeneration and death, and its correlation to key clinical outcomes, will also be assessed.
Results: would elucidate PrimeC's effects on target biomarkers and miRNAs, and their correlation with clinical outcomes and efficacy.
Conclusions: Consolidating this battery of biomarkers will enhance our understanding of PrimeC's MoA and biological activity, setting the stage for a more sophisticated and precisely tailored pivotal study.

NUCLEAR TDP-43 PATHOLOGY DETECTED BY AN RNA APTAMER IS AN EARLY AGGREGATION EVENT THAT CORRELATES WITH STMN-2 CRYPTIC SPLICING AND PRECEDES CLINICAL MANIFESTATION IN ALS

POSTERS: D03. IMAGING, BIOMARKERS, DIAGNOSTICS

Fergal Waldron, Holly Spence, Mathew Horrocks, Jenna Gregory
Institute of Medical Sciences, University of Aberdeen, Institute Of Medical Sciences, Aberdeen, United Kingdom

Aims: The presence of phosphorylated, cytoplasmic TDP-43 (pTDP-43) aggregation is a specific, but not sensitive, marker of regional phenotypic presentation in amyotrophic lateral sclerosis and frontotemporal dementia spectrum disorders (ALSFTSD). The recent identification of cryptic splicing events such as the detection of *Stathmin-2* (*STMN-2*) cryptic exons, are thought to be a sensitive molecular surrogate of TDP-43 pathology and clinical phenotype. Therefore, we set out to assess if alternative methods for the detection of TDP-43 pathology can improve diagnostic sensitivity, rather than relying on molecular surrogates that might lack stability in the clinical setting.
Methods: To do this we use an RNA aptamer that we have previously designed to bind to the RNA-binding domains of TDP-43 (TDP-43^{APT}).
Results: We demonstrate that using an adapted immunostaining protocol, TDP-43^{APT} identifies pathological TDP-43 with high sensitivity and specificity and can detect aggregation events that cannot be detected by classical antibody stains. Furthermore, we show that TDP-43^{APT} detects TDP-43 pathology in distinct cell compartments, and that the protein sub-cellular distribution correlates with both (i) molecular phenotype (*STMN-2* cryptic splicing events) and (ii) clinical phenotype (cognition). In addition, we show that nuclear TDP-43^{APT} pathology, in the form of nuclear membrane accumulation and nuclear puncta, is an early aggregation event that precedes clinical manifestation.
Conclusions: Taken together, our data show that TDP-43^{APT} enables the detection of a wider range of aggregation events, with implications for early diagnostics and improved accuracy in detecting disease phenotypes for future biomarker development.

DEVELOPMENT AND CHARACTERIZATION OF ALPHA-INTERNEXIN ANTIBODIES FOR IMMUNOASSAY DEVELOPMENT

POSTERS: D03. IMAGING, BIOMARKERS, DIAGNOSTICS

Francisco Meda[1], Camilla Johansson[2], Karin Palm[2], Gunnar Brinkmalm[1], Ulf Andreasson[1,2], Kaj Blennow[1,2], Hlin Kvartsberg[1,2], Henrik Zetterberg[1,2,3,4,5,6]
[1]Department of Psychiatry and Neurochemistry, Institute Of Neuroscience And Physiology, The Sahlgrenska Academy, University Of Gothenburg, Mölndal, Sweden, [2]Clinical Neurochemistry Laboratory, Sahlgrenska University Hospital, Mölndal, Sweden, [3]Clear Water Bay, Hong Kong Center For Neurodegenerative Diseases, Hong Kong, Denmark, [4]Department of Neurodegenerative Disease, Ucl Institute Of Neurology, London, United Kingdom, [5]UK Dementia Research Institute, Ucl Institute Of Neurology, London, United Kingdom, [6]Wisconsin Alzheimer's Disease Research Center, University Of Wisconsin School Of Medicine And Public Health, Madison, United States of America

Aims: Alpha-internexin (AINX) is a type IV intermediate filament alongside the neurofilament triplet proteins. Although AINX is mostly expressed during the developing brain, it is still present in mature neurons and said to be involved in axonal outgrowth. Previous work recognized it as a major component aggregating in neuronal intermediate filament inclusion disease (NIFID), a subtype of frontotemporal lobar degeneration with fused in sarcoma aggregates. Based on this, the objective of this project was to produce and characterize antibodies against AINX, in addition to combining them with commercially available antibodies to develop a novel AINX immunoassay.
Methods: In-house monoclonal antibodies originated from mice immunization with two recombinant AINX peptides (Ina1; B15) and posterior fusion of B-cells with a myeloma cell line. Commercial antibodies selected: anti-AINX PA5-95368, anti-AINX NBP2-75407 and anti-AINX NB300-140. Standard ELISA was performed with different combinations of antibodies using in-house produced recombinant AINX89-499 as calibrator. Immunoprecipitation followed by mass spectrometry (IP-MS), using both in-house and commercial PA5-95368 was performed to assess antibody binding and specificity.
Results: The in-house antibodies were successfully raised, purified, and tested on a direct ELISA setup, where the recombinant protein was detected with high affinity. When tested against biological samples (CSF and brain extracts) all antibody combinations detected AINX in sodium dodecyl sulphate (SDS) brain fractions, however in CSF, it was only detected by one combination (B15_PA5-95368). To further assess antibody binding, IP-MS using the in-house antibodies and PA5-95368 revealed that, in SDS brain fractions, PA5-95368 had AINX sequence coverage of 90%, B15 of 56% and Ina1 of 85%.
Conclusions: The antibodies raised in-house alongside PA5-95368 are a promising base for immunoassay development, although further optimization is needed to specifically detect AINX in body fluids.

Aims: The aim of this study was to determine whether antibodies to epitopes of TDP-43 containing phosphoserines differentially detect neurites in the neocortex of an individual affected by primary progressive aphasia (PPA).
Methods: Neuropathologic studies revealed cerebral atrophy with a brain weight of 876.6 grams. Immunohistochemistry was carried out using antibodies targeting TDP-43 phosphoserines 305, 369, 375, and 409/410. Whole slide images were taken using Huron Tissuescope LE120. Images were analyzed using Indica Labs' Halo object colocalization module. Five ROIs were selected across the superior frontal gyrus with each ROI expanding from layer I to layer VI. Statistical test used was students t-test, two tailed. Using Western blot analysis and immunoelectron microscopy, each antibody's immunoreactivity to sarkosyl- insoluble TDP-43 will be determined.
Results: The number of neurites immunolabeled by antibody recognizing phosphoserine 375 matched that obtained using antibody recognizing phosphoserines 409/410. Antibodies recognizing phosphoserines 305 and 369 immunolabeled a statistically significant higher number of neurites as compared to those detected by the antibody recognizing phosphoserines 409/410. When analyzing the density per mm^2 the results were consistent with those of absolute counts.
Conclusions: Previous studies carried out by mass spectrometry have revealed the post translational phosphorylation at S305, S369 and S375 in TDP-43 from FTLD human brain tissue. Such data have revealed the significance of these phosphorylation sites and the necessity of producing and validating new antibodies for characterizing FTLD types. The current results show that antibodies to S305 and S369 immunolabel a significantly higher number of neurites as compared to the currently used antibody to phosphoserines 409/410. Whether these differences between antibodies are related to specific misfolded species of TDP-43 in the aggregates present in neurites needs further investigation.

Aims: Presymptomatic genetic FTD features decreases in cerebral blood flow (CBF) involving frontotemporal and subcortical regions. We investigated whether associations between regional cerebral

hypoperfusion and cognition manifest during the presymptomatic and prodromal stages.
Methods: This study includes individuals from the Genetic FTD Initiative (GENFI). Individuals were classified into groups based on mutation +/- with or without early symptoms as follows: presymptomatic carriers who scored zero on the Clinical Dementia Rating plus NACC FTLD Behavior & Language Domains (CDR+NACC FTLD; n = 196), prodromal carriers who scored a 0.5 on the CDR+NACC FTLD (n = 36), and non-carrier relatives (n = 202). Participants completed a neuropsychological battery covering attention & processing speed, executive function, language, memory recall, visuospatial ability, and social cognition domains, calculated as mean composite z-scores of individual tests. Linear mixed effects models tested the association of regional CBF measured by arterial spin labeling MRI with these domain scores across groups. Models adjusted for the effects of age, sex, and years of education. A random intercept clustered over families was included.
Results: After Bonferroni correction, the interaction between regional CBF and group membership was significantly positive for the attention & processing speed domains in the CDR 0.5 group relative to non-carrier controls within several left hemisphere regions: the superior, medial, and inferior frontal gyri, the inferior & medial temporal gyri, and the medial orbitofrontal cortex. The right thalamus and right temporal pole were also significant for this interaction.
Conclusions: Regional cerebral hypoperfusion may represent an early biomarker of the prodromal stages of genetic FTD and could be considered as a neurophysiological outcome measure in clinical trials.

PLASMA LYSOSPHINGOLIPIDS ARE DISEASE-TRACKING BIOMARKERS IN FRONTOTEMPORAL DEMENTIA ASSOCIATED WITH GRN MUTATIONS

POSTERS: D03. IMAGING, BIOMARKERS, DIAGNOSTICS

Dario Saracino[1], Walid Khrouf[2], Marion Houot[3], Fabienne Clot[4], Foudil Lamari[2], Isabelle Le Ber[1]
[1]Sorbonne Université / Paris Brain Institute / Hôpital Pitié-Salpêtrière, Department Of Neurology, Paris, France, [2]AP-HP.Sorbonne Université, Dmu Biogem-metabolic Biochemistry Department, Neurometabolic And Neurodegenerative Unit - Hôpital Pitié-salpêtrière, Paris, France, [3]Sorbonne Université / Paris Brain Institute / Hôpital Pitié-Salpêtrière, Centre Of Excellence Of Neurodegenerative Disease (coen), Paris, France, [4]Hôpital Pitié-Salpêtrière, AP-HP.Sorbonne Université, Department Of Genetics, Paris, France

Aims: *GRN* mutations are one of the most frequent causes of frontotemporal lobar degeneration with TDP-43 pathology. As progranulin is involved in lysosomal pathways, we aimed to study whether plasma lysosphingolipids, byproducts of lysosomal metabolism, are increased in *GRN* mutation carriers, and to evaluate their possible use as fluid-based biomarkers in frontotemporal dementia (FTD) associated with *GRN* mutations.
Methods: We analyzed plasma levels of four lysosphingolipids (glucosylsphingosin d18:1 [LGL1], lysosphingomyelins d18:1 and isoform 509 [LSM18:1, LSM509] and lysoglobotriaosylceramide [LGB3]) in 128 *GRN* carriers and 142 non-carriers. *GRN* carriers consisted of 102 patients with *GRN*-associated FTD (FTD-*GRN*), and 26 presymptomatic carriers (PS-*GRN*), and we performed longitudinal assessments in the latter. Non-carriers included healthy controls, patients with *C9orf72*-associated FTD, and sporadic FTD. Plasma lysosphingolipids were measured by electrospray ionization-tandem mass spectrometry coupled to ultraperformance liquid chromatography, and neurofilament light chain (NfL) with SIMOA.
Results: *GRN* carriers had higher levels of LGL1, LSM18:1 and LSM509 compared to non-carriers (p<0.0001). Sporadic and *C9orf72*-associated FTD patients had no lysosphingolipid increases. In FTD-*GRN*, LGL1 and LSM18:1 increased along with the age at sampling, and LGL1 with the disease duration. In PS-*GRN* carriers, there was a significant increase of the same two lysosphingolipids over 3.4-year follow-up; notably, LGL1 levels were associated with NfL changes.
Conclusions: This study evidences an age-dependent increase of β-glucocerebrosidase and acid sphingomyelinase substrates in *GRN* patients, with progressive changes along disease course since the presymptomatic phase. Among FTD patients, plasma lysosphingolipids appear to be uniquely elevated in *GRN* carriers, which suggests their use as non-invasive disease-tracking biomarkers of progression, specific to the pathophysiological process. This could be particularly relevant in the context of disease-modifying approaches based on lysosomal function rescue in *GRN* disease.

NASU-HAKOLA DISEASE ASSOCIATED WITH EARLY ONSET DEMENTIA OF FRONTAL LOBE TYPE

POSTERS: D04. GENETICS, EPIDEMIOLOGY

Stanislav Sutovsky[1], Ivana Paucinova[2], Peter Turcani[1]
[1]Comenius University, Faculty of Medicine, First Department Of Neurology, Bratislava, Slovak Republic, [2]University Hospital, Department Of Genetics, Zilina, Slovak Republic

Aims: Nasu-Hakola disease (NHD) is a rare autosomal recessive disorder, pathologically characterized by leukoencephalopathy, astrogliosis, axonal spheroids, and accumulation of microglia. Clinically, it is characterized by cognitive decline, skeletal pain and polycystic osteodysplasia. NHD is caused by a mutation in the TYROBP gene in a homozygous state.
Methods: In this case report we describe a 40 years old patient with progressive cognitive deterioration within four years.
Results: At the forefront of the clinical picture were the symptoms of prefrontal syndrome, memory and concentration disorders and the overall breakdown of personality. Brain MRI showed severe diffuse atrophy and increased white matter signal predominantly periventricular, which was milder than seen in leukodystrophies and ALD. CSF examination showed increased total proteins, increased IgG and absent oligoclonal synthesis of gamma globulins. 14-3-3 protein was negative, and screening for PrP mutations was also negative. WES revealed the mutation c.94G→A in TYROBP gene in the homozygous state confirmed the Nasu-Hakola disease. The patient did not report any skeletal pain, nor did we detect any bone abnormalities. In the genealogical analysis, we did not confirm the consanguinity of the parents, but we found that the parents came from neighbouring villages in a sparsely populated area in the north of Slovakia.
Conclusions: Early onset dementia is always a big diagnostic challenge. In the case of a negative family history, rare autosomal recessive diseases, including Nasu-Hakola disease, should be considered. WES is a reliable method for detecting such rare diseases and a logical step when diagnostic options are exhausted.

Sección De Sistema Nervioso Central., Rúa da Choupana s/n, Spain, [6]Complejo Hospitalario Universitario de Santiago de Compostela, Servicio De Neurología. Unidad De Patología Neuromuscular, Rúa da Choupana s/n, Spain

Aims: Frontotemporal dementia (FTD) is the most prevalent cause of dementia under 45 years of age and the third in global rates. Although very infrequently, mutations in the optineurin gene have been associated with cases of FTD and, likewise, with amyotrophic lateral sclerosis (ALS).
Methods: We report a five-patient cohort, two of them with clinical features that suggest FTD (one behavioral variant and one primary progressive nonfluent aphasia), two with motor neuron disease (a Mills' hemiplegic variant) and one pediatric patient with a dystonic-myoclonic clinical picture.
Results: Complementary tests support the clinical diagnosis in all cases. Despite obvious phenotypic differences, genetic study reveals in all five cases the same variant in OPTN [NM_021980.4:c.1552C>T (p.Gln518*)] in heterozygosis. A systematic review is performed ratifying the association of OPTN with ALS, but also with the ALS/DFT spectrum. No previous descriptions were found of a dystonia-myoclonus phenotype, neither on paediatric age nor in adults. The main pathophysiological scenarios are explained with pathogenic variants affecting OPTN gene domains involved in the mechanism of autophagy, causing accumulation of protein aggregates and mitochondrial dysfunction.
Conclusions: We present a new likely pathogenic mutation with a high clinical expressivity. Its pathophysiological consequences at the molecular level could provide valuable information not only on the cellular basis of genetic neurodegenerative pathologies, but especially on the role that optineurin may play in the FTD-ALS spectrum.

RHEUMATOID ARTHRITIS, SEX DIFFERENCES, COGNITIVE DECLINE AND DEATH IN DEMENTIA: A POPULATION-BASED SWEDISH STUDY

POSTERS: D04. GENETICS, EPIDEMIOLOGY

Minjia Mo[1], Maria Eriksdotter[1], Sumonto Mitra[1], Sofia Ajeganova[2], Sara Garcia-Ptacek[1], Hong Xu[1]
[1]Division of Clinical Geriatrics, Department Of Neurobiology, Care Sciences And Society (nvs), Karolinska Institutet, STOCKHOLM, Sweden, [2]Department of Medicine Huddinge, Department Of Medicine Huddinge, Karolinska Institutet, STOCKHOLM, Sweden

Aims: To determine whether rheumatoid arthritis (RA) is associated with cognitive decline in dementia patients and to explore how sex modifies the association.
Methods: We conducted a population-based cohort study including dementia patients aged 40 years or older identified from the Swedish Registry for Cognitive/Dementia Disorders-SveDem during 2007-2018. We used mixed-effects models to examine the interactive associations of RA and sex on cognitive decline and Cox proportional hazards models to investigate the risk of all-cause mortality.
Results: The final cohort included 24 727 patients with dementia, among them 10 527[42.6%] were men (mean[SD] age, 77.1[7.5] years) and 14 200[57.4%] were women (78.3[7.6] years). The median follow-up was 3.9 years (interquartile range, 2.5-5.6 years) for men and 4.2 years (2.7-5.9 years) for women. In all, 521 persons were diagnosed with RA, of them 147[1.4%] were men and 374[2.6%] women. After adjusted for age, comorbidities, cholinesterase inhibiters, memantine, disease modifying antirheumatic drugs, cognitive trajectories did not differ between RA and non-RA patients. However, compared to non-RA patients, patients with RA had slower cognitive decline in women (0.37 points/y; 95%CI, 0.02 to 0.72 points/y) but not men (0.11 points/y; 95%CI, −0.50 to 0.72 points/y). Compared to non-RA, RA patients with dementia had a higher risk of all-cause mortality (HR[95%CI], 1.22[1.03-1.44]), especially men (HR[95%CI], 1.74[1.28-2.36]). We observed similar results across specific dementia types of Alzheimer's disease and mixed dementia.
Conclusions: In this cohort study, we found that compared to non-RA patients, cognitive decline to a lower extent in female than in male dementia patients with RA, but a higher risk of mortality was found in men, which might be related to the sex differences in comorbidities and comedications.

UNRAVELING THE MOLECULAR CONSEQUENCES OF THE FUSION BETWEEN YAF2 AND RYBP IN AMYOTROPHIC LATERAL SCLEROSIS.

POSTERS: D04. GENETICS, EPIDEMIOLOGY

Tiziana Petrozziello, Sommer Huntress, John Lemanski, Maheswaran Kesavan, Ayleen Castillo-Torres, Celine De Esch, Dadi Gao, Merit Cudkowicz, James Berry, Ricardo Mouro Pinto, Micheal Talkowski, Ghazaleh Sadri-Vakili
Mass General Brigham, Neurology, Boston, United States of America

Aims: Recently, we demonstrated an enrichment in gene fusion events in ALS post-mortem brain and spinal cord using STAR-Fusion to assess publicly available RNA-Seq datasets. Here, we began to assess the consequences of these fusion events with a focus on one of the most recurrent gene fusions identified in ALS: the inter-chromosomal fusion between YY1 Associated Factor 2 (YAF2) and RING1 and YY1 Binding Protein (RYBP). Both genes are involved in chromatin remodeling and transcriptional regulation through ubiquitination of histone H2 ($H2AK119ub_1$) and interaction with polycomb (PcG) proteins.
Methods: Human neuroblastoma SH-SY5Y cells were transfected with plasmids coding for either YAF2, RYBP or YAF2-RYBP fusion. Immunocytochemistry followed by immunofluorescence was performed to assess $H2AK119ub_1$ levels as well as interactions with PcG proteins. Western blots were performed to assess PcG proteins and $H2AK119ub_1$ levels in human control and ALS post-mortem motor cortex (mCTX).
Results: Our results indicated that YAF2 and RYBP interact with three PcG proteins in SH-SY5Y cells: EZH2, RING1A and histone H3 tri-methylated at lysine 27 ($H3K27me_3$). While YAF2-RYBP fusion did not alter EZH2, and $H3K27me_3$ levels, there was a significant increase in RING1A levels in YAF2-RYBP fusion-transfected cells compared to EGFP- and RYBP-transfected cells. Consistently, YAF2-RYBP fusion significantly decreased $H2AK119ub_1$ levels in SH-SY5Y cells. Lastly, our results did not reveal any changes in EZH2, RING1A, $H3K27me_3$, and $H2AK119ub_1$ levels in ALS mCTX compared to controls, thus supporting a role for YAF2-RYBP fusion in modulating these proteins.
Conclusions: Altogether, our results demonstrate that YAF2 fusion to RYBP regulates interaction with RING1A in ALS. Ongoing RNA-Seq and transposase-accessible chromatin with sequencing (ATAC-Seq) studies will determine whether YAF2-RYBP fusion alters chromatin accessibility and thereby gene expression in ALS.

AMYGDALA TDP-43 PATHOLOGY IS ASSOCIATED WITH FERRITIN ACCUMULATION AND BEHAVIOURAL DYSFUNCTION IN AMYOTROPHIC LATERAL SCLEROSIS

POSTERS: D03. IMAGING, BIOMARKERS, DIAGNOSTICS

Olivia Rifai[1], Fergal Waldron[2], Judi O'Shaughnessy[1], Fiona Read[2], Martina Gilodi[3], Neil Shneider[4], Gian Tartaglia[3], Elsa Zacco[3], Mathew Horrocks[5], Holly Spence[6], Jenna Gregory[6]
[1]Centre for Discovery Brain Sciences, University of Edinburgh, UK, Centre For Discovery Brain Sciences, Edinburgh, United Kingdom, [2]University of Aberdeen, The Institute Of Medical Sciences,, Aberdeen, United Kingdom, [3]RNA system Biology Lab, Istituto Italiano di Tecnologia, Rna System Biology Lab, Genoa, Italy, [4]Department of Neurology, Center for Motor Neuron Biology and Disease, Columbia University, Department Of Neurology, New York, United States of America, [5]EaStCHEM, School Of Chemistry, Edinburgh, United Kingdom, [6]Institute of Medical Sciences, University of Aberdeen, Institute Of Medical Sciences, Aberdeen, United Kingdom

Aims: Cognitive and behavioural deficits are observed in around 50% of ALS patients. While it is thought that cognitive deficits are largely driven by TDP-43 pathology, there is currently no sensitive pathological correlate of behavioural deficits.
Methods: The current cohort consisted of 30 sporadic ALS patients who underwent neuropsychological behavioural assessment as part of the Edinburgh Cognitive ALS Screen (ECAS). In these patients we examined post-mortem brain tissue from 6 brain regions (i) amygdala, (ii) orbitofrontal cortex (BA11/12), (iii) ventral anterior cingulate (BA24), (iv) medial prefrontal cortex (BA6), (v) prefrontal cortex (BA9) and (vi) the dorsolateral prefrontal cortex (BA46).
Results: ECAS behavioural screen predicted pTDP-43 pathology with 100% specificity and 86% sensitivity with amygdala showing best sensitivity and specificity. In the amygdala we show that presence and severity of intra-neuronal pTDP-43 pathology but not astroglial or Tau pathology is associated with clinically detectable behavioural deficit. Severity of TDP-43 aptamer staining was also associated with clinically detectable behavioural deficit and exhibited a positive correlation with ferritin immunoreactivity (regardless of phenotype).
Conclusions: This suggests that TDP-43 pathology in the amygdala is associated with ECAS determined behavioural deficit and that ferritin increases occur upstream of behavioural deficit.

APEX2-BIOTINYLATION PROTEOMICS DISCOVERED THAT POLY (A)-BINDING PROTEIN MEDIATES THE DEGRADATION OF C9ORF72-GGGGCC REPEAT RNA

POSTERS: D05. CELL, MOLECULAR AND SYSTEMS BIOLOGY

Ryota Uozumi[1], Kohji Mori[1], Shiho Gotoh[1], Tesshin Miyamoto[1], Shizuko Kondo[1], Tomoko Yamashita[1], Yuya Kawabe[1,2], Shinji Tagami[2,3], Shoshin Akamine[1], Manabu Ikeda[1]

Aims: Neurodegeneration in *C9orf72*-linked frontotemporal lobar degeneration (FTLD)/amyotrophic lateral sclerosis (ALS) is known to be caused by the toxicities of transcribed GGGGCC repeat RNA (repeat RNA) itself and/or its repeat-associated non-AUG (RAN) translation products, dipeptide repeat protein (DPR). We previously reported that hnRNPA3, through binding to repeat RNA, suppressed the accumulation of repeat RNA and DPR. It indicates that hnRNPA3 promotes the degradation of the repeat RNA; however, hnRNPA3 itself is not structurally expected to function as an RNase. Here, we aimed to identify RNA degradation-associated proteins that interact with hnRNPA3.
Methods: In the presence or absence of (GGGGCC)80 repeat RNA, we performed proximity biotin-phenol labeling assays, known as APEX2 proteomics, to biotinylate and purify the proximate interactors of fused hnRNPA3-APEX2 in HeLa cells. Biotinylated interactors were then identified by LC-MS/MS. To test their effects on repeat RNA accumulation, siRNA-mediated knockdown screenings were performed. Further validation was conducted on endogenous repeat RNA using fibroblasts derived from *C9orf72* GGGGCC expansion mutation carriers.
Results: hnRNPA3-APEX2 proteomics identified 190 proteins whose biotinylation state changes in the presence or absence of the repeat RNA; however, no apparent RNases were included. Accordingly, we performed a stringent filtering of the 190 proteins and selected nine RNA-binding proteins (GO: 0003723) as candidate interactors that might be involved in repeat RNA degradation. The following siRNA-screening identified reduction of PABPC1 (a cytoplasmic isoform of poly adenylate-binding protein) increased the repeat RNA accumulation in HeLa cells, as well as hnRNPA3. In addition, *In Situ* Hybridization revealed that the siRNA-mediated PABPC1 reduction also promoted the accumulation of repeat RNA foci in (GGGGCC)80 repeat expression HeLa cells and in *C9orf72* mutation carrier-derived fibroblasts.
Conclusions: With APEX2 proteomics, we identified that PABPC1 interacts with hnRNPA3 and mediates the degradation of the pathogenic *C9orf72* repeat RNA. Our results have the potential for the development of novel therapies targeting repeat RNA for *C9orf72*-FTLD/ALS.

Aims: Amyotrophic lateral sclerosis (ALS) is a non-cell autonomous disorder as many cell types contribute to motor neurons death. The lack of effective treatments is due to the absence of a realistic model.Organoids are stem cell-derived self-organizing structures that allow in vitro generation of tissues. Thus, aim of the work was to develop and characterize a 3D organoid model for the study of ALS pathogenesis.
Methods: We started from iPSCs obtained from healthy controls and sporadic ALS (sALS) patients. We differentiated iPSCs into neural stem cells (NSCs). We dissociated NCSs using StemPro Accutase and a cell strainer. Then, we plated NSCs on low-attachment plates and we cultured them in floating conditions using an orbital shaker. We differentiated NSCs to generate SCOs. We then characterized SCOs by phase-contrast microscope, confocal microscopy and transcriptomics analysis.
Results: We found that SCOs derived from sALS patients were smaller and with irregular morphology compared to controls. Using the GFAP marker, we found that sALS SCOs have a thicker glial layer. We also found that sALS SCOs show shorter neurites. By RNAseq, we found a ten-fold increase of deregulated gene in SCOs respect to 2D cell models. Moreover, in ALS SCOs we found an extensive deregulation of genes involved in extracellular matrix organization when compared to control. Finally, we compared transcriptomic profile of both sALS SCOs and human spinal cord tissue, finding many similarities.
Conclusions: Our data suggest that brain organoids represent a promising tool for the investigation of pathogenic mechanisms of ALS. Indeed, we found typical pathological hallmarks of the pathology, such as the presence of gliosis, the smaller length of neurites, and decreased level of mature MNs. Moreovers sALS SCOs transciptomics signature shares many similarities with the spinal cord tissue.

SHORT- AND LONG-READ TRANSCRIPTOMICS IN FTLD-TDP TO IDENTIFY DISEASE-ASSOCIATED TRANSCRIPTS GENERATED BY ABERRANT SPLICING

POSTERS: D05. CELL, MOLECULAR AND SYSTEMS BIOLOGY

Júlia Faura[1,2], Bavo Heeman[1,2], Cyril Pottier[1,2,3], Matthew Baker[4], Mariely Dejesus-Hernandez[4], Laura Heiß[1,2], Sarah Wynants[1,2], Marleen Van Den Broeck[1,2], Tim De Pooter[1,2], Geert Joris[1,2], Peter De Rijk[1,2], Nicole Finch[4], Marka Van Blitterswijk[4], Joanna Biernacka[5], Yan Asmann[6], Mojca Strazisar[1,2], Melissa Murray[4], Leonard Petrucelli[4], Keith Josephs[7], Ronald Petersen[8], Bradley Boeve[7], Neill Graff-Radford[9], Dennis Dickson[4], Rosa Rademakers[1,2]
[1]VIB, Vib Center For Molecular Neurology, Antwerp, Belgium, [2]University of Antwerp, Biomedical Sciences, Antwerp, Belgium, [3]Mayo Clinic Florida, Neuroscience, Jacksonville, United States of America, [4]Mayo Clinic, Neuroscience, Jacksonville, United States of America, [5]Mayo Clinic, Quantitative Health Sciences, Jacksonville, United States of America, [6]Mayo Clinic, Quantitative Health Sciences, Rochester, United States of America, [7]Mayo Clinic, Neurology, Rochester, United States of America, [8]Mayo Clinic, Department Of Neurology, Rochester, United States of America, [9]Mayo Clinic, Neurology, Jacksonville, United States of America

Aims: Dysregulation of TDP-43 as seen in TDP-43 proteinopathies leads to specific RNA splicing dysfunction. While short-read RNA-sequencing (SR-RNA-seq) has been widely used for transcriptomics profiling, long-read (LR) RNAseq is emerging as a powerful alternative. We hypothesize that the combination of SR- and LR-RNAseq data can highlight novel disease-associated transcripts with relevance to the identification of disease pathways and biomarkers.
Methods: We performed the largest differential splicing analysis to date in FTLD-TDP patients using SR-RNA-seq data from frontal-cortex (FCX) tissue of 127 patients and 22 control subjects (Mayo Clinic Brain Bank; Illumina), using LeafCutter. In addition, we generated LR-RNAseq data from (1) TDP-43 knockdown (KD) iPSC-derived neurons at different levels of TARDBP KD and (2) FCX brain tissue, using the Oxford Nanopore Technology. Reads were aligned with minimap2 and isoform quantification was performed with IsoQuant.
Results: In human brain, we identified 4234 differentially spliced events (FDR<0.05, |dPSI|>0.05) between FTLD-TDP patients and controls in 1644 unique genes. To prioritize events driven by TDP-43 loss-of-function rather than cellular composition, we created a second dataset of TARDBP targets by correlating the expression of TARDBP in the different KD neurons with the expression of each detected transcript. We identified 1377 isoforms negatively correlated (R<-0.8) and 1937 positively correlated (R>0.8) with TARDBP expression. When overlapping both datasets, 25 genes showed extensive evidence for regulation by TARDBP in neurons and a significant differential splicing of transcripts in FTLD-TDP brains.
Conclusions: Twenty-five potential TDP-43-driven splicing events have been identified by combining SR- and LR-RNAseq data. They will be further explored in the LR-RNAseq data from FTLD-TDP and control brain and their proteoform expression will be explored in already generated cerebrospinal fluid and plasma proteomics data to study their potential as biomarkers.

EIF5 REGULATES POLY-GA RAN TRANSLATION IN A CELLULAR MODEL OF C9ORF72 FTLD/ALS.

POSTERS: D05. CELL, MOLECULAR AND SYSTEMS BIOLOGY

Shiho Gotoh[1], Kohji Mori[1], Yoshitaka Nagai[2], Manabu Ikeda[1]
[1]Osaka University, Department Of Psychiatry, Osaka, Japan, [2]Kindai University, Department Of Neurology, Osaka, Japan

Aims: *C9orf72* related frontotemporal lobar degeneration and amyotrophic lateral sclerosis (C9-FTLD/ALS) patients have unusually expanded GGGGCC (G_4C_2) repeat sequence in intron 1 of *C9orf72* gene. G_4C_2 repeat sequence is transcribed and then translated into di-peptide repeat proteins (DPR) via repeat associated non-AUG (RAN) translation. DPR accumulates in the C9-FTLD/ALS patient's brain. DPR toxicity has revealed in multiple models. Suppression of DPR expression levels via inhibition of RAN translation would have a therapeutic potential for C9-FTLD/ALS. In this study we propose eukaryotic initiation factor 5 (eIF5) as a novel regulator of RAN translation.
Methods: We used cellular model expressing $(G_4C_2)_{80}$ repeats. Western blotting was performed for detect poly-GA DPR expression. Puromycin incorporation assay was performed for quantify the global translation.
Results: siRNA-mediated knockdown of eIF5 decreased the expression level of poly-GA DPR. Conversely, overexpression of eIF5 increased poly-GA expression level. Moreover, inactivation of eIF5 by site directed mutagenesis reduced poly-GA expression. Puromycin incorporation assay revealed that eIF5 preferentially upregulates poly-GA DPR through RAN translation over global translation.
Conclusions: In conclusion, we revealed that eIF5 stimulates poly-GA DPR translation through its intrinsic activity. Further investigation of the mechanism by which eIF5 regulates RAN translation could lead to the development of a new treatment for C9-FTLD/ALS.

CHARACTERIZING THE EFFECTS OF TMEM106B PROTEIN LEVELS IN THE ENDOLYSOSOMAL PATHWAY

POSTERS: D05. CELL, MOLECULAR AND SYSTEMS BIOLOGY

Miranda Lastra Osua, Bavo Heeman, Rafaela Policarpo, Paula Miquel, Maxim Van Hoek, Simona Manzella, Bob Asselbergh, Renzo Mancuso, Rosa Rademakers
University of Antwerp, Vib-uantwerp Center For Molecular Neurology (cmn), Antwerpen, Belgium

Aims: *TMEM106B* haplotypes have been found to modulate the risk for several neurodegenerative diseases such as Frontotemporal lobar degeneration with TDP-43 aggregates and Alzheimer's disease and were shown to impact healthy aging and neuronal reserve, suggesting that they determine neuronal vulnerability to external stressors. These haplotypes are thought to regulate expression of TMEM106B, a lysosomal type-II transmembrane protein, with a slight increase in expression associated with the risk haplotype. In this project we assessed how subtle changes in TMEM106B protein levels condition neuronal fitness by dysregulating lysosomal physiology.
Methods: We generated isogenic pluripotent stem cell (PSC)-derived cortical neurons with different TMEM106B expression levels: a full knockout (*TMEM106B*$^{-/-}$) and an inducible-reversible overexpression (*TMEM106B*^{OE}) model. In depth characterization of the endolysosomal pathway of these neurons *in vitro* is currently performed by analyzing their proteome with lysosomal immunoprecipitation and mass spectrometry, whereas lysosomal trafficking with live cell imaging, lysosomal enzymatic activity, as well as lysosomal size and localization with expansion microscopy were already analyzed.
Results: Both *TMEM106B*$^{-/-}$ and *TMEM106B*^{OE} human mature cortical neurons show a dysfunctional endolysosomal pathway. These cells show enlarged lysosomes by expansion microscopy, in which large Cathepsin D and LAMP1 positive structures cluster perinuclearly in the somas of these cells. *TMEM106B*$^{-/-}$ and *TMEM106B*^{OE} neurons also show an increased intensity of Lysotracker in the somas together with a dysregulated lysosomal transport and enzymatic activity, potentially due to changes in lysosomal pH.
Conclusions: Our results show that dysregulations of TMEM106B protein levels, both an increase and a decrease, lead to dysregulations of the endolysosomal pathway. Further understanding of the mechanisms that link this lysosomal dysfunction to neuronal resilience will be essential for the development of drugs that improve the survival of neurons in neurodegenerative diseases.

KNOCKDOWN SCREENING FOR POTENTIAL RAN TRANSLATION MODULATORS IN CELLULAR MODELS OF C9ORF72 FTLD/ALS

POSTERS: D05. CELL, MOLECULAR AND SYSTEMS BIOLOGY

Kohji Mori[1], Shiho Gotoh[1], Ryota Uozumi[1], Tesshin Miyamoto[1], Shizuko Kondo[1], Yuya Kawabe[1], Shoshin Akamine[1], Yoshitaka Nagai[2], Manabu Ikeda[1]
[1]Osaka University, Department Of Psychiatry, Osaka, Japan, [2]Kindai University, Department Of Neurology, Osaka, Japan

Aims: A hexanucleotide expansion in the intron of C9orf72 is the most frequent cause of genetic form of FTLD/ALS. The expanded DNA repeat suffers transcription and produces repeat RNA. The repeat RNA further undergoes repeat associated non-AUG (RAN) translation. In the expanded C9orf72 repeat, RAN translation produces five distinct dipeptide repeat proteins (DPR) that are considered to be highly neurotoxic. Therefore, selective inhibition of RAN translation could have therapeutic potential. Although several factors have been proposed as potential RAN translation modulators, detailed mechanism of RAN translation remains obscure.
Methods: Here we have utilized nano-luciferase based RAN translation reporters that can monitor either poly-GA or poly-GR expressions. Conventional AUG dependent translation was monitored with firefly luciferase reporter activity.
Results: With 22 different siRNA-mediated knockdowns of translation-related factors, we have identified several factors that significantly inhibit/stimulate relative signals of RAN translation reporter over conventional AUG dependent reporter.
Conclusions: These results implicate that C9orf72 RAN translation could be modulated via multiple endogenous factors. Further experimental work will clarify how these factors contribute to RAN translation, thereby elucidating an important aspect of the pathogenesis of C9orf72 FTLD/ALS.

Institute Of Biochemistry, Kiel, Germany, [5]Mayo Clinic, Neuroscience, Jacksonville, United States of America, [6]TU Delft, Delft Bioinformatics Lab, CB, Netherlands

Aims: GWASs have identified a common haplotype in *TMEM106B* associated with increased risk for neurodegeneration. This risk haplotype reportedly increases TMEM106B aggregation in human brains, and is sensitive to decreased activity of TDP-43. Here, we investigated if structural variants (SVs) in the *TMEM106B* risk haplotype mediate these interactions.
Methods: We performed long-read whole-genome sequencing of 209 individuals: 92 AD patients and 117 cognitively healthy centenarians. SVs in *TMEM106B* were identified using *sniffles2*, and further characterised through haplotype-phased *de novo* assembly. We performed linkage disequilibrium (LD) of SVs and previously reported GWAS-SNPs in the risk haplotype. We used *pg-CpG-tools* to evaluate methylation status across the *TMEM106B* haplotypes, as well as *TARDBP*. Finally, we compared *TMEM106B* haplotype sequences of AD and centenarian genomes with 47 genomes from the Human Pangenome Research consortium.
Results: We identified an AluYb8 retrotransposon in the 3' UTR of the *TMEM106B* in complete LD with the risk haplotype. Alu-elements can mediate (post-)transcriptional interference of nearby genes. When transcriptionally, active, Alu-elements can further propagate throughout the genome. We found that the risk haplotype is more methylated than the protective haplotype, likely a consequence of an evolutionary selection to suppress AluYb8 activation and propagation. Similarly, we observed age-related demethylation of *TARDBP*, which may dysregulate TDP-43 and enable further dysregulation of *TMEM106B* via the AluYb8. Additionally, we observe convergent evolution for retaining SINE-retrotransposon insertions in the 3' UTR of *TMEM106B* orthologs across species, suggesting evolutionary significance, such as immune-related benefit in lung-tissues. Finally, we found that African genomes harbour two unique haplotype sequences of *TMEM106B*, explaining why LD is reduced in *TMEM106B* in non-European genomes.
Conclusions: An AluYb8 retrotransposon is a candidate causal variant driving association of *TMEM106B* with different neurodegenerative diseases.

LONGITUDINAL CHARACTERIZATION OF B6.SOD1G93A TRANSGENIC MICE

POSTERS: D06. ANIMAL MODELS

Roland Rabl, Aaron Fantina-Woblistin, Tina Loeffler, Livia Breznik, Magdalena Daurer, Stefanie Flunkert, Manuela Prokesch
QPS Austria GmbH, Neuropharmacology, Grambach, Austria

Aims: A range of human mutant SOD1 transgenic mouse models has been developed that is shown to mimic amyotrophic lateral sclerosis (ALS). Of these models, the most widely used is the SOD1(*G93A)1Gur mouse (Gurney et al., 1995) that is bred on a mixed C57BL/6 x SJL background. Although the SOD1G93A mouse has been a bedrock for ALS research and is a well-used model for over a decade, there are some concerns about its strong and early phenotype. The SOD1 mouse model bred on a pure C57BL/6 background might thus be a suitable alternative since it presents with a delayed ALS phenotype onset compared to the original strain and therefore can provide a longer treatment window for interventions. The aim of this study was to longitudinally evaluate the behavioral phenotype as well as electromyography (EMG) and neurofilament-light chain (NF-L) pathology of B6.SOD1G93A mice.
Methods: B6.SOD1G93A mice (JAX mouse #004435) of mixed sex were longitudinally analyzed for motor deficits using Vercelli score, wire suspension test, beam walk test, grip strength test, and pasta gnawing test at an age of 8, 14, and 20 weeks. Additionally, Compound Muscle Action Potential (CMAP) and Motor Unit Number Estimation (MUNE) was measured. In vivo blood of these mice was evaluated for NF-L levels.
Results: Behavioral tests are completed and are currently statistically analyzed. Animals do show a progressive motor phenotype which correlates with a reduction in CMAP and MUNE. NF-L level analyses are currently ongoing.
Conclusions: The progressive pathology observed in B6.SOD1G93A mice could provide a more appropriate model for studying early-stage pathological processes in ALS and provide a longer treatment window for the development of new therapies.

TMEM106B C-TERMINAL FRAGMENTS DRIVE A DISTINCT NEURODEGENERATIVE PROTEINOPATHY IN C. ELEGANS.

POSTERS: D06. ANIMAL MODELS

Ruben Riordan[1], Brian Kraemer[2,3]
[1]University of Washington, Gerontology, SEATTLE, United States of America, [2]VA Puget Sound Health Care System, Grecc, Seattle, United States of America, [3]University of Washington, Medicine, Seattle, United States of America

Aims: Genetic variation of lysosomal protein, transmembrane protein 106B (TMEM106B) has long been known as a risk factor for a diverse range of neurodegenerative disorders, especially FTLD with progranulin (GRN) haplo-insufficiency, though the mechanisms involved are not yet understood. Recently, through advances in cryo-electron microscopy (cryo-EM), aggregates of the C-Terminal domain of TMEM106B (TMEM CT) were shown to make up previously unidentifiable protein aggregates in the brains of human FTLD, AD, progressive supranuclear palsy (PSP), and dementia with Lewy Bodies (DLB) patients.
Methods: To determine the TMEM CT aggregation propensity and neurodegenerative potential, we generated a new transgenic C. *elegans* proteinopathy model pan-neuronally expressing the TMEM CT fragment constituting the fibrillar core in FTLD cases.
Results: We found that C. *elegans* pan-neuronal expression of TMEM CT causes neuronal dysfunction as evidenced by behavioral analysis. TMEM c-terminal fragments accumulate as detergent insoluble material. Behavioral dysfunction was accompanied by neurodegeneration as illustrated by loss of GABAergic neurons. To investigate the mechanisms driving TMEM106B proteinopathy, we aimed to explore the impact of GRN loss on the neurodegenerative effect of TMEM CT expression. To this end, we generated TMEM CT expressing C. *elegans* with PRGN loss of function. We found that loss of PGRN did not alter TMEM phenotypes confirming PGRN loss of function is upstream of TMEM aggregation. We also observed TMEM neurodegenerative phenotypes exhibit a distinct set of genetic modifiers as strong suppressors of tauopathy such as spop-1, sut-2 sut-6 show only modest modification of TMEM proteinopathy.
Conclusions: Taken together, our data suggest expression of TMEM CT in C. *elegans* neurons provides a useful model for the functional characterization of TMEM106B proteinopathy in neurodegenerative disease. Comparison with other proteinopathy models will inform potential disease mechanisms.

GENERATION AND SCREENING OF MOUSE MODELS OF ADRD WITH MULTIPLE GENETIC MANIPULATIONS TO MODEL DEMENTIA WITH MIXED BRAIN PATHOLOGIES.

POSTERS: D06. ANIMAL MODELS

Bethany Macdonald[1], Harpreet Kaur[1], Andrew Tooley[2], Aamir Zuberi[2], Cathleen Lutz[2], Kristen O'Connell[2], Amy Dunn[2], Catherine Kaczorowski[3]
[1]University of Michigan, Neurology, Ann Arbor, United States of America, [2]The Jackson Laboratory, Research, Bar Harbor, United States of America, [3]The University of Michigan, Neurology, Ann Arbor, United States of America

Aims: Alzheimer's disease-related dementias (ADRD) encompass a wide range of neurodegenerative diseases including Alzheimer's disease, vascular dementia, frontotemporal dementia (FTD), Lewy body dementia (LBD), amyotrophic lateral sclerosis (ALS), Parkinson's disease (PD), and mixed dementia. The heterogeneity of ADRDs presents challenges for animal modeling of disease mechanisms to recapitulate the full spectrum of human disease.
Methods: Mouse strains carrying disease associated alleles in the Psen, App, Apoe, Tardbp, Mapt and Scna on the C57BL/6J genetic background were breed to homozygosity and then crossed to either B6, DBA/2J, FVB/NJ or WSB/EiJ to generate a set of 36 unique ADRD models. The generated models were assessed using a high-capacity multi-domain screening to prioritize future ADRD modeling of drug discovery, preclinical testing, and disease pathology.
Results: We found that the genetic background of strain significantly influenced the onset of behavioral deficits. Male and female App/Psen1/Mapt/Tardbp mice on an FVB or WSB background met our "no-go" criteria by showing elevated body temperature, reduced activity or increased frailty at 6 months of age. However, the same 4xKI mutations on a B6 (heterozygous and homozygous KI) or D2 (heterozygous KI) background are our top candidates as they show a late-onset trajectory of decline suggestive of a translatable ADRD model.
Conclusions: Our results demonstrate that combining ADRD mutations across genetically distinct backgrounds is a promising strategy to generate new mouse models that better model the human mid and late-life onset of deficits associated with ADRD. We identified several promising models of ADRD that exhibited late-onset frailty and motor deficits as function of mutation burden. The resulting model(s) will be translationally relevant and provide important insight into disease mechanisms for the future of ADRD research and drug discoveries.

EPIGENETIC CHARACTERIZATION OF CONTROL AND SALS MOTOR NEURON ORGANOIDS

POSTERS: D05. CELL, MOLECULAR AND SYSTEMS BIOLOGY

Eveljn Scarian[1], Matteo Bordoni[1], Camilla Viola[2], Francesca Dragoni[2], Rosalinda Di Gerlando[2], Luca Diamanti[3], Stella Gagliardi[4], Orietta Pansarasa[1]
[1]IRCCS Mondino Foundation, Cellular Model And Neuroepigenetics Unit, Pavia, Italy, [2]University of Pavia, Dep. Of Biology And Biotechnology, Pavia, Italy, [3]IRCCS Mondino Foundation, Neuroncology Unit, Pavia, Italy, [4]IRCCS Mondino Foundation, Molecular Biology And Transcriptomics Unit, Pavia, Italy

Aims: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease (NDD) with a progressive clinical course that affects upper and lower motor neurons (MNs). There are two typical forms of ALS, the sporadic (sALS) and the familial one. Until now, only symptomatic treatments are available, for the lack of realistic models. Organoids are pluripotent stem cell-derived self-organizing structures which can recapitulate the tissue of origin in vitro. Aim of this project was the investigation of the epigenetic characteristics of motor neuron organoids (MNOs) at each differentiation step, neural stem cells organoids (NSCO), motor neuron progenitor organoids (MNOPs) and MNOs and the comparison of these characteristics which the ones of 2D cultured cells.
Methods: We performed an ELISA assay for DNA methylation status on 5-methylcytosine (5-mC) and a western blot analysis to test the expression of two key methylating enzymes, the DNA methyltransferase 1 (Dnmt1) and the DNA methyltransferase 3a (Dnmt3a). The gene expression of Dnmt1 and Dnmt3a was tested by Real-Time qPCR. Finally, we performed a western blot analysis to test the methylation status of two sites involved in ALS pathology, lysine 9 and lysine 27, both on histone 3.
Results: By ELISA assay we found a decreased methylation in sALS MNOs, which was due to the decrease in the protein expression of Dnmt1 in sALS MNOs when compared to the corresponding 2D MNs. By RT-qPCR we observed some differences both between organoids and 2D cultured cells and between CTRL and sALS cultures. Finally, we found an increasing trend of the trimethylation of lysine 9 and 27 during the differentiation protocol.
Conclusions: In conclusion, we confirmed the major deregulation of MNOs when compared to 2D cultured cells, already seen by our group through RNA-seq.

MOYAMOYA DISEASE EMERGING AS AN IMMUNE-RELATED ANGIOPATHY

POSTERS: E01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Caroline Asselman[1,2,3], Dimitri Hemelsvoet[2,3,4], Denzel Eggermont[1], Evelien Van Hamme[1], Elke Bogaert[2,3], Jo Van Dorpe[5], Francis Impens[1,2,3], Bart Dermaut[2,3]
[1]VIB, Vib-ugent Center For Medical Biotechnology, Ghent, Belgium, [2]Ghent University Hospital, Center For Medical Genetics, Ghent, Belgium, [3]Faculty of Medicine and Health Sciences, Ghent University, Department Of Biomolecular Medicine, Gent, Belgium, [4]Ghent University Hospital, Department Of Neurology, Ghent, Belgium, [5]Ghent University Hospital, Department Of Pathology, Ghent, Belgium

Aims: Moyamoya disease is a rare cerebrovascular disorder with unknown etiology characterized by progressive narrowing of arteries of the brain and the formation of a compensatory network of fragile vessels. Genetic studies have identified RNF213, also known as mysterin, as a susceptibility gene for MMD. Given the low penetrance of RNF213 variants in genetically susceptible individuals, a second still unidentified hit is necessary to trigger disease onset. Recently, several molecular studies uncovered RNF213 as a key antimicrobial protein with important functions in the immune system. Furthermore, an increasing number of clinical reports describe the development of moyamoya angiopathy in association with infection or autoimmune disorders. Together, providing a growing body of molecular and clinical evidence pointing towards immune-related responses as second hits to trigger MMD onset. We hypothesize that the disease originates from an aberrant immune response to infection in patients carrying RNF213 mutations.
Methods: To address this, we compiled a Moyamoya cohort of 12 patients with age-matched healthy controls. Blood and tissue samples were collected and transmitted to our multi-omics pipeline including genomic and plasma proteomics.
Results: In 10 patients we were able to identify genetic variations in MMD susceptibility genes. In plasma, several proteins are differentially expressed. Further data analysis is ongoing to identify disease-relevant pathways. Data integration of these data with our clinical data will be the next step. In addition to this study, we applied a spatial proteomics technique (MACsima) on affected brain tissue of one MMD patient to characterize the immune environment of Moyamoya vessels.
Conclusions: These experiments have the potential to further elucidate the etiology of Moyamoya disease, and potentially lead to novel insights into cellular processes that link cellular immunity with vascular remodeling.

Aims: Cerebral amyloid angiopathy (CAA) is a condition characterized by the accumulation of beta-amyloid within the walls of cortical and leptomeningeal blood vessels. This deposition leads to various vascular issues, including rupture, fibrinoid necrosis, and obstruction. Recently, a novel condition known as iatrogenic CAA (iCAA) has emerged. iCAA is believed to arise from the inadvertent transmission of beta-amyloid between individuals through the use of cadaveric materials or neurosurgical instruments. This unique variant of CAA tends to manifest at an earlier age, typically presenting with symptoms such as lobar hemorrhages, seizures, and cognitive impairment. The introduction of diagnostic criteria for iCAA has resulted in greater awareness and recognition of cases. Our aim is to describe the clinical, radiological and biomarker features in a case of iCAA.
Methods: Presentation of a case report.
Results: A 48-year-old woman, with a history of childhood encephalocele repair, initiated follow-up at the age of 37 due to the presence of multiple lobar hematomas. A cranial MRI revealed chronic bilateral cortico-subcortical microbleeds, superficial siderosis, and leukoaraiosis. Additionally, PET-amyloid imaging displayed a positive result, while the analysis of cerebrospinal fluid biomarkers indicated low beta-amyloid levels, slightly elevated t-tau, and normal p-tau. ApoE genotyping confirmed E2/E3 genotype. Furthermore, genetic evaluations for Fabry, CADASIL, COL4A1, PSEN1, PSEN2, APP, CST3, and exome capture all returned negative results.
Conclusions: While the reported cases od iCAA remain limited, it is crucial to maintain a high level of suspicion for this condition in patients experiencing early-onset CAA, with a specific focus on scrutinizing their medical history for prior procedures. Our case aligns with the diagnostic criteria set forth for this emerging entity and supports the potential transmission of amyloid through a neurosurgical intervention.

REPORTED COGNITIVE AND DEPRESSIVE SYMPTOMS IN RELATION TO HISTORY OF TIA/STROKE IN CADASIL PATIENTS IN SWEDEN

POSTERS: E01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Pia Andersen[1], Helena Karlström[2], Matti Viitanen[1], Anne Börjesson-Hanson[1]
[1]Karolinska Institutet, Department Of Neurobiology, Care Sciences And Society, Huddinge /Stockholm, Sweden, [2]Karolinska Institutet, Neurobiology, Care Sciences And Society Division Of Neurogeriatrics, Stockholm, Sweden

Aims: Cognitive impairment and mood disorders are common after stroke, even if the underlying mechanisms aren't fully understood. In this study we evaluated associations between reported cognitive and psychiatric symptoms and a history of TIA/stroke in a subsample of the Swedish CADASIL-cohort.
Methods: Forty-two individuals with clinical or preclinical CADASIL (*NOTCH3*-mutations confirmed) were evaluated by semi-structured systematic interviews covering medical and social history, lifestyle, symptoms, and course of disease. Medical records were evaluated. Crosstabulation was applied for analyzing relationships between groups and Chi-square test for the test of associations. When the sample size was small, the Fisher's exact test was applied instead.
Results: We evaluated 16 men and 26 women, aged 25-77 years. Twenty-four had a history of ischemic events with a mean age of 50 for the first event. Both cognitive and psychiatric problems were commonly reported. There was a trend for the association between the history of an ischemic event and reported cognitive problems (concentration difficulties, stress sensitivity, difficulty finding words, lack of initiative or memory problems), but not between the ischemic event and psychiatric symptoms. None of the results were clinically significant. No significant differences were observed between men and women in any of the parameters explored.
Conclusions: We found a trend for a higher frequency of cognitive problems in patients with the history of ischemic events but this was not statistically significant. No trend, nor associations were found between psychiatric symtoms and the history of ischemic events. Both the small sample size and the self-reported data are limitations in this study. Cognitive testing of patients, MRI analysis and potential biomarkers and are planned on our project and can hopefully give a better perspective for analyzing the background of these clinical manifestations.

UNRAVELLING DISEASE PATHOLOGY FOR A NOVEL APP INTRACELLULAR DOMAIN VARIANT USING HIPSC-BASED 2D AND 3D MODELS

POSTERS: E01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Bas Voesenek[1], Elena Daoutsali[1], Julie Rutten[2], Saskia Lesnik Oberstein[2], Willeke Van Roon-Mom[1], Ronald Buijsen[1]
[1]LUMC, Human Genetics, Leiden, Netherlands, [2]LUMC, Clinical Genetics, Leiden, Netherlands

Aims: The Amyloid Precursor Protein (APP) has gained great interest in biomedical research due to its causal involvement in Alzheimer's Disease (AD) and Cerebral Amyloid Angiopathy (CAA). The vast majority of pathogenic variants causing AD or CAA are located inside or around the Amyloid-Beta (Aβ) domain of APP. To date, only one pathogenic variant (associated with AD) has been found in the APP intracellular domain (AICD). We report a novel AICD variant in the VTPEER motif in a patient with recurring strokes and aim to unravel pathomechanisms.
Methods: We obtained a skin biopsy from this patient and measured APP expression levels and its subcellular localization in fibroblasts. We will generate isogenic induced pluripotent stem cells (iPSCs) from these fibroblasts, which will be used to generate 2D neuronal cultures where we will measure APP expression and its subcellular localization. We will apply mass-spectrometry to identify changes in AICD interactors. In 3D cerebral organoids and neuro-mesodermal assembloids (to better capture the neurovascular phenotype) we will use single-cell RNA sequencing to investigate changes in gene expression and employ the recently published SCOUT pipeline to extensively characterize multiscale features of 3D fluorescence imaging datasets.
Results: Experiments in patient fibroblasts have shown no differences in APP RNA and protein levels compared to controls. However, presence of APP C-terminus in lysosomes was increased in the patient line. Moreover, we successfully reprogrammed patient fibroblasts into iPSCs and have implemented the SCOUT pipeline on our control cerebral and striatal organoids.
Conclusions: We identified a novel *APP* variant associated with stroke in the AICD. This variant may increase APP abundance in lysosomes. Using iPSC-based models, we will further investigate disease mechanisms in more relevant cell types.

DECREASED EXPRESSION OF CLAUDIN-5 IN CEREBRAL AMYLOID ANGIOPATHY-ASSOCIATED INTRACEREBRAL HAEMORRHAGE

POSTERS: E01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Lieke Jäkel[1], Kiki Claassen[1], Anna De Kort[1], Benno Küsters[2], Floris Schreuder[1], Catharina Klijn[1], H. Bea Kuiperij[1], Marcel Verbeek[1]
[1]Radboud University Medical Center, Neurology, Nijmegen, Netherlands, [2]Radboudumc, Pathology, Nijmegen, Netherlands

Aims: Cerebral amyloid angiopathy (CAA) is characterized by the deposition of the amyloid β (Aβ) protein in the cerebral vasculature which poses a major risk factor for the development of intracerebral haemorrhages (ICH). However, only a minority of patients with CAA develops ICH (CAA-ICH), and to date it is unclear which mechanisms determine why some patients with CAA are more susceptible to haemorrhage than others. Claudin-5 is a tight junction protein critical for functioning of the blood-brain barrier (BBB). We hypothesized that the expression of claudin-5 is altered in CAA-ICH cases compared to non-hemorrhagic CAA (CAA-NH) cases.
Methods: Using immunohistochemistry, we assessed the expression of claudin-5 in the microvasculature of occipital lobe and temporal lobe tissue from cases with CAA-associated ICH (CAA-ICH; n=20) and non-haemorrhagic CAA (CAA-NH; n=40). Also 42 control cases free of stroke and neurodegenerative pathologies were included. Group differences were assessed using linear regression with correction for potential confounders (age, sex, and biobank).
Results: We found lower levels of claudin-5 expression in the microvasculature of CAA-ICH cases compared to CAA-NH cases in both occipital (p=0.027) and temporal (p=0.035) grey matter, and in these patients, claudin-5 expression did not correlate to CAA severity. Claudin-5 expression was also reduced in the overlying white matter of the occipital (p=0.018) and temporal (p=0.015) lobe tissue of CAA-ICH cases compared to CAA-NH cases.
Conclusions: We provide evidence that decreased levels of claudin-5, potentially reflecting impaired BBB integrity, might be associated with the development of CAA-associated ICH. Future studies in larger cohorts with more biomarkers of BBB function are needed to substantiate these findings.

LINKING CEREBRAL DEMYELINATION TO VASCULAR RISK FACTORS USING ADVANCED QUANTITATIVE MAGNETIC RESONANCE IMAGING

POSTERS: E01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Mustapha Bouhrara, John Laporte, Mary Faulkner, Zhaoyuan Gong
National Institutes of Health, National Institute On Aging, Baltimore, United States of America

Aims: It is increasingly established that vascular risk factors (VRF), especially hypertension, obesity and arterial stiffness, represent contributing factors to Alzheimer's and Parkinson's diseases (AD, PD). Further, vascular dysregulation due to potential synergetic effects of arterial remodeling and blood pressure may lead to transient reductions in cerebral blood flow (CBF) resulting in hypoglycemia, hypoxia and lack of essential nutrients and concomitant cerebral tissue damage. However, the implication of these VRF on myelin degeneration has received little attention. Yet, myelin breakdown is associated with decline in cognition, and has been demonstrated to represent a potential major hallmark of AD and PD.
Methods: Our studies were conducted on participants drawn from the BLSA, GESTALT and CARDIA cohorts. For each participant, myelin content was measured using our advanced MRI method of myelin water fraction (MWF), a direct measure of myelin content, or fractional anisotropy (FA) and mean diffusivity (MD) DTI metrics. CBF was measured using our implementation of NESMA-ASL MRI. Finally, Hypertension, obesity, and arterial stiffness were also measured within a few hours from the MRI scans.
Results: Our results revealed lower myelin content in subjects with hypertension despite use of blood control medication. Further, higher arterial stiffness and obesity were also linked to lower myelin content. Finally, participants with lower CBF exhibited steeper longitudinal decline in myelin content and white matter integrity.
Conclusions: Our original findings revealed strong and significant relationships between various vascular risk factors and white matter degeneration, especially of myelin content. These results identify potential modifiable targets to prevent neurodegeneration, and highlight the need for a life course approach which can be combined with remyelination to restore normal axonal function and protects against neuro-axonal loss.

Aims: We develop a proteogenomic workflow on the CosMx™ Spatial Molecular Imager (SMI), a single-cell spatial biology platform that leverages cyclic *in situ* hybridization chemistry to enable high-plex detection of proteins and RNAs at subcellular resolution. To validate the proteogenomic workflow, we profiled uninfected and infected mouse brain with West Nile Virus (WNV) encephalitis.
Methods: We measure 68 proteins (CosMx Mouse Neural Cell Typing and Alzheimer's Pathology Panel) and 1,000 RNA targets (CosMx Mouse Neuroscience Panel) on the same 5 µm thick FFPE section of mouse brain.
Results: As expected from WNV encephalitis, we observed persistent neuroinflammation that includes the recruitment and activation of CD8+ T cells and microglia. We captured the major cell types that comprise inflammatory nodules in post-WNV mouse brain (neurons, microglia, and astrocytes) and identified the signaling pathways that underlie persistent microglial-driven neuroinflammation after WNV encephalitis, and illuminates key aspects of neurodegeneration, neurodevelopment, cell state and signaling, including numerous ligands and receptors involved in neuron-glia communication. Our analysis identified pathways related to inflammation and cellular damage in neurons, astrocytes, microglia and T cells.
Conclusions: We use the CosMx SMI platform to show, for the first time, that large numbers of mouse neuronal cells can be profiled with both protein and RNA at single-cell resolution in a spatial context. This integrated system maximizes the information content per single cell to enable mechanistic understanding into infectious disease pathology and inflammatory response in the brain.

Aims: Genetic variation in Transmembrane protein 106B (TMEM106B) is known to influence the risk and presentation in several neurodegenerative diseases and modifies healthy aging. Current evidence suggests that the risk allele is associated with higher levels of TMEM106B. However, the precise function of TMEM106B is undetermined and it remains unclear how TMEM106B modulates disease risk.
Methods: To study the effect of increased TMEM106B levels, we generated Cre-inducible transgenic mice expressing human wild-type TMEM106B. Our model stably expresses the transgene resulting in increased TMEM106B RNA and protein levels, unlike a previous model that failed to induce overexpression due to the tight regulation of Tmem106b levels. Detailed biochemical and neuropathological characterizations as well as behavioral analyses of this model are ongoing.
Results: We show that embryonic fibroblasts derived from this model are filled with large vacuoles, which are not acidic, and show increased levels of Lamp1 and Progranulin. This indicates that the increase in TMEM106B levels leads to severe lysosomal dysfunction. We performed bulk RNA sequencing on brain tissue from 15-month-old animals and identified the downregulation of genes associated with neuronal plasticity, learning, and memory. Pathway enrichment analysis confirmed the dysregulation of neurotrophin signaling, which was validated in primary cortical neurons.
Conclusions: We created a novel TMEM106B overexpression model and show that overexpression of TMEM106B induces severe lysosomal dysfunction. We show that increased levels of TMEM106B lead to dysregulation of neurotrophin signaling which may underly the disease-modifying effect and may contribute to neurodegeneration *in vivo*. Together, our data further supports the hypothesis that TMEM106B modulates the resilience or vulnerability of the brain to neurodegeneration and aging.

CLINICAL AND DIAGNOSTIC CHARACTERISTICS OF HEADACHE IN PATIENTS WITH SMALL VESSEL DISEASE.

POSTERS: E01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Victoria Vershuta
Sechenov First State Medical University, Neurology, Moscow, Russian Federation

Aims: Small vessel disease(SVD) is one of the most pressing problems of modern medicine.The leading complaint in SVD is headache(HA). **Aim:**Determination of clinical and diagnostic characteristics of HA in SVD.
Methods: The study included 72 patients suffering from SVD. The patients were divided into two groups: group 1 - 44 patients suffering from HA, control group -28 patients without HA.Patients underwent the questionnaire survey: MOCA test, HADS, sleep questionnaire, MRI of the brain
Results: Tension-type headache(TTH) was detected in 27(37.5%)patients, migraine -11(15.3%), migraine and TTH - 6(8.3%). Cognitive impairment in migraine occurred in 8(72.7%) people, in TTH in 17(62.9%), in migraine and TTH in 5(83,3%). In patients with TTH, sleep was disturbed in 18 (66.7%)cases, with migraine in 9(81.8%), with migraine and TTH in 6(100%). Anxiety in TTH patients was diagnosed in 21(77.8%) patients, migraine - 6(54.5%), depression in patients with TTH - 10(37%), with migraine - 7(63.6%). With migraine and TTH, anxiety was diagnosed in 4 (66.7%)cases, depression in 5(83.3%). According to MRI of the brain, white matter pathology corresponding to grade 3 Fazekas was diagnosed in 6(54.5%) patients with migraine, with TTH in 6(22.2%), with TTH and migraine -4(66, 7%)
Conclusions: 44(61.1%) people suffering from SVD complained of HA,while the diagnosis of HA was previously established in 11(15.3%). TTH was the most common among patients with SVD(37.2%). Among patients with migraine cognitive impairment was 9.8% more common than in TTH, as well as more pronounced white matter changes according to MRI of the brain. Anxiety(77.8%) and sleep disorders(66.7%) prevailed among patients with TTH, depression(66.7%) among patients with migraine and TTH. Thus, the majority of patients with SVD suffered from primary HA, the course of which was aggravated by emotional and sleep disturbance.

ACTIVATION OF WNT/B-CATENIN PATHWAY IN THE BRAIN ENDOTHELIUM MITIGATES AB-INDUCED BLOOD-BRAIN BARRIER DYSFUNCTION IN ALZHEIMER'S DISEASE

POSTERS: E01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Chenju Yi
SEVENTH AFFILIATED HOSPITAL OF SUN YAT-SEN UNIVERSITY, Research Center, SHENZHEN, China

Aims: Alzheimer's disease (AD) is the leading cause of age-related neurological and cognitive decline. As the mechanisms of this disease are yet to be fully understood, the treatments for AD pose a significant challenge. Dysfunction of the blood-brain barrier (BBB) is increasingly recognized as a major contributor to the pathophysiology of AD, especially at the early stages of the disease. However, underlying mechanisms remain poorly characterized, while few molecules can directly target and improve BBB function in the context of AD.
Methods: Here using both AD patients and APPswe/PS1dE9 (APP/PS1) mouse model of AD, BBB damage and the underlying molecular mechanism were examined.
Results: We showed dysfunctional BBB in AD patients indicated by perivascular accumulation of blood-derived fibrinogen in the hippocampus and cortex, accompanied by decreased tight junction proteins Claudin- 5 and glucose transporter Glut-1 in the brain endothelial cells (BECs). In the APP/PS1 mice, BBB dysfunction started at 4 months and became severe at 9 months. In the cerebral microvessels of APP/PS1 mice and Aβ- treated BECs, we found suppressed Wnt/β-catenin pathway triggered by an increase of GSK3β activation, but not an inhibition of the AKT pathway or switch to the Wnt/planar cell polarity pathway. Furthermore, using our newly developed optogenetic tool for controlled regulation of LRP6 (upstream regulator of the Wnt signaling) to activate Wnt/β-catenin pathway, Aβ-inhibited BBB function was restored by promoting the barrier repair and preventing Aβ-induced BEC impairments.
Conclusions: Targeting LRP6 in the Wnt/β-catenin pathway in the brain endothelium can alleviate BBB dysfunction induced by Aβ, which may be a potential treatment strategy for AD.

COMPARISON OF DIFFERENT APPROACHES FOR COGNITIVE REHABILITATION AFTER STROKE

POSTERS: E02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Anna Bezdenezhnykh, Semen Prokopenko
FSBEI HE Prof. V.F. Voino-Yasenetsky KrasSMU MOH Russia, Department Of Nervous Diseases With A Pe-course, Krasnoyarsk, Russian Federation

Aims: The aim of the study is to compare the effectiveness of different methods for cognitive rehabilitation after stroke.
Methods: 111 patients after hemispheric stroke in the recovery period with cognitive impairments without dementia (age 40-70) were randomized into four groups. All patients received conventional rehabilitation. Patients in the computer intervention group had 10 daily training sessions with a special neuropsychological software of 40 min duration. The participants in the active control group played entertaining computer games keeping the identical regimen. The patients in the classic intervention group were individually trained by a neuropsychologist using the Luria's approach. The passive control group patients received conventional physical rehabilitation only.
Results: After the treatment period there were improvements in both intervention groups and the active control group on MoCA, MMSE, FAB. In the passive control group only the increase of attention was observed on the Shulte's table test. The increase of IADL was found in the classic and computer intervention groups. Improvements of cognitive functions in the computer intervention group were significantly better than in the control groups and there were some advantages compared with the classic intervention group. In the classic intervention group significant improvements were observed compared to the passive control (ΔMMSE 8 %, ΔFAB 14 %, ΔMoCA 17 %). Effectiveness of cognitive functions restoration in the active control was statistically insignificant compared to the passive control ($p>0,05$). Considering functional status, meaningful advantages of the classic intervention group were found in comparison to other groups (IADL 28%).
Conclusions: The computer cognitive training and the classic neuropsychological approach are both effective methods for post stroke cognitive rehabilitation. Entertaining computer games probably increase the attention but their effectiveness is insignificant compared to the passive control.

ALLEVIATING ALZHEIMER'S PATHOLOGY IN A RAT MODEL THROUGH ORAL SOLUBLE EPOXIDE HYDROLASE INHIBITION

POSTERS: E02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Fan Fan[1], Jane Border[2], Chengyun Tang[1], Huawei Zhang[2], Xing Fang[2], Seung Min Shin[3], Hongwei Yu[3], Bruce Hammock[4], Richard Roman[2]
[1]Augusta University, Physiology, Augusta, United States of America, [2]University of Mississippi Medical Center, Pharmacology, MS, United States of America, [3]Medical College of Wisconsin, Anesthesiology, Milwaukee, United States of America, [4]University of California - Davis, Entomology & Ucd Comprehensive Cancer Center, Davis, United States of America

Aims: Objectives. Alzheimer's Disease and Alzheimer's Disease-Related Dementias (AD/ADRD) pose a global healthcare crisis with complex mechanisms. Genome-wide studies reveal AD-associated SNPs in soluble epoxide hydrolase (sEH). Elevated sEH levels occur in AD/ADRD humans and animal models. sEH inhibition enhances cognition and neuroprotection in AD mice. This study investigates the impact of sEH inhibition on cerebral vascular function and AD pathology in a rat model.
Methods: Methods. The translational potential of sEH inhibition was evaluated using TgF344-AD rats. These rats were administered orally TPPU, a sEH inhibitor, at 1 mg/kg/day via their drinking water for three months. Various parameters were assessed, including cognitive function using an eight-arm water maze, cerebral vascular function through myogenic response of the middle cerebral artery using a pressure myography, cerebral blood flow autoregulation using laser-Doppler flowmetry, amyloid plaques examined via MOAB antibody and Congo Red staining, and neurodegeneration assessed through Nissl staining.
Results: Results. TPPU treatment rescued impaired learning and memory in AD rats. The myogenic responses of the middle cerebral artery and cerebral blood flow autoregulation were impaired in AD rats and were normalized with TPPU. TPPU significantly reduced amyloid plaques in the cortex and hippocampus. Neuronal counts in the hippocampus increased in TPPU-treated AD rats (86.91 ± 3.71 vs. 64.57 ± 3.92).
Conclusions: Conclusions. These results underscore the potential of chronic sEH inhibition as a multifaceted therapeutic approach for AD/ADRD. By enhancing cognition, restoring cerebrovascular functions, reducing neurodegeneration, and mitigating amyloid plaque formation in AD rats, sEH inhibition emerges as a promising avenue for addressing the challenges posed by AD/ADRD. Further research and clinical exploration of sEH inhibition promises to advance our understanding and treatment of this pressing healthcare concern.

LIPIDIZED PRRP ANALOG EXHIBITS A NEUROPROTECTIVE EFFECT IN SHRSP RATS

POSTERS: E02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Silvie Hojna[1], Jaroslav Kuneš[2], Lenka Maletínská[3], Lucia Mrazikova[3]
[1]Czech Academy of Sciences, Institute Of Fhysiology, Prague, Czech Republic, [2]Institute of Physiology, Experimental Hypertension, Prague, Czech Republic, [3]IOCB CAS Prague, Biochemistry And Molecular Biology, Prague, Czech Republic

Aims: Stroke-prone spontaneously hypertensive rats (SHRSP) are an animal model of essential hypertension with a high incidence of brain stroke and other marks of microbleeding which appear also in patients and lead to dementia. Incidence and sizes of brain lesions are known to relate to the age and neuroinflammation. Recently, neuropeptides regulating food intake were proposed for treatment of neurodegenerative disorders. One of them, palmitoylated analog of prolactin-releasing peptide (Palm^{11}-PrRP31), is a novel modified anorexigenic neuropeptide with a potential neuroprotective effect.
Methods: Six months old SHRSP rats were treated with Palm^{11}-PrRP31 (5 mg/kg ip.) for 8 weeks. Age-matched, not treated Wistar-Kyoto (WKY) rats were used as controls. Acute phase and late phase of peripheral inflammation were tested using CRP ELISA kit, MCP-1 ELISA kit respectively. The level of astrogliosis was determined by immunohistochemical (IHC) analysis using astrocyte marker glial fibrillary acidic protein (GFAP).
Results: Hypertophic heart and kidney of both groups of SHRSP rat confirmed developed hypertension. Neither experimental group showed any marks of peripheral inflammation as well as brain microbleeding. On the other hand, we were able to prove, that SHRSP rats at the age of 8 months have significantly increased positive GFAP labelling in the cerebral cortex and even more in the hippocampus compared to WKY rats. This astrogliosis was improved by treatment with Palm^{11}-PrRP31. The intervention also significantly decreased the body weight gain of SHRSP rats compared to not treated animals.
Conclusions: Even though 8 months old SHRSP animals did not developed any brain lesions, astrogliosis in the brain cortex and in the hippocampus was set up. Our study indicate that Palm^{11}-PrRP31 can improve the neuroinflammation. Exact mechanism must be elucidated.

BIOMARKER AND EDEMA ATTENUATION IN INTRACEREBRAL HEMORRHAGE (BEACH): A PHASE 2A PROOF-OF-CONCEPT STUDY OF AN ANTI-NEUROINFLAMMATORY SMALL MOLECULE DRUG CANDIDATE

POSTERS: E02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Linda Van Eldik[1], Wendy Ziai[2], Lauren Sansing[3], Daniel Hanley[2]
[1]University of Kentucky, Sanders-brown Center On Aging, Lexington, United States of America, [2]Johns Hopkins University, Bios Clinical Trials Coordinating Center, Baltimore, United States of America, [3]Yale University, Neurology, New Haven, United States of America

Aims: Patients with acute spontaneous intracerebral hemorrhage (ICH) develop secondary neuroinflammation and cerebral edema that can further damage the brain. Preclinical studies in acute brain injury models have shown that the investigational drug candidate, MW01-6-189WH (MW189), decreases neuroinflammation and cerebral edema and improves functional outcomes. MW189 was also safe and well tolerated in phase 1 clinical trials in healthy adults. Therefore, we designed the first-in-patient exploratory trial to determine safety and tolerability of MW189 in acute ICH patients, identify trends in potential mitigation of neuroinflammation and cerebral edema, and assess effects on functional outcomes.
Methods: The **B**iomarker and **E**dema **A**ttenuation in Intra**C**erebral **H**emorrhage (BEACH) trial is a first-in-patient phase 2a, proof-of-concept study of MW189 in patients with ICH. This multicenter, prospective, randomized, double-blind study will enroll 120 non-traumatic ICH participants, with an anticipated average age in their mid-60s and substantial numbers of individuals with cerebral small vessel disease and cerebral amyloid angiopathy. Patients will be randomly assigned 1:1 to receive intravenous MW189 (0.25 mg/kg) or placebo (saline) within 24 hours of symptom onset and every 12 hours for up to 5 days or until hospital discharge.
Results: The trial is actively enrolling participants. The primary outcome is all cause-mortality within 7 days post-randomization between treatment arms. Secondary endpoints include all-cause mortality at 30 days, perihematomal edema volume after symptom onset, adverse events, vital signs, pharmacokinetics of MW189, and inflammatory cytokine concentrations in plasma (and cerebrospinal fluid if available). Other exploratory endpoints are functional outcomes collected on days 30, 90, and 180.
Conclusions: BEACH will provide important information about the utility of targeting neuroinflammation in ICH and will inform the design of future larger trials of acute CNS injury.

QUANTITATIVE ANALYSIS OF WHITE MATTER NEUROIMAGING BIOMARKERS IN A US CADASIL CONSORTIUM

POSTERS: E03. IMAGING, BIOMARKERS, DIAGNOSTICS

H. Bockholt[1], Bradley Baker[1], Nicholas Pasley[1], Jordan Clemsen[1], Laura Eisenmenger[2], David Liebeskind[3], Michael Geschwind[4], Vince Calhoun[1], Jane Paulsen[5]
[1]Tri-Institutional Center for Translational Research in Neuroimaging and Data Science (TReNDS), Georgia State University, Georgia Institute of Technology, and Emory University, Neuroinformatics, Atlanta, United States of America, [2]University of Wisconsin-Madison, Radiology, Madison, United States of America, [3]University of California, Los Angeles, Neurology, Los Angeles, United States of America, [4]University of California, San Francisco, Neurology, San Francisco, United States of America, [5]University of Wisconsin-Madison, Neurology, Madison, WI, United States of America

Aims: This study seeks to identify white matter neuroimaging biomarkers within a US-based CADASIL consortium. CADASIL (Cerebral Autosomal Dominant Arteriopathy with Subcortical Infarcts and Leukoencephalopathy) is a notable genetic small vessel disease. Accurately delineating its neuroimaging biomarkers proves critical for early diagnosis, progression assessment, and targeted intervention strategies.
Methods: The investigation encompasses a cohort of 120 NOTCH3 positive patients: 50 non-symptomatic and 70 symptomatic. For comparative analysis, 5 family controls are also included. The study employs a range of neuroimaging modalities to assess white matter lesions, lacunes, enlarged perivascular spaces, microbleeds, and altered diffusion characterized by the peak width of skeletonized mean diffusivity (PSMD). Additionally, it examines alterations in both functional and structural connectivity, emphasizing changes within the basal ganglia circuits.
Results: Preliminary data reveal distinct white matter pathology patterns between symptomatic and non-symptomatic groups. Through this technical exploration, a set of definitive neuroimaging markers is being established.
Conclusions: These findings aim to advance the understanding of CADASIL, potentially refining diagnostic criteria and guiding effective clinical management.

PLASMA VEGF-A AND PLGF IMPACT LONGITUDINAL TAU AND COGNITION IN PRECLINICAL ALZHEIMER'S DISEASE

POSTERS: E03. IMAGING, BIOMARKERS, DIAGNOSTICS

Hyun-Sik Yang[1], Wai-Ying Wendy Yau[1], Becky Carlyle[2], Bianca Trombetta[2], Zahra Shirzadi[2], Aaron Schultz[2], Jennifer Rabin[2], Jeremy Pruzin[2], Rudolph Tanzi[2], Keith Johnson[3], Reisa Sperling[1], Steven Arnold[2], Jasmeer Chhatwal[2]
[1]Brigham and Women's Hospital, Neurology, Cambridge, United States of America, [2]Massachusetts General Hospital, Neurology, Boston, United States of America, [3]Massachusetts General Hospital, Harvard Medical School, Department Of Radiology, Boston, United States of America

Aims: Vascular dysfunction is increasingly recognized as an important contributor to the pathogenesis of Alzheimer's disease. Alterations in vascular endothelial growth factor (VEGF) signaling have been implicated as potential mechanisms, though the specific impacts of VEGF pathway dysregulation in preclinical Alzheimer's disease remain to be elucidated.
Methods: We examined VEGF family protein levels (VEGF-A, VEGF-C, VEGF-D, PlGF, and FLT1) in plasma from 320 older adults participating in the Harvard Aging Brain Study, a cohort of individuals who were cognitively unimpaired at baseline and followed longitudinally for up to 12 years. Using linear mixed effects models, we examined the interactive effects of baseline plasma VEGF proteins and amyloid PET burden (C11-Pittsburgh Compound-B PET) on longitudinal cognition (Preclinical Alzheimer Cognitive Composite-5) and neocortical tau accumulation (F18-Flortaucipir PET).
Results: Lower VEGF-A and higher PlGF were associated with greater prospective cognitive decline in individuals with elevated amyloid, i.e. those on the Alzheimer's disease continuum. Similarly, lower VEGF-A and higher PlGF were associated with accelerated longitudinal tau accumulation in this population. The effects of VEGF-A and PlGF on tau and cognition remained similar after adjusting for cardiovascular risk score or white matter hyperintensity volume.
Conclusions: Our findings implicate low VEGF-A and high PlGF in accelerating early neocortical tau pathology and cognitive decline in preclinical Alzheimer's disease. Additionally, our results underscore the potential of these minimally-invasive plasma biomarkers to inform the risk of Alzheimer's disease progression in the preclinical population. Lastly, these results highlight the VEGF pathway as a potential therapeutic target to delay or prevent the onset of cognitive decline, either alone or in combination with anti-amyloid or traditional vascular risk reduction therapies.

SUBCLINICAL CORONARY ATHEROSCLEROSIS AND ITS EFFECTS ON COGNITIVE, BLOOD, AND NEUROIMAGING MARKERS IN COGNITIVELY HEALTHY ADULTS

POSTERS: E03. IMAGING, BIOMARKERS, DIAGNOSTICS

Sofia Marcolini, Ingeborg Frentz, Jaime Mondragon, Peter De Deyn
University Medical Center Groningen, Neurology, Groningen, Netherlands

Aims: Atherosclerosis is related to a higher risk of dementia and cognitive decline. We aim to individuate individuals at high risk of cognitive decline using different biomarkers.
Methods: 280 cognitively healthy individuals of mean age 68.05 (SD=8.57), education 13.58 (SD=3.80) years, 42% females, were recruited through the Lifelines study. All participants underwent nonenhanced cardiac computed tomography scanning to obtain a coronary artery calcium score, a proxy of low (scores of 0) or high (scores >300) subclinical coronary atherosclerosis. Participants were administered cognitive and behavioural tests; serum blood biomarkers for inflammation (IL-1beta, IL-6, TNF-alpha, CRP) and Alzheimer's disease (amyloid-β40, amyloid-β42, NfL, p-tau181, GFAP) were collected. Finally, extensive brain magnetic resonance imaging (MRI) data was acquired to assess cerebrovascular function. Analysis of covariance was used to compare the groups; MRI data is currently being analyzed.
Results: After correcting for age and sex, groups differed only in GFAP serum levels (p=0.02) with the high coronary artery calcium score group having lower GFAP values compared to the low coronary artery calcium score. The group with high coronary artery calcium also showed worse quality of life (p=0.03) and worse verbal fluency (p=0.04) compared to the low coronary artery calcium group. Cerebral blood flow data, assessed with multiple post-labeling delayed vessel-encoded arterial spin labeling imaging, has been pre-processed, group comparisons are currently being run, together with white matter lesion quantifications.
Conclusions: These preliminary results suggest that subclinical coronary atherosclerosis might affect some cognitive functioning domains and an Alzheimer's disease marker. How these variables relate to each other is being further studied. The ongoing analysis of cerebral blood flow and other small vessel disease markers will help us further understand the relationship between these variables and the underlying mechanisms.

THE IMPACT OF CEREBRAL WHITE MATTER LESIONS ON COGNITIVE FUNCTION IS ASSOCIATED WITH BRAIN VOLUME AND ALZHEIMER'S DISEASE BIOMARKER STATUS

POSTERS: E03. IMAGING, BIOMARKERS, DIAGNOSTICS

Sho Miki[1], Shuko Takeda[2,3], Tsuneo Nakajima[1], Sho Yamamoto[1], Naoki Hayakawa[1], Yoshinobu Kisino[1], Shin Teshirogi[1], Momoko Ookawara[1], Yuki Ito[2,3], Nanami Sugihara[2], Kunihiro Miki[2], Yoichi Takami[1], Yasushi Takeya[1,4], Koichi Yamamoto[1], Hiromi Rakugi[1], Ryuichi Morishita[2]
[1]Graduate school of medicine, Osaka University, Geriatric And General Medicine, Suita, Osaka, Japan, [2]Graduate school of medicine, Osaka University, Department Of Clinical Gene Therapy, Suita, Osaka, Japan, [3]Osaka Psychiatric Research Center, Osaka Psychiatric Medical Center, Hirakata, Osaka, Japan, [4]Graduate School of Medicine, Osaka University, Division Of Health Sciences, Suita, Osaka, Japan

Aims: Cerebral white matter lesions (WML) are known to affect the severity of cognitive impairment in patients with dementia. Recent studies have suggested that there is a diversity in the impact of WML on cognitive function depending on patients' brain volume or neuropathological background. In this study, we investigated the correlations between WML and cognitive scores in subgroups stratified based on brain volume and Alzheimer's disease (AD) biomarker status.
Methods: Elderly patients with dementia and MCI at Osaka University Hospital (n = 441) underwent brain MRI, a neuropsychological assessment (MMSE), and cerebrospinal fluid (CSF) biomarker testing. BAAD (Brain Anatomical Analysis using Diffeomorphic deformation) software was used to quantitatively determine the brain volume and WML. Then, patients were divided into one of three subgroups based on the severity of brain atrophy; minimal atrophy ($z < 1$, n = 164), mild atrophy ($1 \leq z < 2$, n = 147), and moderate atrophy ($2 \leq z$, n = 130). CSF p-tau/Aβ42 ≥ 0.087 was regarded as a positive biomarker for AD.
Results: In the subgroup with minimal atrophy, WML volumes were negatively correlated with MMSE scores in both AD biomarker-positive ($r = -0.17$) and -negative ($r = -0.27$) patients with statistical significance ($p < 0.01$, Spearman). In the mild atrophy subgroup, no significant correlations were observed in either AD biomarker population. In the moderate atrophy subgroup, a significant correlation was observed in the AD biomarker-negative patients ($r = -0.32$, $p < 0.05$, Spearman).
Conclusions: The impact of WML on cognitive function can be affected by the severity of brain atrophy and a patient's AD biomarker status.

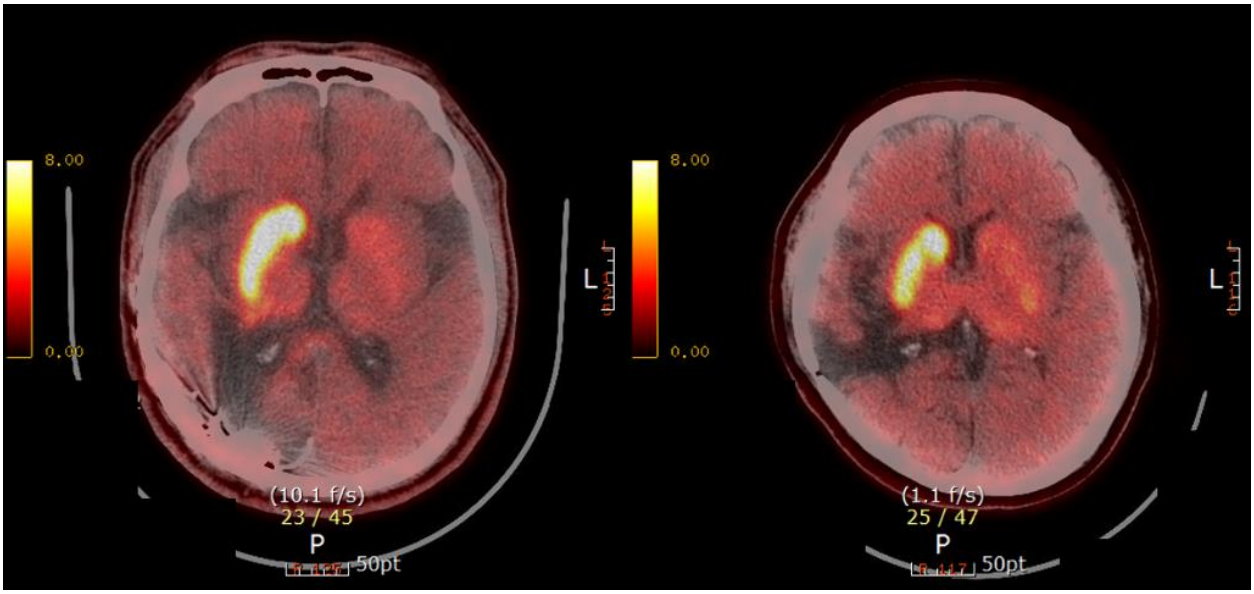
2 CASES OF KERNOHAN'S NOTCH HEMIPARKINSONISM AND HOLME'S TREMOR

POSTERS: E03. IMAGING, BIOMARKERS, DIAGNOSTICS

Eungseok Oh
Chungnam National University Hospital, Neurology, Daejeon, Korea, Republic of

Aims: We experienced the two patients who showed hemiparkinsonism and Holme's tremor after intracerebral hemorrhage (ICH) due to spontaneous rupture of arteriovenous malformation (AVM). Dopamine transporter images of them were nearly non-visible at the unilateral ICH area. Therefore, we report the Kernohan's notch injury and pathomechanism of unilateral dopamine damage.
Methods: We retrospectively review the dopamine transporter images of hemiparkinsonism and Holms' tremor patients to evaluate the relationship between dopamine depletion and parkinsonism and tremor. Among them, two patients showed severe unilateral dopaminergic deficit (nearly not showing any dopamine uptake) and contralateral Holme's tremor and parkinsonism. Their symptoms elicited after large ICH due to AVM.
Results: One patient showed hemiparkinsonism on his right arm and leg and Holme's tremor on his right arm. This symptom occurred after 11 months of large lobar ICH on Rt parietal occipital area and he operated craniectomy and hematoma evacuation, and then AVM embolization was done. He complained of dizziness and clumsiness of his right arm and leg moreover, an uncontrolled tremor that was wax and wane. His symptoms were not well controlled with levodopa, beta-blocker, primidone, levetiracetam, and rivotril. He showed only right-side dopamine uptake on FP-CIT PET (image 1). Another patient showed Holme's tremor without parkinsonism on her right arm and leg. She also injured spontaneous ICH on the right temporoparietal area due to AVM, and a craniotomy was done. She showed only right-side dopamine uptake on FP-CIT PET (image 1). Her symptoms were very well controlled with low-dose levodopa and
levetiracetam.



Conclusions: Kernohan notch injury caused by acute large hemorrhage such as midline shifted lesions. It caused damage to the contralateral dopaminergic tract and then caused contralateral Holme's tremor or hemiparkinsonism.

A MODERN APPROACH TO THE DIAGNOSIS AND TREATMENT OF COGNITIVE DISORDERS IN HYPERTENSIVE DISEASES.

POSTERS: E03. IMAGING, BIOMARKERS, DIAGNOSTICS

Raykhon Rasulova[1], Satima Kuranbaeva[2]
[1]Termiz branch of Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan, [2]Tashkent Medical Academy, Neurology, Tashkent, Uzbekistan

Aims: to determine the level of cognitive impairment in hypertension and determine the modern treatment measure.
Methods: The research is based on the examination data of 48 hypertensive patients (12 men 25%, 36 women 75%) of different age, gender, education, profession. The patients in the study underwent a clinical and neurological examination taking into account the level of cognitive impairment using outpatient questionnaires, brain MRI and scales MMSE, clock drawing test, MOCA. Choline alfoscerate was recommended for patients with moderate cognitive impairment.
Results: Before treatment, the level of cognitive impairment in patients was 22±1.8 points on the MMSE scale. According to the examination of the clock drawing test, patients scored 6±1.0 points, nodement cognitive impairment, i.e. "forehead-subcortical" type of cognitive impairment was detected in 32 patients (66.7%). According to the MOCA scale, the indicators of cognitive impairment were 22±2.2 points. According to the results of the examination and observation, patients with hypertension were treated with choline alfoscerate in 38 of the patients in the examination, in addition to slowing down the process of cognitive impairment and increasing work ability.
Conclusions: Long-term therapy of patients with hypertension with choline significantly improved cognitive functions and improved the quality of life of patients of all age groups, increased work ability.

EFFECT OF THE MIND+SOUL DIET INTERVENTION ON CARDIOMETABOLIC BIOMARKERS RELATED TO ALZHEIMER'S DISEASE AMONG OLDER AFRICAN AMERICANS

POSTERS: E03. IMAGING, BIOMARKERS, DIAGNOSTICS

Ashley Shaw[1,2], Eric Vidoni[2], Janette Berkley-Patton[3], Debra Sullivan[4], Jill Morris[2], Jeff Burns[2]
[1]University of Kansas Medical Center, 2. university Of Kansas Alzheimer's Disease Research Center, Fairway, United States of America, [2]University of Kansas Medical Center, Department Of Neurology, Kansas City, United States of America, [3]University of Missouri-Kansas City, 4. Department Of Biomedical And Health Informatics, Kansas City, United States of America, [4]University of Kansas Medical Center, Dietetics And Nutrition, Kansas City, United States of America

Aims: Objective: Cardiovascular and metabolic disease are associated with an increased risk of Alzheimer's disease (AD), which disproportionately affect African Americans (AA) who are 2 to 3 times more likely to develop AD. Emerging evidence indicates that up to 50% of AD cases are a result of modifiable cardiovascular and metabolic risk factors, therefore prevention strategies may play a critical role in reducing AD risk for AAs. The overall objective of the study was to examine the effect of an adapted brain healthy diet (MIND+SOUL) on cardiometabolic risk among older AAs at risk for AD. The primary aim was to assess the response of cardiometabolic biomarkers (body composition, lipid profile, glucose metabolism, and inflammation) for AD to the MIND+SOUL diet intervention.
Methods: Methods: We conducted a single arm 12-week culturally tailored dietary intervention (MIND+SOUL) in 3 waves that consisted of a total of 30 cognitively normal older AAs, aged 55 years and older who had one or more cardiovascular risk factor. The MIND+SOUL intervention encompassed dietary education classes, health coaching sessions, and weekly groceries. Cardiometabolic risk profile assessments were collected at baseline and at the 12-week mark.
Results: Results: A total of 28 AAs completed the intervention with a retention rate of 93%. From baseline to 12 weeks, improvements in cardiometabolic risk were observed in body mass index (p=0.249) and glucose (p=0.456).
Conclusions: Conclusion: Results from this study indicate the MIND+SOUL intervention is feasible for older AA and changes in cardiometabolic risk from baseline to 12 weeks differ, but are not significant. Also, results from this study will inform the development of a R01-scale randomized control trial that will test the efficacy of the MIND+SOUL intervention among older AA across a larger geographical area.

CHARACTERIZING SMALL VESSEL DISEASE IN NATIVE HAWAIIAN AND OTHER PACIFIC ISLANDERS WITH DEMENTIA: A RETROSPECTIVE PILOT STUDY

POSTERS: E03. IMAGING, BIOMARKERS, DIAGNOSTICS

Michelle Trinh[1,2], Sarah Song[1], Elise Wong[1], Megan Baldemor[1], Tyson Wu[1], Julia Jahansooz[1,2], Edward Weldon Iv[1,2], Anson Lee[1,2], Chathura Siriwardhana[2], Yone-Kawe Lin[2], Jason Viereck[1], Kore Liow[1,3], Enrique Carrazana[1]
[1]Hawaii Pacific Neuroscience, Memory Discovery Center Alzheimer's Disease Research Unit, Honolulu, United States of America, [2]University of Hawaii, John A. Burns School Of Medicine, Honolulu, United States of America, [3]John A. Burns School of Medicine, University of Hawaii, Department Of Quantitative Health Science, Honolulu, United States of America

Aims: Small vessel disease (SVD), a major cause of age-related cognitive decline, affects small cerebral blood vessels, leading to cerebral hypoperfusion. Native Hawaiians and other Pacific Islanders (NHOPI) are reported to have higher rates of vascular risk factors of SVD, such as hypertension. This study aims to characterize the prevalence and severity of SVD in NHOPI dementia patients compared to their Caucasian and Asian counterparts.
Methods: This retrospective chart review analyzed data from dementia patients ≥ 18 years old with a brain MRI and MMSE score between 23-27. Each NHOPI patient was matched with a Caucasian and Asian patient based on age, sex, and MMSE score. Patient charts were reviewed for demographics, comorbidities, medications, and SVD MRI findings at time of presentation of memory concerns.
Results: Overall, 108 patients were included, with 36 patients in each racial group, a mean patient age of 72.1 years, and 72 (66.7%) females. NHOPI patients had a higher BMI ($p<0.001$) and higher rates of hypertension ($p=0.024$), diabetes mellitus ($p=0.020$), and coronary artery disease ($p=0.026$). NHOPI had higher rates of reporting attention deficits as a symptom of dementia ($p=0.015$). However, there were no significant differences in prevalence or severity of white matter lesions, subcortical infarcts, or brain atrophy among the racial groups.
Conclusions: NHOPI patients were significantly associated with higher rates of vascular risk factors and showed differences in presentation of dementia. Further investigation is needed to identify potential preventative targets and improve risk predictions for individuals with SVD.

DIETARY INTERVENTION WITH CALORIC RESTRICTION OR ITS MIMETIC RESVERATROL ALTERS RELATIVE CEREBRAL BLOOD FLOW IN WILD TYPE AND TGF344-AD RATS

POSTERS: E03. IMAGING, BIOMARKERS, DIAGNOSTICS

Judith Van Rooij[1,2], Tamara Vasilkosvka[1,2], Johan Van Audekerke[1,2], Ignace Van Spilbeeck[1,2], Monica Van Den Berg[1,2], Lauren Kosten[2], Daniele Bertoglio[1,2], Marleen Verhoye[1,2]
[1]uNeuro Research Centre of Excellence, University of Antwerp, Faculty Of Pharmaceutical, Biomedical And Veterinary Sciences, Antwerpen, Belgium, [2]Bio-Imaging lab, University of Antwerp, Pharmaceutical, Biomedical And Veterinary Sciences, Wilrijk, Belgium

Aims: Alzheimer's disease (AD) is a neurodegenerative disorder hallmarked by amyloid-beta and cerebral amyloid angiopathy, which influences vascular reactivity and neurovascular coupling. Caloric restriction (CR) or its mimetic resveratrol (Rsv) have shown to improve vascular health and could therefore possibly delay neurodegeneration in AD. To address their potential vascular effects, we assessed relative cerebral blood flow (rCBF) in healthy (WT) and TgF344-AD (Tg) rats under normal and hypercapnic conditions, using pseudo-continuous Arterial Spin Labeling (pCASL) MRI. Our aim was to establish whether dietary intervention 1) alters rCBF and 2) could possibly preserve healthy vascular physiology in a rat model of AD.
Methods: Graphical abstract of study design and data acquisition:

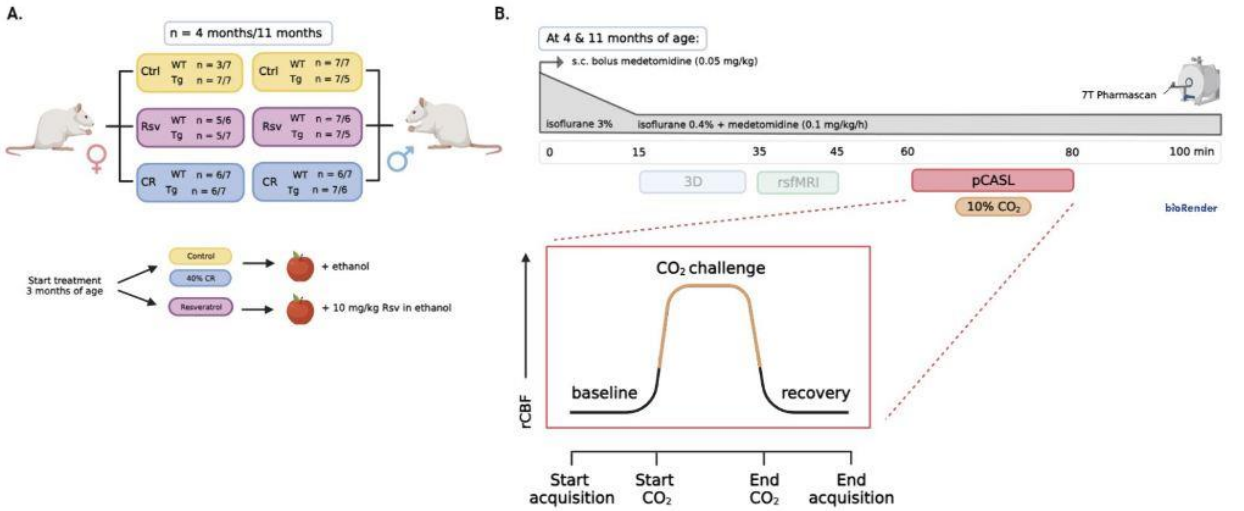

Fig. 1: (A.) TgF344-AD rats and wild-type littermates were randomly divided in 3 treatment groups, with dietary intervention starting at 3 months of age. Resveratrol was supplemented using dried apple chips, with control and CR groups recieving apple chips with vehicle (ethanol) only (B.) Animals were subjected to perfusion MRI scans at 4 and 11 months of age after which data were processed to extract rCBF at baseline (b) hypercapnic (ch) and recovery (r) conditions.

Results: Whole brain analysis revealed differences in rCBF in males, while none of these differences were observed in females (Fig.2A). At baseline conditions, CR lowered rCBF compared to control and Rsv treated male rats (Fig.2B). In addition, we observed a lowered rCBF in aged Tg male rats, different from their age matched WT controls (Fig.2C). The observed lowering of rCBF due to aging or CR treatment, persisted during the CO2 challenge (Fig.2D), where additionally, Rsv Tg males showed higher rCBF, compared to their age matched Tg controls. During the recovery phase, CR lowered rCBF compared to Rsv treated male rats (Fig.2E), similar to the effect observed at baseline.

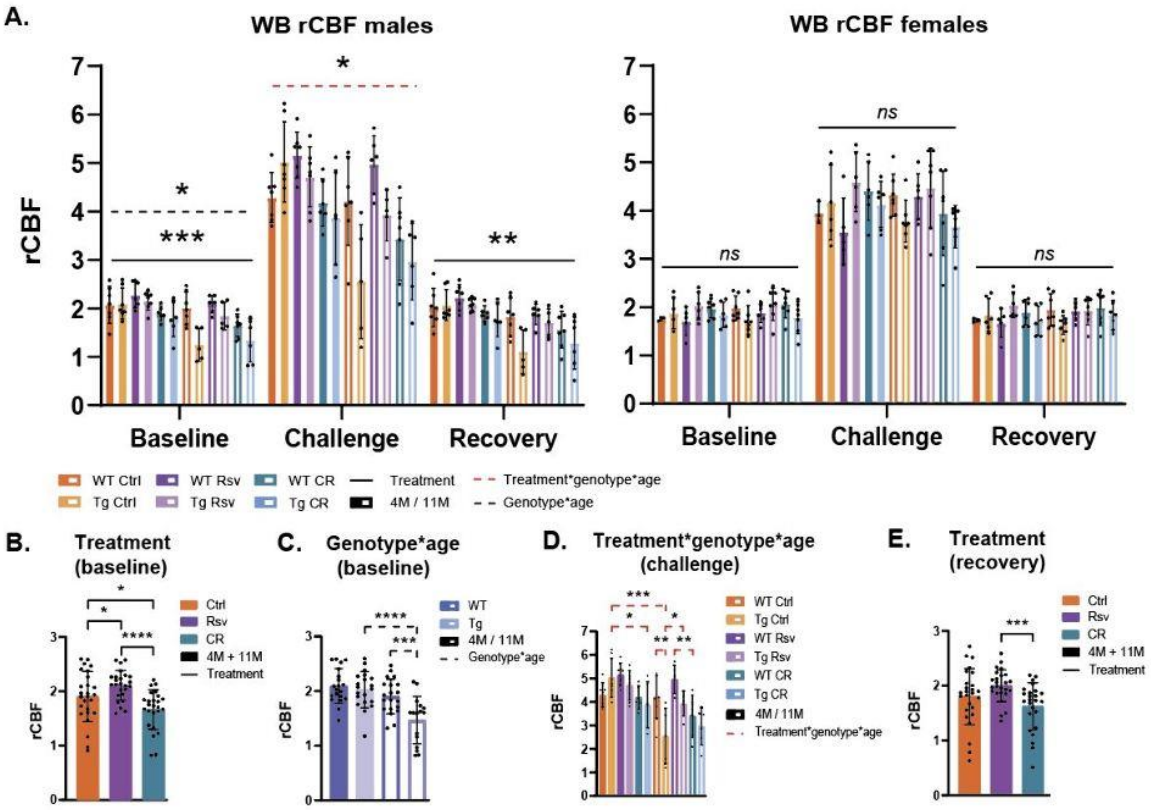

Fig. 2: Whole-brain (WB) rCBF (A.) for both male and female rats, wildtype (WT) and TgF344-AD (Tg) at both 4 (filled bars) and 11 months (open bars) of age for the three conditions. Post-hoc results of the main and interaction effects in the males are shown in B.- E. Groups means ± SD are presented together with the individual subjects data (dots). The asterisks indicate significant differences based on analyses after linear mixed model analysis with corresponding post-hoc testing: *p<0.05, **p<0.01, ***p<0.001, ****p<0.0001.

Conclusions: In this MRI study, we provide evidence of differences in blood flow between sexes as well as a contrasting change of rCBF in response to dietary intervention using CR or Rsv in WT- and TgF344-AD rats. To further unravel the difference between these treatments in this model of AD, ongoing work is focusing on the molecular underpinning of mechanisms resulting in the observed rCBF responses.

MAPPING OF PARKINSON'S DISEASE AND PARKINSONIAN SYNDROMES IN THE TROPICS: 94 CASES OBSERVED AT CONAKRY UNIVERSITY HOSPITAL

POSTERS: E04. GENETICS, EPIDEMIOLOGY

Souleymane M'Bara Diallo[1], Mariama Boubacar Diallo[2], Mohamed Lamine Toure[1], Amara Cisse[1]
[1]Hopital National Igance Deen, Neurology Department, Conakry, Guinea, [2]Hopital National Igance Deen, Neurology, Conakry, Guinea

Aims: In tropical environments, the diagnostic criteria for Parkinson's disease established by MDS remain an essential tool in the clinical approach despite the fact that family forms remain difficult to establish. We report 94 cases of the Guinean geographic distribution of Parkinson's disease and Parkinsonian syndromes over a 2-year period for epidemiological, clinical and prognostic re-evaluation.
Methods: This was a 2-year prospective descriptive study from November 1, 2020, to October 30, 2022, conducted at the Conakry Neurology Department, which is the country's only centre for the management of neurological diseases and Parkinsonian syndromes. The diagnosis of Parkinson's disease was based on the use of the UPDRS scale from the first consultation. Parkinsonian syndromes were identified by clinical semiology and MRI data.
Results: The survey involved 94 patients, including 12 cases of Parkinson's disease with a male predominance of 56.26% with a sex ratio of 1.29. Clinical symptomatology was dominated by tremors, followed by hypertonia and akinesia at 95.74%, 94.68% and 34.04, respectively.We noted an improvement in the quality of life of our patients with a frequency of 45% during our study. The impact of the environment was assessed because more than 62% was identified in Lower Guinea in the region where bauxite mining is open-cast by mining companies suggesting an interaction between the environment and Parkinsonian syndromes.
Conclusions: It appears that Parkinsonian syndromes are identified in Lower Guinea where the exploitation of bauxite is open-cast, which can evoke a major role in relation to the regions.

ALZHEIMER'S DISEASE AND CAROTID ARTERY PLAQUE: A MENDELIAN RANDOMIZATION STUDY

POSTERS: E04. GENETICS, EPIDEMIOLOGY

Devendra Meena[1], Jian Huang[1], Marie-Joe Dib[2], Paul Elliot[1], Abbas Dehghan[1], Ioanna Tzoulaki[1]
[1]Imperial College London, Epidemiology And Biostatistics, London, United Kingdom, [2]Hospital of the University of Pennsylvania,, Division Of Cardiovascular Medicine, Philadelphia PA, United States of America

Aims: To explore the potential causal relationship between Alzheimer's disease and carotid artery plaque using a two-sample Mendelian randomization approach
Methods: We performed a Mendelian randomization (MR) study to investigate the potential causal effect of Alzheimer's disease (AD) on carotid artery plaque (CAP). Single nucleotide polymorphisms (SNPs; P<5e-8) for AD and CAP were obtained from the International Genomics of Alzheimer's Project (IGAP; n=63926 discovery sample, 18,845 replication and 11,666 post-replication) and the Cohorts for Heart and Aging Research in Genomic Epidemiology (CHARGE) consortium and the UCL-LSHTM-Edinburgh-Bristol (UCLEB) (n=48,434) consortium, respectively. Inverse-variance weighted (IVW) was employed as the primary analysis and weighted median, MR-Egger, MR-PRESSO, and MR-Lasso as sensitivity analyses. In addition, we used Steiger filtering to identify SNPs that explain more variance in the exposure (AD) than the outcome (CAP).
Results: We found that genetically predicted AD was causally associated with CAP (β_{IVW}=0.10, 95%CI 0.03 to 0.1, P<0.0001). Sensitivity methods including weighted median, MR-Egger, and MR-Lasso showed consistent direction of effect with IVW. A multivariable MR of AD, high-density lipoprotein cholesterol (HDL), and low-density lipoprotein cholesterol (LDL) on CAP showed that AD was not associated with CAP after adjusting for HDL and LDL, with strong evidence of LDL leading to higher CAP (β_{IVW}=0.35, 95%CI 0.25 to 0.44, P<0.0001).
Conclusions: Our study suggests AD as a potential causal risk factor for CAP.

Aims: After acute ischemic stroke (AIS), more than 40% of patients with large vessel occlusion remain disabled at 3 months despite successful reperfusion therapies like intravenous thrombolysis and endovascular therapy (EVT). Glycoprotein YKL40 is a biomarker of astrocytic and microglial activation. It is elevated in plasma in numerous neurodegenerative disorders but also in AIS. We investigated dynamics of microglial activation at hyperacute phase of an AIS and tested the hypothesis that elevation of YKL40 was predictive of functional outcome at 3 months.
Methods: Monocentric prospective study included patients treated with EVT, for whom 3 blood samples (before, within 1-h, 24-h post-EVT) were drawn to measure plasma YKL40 concentration as a marker of microglial activation. Excellent outcome was defined as a modified Rankin scale (mRS) between 0-1 at 3 months.
Results: We included 120 patients between 2016-2020. Median NIHSS was 17 and median ASPECT score was 7. Reperfusion was achieved at a mean delay of 5h44. After three months, median mRS was 3 and 25% of patients with pre-stroke mRS< 2 had excellent outcome. We found that in patients presenting with large vessel occlusion treated by EVT, excellent clinical outcome was significantly associated with lower plasma YKL40 levels at time of stroke (before EVT and within 1h post-EVT) but not with YKL40 plasma levels at 24h post-AIS after adjustment on age, NIHSS and delay since onset.
Conclusions: Our results suggest that critical activation of microglia occurs very early in AIS course. Plasma YKL40 could a candidate predictor of the functional outcome at 3 months in AIS treated by EVT. This novel biomarker could help optimizing post-stroke care and give new insight on pathophysiology of pathological brain changes after AIS.

DECIPHERING MOLECULAR MECHANISMS UNDERLYING BBB DYSFUNCTION IN ALZHEIMER'S DISEASE: A MULTI-OMICS SYSTEMS BIOLOGY APPROACH

POSTERS: E05. CELL, MOLECULAR AND SYSTEMS BIOLOGY

Karunya Kandimalla[1], Zengtao Wang[1], Xiaojia Tang[2], Kevin Thompson[2], Krishna Kalari[2]
[1]University of Minnesota, Pharmaceutics And Brain Barriers Research Center, Minneapolis, United States of America, [2]Mayo Clinic, Quantitative Health Sciences, Rochester, United States of America

Aims: Time-series transcriptomics analyses have shown that insulin-signaling regulates critical blood-brain barrier (BBB) functions. Alternatively, insulin resistance triggers BBB dysfunction and exacerbates Alzheimer's progression. Our aim is to develop a mechanistic systems biology model to quantitatively describe the role of insulin signaling on BBB integrity and function and predict the impact of insulin resistance on cerebrovascular inflammation prevalent in Alzheimer's disease (AD).
Methods: A systems model incorporating multi-omics data was developed with two interrelated subsystems: insulin-signal transduction and turnover of VCAM1, a marker for cerebrovascular inflammation. Effects of time and insulin exposure on the expression of proteins/phosphoproteins were identified in BBB models *in-vitro* as well as in mouse cerebral microvasculature *in-vivo* using western blots and reverse-phase protein arrays (RPPA). Kinetic parameters were determined by fitting the model to both newly generated and previously published data, utilizing Matlab Simbiology®. The model was subsequently validated using independent datasets obtained from BBB endothelium overexpressing insulin receptors and AD transgenic mouse data. The high throughput RPPA data was incorporated into the validated model to predict insulin signal disruptions and the VCAM1 expression.
Results: As expected, insulin-signaling was triggered in a time- and dose-dependent manner in polarized BBB monolayers *in-vitro;* alternatively, VCAM1 expression was found to be reduced upon insulin exposure via PI3K/AKT/eNOS pathway. Moreover, Aβ exposure was shown to inhibit insulin signaling, but increased VCAM1 expression and the associated cerebrovascular inflammation. Moreover, the systems biology model has successfully predicted insulin-signaling disruptions and greater VCAM1 expression in the BBB endothelium upon Aβ exposure *in-vitro;* AD transgenic mice *in-vivo,* as well as in AD patients compared to normal individuals.
Conclusions: A multi-omics systems biology approach is effective in deciphering molecular mechanisms underlying BBB dysfunction in AD and metabolic syndrome.

THERAPEUTIC EFFECTS OF AR1001, A PHOSPHODIESTERASE 5 INHIBITOR, IN THE MIDDLE CEREBRAL ARTERY OCCLUSION MODEL OF STROKE IN RATS

POSTERS: E06. ANIMAL MODELS

Singh Padmanabh[1], Fred Kim[2], Ashish Kumar[1], Dong-Keun Song[1], Jai Jun Choung[2], Sae Kwang Ku[3]
[1]AriBio Co., Ltd., Brain Research Center, Seongnam-si, Korea, Republic of, [2]AriBio Co., Ltd., Management, Seongnam-si, Korea, Republic of, [3]DAEGU HAANY UNIVERSITY, Anatomy And Histology, Gyeongsan-si, Korea, Republic of

Aims: AR1001, mirodenafil, is a potent phosphodiesterase 5 (PDE5) inhibitor with blood-brain barrier permeability. AR1001 can effectively reduce Aβ and pTau levels and improve cognitive functions in Alzheimer's disease mouse models. In the present study, we investigated the effect of AR1001 in the transient and permanent middle cerebral artery occlusion (tMCAO and pMCAO) models of stroke in rats.
Methods: AR1001 was administered subcutaneously at the doses of 0.5, 1, and 2 mg/kg per day for 9 days starting 24 h after tMCAO induction or 1 mg/kg per day for 14 days starting 24, 72 or 168 h after pMCAO induction. Sensorimotor functions were evaluated using limb placing test and body swing test. For cognitive functions the time and distance to reach the escape platform were evaluated using the Morris water maze test. Brain morphological damage was evaluated by measuring the infarct volume, and the number of cleaved caspase-3 and PARP immunoreactive cells.
Results: Sensorimotor dysfunctions and cognitive impairment were observed in tMCAO and pMCAO rats as compared to the sham control. Further, brain atrophy and the number of cleaved caspase-3 and PARP-immunoreactive cells were increased compared to sham control rats. AR1001 significantly attenuated the tMAO-induced sensorimotor and cognitive dysfunctions and the increased number of cleaved caspase-3 and PARP-immunoreactive cells in a dose-dependent manner with the peak efficacy at 1 mg/kg. AR1001 also demonstrated protective effects in sensorimotor and cognitive dysfunctions after pMCAO induction. Furthermore, AR1001 significantly decreased cleaved caspase-3 and PARP - immunoreactive cells in pMCAO rats, but had minimal effects on the infarct volume for both tMCAO and pMCAO rats.
Conclusions: AR1001 demonstrated protective effects in MCAO-induced mild and severe stroke rate models.

THE ROLE OF CEREBROVASCULAR PERMEABILITY IN NEURODEGENERATION DURING TRAUMATIC BRAIN INJURY

POSTERS: E06. ANIMAL MODELS

David Lominadze, Nurul Sulimai, Jason Brown
University of South Florida, Department Of Surgery, Morsani College Of Medicine, Tampa, United States of America

Aims: Traumatic brain injury (TBI) triggers a cascade of effects that cause immediate and delayed pathologies contributing to neurodegeneration and cognitive impairment. Fibrinogen is not only a marker of inflammation, but also a cause of the inflammatory responses. We previously showed that when the blood content of fibrinogen increases during mild-to-moderate TBI (m-mTBI), it results in enhanced cerebrovascular permeability. Here we investigate the effects of the increased cerebrovascular permeability and the resultant extravascular deposition of fibrinogen during m-mTBI.
Methods: M-mTBI was generated in C57BL/6 mice. The resultant extravascular deposits of fibrinogen, astrocyte activation, neurodegeneration, and the expression of nuclear factor-κB (NF-kB) were assessed by immunohistochemistry 14 days after head injury. The specific effects of fibrinogen on neurons were tested using cultured mouse brain neurons and astrocytes. Astrocyte activation, neuronal death, neuronal NF-kB expression, and the generation of reactive oxygen species (ROS) were tested using immunohistochemistry, western blot, and ELISA. Short-term memory (STM) was assessed with novel object recognition and fear conditioning tests.
Results: Fibrinogen increased cerebrovascular permeability and resulted in an increase of fibrinogen deposits in the vasculo-astrocyte interface. These effects were associated with the increased activation of astrocytes, neurodegeneration, the enhanced expression of neuronal NF-kB, the generation of ROS, and a reduction in STM in mice.
Conclusions: Our results suggest that a TBI-induced increased blood level of fibrinogen contributes to increased cerebrovascular permeability, resulting in deposits of fibrinogen in the vasculo-astrocyte interface, leading to the activation of astrocytes and neurodegeneration. Neuronal activation can be a result of the overexpression of NF-kB and the overgeneration of ROS. These effects contribute to the reduction of STM, indicating that TBI-induced increased cerebrovascular permeability has a significant effect on cognition during neuroinflammatory diseases such as TBI.

AN INCREASE IN PRION SUBSTRAIN DIVERSITY CORRESPONDS WITH PRION STRAIN EMERGENCE

POSTERS: F01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Jason Bartz, Tess Gunnels, Taylor York, Alyssa Block, Ronald Shikiya
Creighton University, Medical Microbiology And Immunology, Omaha, United States of America

Aims: Prions are composed of PrP^{Sc}, the disease specific conformation of the host encoded prion protein. Treatment of rodents with anti-prion drugs results in the emergence of drug-resistant prion strains, suggesting prions are comprised of a dominant strain and substrains. While considerable experimental evidence supports this hypothesis, direct observation of substrains has not been observed. The objective of this study was to directly investigate if prion strains contain substrain diversity.
Methods: We investigated the presence of substrain diversity in a biologically stable hamster-adapted prion strain, DY TME and a biologically unstable hamster-adapted prion strain 139H that, following serial passage at high titer, can breakdown into a strain with a shorter incubation period. Both strains were probed for substrains by selectively reducing the abundance of the dominant strain PrP^{Sc} using either extended digestion with proteinase K or with chaotropic treatment. The remaining PrP^{Sc} was subjected to protein misfolding cyclic amplification to probe for substrains.
Results: Selective reduction of DY or 139H PrP^{Sc} using a combination of biochemical methods resulted in the emergence of strains with properties that differed from DY or 139H and were consistent with the selection criteria. Substrains identified in 139H-infected brains were similar to the strains that emerged in animals following strain breakdown.
Conclusions: The substrain selection methods occurred outside of prion formation, providing direct evidence for the preexistence of substrains. Furthermore, we hypothesize that substrains are a common feature of prions as they were identified in a stable, biologically-cloned prion strain. The identification of preexisting substrains may contribute to the ability of prions to rapidly adapt to new replication environments such as transmission to a new species or replication in the presence of anti-prion drugs.

Aims: This study investigated the relationship between pTau181 levels in plasma, expected symptom onset, and cognitive function in healthy individuals carrying E200K mutation
Methods: Data from 48 individuals were analyzed. The number of years to expected symptom onset (at the time of data and samples collection) was calculated based on a published model. Two groups were compared: the first included individuals more than 2 years before expected onset (n=39) and the second included individuals less than 2 years from expected onset (n=9)
Results: Mean age was 54.8 years (SD=5.6) vs. 67.8 years (SD=3) ($p<0.001$), mean years of education was 14.4 (SD=1.8) vs. 12.7 (SD=3.2) ($p=0.03$), 54% vs. 78% females ($p=0.27$) for the first and second groups, respectively. ANCOVA analysis was performed to compare pTau181 levels in plasma between the two groups, with age included as a covariate. The overall model was significant, indicating that the combination of the grouping variable and age explained a significant proportion of the variance in pTau181 levels (Adjusted R-squared = 0.310). The main effect of the grouping variable was also significant, with the second group having higher pTau181 levels than the first group (1.726 pg/ml vs. 1.026 pg/ml). ANCOVA was conducted to compare cognitive function between the groups, controlling for age and years of education. No significant differences were found in MoCA scores, TMT-A, and digit span. However, TMT-B and phonemic verbal fluency showed significant differences between the groups (TMT-B z-scores were -1.55 (SD=1.8) vs. -6.7 (SD=7.3), and phonemic verbal fluency z-scores were 0.09 (SD=1.24) vs. -1.37 (SD=0.89) in the first and second groups, respectively
Conclusions: healthy carriers of the E200K mutation may exhibit increased pTau181 levels in plasma and subtle changes in executive functions prior to symptoms onset.

FAITHFUL SEEDED AMPLIFICATION OF PRION STRAIN-SPECIFIC CONFORMATION TO RECOMBINANT PROTEIN

POSTERS: F01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Fei Wang[1], Victor Banerjee[1], Carla Barria[1], Damian Gorski[1], Tyler Allison[1], Nicole De Gregorio Carbonell[1], Santiago Ramirez[1], Claudio Soto[1,2]

Aims: Neurodegenerative disease-associated protein aggregates, such as Amyloid beta plaques and Tau tangles in AD and Lewy bodies in PD, are believed to self-propagate and spread across brain regions following the "prion-like" mechanism. Prions replicate through the template-guided conversion of the normally folded prion protein (PrP^{C}) by its misfolded, infectious form (PrP^{Sc}). Prion strains composed of PrP^{Sc} sharing identical primary sequences are known to exhibit distinguishable biological and structural properties. Using the PMCA (Protein Misfolding Cyclic Amplification) technique, it has been reported that bona fide recombinant prions can be generated using bacterially expressed recombinant PrP (recPrP) with specific cofactors, either spontaneously or in seeded reactions. However, previous efforts to faithfully propagate native prion strain properties with recPrP as substrate have failed. Here, we studied whether recPrP can serve as the substrate for efficient and faithful *in vitro* propagations of a mouse prion under specific PMCA conditions.
Methods: In a seeded PMCA reaction supplemented with anionic cofactors, 10% brain homogenate (BH) from the RML mouse prion-infected terminally ill mouse was used as the template to amplify the protease-resistant PrP species (PrP-res) from the protease-sensitive recPrP. The newly generated recPrP-res was subjected to biological characterization using wild-type mice and structural studies using cryogenic electronic microscopy (Cryo-EM).
Results: Wild-type mice infected with RML-seeded recPrP-res developed classical prion clinical signs with a very synchronized incubation time, similar to that of the RML-infected mice. Further biochemical and histopathological analyses confirmed that these animals succumbed to the RML prion disease. Cryo-EM studies provided the structural evidence for the *in vitro* replication of RML-specific strain conformation.
Conclusions: As a proof of concept, our results support the notion that seeded amplification can faithfully replicate prion conformations to recombinant proteins under defined conditions.

Aims: Mutations in RNF216, an E3-ubiquitin ligase, have been identified as the genetic cause of Gordon Holmes syndrome (GHS), a rare recessive neurodegenerative disease. Various loss-of-function (LOF) mutations inside and outside the catalytic domain of RNF216 have been described. However, how mutations outside the catalytic domain result in LOF and how mutations in RNF216 give rise to neurodegeneration, remains unclear. We hypothesize that the heterogenous group of mutations result in a common distorted pathway resulting in the formation of toxic aggregates and hence neurodegeneration. Identifying these pathways is our main objective.
Methods: Like most neurodegenerative diseases RNF216 mediated neurodegeneration is associated with the abnormal protein deposits in the brain of patients. We will use spatial proteomics to unravel its associated aggregome. In addition, the interactome of both WT and mutated RNF216 will be mapped using proximity-dependent biotin identification (BioID). A comparison of the interactome and an integration with the data obtained from the aggregome experiment will shed light on the disease pathways at play.
Results: Immunohistochemical analysis showed ubiquitin-positive and p62 immunoreactive intranuclear inclusions in the neurons of the neostriatum, CA1 and CA2 of the hippocampus and aria striata. These inclusions were negative for AT8,4G8 and TDP43. Aggregates are collected using laser capture microdissection and subsequently subjected to mass-spectrometry.
Conclusions: The physiological and pathological mechanisms explored in this project hold the potential to greatly improve our understanding of GHS, shed light on novel key players in neurodegeneration, and open new avenues for a novel therapeutic target for this rare neurodegenerative disease.

ANALYSIS OF VARIANTS IN THE SIRT1 GENE PROMOTER AND SIRT1 PROTEIN CONCENTRATION ASSOCIATED WITH CIRCADIAN RHYTHM DISTURBANCES IN PATIENTS WITH PARKINSON'S DISEASE

POSTERS: G01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Jolanta Dorszewska, Thomas Piekut, Jolanta Florczak-Wyspiańska, Wiktoria Szablikowska, Izabela Korczowska-Łącka, Wojciech Kozubski
Poznan University of Medical Sciences, Department Of Neurology, Labratory Of Neurobiology, Poznan, Poland

Aims: Objectives. Parkinson's disease (PD) is a common neurodegenerative disease. It is characterized by motor and non-motor disorders. Non-motor disorders include neuropsychiatric disorders, autonomic system disorders, pain, and sleep disorders. The most common sleep disorders are sleep fragmentation/premature rising and daytime sleepiness. Despite the update of the "Parkinson's Disease Sleep Scale" (PDSS), precisely determining whether these disorders constitute a disease state and whether they are related to PD remains a significant diagnostic problem. The *SIRT1* gene product is responsible for maintaining the endogenous circadian rhythm. The reduced levels of the SIRT1 protein in PD lead to reduced melatonin levels and more frequent night waking. The aim of this study is to analyze genetic variants in the *SIRT1* promoter and the concentration of its protein product in PD patients suffering from clinically diagnosed sleep disorders.
Methods: Methods. The studies were conducted on 85 individuals (PD and controls).
The *SIRT1* (rs12778366) genetic variants were determined by HRM and sequencing. The SIRT1 concentration was determined by the ELISA method.
Results: Results. We have demonstrated the presence in the *SIRT1* (rs12778366), one described genetic variant, *SIRT1* T>C, and two not yet described in the literature, ch10:67883352 G>A, and chr10:67883370 G>C. *SIRT1* genotypes occurred with variable frequency in PD and controls. The CG genotype of the *SIRT1* chr10:67883370 G>C gene was present only in PD ($p<0.05$). Moreover, a higher mean number of PDSS points was found in PD (23.3±10.3) compared to controls (12.0±8.4), ($p<0.001$), expressed by lower SIRT1 concentration in PD (10.6±15.0) as compared with controls (17.2±18.7), ($p<0.01$), indicating the occurrence of circadian rhythm disturbances.
Conclusions: Conclusions. Assessment of sleep disorders on the PDSS and analysis of the *SIRT1* gene may contribute to improving the diagnosis of PD.

THE HUNTINGTIN-MEDIATED MEMBRANE INTERACTOME AND KINOME FROM NEURONS DIFFERENTIATED FROM HUNTINGTON'S DISEASE (HD) PATIENT-DERIVED IPSCS

POSTERS: G01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Shermali Gunawardena
SUNY at Buffalo, Department Of Biological Sciences, Hochstetter Hall Rm 540, Buffalo, United States of America

Aims: Huntingtin (HTT) can interact with a plethora of partners, but a clear cellular function has yet to emerge. A number of membrane-related functions for HTT have been isolated, but several questions still remain. Here we test the hypothesis that HTT acts as a scaffolding protein on membranes for distinct functions. Since the proposed HTT membrane binding regions are also post-translationally modified (PTM), we predict that PTMs play a key role in regulating HTT's scaffolding function.
Methods: To identify how the HTT interactome on membranes changes under normal and disease conditions we used neurons differentiated from HD patient-derived iPSCs coupled with quantitative LC–MS. To identify how PTM modifications in HTT affect function we isolated the HTT kinome network on membranes.
Results: LC-MS analysis of the HTT interactome on membranes showed 87 lost, 714 grained, 224 increased and 15 decreased proteins as a consequence of HD. PolyQ-HTT showed strong associations with cellular compartments related to neuronal translation, trafficking, axon guidance, and signal transduction postulating roles for HTT in these processes. Kinome analysis indicated a dramatic redistribution of HTT-kinase associations on HD membranes. 66 gained/increased and 3 lost/decreased associations were observed with polyQ-HTT. However, 31 kinases exhibited gained/increased associations with polyQ-HTT with a concomitant lost/decrease with membranes, suggesting that polyQ-HTT-mediated abnormal interactions may impede these kinases from being appropriately recruited to their respective target sites.
Conclusions: Our analysis provides evidence for how HTT likely functions as a scaffolding protein and how these functions are disrupted during disease. Further, the significant redistribution of kinase associations with HTT on membranes under disease conditions suggests that PTMs of HTT likely play key roles during disease. Future work will isolate the mechanistic aspects of how these kinases contribute to HD.

EFFECTS OF EMOTIONAL CHANGES IN BRAIN NEURAL ACTIVITY IN RELATION TO FOOD INTAKE.

POSTERS: F03. IMAGING, BIOMARKERS, DIAGNOSTICS

Yoko Hasegawa[1], Shogo Yoshimura[1], Tatsuya Suzuki[2], Masako Shiramizu[3], Ma. Therese Sta. Maria[1,4], Kensuke Yamamura[5], Yumie Ono[6], Takahiro Ono[7]
[1]Niigata University Graduate School of Medical and Dental Sciences, Division Of Comprehensive Prosthodontics, Niigata, Japan, [2]Graduate School of Science and Technology, Meiji University, Electrical Engineering Program, Kawasaki, Japan, [3]Otemae Junior College, Department Of Dental Hygiene, Nishinomiya, Japan, [4]Faculty of Dentistry, Manila Central University, Department Of Prosthodontics, Caloocan, Philippines, [5]Niigata University Graduate School of Medical and Dental Sciences, Division Of Oral Physiology, Niigata, Japan, [6]Meiji University, Department Of Electronics And Bioinformatics, School Of Science And Technology, Kawasaki, Japan, [7]Osaka Dental College School of Dentistry, Department Of Geriatric Dentistry, Osaka, Japan

Aims: This study aimed to explore the relationship between emotional changes and biological responses during eating by measuring brain neural activity through functional near-infrared spectroscopy (fNIRS). Unlike prior research that used uniform test foods, this study tailored the test foods to individual preferences to assess changes in cerebral hemodynamics when consuming palatable and unpalatable foods, shedding light on how emotional shifts affect neural activity during food intake.
Methods: Twenty-one right-handed, healthy individuals aged 20-35 (10 males, 11 females) participated. Food selection was based on answers obtained via Google Forms, considering allergies. A combination of closed and open questions was used to determine participants' food preferences. The experimental setup involved measuring cerebral blood flow with fNIRS during food intake of three foods: control (Aito® rice), palatable, and unpalatable, each ingested at 4g per spoonful. Participants rated food desirability on a visual analog scale (VAS). fNIRS data were analyzed with a general linear model.
Results: Increased activity was observed in the left dorsolateral prefrontal cortex (BA 9, BA 46) when emotional valence was high during food intake. Additionally, there was altered activity in parts of BA 6 in the right hemisphere. The dorsolateral prefrontal cortex plays a crucial role in appetite control, food craving, and executive functions, impacting memory, attention, learning, and behavior. These findings suggest that emotional changes related to eating may influence cognitive functions. Specifically, the "taste" of a meal could affect higher-order functions like memory and learning.
Conclusions: This study demonstrated that emotional responses to food can significantly impact neural activity in brain regions associated with cognitive functions, emphasizing the intricate connection between food preference, emotions, and cognitive processes during eating.

Aims: Deleterious mutations in the *TANK1-binding kinase 1* (*TBK1*) cause amyotrophic lateral sclerosis (ALS). Our group generated *Tbk1*^{E696K} knock-in mice carrying the *TBK1* missense mutation p.E696K leading to an impairment of autophagy. The mutant mice show age-dependent ALS-like motor and neuropathological phenotypes, such as distal muscle paresis and increased accumulation of cytosolic p62 positive inclusions. Previous evidence showed that TBK1 phosphorylates mutant Huntingtin (mHTT) and attenuates its aggregation in vitro and in less sophisticated organismal models. In this study, we apply the *Tbk1*^{E696K} knock-in mouse model to understand: 1) the cellular and molecular dysfunction linked to the onset and progression of mutant TBK1 (mTBK1) pathology, and 2) the functional interaction of TBK1 with mHTT during disease progression.
Methods: To investigate the cell type- and stage-specific molecular deficits triggered by mTBK1 in the vulnerable spinal cord tissue, we used single nuclei RNA-Sequencing (snRNA-Seq) by the 10x Genomics platform in the *Tbk1*^{E696K} knock-in at pre- and early-symptomatic stages. In parallel, we crossed the *Tbk1*^{E696K} knock-in with a model of Huntington's disease (HD) carrying a *mHTT* allele. In these double knock-in mice, we analyzed the impact of *Tbk1*^{E696K} on the accumulation of mHTT protein inclusions in different brain regions over time.
Results: In the *Tbk1*^{E696K} knock-in mice we detected transcriptional dysregulation in microglia and macrophages already at pre-symptomatic stages. Moreover, the number of mHTT and p62 positive inclusions increases in the double mutant mice, supporting that the p.E696K mutation can impair clearance of aggregation-prone proteins.
Conclusions: We identified cell-type and age-dependent dynamics of gene dysregulation in *Tbk1*^{E696K} knock-in mice. Moreover, we demonstrated during disease progression a role of TBK1 for the accumulation of mHTT inclusions in a mammalian model of HD.

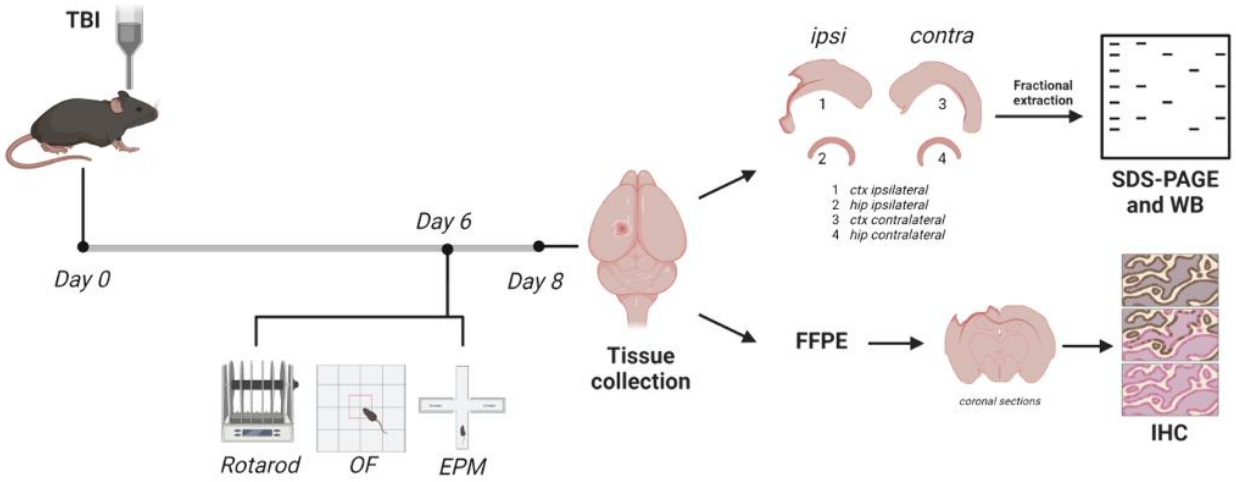
TRAUMATIC BRAIN INJURY EXACERBATES DISEASE PATHOLOGY IN A MOUSE MODEL OF ALZHEIMER'S DISEASE

POSTERS: G01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Miheer Sabale[1], Lars Ittner[2], Yazi Ke[2]
[1]Macquarie University, Dementia Research Center, Macquarie Medical School, Macquarie Park, Australia, [2]Macquarie University, Dementia Research Center, Macquarie Medical School, Macquarie University, Australia

Aims: We established an in-vivo model to study traumatic brain injury (TBI) in the context of Alzheimer's disease (AD) pathogenesis (Aim 1) followed by investigating the role of pathologically mutated tau in disease progression (Aim 2)
Methods: This study uses two well characterized AD mouse models; Tau58/2 (tau P301L) and Alz17 (unmutated tau). At 3 months, mice underwent surgery to induce a single TBI using a controlled cortical impact (CCI) device. On day 6 after surgery mice underwent behaviour testing: rotarod (motor deficits), elevated plus maze (anxiety) and open field (exploratory and locomotor activity). Mice were perfused on day 8 and tissue was collected for analysis by western blot (contralateral and ipsilateral) and by immunohistochemistry (coronal)



Results: Our behavioural and biochemical data reveal that a single severe TBI induced by a CCI device leads to an earlier onset and increased severity of cognitive deficits in Tau58/2 mice when compared to Alz17 mice. This was observed alongside an increase in reactive astrocytosis and microgliosis
Conclusions: This study established two well characterized AD models as a tool to study the pathogenesis of TBI. Our findings indicate that injury in mice with tau mutated at P301L leads to an accelerated onset of AD-like symptoms, including increased astrocytosis and gliosis. Inflammation is a key mediator of both AD and TBI and clinical trials of immune modulation therapies after TBI are still in their infancy. The disease models described in this study will allow for the study of key mechanisms driving inflammation in both disorders and help identify novel therapeutic targets

PARAMETERS OF VARIATIONS IN AERODYNAMIC AND ACOUSTIC MEASUREMENTS IN WOMEN WITH PARKINSON'S DISEASE

POSTERS: G01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Clara Ponchard[1], Didier Demolin[1], Lise Crevier-Buchman[1,2], Alain Ghio[3], François Viallet[3,4]
[1]Laboratoire de Phonétique et Phonologie, (cnrs & U. Sorbonne Nouvelle), Paris, France, [2]Ho_pital Foch, Université Paris-saclay, Surennes, France, [3]Aix-Marseille Université, Cnrs Lpl, Umr 7309, Aix-en-Provence, France, [4]Service de Neurologie, Centre Hospitalier Du Pays D'aix, Aix-en-Provence, France

Aims: The main objective of this study is to contribute to the modeling of phonation in women with Parkinson's disease.
Methods: Our study stands out by (1) providing a conceptual and methodological framework for the segmentation of aerodynamic and acoustic data; (2) performing a multiparametric study; (3) identifying the sources of variation in aerodynamic and acoustic parameters; and (4) identifying parameters that characterize Parkinsonian speech. Data from 74 French native-speaking women (37 with Parkinson's, 37 controls) divided into age groups (under 60, 60-70, over 70 years) from the AHN corpus [1] were analyzed. For Parkinsonian women, data were assessed in two pharmacological states: with L-DOPA (ON-DOPA) and without (OFF-DOPA). Parameters included estimated subglottic pressure (ESGP) and fundamental frequency (F0) during sentence repetition, examining variations in age, /p/ position, F0 during its temporal course and at different positions in sentences, and the impact of L-DOPA treatment.
Results: Parkinsonian speech is characterized by significantly lower ESGP levels and a significant decline throughout sentences across three age groups. Parkinsonian F0 of women under 60 is significantly higher than healthy women. Between 60 and 70, there's no significant difference, but after 70, Parkinsonian women show significantly lower F0. A pronounced F0 decline was observed in all age groups. Our results also revealed that L-DOPA's impact on ESGP and F0 varies by age: in women under 70, L-DOPA administration led to a significant increase in ESGP. Similarly, a significant F0 increase is noted, but only in women under 60 years. L-DOPA effectively reduces F0 and ESGP decline across all age groups.
Conclusions: Our results are innovative in being the first to demonstrate a differentiated effect of Parkinson's disease alterations and L-DOPA administration based on the age of women.

TO INVESTIGATE THE EFFECT AND MECHANISM OF VERBASCOSIDE ON NEURAL TUBE DEFECTS BASED ON SONIC HEDGEHOG SIGNALING PATHWAY

POSTERS: G02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Lianggi Xie, Chai Zhi, Xin-Liang Wang, Yi Ru, Min Hu, Si Xiang Niu, Bao Guo Xiao, Hui-Jie Fan
shanxi university of chinese medicine, College Of Basic Medicine, shanxi, China

Aims: Neural tube defects (NTDs) are birth defects caused by incomplete closure of neural tubes during embryonic development, the common phenotypes are cerebral malformation, encephalocele, spina bifida, myelomeningoceled and so on. It is a common congenital malformation of newborns, second only to congenital heart disease in incidence. According to traditional Chinese medicine, kidney deficiency is the basic pathogenesis of NTDs. Verbascoside is one of the main active ingredients of Wuzi Yanzong Pill（ WYP）. The closure of neural tube is mainly affected by apoptosis and cytoskeleton regulation. We will explore the mechanism of VB prevention and control of NTDs through the Shh signaling pathway.
Methods: In this study, all-trans-retinoic acid (atRA) was used to establish NTDs model, the optimal dose group of VB was selected by statistical analysis of the NTDs rate of fetal mice, and the normal group, atRA group, VB group and FA group were set. Shh, Smo, P-smo ptch1 and Gil1 were detected by Western blot. HE staining was used to observe neural tube closure, We then add cyclopamine, an inhibitor of the SHH signaling pathway and detect the expression of downstream proteins. Tunel staining was used to detect apoptosis.
Results: Compared with the NTDs rate, it was found that the middle-dose group of VB had obvious therapeutic effect on NTDs, and HE staining showed that the neural tube of the malformed mice was not closed. Comparing the expression of Shh, Smo, P-smo ptch1 and Gil1 in different groups, it was found that VB could improve the expression of Shh, Smo, P-smo ptch1 and Gil1. Tunel staining also showed that VB could reduce neural tube cell apoptosis and inhibitor group increased apoptosis in fetal rats.
Conclusions: It is likely that VB prevents NTDs by regulating Shh signaling pathway to inhibit apoptosis.

Aims: Aging is a complex biological process characterized by a gradual decline in individual adaptability, physiological, cognitive, and memory impairment. The problem of food reserves is considered urgent in the context of current shortages caused by epidemics, natural disasters and global climate change. Insects are evaluated as a potential source for used as a new food substitute rich in protein and nutritional value. This study evaluated the effects of *X* and *Y* extracts in a D-Galactose (D-Gal)-induced mouse model of aging.
Methods: We examined the expression level of tight junction protein through western blot method, and histology staining for the formation of amyloid β plaques, neuron damage and intestinal inflammation as well as biochemistry assay for oxidative stress.
Results: *X* and *Y* extracts increased levels of glutathione, superoxide dismutase, and catalase; protected neurons in the brain; prevent blood-brain barrier (BBB) disruption and cerebral edema; prevent the deposition of amyloid β (Aβ) plaques in various regions of the brain. Furthermore, both extracts prevent gut-blood barrier (GBB) disruption as well as improve intestinal inflammation.
Conclusions: Collectively, these new findings suggest a possible therapeutic role of insect extracts in D-Gal-induced damage and dysfunction through gut-brain axis control as a potential functional food.

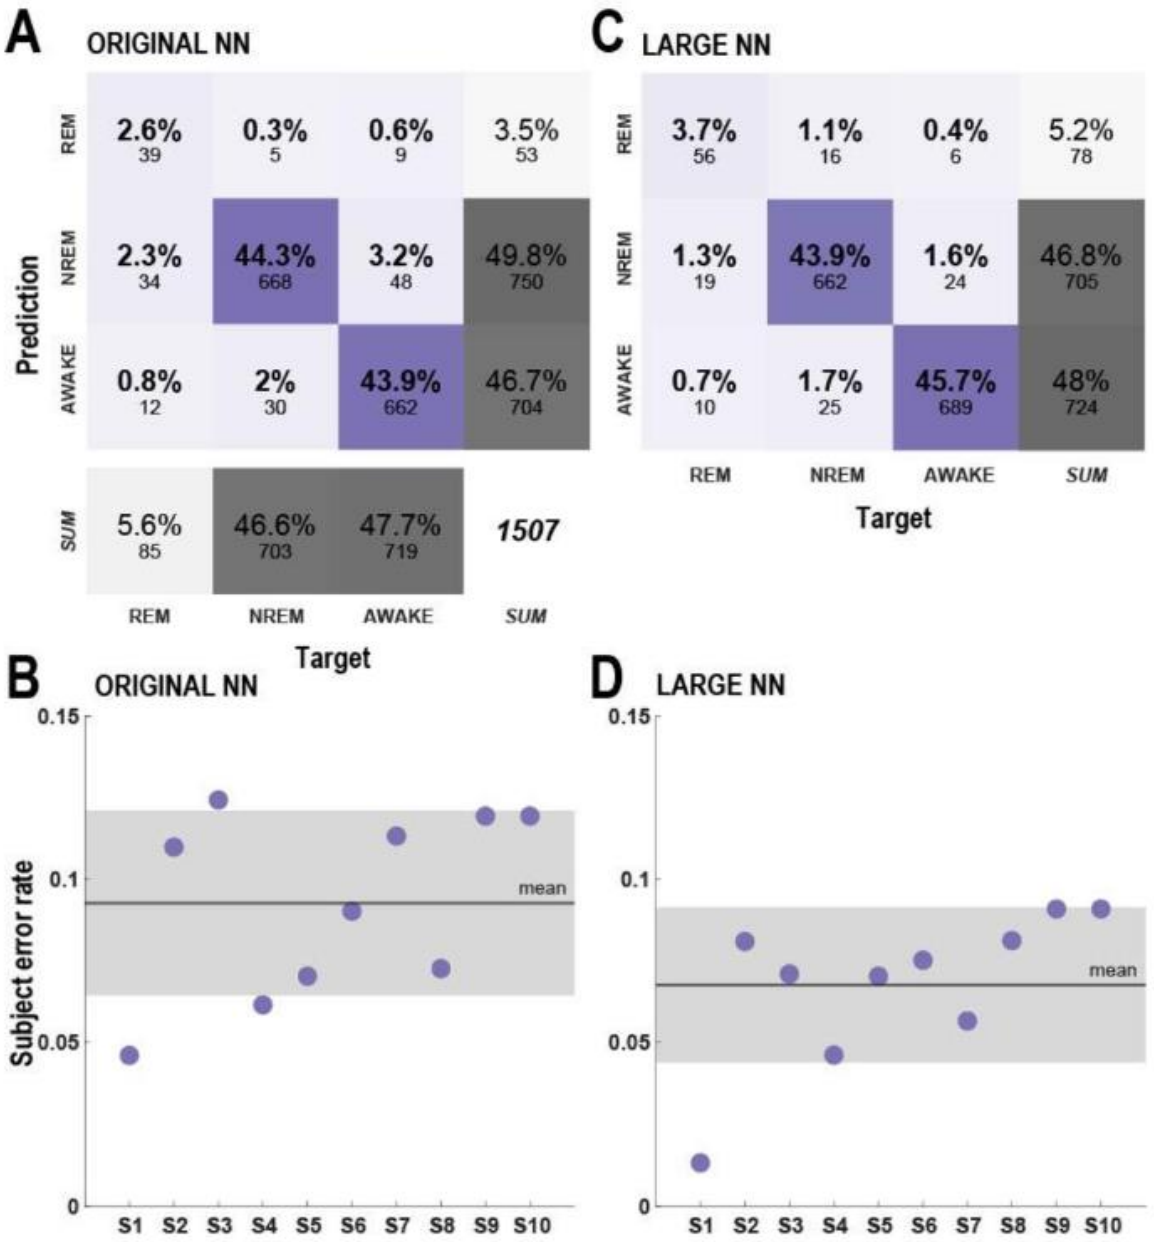
TOWARDS ADAPTIVE DEEP BRAIN STIMULATION TARGETING PARKINSON'S DISEASE SLEEP DYSFUNCTION USING NEURAL NETWORKS

POSTERS: G02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Katrina Carver[1], Karin Saltoun[2], Elijah Christensen[3], Aviva Abosch[4], Joel Zylberberg[5], John Thompson[6]
[1]University of Toronto, Medical Biophysics, Toronto, Canada, [2]McGill University, Biomedical Engineering, Montreal, Canada, [3]University of Colorado, Anesthesiology, Aurora, United States of America, [4]University of Nebraska, Neurosurgery, Omaha, United States of America, [5]York University, Physics And Astronomy, Toronto, Canada, [6]University of Colorado, Neurosurgery, Aurora, United States of America

Aims: We address the demand for sleep dysfunction therapies in Parkinson's Disease (PD) by considering the concept of a deep brain stimulation (DBS) device which can determine the sleep state of the user and modify its stimulation for maximal benefit. Here, we create neural networks (NNs) that can classify sleep state using subthalamic nucleus (STN) local field potential (LFP) data collected by the DBS. We analyze the contribution of each recorded STN LFP frequency band (alpha, theta, etc.) to model prediction to analyze the viability of our NN in commercially available devices with lower sampling frequencies.
Methods: A feedforward artificial NN (ANN) was trained with STN LFP data transformed to 8 frequency power bands, from 10 idiopathic PD patients with unilateral DBS. Ground truth labels arose from simultaneous polysomnography recordings. A lower-resolution ANN was created to match the frequency range of commercial DBS by downsampling the LFP recordings. Finally, SHAP analysis was used to determine the contribution of each LFP band to the model's prediction using the full-resolution data.
Results: We compared the "Original" NN by Christensen et. al (2019) to our "Larger" NN with two hidden layers and 1000 rectified linear units. We found improved performance on the three-state (Awake, REM, NREM) labeling problem, and were able to differentiate multiple non-REM states (splitting NREM into NREM1 and a combined NREM2/3 label). SHAP analysis revealed that the highest frequency bands were less important to the model prediction than middling frequency bands.



Conclusions: In sum, this research explores a new treatment avenue for a more tailored approach to sleep dysfunction in PD, with the prospect of implementation on a wider range of commercially available DBS devices.

Aims: Parkinson's Disease (PD) is a chronic neurodegenerative disorder affecting up to 10 million people worldwide, which current therapeutic approaches can only target the symptoms. As symptomatic therapies lose effectiveness over time, patients end up with no therapeutic options. Therefore, delaying the disease progression became a promising solution to deal with this disorder. PD pathogenesis is highly influenced by oxidative stress, and we have previously shown that ROS generated by NADPH oxidase 1 (Nox1) has detrimental impacts on dopaminergic neurons, being a valuable target for therapeutic developments. Inline, we aimed to test a chemical inhibitor ionic liquid for Nox1 inhibitor (N1inh-IL) capable of preventing neurodegeneration in experimental PD models.
Methods: N27 dopaminergic cell line were exposed to the neurotoxins 6-hydroxydopamine (6OHDA) and 1-methyl-4-phenylpyridinium (MPP+) and two animal models for PD, one induced by intrastriatal injection of 6OHDA and the other by chronic exposure to paraquat (PQ) were used. Dopaminergic cell viability and motor dysfunction were evaluated.
Results: *In vitro* studies showed that N1inh-IL has no cytotoxic effect on N27 neurons, while it significantly prevents the neurotoxic effect of two specific neurotoxins 6-hydroxydopamine (6OHDA) and 1-methyl-4-phenylpyridinium (MPP+). *In vivo*, the dopaminergic neuroprotective capacity of N1inh-IL was evaluated. The infusion of the N1inh-IL into the right ventricle did not cause neuronal toxicity, while it could prevent 6OHDA-induced neurodegeneration in the *substantia nigra* (SN) of mice. Moreover, four weeks after been exposed to PQ, the brain intraventricle diffusion or the intranasal delivery of N1inh-IL in rats was capable to prevent the motor dysfunction induced by the toxin and the accumulation of alpha-synuclein in the SN.
Conclusions: These results highlight that N1inh-IL can be an innovative therapy to reduce the speed of the progression of PD.

MODIFIED IMAGING PROTOCOL FOR DBS IN IPD

POSTERS: G02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Sunil Gupta[1], Navneet Singla[1], Ashish Aggarwal[1], Sahil Mehta[2]
[1]PGIMER, Neurosurgery, Chandigarh, India, [2]PGIMER, Neurology, Chandigarh, India

Aims: Background: The success of DBS in IPD is dependent upon the precision with which the STN is localized. In the past, the STN was localized using standard atlas but with present day MRI, STN can be directly visualized. The steps required on the day of surgery include performing an MRI, fixing the frame and then repeating the MRI. This can be time consuming. We describe a different protocol to save time and for more patient convenience.
Methods: In our institution, CEMRI of the brain is done a few days before surgery. On the day of surgery Leksell frame is applied. Patient undergoes CECT head with frame. Both the MRI and CT images are then fused using a software (FRAMELINK). STN is localized using AC-PC method. Our rationale of using CT and not MRI after frame application is that it saves time on the day of surgery.
Results: Because of excessive patient load & since MRI is time consuming, we devised this protocol of performing CT on the day of surgery. After surgery and taking out frame, MRI is done to confirm lead placement in relation to STN. We found that in post-op MRI the lead placement is precise using this method. The clinical response in the patients also signifies that lead placement in STN is accurate using CECT after frame application.
Conclusions: This modified protocol saved time and was more comfortable for the patient with no loss of precision in electrode placement in patients with Idiopathic Parkinson's Disease

Aims: To use human cell-based assays to identify small molecules as potential disease-modifying treatments for HD.
Methods: Previously we established a human neuronal model by immortalizing and differentiating HD patient iPSCs into highly homogeneous striatal precursor neurons (SPN), which resembled HD-like phenotypes of the parental iPSCs including expression of MAP2/DARPP32 (Akimov et al, Hum Mol Genet. 2021 Nov 30;30(24): 2469-2487). Further, we developed a 96-well plate screening platform using CellTiter-Glo luminescent cell viability assay in the SPNs and screened a kinase inhibitor library (ApexBio) containing 765 compounds in HD SPNs expressing 180 CAG repeats (180Q-SPNs).
Results: We identified approximately 20 compounds that exhibited protection to HD SPNs upon stress-induced neuronal toxicity. Among the hits, there was a small molecule PKC-a and ß1 inhibitor, GO6976, that we validated and prioritized. We found that GO6976 rescued HD SPNs from stress-induced toxicity through a dose-dependent manner. Furthermore, we examined PKCa / ß1 activity and protein expression levels in HD conditions. The activity of PKCa and PKCß1 was significantly increased in HD ISPNs, mouse brains, and human brains. Moreover, PKCa and PKCß1 interacted with both wild-type and mutant HTT and their overexpression was toxic to HD SPNs.
Conclusions: These findings suggest that PKCa/ß1 may play roles in neuronal cell toxicity in this model. Inhibition of PKCa/ß1 activity may attenuate mutant HTT toxicity and provide novel therapeutic targets for developing neuroprotective HD treatments.

TABEBUIA IMPETIGINOSA BARK ANTIPARKINSONIAN ACTIVITY AND BIOCHEMICAL INVESTIGATION OF DOPAMINE IN RAT BRAIN HOMOGENATES

POSTERS: G02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Dr Sunil Kumar Kadiri
College of Pharmaceutical Sciences, Dayananda sagar university, Bengaluru, Pharmacology, Bengaluru, India

Aims: Improving economy and wellbeing in creating nations like India has expanded life expectancy and changed the accentuation from transferable to non transmittable sicknesses such as Parkinson's disease. *Tabebuia impetiginosa* has been utilized by cultivators as a general tonic, immunostimulant, adaptogen and also in motor disorders. The present investigation was to explore the antiparkinsonian activity of *Tabebuia impetiginosa* bark by experimental methods.
Methods: Control group-I was served with distilled water. Group-II was considered as pathological control [1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) 2 mg/nostrils i.n, Reserpine 40 mg/kg s.c, Haloperidol 0.5 mg/kg, i.p]. Group-III served with standard drug (Apomorphine 40 mg/kg, s.c). Group IV and V received aqueous extract of *Tabebuia impetiginosa* bark aqueous extract in doses of 300 and 500 mg/kg/ day respectively. Tremor, hypokinesia, muscular rigidity, catatonia, postural immobility, postural instability, and catalepsy were assessed for antiparkinsonian activity.
Results: The bark extract served group exhibited increased levels of dopamine (5700 ±1.84 ng/g) when compared to control groups (4300 ± 3.17 ng/g). The extract at both doses displayed a significant reduction in postural flexion, a moderate decrease in tremor, muscular rigidity, and postural immobility scores but did not exhibit significant lowering of hypokinesia score in reserpine induced Parkinsonian model. The reduction in catatonia and catalepsy scores is more remarkable in the case of a high dose of extract (500 mg/kg) compared to the standard drug in Neuroleptic induced Parkinsonism.
Conclusions: The findings demonstrate that *Tabebuia impetiginosa* bark extract has significant anti-cataleptic potentials and the antioxidant effect of the bark may also be a significant contributor to its antiparkinsonian activity. Traditionally reported napthoquinone compounds present in the bark such as Lapachol and β-Lapachone are responsible for neuroprotective effect in Parkinsonism.

APPLICATION OF DIRECT REPROGRAMMING TECHNIQUES TO STUDY THE PATHOGENESIS OF HUNTINGTON'S DISEASE

POSTERS: G02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Nina Kraskovskaia, Polina Parfionova, Arina Maligina, Mikhail Khotin, Natalia Mikhailova
Institute of cytology RAS, Cellular Technologies Center, Saint-Petersburg, Russian Federation

Aims: Aim of the study is to evaluate Huntington's disease (HD) phenotype in induced striatal neurons obtained with transdifferentiation from dermal fibroblasts of healthy individuals and HD patients
Methods: Using an optimized direct reprogramming protocol based on the use of microRNA9-124 and the transcription factors MYT1L, DLX2 and CTIP2 we obtained population of induced striatal neurons (ISN) from 3 patients with HD and from 3 healthy donors matched for gender and age.
Results: In induced stratum neurons (ISN) derived from fibroblasts from patients with HD were detected aggregates of mutant huntingtin , which is the main histopathological feature of this neuropathology. However, the number of cells containing such intracellular aggregates were less than 5%. ISNs derived from fibroblasts from patients with HD are also characterized by altered morphology, reflected in a decrease in the number of primary processes, the total number of processes, the length of dendrites and the branching of the dendritic tree. In addition, compared with the control, in ISNs from fibroblasts of patients with HD, a decrease in the mitochondrial membrane potential is observed, which indicates a decrease in metabolic activity in mitochondria. Finally, ISNs derived from fibroblasts from patients with HD are more susceptible to cell death upon application of a proteasome inhibitor MG132 as well as upon removal of brain-derived neurotrophic factor from the culture medium.
Conclusions: Thus, the proposed cellular model of HD reflects the main pathological changes that occur in neurons during the development of the disease and can be used as a platform for assessing the effectiveness of potential drugs at the preclinical stages of research.
The work was carried out with financial support from the Russian Science Foundation grant No. 22-75-00106.

PROTECTIVE EFFECTS OF NATURAL EXTRACTS AS AN EFFECTIVE THERAPY FOR IMPROVING A BEHAVIORAL DISORDER AND TYROSINE HYDROXYLASE EXPRESSION IN MPTP INDUCED PARKINSON'S DISEASE MICE

POSTERS: G02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Haesung Lee, Ngoc Buu Tran, Ngo Hoang Long, Sook Jeong Lee
Jeonbuk national university, Bioactivematerials, Baekje-daero, Deokjin-gu, Jeonju-si, Jeollabuk-do,, Korea, Republic of

Aims: Parkinson's disease (PD) is a brain disorder that causes unintended or uncontrollable movements. Symptoms usually begin gradually and worsen over time. The most stand out signs and symptoms of PD occur when neuron cells in the substantia nigra pars compacta (SNpc), an region of the brain that controls movement, become impaired or die. Dopanminergic neurons, produce an important brain chemical known as dopamine, and the neurons die or become impaired from less dopamine production, finally leading to the movement problems associated with the disease. MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine), one of the most chemical for investigations into the mechanisms involved in the death of dopaminergic neurons in PD. We found extracted active ingredients using natural products A and B that are believed to be effective in various diseases and evaluated the therapeutic effect on PD.
Methods: A PD model was established by injecting or oral administration of MPTP and natural extracts in C57 mice for 4 weeks. In addition, the behavioral ability of PD mice was evaluated through Paraller bar and horizontal bar behavior experiments. After the behavioral experiment, mice was sacrifice and isolation the brains. SNpc was isolated to confirm protein expression with Western blot.
Results: MPTP caused behavior impairment and loss of dopaminergic neurons. Extracts increased levels of tyrosine hydroxylase expression and improved a behavioral disorder like tremor, impaired posture and balance, and slowed movements.
Conclusions: As a results, these new theraputic findings suggest a possible role of natural extracts in behavioral disorders and cranial nerve damage caused by PD and the potential function of improving its symptoms.

ALTERED GUT MICROBIOTA AND PHYSIOLOGY IN A DROSOPHILA MODEL OF HUNTINGTON'S DISEASE

POSTERS: G01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Jasmine Speranza, Julian Ketley, Flaviano Giorgini
University of Leicester, Department Of Genetics & Genome Biology, Leicester, United Kingdom

Aims: Huntington's disease (HD) is a fatal neurodegenerative condition caused by the expansion of a CAG trinucleotide repeat in the *HTT* gene, which encodes a mutant form of the HTT protein with an extended polyglutamine tract. Recent research suggests that the gut microbiota (GM) – a complex ecosystem composed of bacteria, viruses, and fungi – modulates host metabolism, inflammation, and immune responses, possibly influencing the pathogenesis of brain disorders/diseases, including HD. Therefore, we have used a *Drosophila* model of HD to investigate the effects of pan-neuronal mutant HTT (mHTT) expression on the GM and gut physiology.
Methods: GM were analysed *via* the colony forming unit assay and metagenomics analysis. The faecal transplantation assay was performed as an approach to modulate the observed gut dysbiosis. Gut physiology was studied through the Smurf assay and RNAseq analysis.
Results: mHTT flies exhibited a higher abundance of culturable bacteria compared to wild-type HTT *Drosophila,* specifically *Lactobacillus ssp.* and *Acetobacter ssp.* This gut dysbiosis was treated by faecal transplantation, which increased the lifespan and median survival of mHTT flies. mHTT flies exhibited an increased permeability to blue dye, suggesting dysfunction or loss of the intestinal barrier, a phenomenon commonly associated with ageing and altered metabolism/immunity in *Drosophila*. Differentially expressed genes in the gut of mHTT flies highlight alterations in cell proliferation/differentiation processes (*chinmo*, *D*, *Notum*), as well as lipid (*FASN3*, *Fad2*), carbohydrate (*LMan*, *Mal-B1*) and chitin metabolism (*Cht5*, *Cht9*).
Conclusions: Our study supports the influence of HD on GM content and epithelial physiology, suggesting a possible causative relationship between mHTT and altered gut bacteria homeostasis, dysregulation of cell gut proliferation/differentiation processes and disruption of gut metabolism.

Aims: Spinocerebellar ataxia type-3 (SCA3) is a rare form of inherited ataxia without cure. It is caused by an expansion of a trinucleotide CAG repeat in the ATXN3 gene, translated to an expanded polyglutamine (PolyQ) tract in the ataxin-3 protein (Atx3). When the PolyQ tract in Atx3 expands, it causes the protein to aggregate and accumulate Atx3 in degenerating brain regions. Atx3 follows a complex self-assembly pathway initiated by an aggregation-prone region in its globular Josephin (JD) domain. As many of the critical structural elements driving JD self-assembly contain several positively charged residues, we hypothesized that CLR01, a molecular tweezer that binds to exposed lysines and arginines, could interfere with Atx3 aggregation both in vitro and in vivo.
Methods: We employed a comprehensive and interdisciplinary approach to assess how CLR01 affects Atx3 self-assembly. Our investigation began with molecular-scale analyses to examine the interaction mechanisms, followed by assessing its impact on in vitro aggregation and amyloid fibril formation. Finally, we validated our discoveries using SCA3 cell and animal models.
Results: Our results show that CLR01 binds to Atx3 JD, limiting its flexibility and altering Atx3 aggregation pathways. In line with the biophysical data, CLR01 decreases aggregation and reverses synaptic defects in primary neurons expressing polyQ-expanded Atx3, and reduces motor defects in a SCA3 worm model. Furthermore, treatment of the CMVMJD135 SCA3 mouse model with CLR01 delayed symptom onset and improved motor function in correlation with rescued motor neuron pathology.
Conclusions: CLR01 has the potential to mitigate the harmful effects of Atx3 aggregation in SCA3 and can contribute to the development of molecules that specifically target neurotoxic pathways.

Aims: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease, defined by motor neuron loss, muscle paralysis, and death. Mitochondrial dysfunction and oxidative stress are implicated in ALS pathology. Thus, ameliorating mitochondrial function and/or antioxidant defenses with novel mitochondria-targeted antioxidants (*e.g.,* AntiOxCIN4), may constitute promising therapies to delay ALS progression. We hypothesized that AntiOxCIN4 can mitigate brain and skeletal muscle oxidative/nitrosative stress in the *SOD1^{G93A}* ALS mice.
Methods: Early adult *SOD1^{G93A}* ALS mice were subcutaneously injected with AntiOxCIN4 (0.1 mg/Kg/day), for 2 months. We prepared brain cortical and skeletal muscle homogenates and used colorimetry-/fluorimetry-based methods to assess the effect of AntiOxCIN4 in animal's longevity, oxidative/nitrosative stress markers, and activities of the antioxidant enzymes superoxide dismutase (total SOD, SOD-2) and glutathione reductase (GRed).
Results: AntiOxCIN4 extended the survival rate of female ALS mice (P=0.05). This was accompanied by a slight increase of 51 and 92% in brain total SOD and SOD-2 activities, while their skeletal muscle activities were reduced by 42 and 32% (P=0.07, P=0.08). Moreover, AntiOxCIN4 enhanced skeletal muscle GRed activity (P=0.01), while reducing the levels of hydroperoxides in skeletal muscle (P=0.009) and nitrites in brain and skeletal muscle (P=0.002, P<0.001) of ALS mice.
Conclusions: In sum, AntiOxCIN4-associated increase in longevity of ALS mice may result from a protection from brain and skeletal muscle oxidative/nitrosative stress. However, more studies are required to uncover why this protection delays ALS progression. Aims: To describe the study design and proposed timeline of the first interventional study in participants with early Neuronal α-Synuclein Disease (NSD). Background: we have recently proposed new biological definition and Integrated Staging System of Neuronal Alpha-Synuclein Disease (NSD-ISS). The major objective of NSD-ISS is to inform our understanding of early disease and accelerate development of disease-targeted therapies. We plan to apply NSD-ISS staging as inclusion criteria for P2P study.
Methods: P2P is planned as a platform, Phase 2 randomized double blind multi-center, multi-regimen clinical trial evaluating the safety and early efficacy of investigational products for the treatment of early, stage 2B, NSD. The study is "nested" within PPMI and sponsored by the MJFF. Qualified participants will be recruited from PPMI, based on the presence of aSN neuronal pathology (SAA in spinal fluid), dopaminergic dysfunction (DaTscan imaging) and subtle clinical features (stage 2B NSD) but no functional impairment. The study's Multiple Primary Endpoints include 1) DAT imaging as measured by the rate of progression in the mean striatum Specific Binding Ratio (SBR) and 2) rate of progression in the MDS-UPDRS part III score. Secondary endpoints include safety, tolerability and feasibility. The study will have an array of exploratory clinical (including digital) and biomarker measures. Intervention duration will be at least 24 months.
Results: Interventions are being selected by a Therapeutic Evaluation Committee from > 15 industry submitted applications. The study targets to start enrolment in the first 2 regimens in 2025.
Conclusions: We report the design of the first platform interventional study targeting the stage 2B NSD population. Platform design allows efficiency of operational infrastructure, ability to share placebo arm and perpetual testing of the promising interventional candidates.

Aims: Cerebral palsy (CP) is one of the most-devastating neurological disorders in children. Since neuroprotective molecules are released from stem cells, the CP-therapeutic effects of an exosome rich-conditioned medium (ERCM) derived from human amniotic membrane stem cells (AMSCs) were investigated.
Methods: ERCM containing a large amount of growth factors (GFs) and neurotrophic factors (NFs) was obtained via hypoxic (2% O_2) culture of AMSCs. In vitro cytoprotective activity was assessed against lipopolysaccharide (LPS) and KCN cytotoxicity in human neural stem cells (F3) and oligodendrocyte progenitor cells (F3.olig2). Male neonatal rats (at postnatal day 5) were subjected to hypoxia-ischemia-LPS (HIL) surgery, and treated IV once or 4 times with ERCM. Neurobehavioral functions were assessed via locomotor activity, rota-rod running, passive avoidance, and Morris water-maze performances. Neuroprotective effects were evaluated by analyzing neuronal apoptosis and inflammatory response, GFs and NFs, demyelination in the corpus callosum, and oligodendrocyte makers.
Results: ERCM protected against LPS and KCN cytotoxicity in F3 and F3.olig2 cells by regulating apoptotic and inflammatory genes. ERCM markedly recovered the motor and cognitive functions in HIL animals. As shown in vitro, ERCM suppressed neuronal apoptosis and inflammatory responses, which was supported by the recovery of brain GFs and NFs including BDNF, NGF, CNTF, GDNF, NT-3, and PDGF. It was confirmed that ERCM attenuated demyelination in the corpus callosum, a white matter region vulnerable to CP, wherein oligodendrocyte makers such as NKX2.2, Olig2, CNPase, and MBP were restored.
Conclusions: The results indicate that ERCM exerts CP-therapeutic effects in vitro and in vivo by preserving neural stem cells and oligodendrocyte progenitor cells through regulation of apoptotic signaling, inflammatory response, and differentiation and maturation of stem and progenitor cells to oligodendrocytes.

ACCELERATING THE DEVELOPMENT OF THERAPIES USING AN ENGINEERED HUMAN NEUROMUSCULAR JUNCTION- ON-A-CHIP PLATFORM

POSTERS: G02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Carolin Madwar, Margaret Magdesian, Victoria Kwok
Ananda Devices Inc., Biochemistry, Laval, Canada

Aims: Currently available in-vitro models fail to reproduce the pathological complexities of most neuromuscular diseases, including Myasthenia gravis (gMG), a rare autoimmune disease driven by autoantibodies targeting components of the neuromuscular junction (NMJ). For the successful development of new therapies, robust alternative approaches methods (NAMs) that specifically mimic the human NMJ function are required to elucidate the toxicity mechanism of autoantibodies in gMG.
Methods: In this study, the Ananda Devices microfluidic platform NeuroMuscle™ was used to create an in vitro 3D co-culture of motor neurospheres derived from human induced pluripotent cells and primary human skeletal muscle fibers that reproduces a functional NMJ.
Results: The platform was validated for robust detection of muscle contraction after stimulation with acetylcholine; reproducible detection of NMJ function by quantifying muscle contraction after neuronal stimulation with glutamate and rapid detection of NMJ function inhibition by alpha-bungarotoxin and D-tubocurarine. Functional connectivity was assessed with glutamate stimulation of neurospheres and subsequent calcium transients in GCaMP6-transduced muscle fibres. AChR antagonists also confirmed functional connections of NMJ co-cultures developed in the NeuroMuscle™ platform. Next, the NMJ cultures in the NeuroMuscle™ platform were incubated with sera from healthy and gMG patients which induced complement activation and impaired neurotransmission.
Conclusions: The data highlight how Ananda Devices' human based, in vitro, NeuroMuscle™ platform could support drug discovery in NMJ-related diseases and could be used to test compounds to understand efficacy and mechanistic rationale. In addition, Ananda Devices' NeuroMuscle™ platform is scalable, compatible with standard laboratory equipment and uses human derived reagents and cells.

NEUROPROTECTIVE EVALUATION OF OCCIDENTALIN-1202 PEPTIDE IN A MURINE MODEL OF PARKINSON'S DISEASE

POSTERS: G02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Henrique Amaral[1], Miguel Tavares[2], Márcia Renata Mortari[3]
[1]University of Brasilia, Institute of Biological Sciences, Department Of Physiological Sciences, Laboratory Of Neuropharmacology, Asa Norte, Brasília, Brazil, [2]NeuropharmaLab, Department Of Physiology, Brasília, Brazil, [3]Institute of Biological Science, Department Of Physiology, Brasília, Brazil

Aims: The purpose of this study was to investigate the antiparkinsonian effect of the OcTx-1202 peptide in a mouse model of parkinsonism, using three different doses (1, 2.5, and 4 mg/kg).
Methods: The animals were divided into three experimental groups: 6-OHDA group consisting of animals with parkinsonism treated with vehicle solution (n=6), OcTx-1202 group consisting of animals with parkinsonism treated with the peptide at three different doses: 1 mg/kg (n=6), 2.5 mg/kg (n=8), and 4.5 mg/kg (n=6), and healthy group consisting of healthy animals treated with vehicle solution (n=8). The behavioral tests consisted on the Rotarod test for evaluation of motor activity, conducted over a period of 6 hours on the Rotarod apparatus, and the apomorphine-induced rotation test. Subsequently, an immunohistochemical analysis was conducted to quantify the proportion of viable neurons in the SN.For groups with more than two samples, one-way analysis of variance (ANOVA) followed by Tukey's test was employed for normally distributed data with similar variances. A significance level of $p<0.05$ was considered, with Bartlett's test being performed afterwards. Results that exhibited normal distribution and two variables were subjected to two-way repeated measures analysis of variance (two-way ANOVA), with Bonferroni's post-test being used.
Results: Regarding the immunohistochemical, the peptide was not able to reduce neuronal death. In the motor coordination test on the Rotarod, animals that received the dose of 4 mg/kg showed improvement in motor condition ($p<0.0001$). Additionally, in the apomorphine test, both doses of 2.5 and 4 mg/kg decreased the number of rotations ($p<0.001$).
Conclusions: These results suggest that the OcTx-1202 peptide may have a positive effect on improving motor symptoms associated with Parkinson's disease. However, the assays conducted did not show a significant neuroprotective effect of the peptide.

PR006A GENE THERAPY INCREASES PROGRANULIN LEVELS AND IMPROVES FTD-GRN RELATED PHENOTYPES IN AN IN VITRO AND AN IN VIVO MODEL

POSTERS: G02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Ambika Tewari[1], Patty Biezonski[1], Laura Heckman[1], Suzanne Burstein[1], Li Chin Wong[2], Asa Abeliovich[1], Sid Kamalakaran[1], Jorge Haller[1], Stuart Nelson[1], Priyam Raut[1], Raghu Gowda[1], Zoe Zhaostein[1], Zhaohui Yang[1], Hsuan-Ni Lin[1], Franz Hefti[1]
[1]Prevail Therapeutics, a wholly owned subsidiary of Eli Lilly and Company, Neuroscience, New York, United States of America, [2]Prevail Therapeutics, Clinical Development, New York, United States of America

Aims: Objective: *GRN* haploinsufficiency in humans leads to a very high risk of developing FTD-GRN. FTD-GRN is a neurogenerative disease characterized by impairment of executive function, changes in behavior, and language difficulties. To address an unmet clinical need, we developed PR006A, an investigational gene therapy comprising an AAV9 capsid and *GRN* transgene, with the aim of increasing human progranulin levels in the CNS, thereby slowing disease progression.
Methods: PR006A was tested in two models of FTD-GRN: (1) an *in vitro* induced pluripotent stem cell (iPSC)-derived neuronal model using cells from patients carrying heterozygous GRN mutations and (2) an *in vivo Grn* knockout (KO) genetic mouse model that have a complete loss of progranulin, display age-dependent phenotypes, including lysosomal alterations, lipofuscin accumulation, microgliosis, and neuroinflammation, thus reflecting key pathological features of human FTD-GRN.
Results: PR006A effectively transduced human FTD-GRN iPSC-neurons *in vitro*, resulting in a dose-dependent production of progranulin which reversed functional deficits of the lysosomal enzyme cathepsin D and ameliorated TDP-43 pathology. PR006A administered to *Grn* KO mice via intracerebroventricular (ICV) injections reduced key FTD-GRN-related phenotypes in the brain, including accumulation of lipofuscin and ubiquitin, markers indicative of lysosomal abnormalities, and proinflammatory cytokine expression and microgliosis, markers indicative of CNS inflammation. Safety endpoints captured as part of the GRN KO mouse experiments revealed no adverse PR006A-related histopathological findings. A 6-month GLP toxicity study in non-human primates revealed no adverse in-life observations or histopathological findings.
Conclusions: PR006A treatment was well tolerated and without adverse findings in mouse and non-human primate studies and demonstrated efficacy in human *in vitro* and mouse *in vivo* models of FTD-GRN. PR006A is currently being studied in the Phase 1/2 PROCLAIM clinical trial.

DATA FUSION IN HUNTINGTON'S DISEASE RESEARCH: A HOLISTIC APPROACH TO NEUROIMAGING BIOMARKERS

POSTERS: G04. IMAGING, BIOMARKERS, DIAGNOSTICS

H. Bockholt[1], Bradley Baker[1], Cara Joyce[2], William Adams[2], Jordan Clemsen[1], Nicholas Pasley[1], Vince Calhoun[1], Jane Paulsen[3]
[1]Tri-Institutional Center for Translational Research in Neuroimaging and Data Science (TReNDS), Georgia State University, Georgia Institute of Technology, and Emory University, Neuroinformatics, Atlanta, United States of America, [2]Loyola University Chicago, Biostatistics, Chicago, United States of America, [3]University of Wisconsin-Madison, Neurology, Madison, WI, United States of America

Aims: As the complexity of understanding Huntington's Disease (HD) advances, it becomes imperative to harness the vast array of neuroimaging data types in a synergistic manner. This study champions a data fusion approach, combining functional network connectivity (FNC), diffusion tensor imaging (DTI), structural connectivity, and volumetric measures to provide a comprehensive understanding of HD's neural underpinnings. The emphasis is placed on the basal ganglia, given its vital role in HD pathology.
Methods: The study encompasses 101 gene-positive individuals and 28 gene-negative family controls. Each participant undergoes a series of neuroimaging protocols to capture the multifaceted nature of HD-induced brain changes. Beyond individual analyses, the study employs a cutting-edge data fusion technique known as the Joint Estimation of Linked Functional Network Variability and Structural Covariation. This approach leverages the interplay between different neuroimaging measures to derive more holistic and nuanced insights into HD progression.
Results: Preliminary findings reveal that while individual neuroimaging metrics shed light on specific aspects of HD pathology, the combined data fusion approach offers a more integrative understanding of disease dynamics. For instance, the interrelationship between structural connectivity changes and FNC variability becomes clearer, providing a multi-dimensional perspective of neural alterations.
Conclusions: This innovative approach underscores the potential of combining multiple neuroimaging datasets, moving towards a more unified framework in HD research. Such a holistic perspective not only enhances diagnostic accuracy and disease tracking but also paves the way for tailored therapeutic interventions, drawing from a broader understanding of HD's neural landscape.

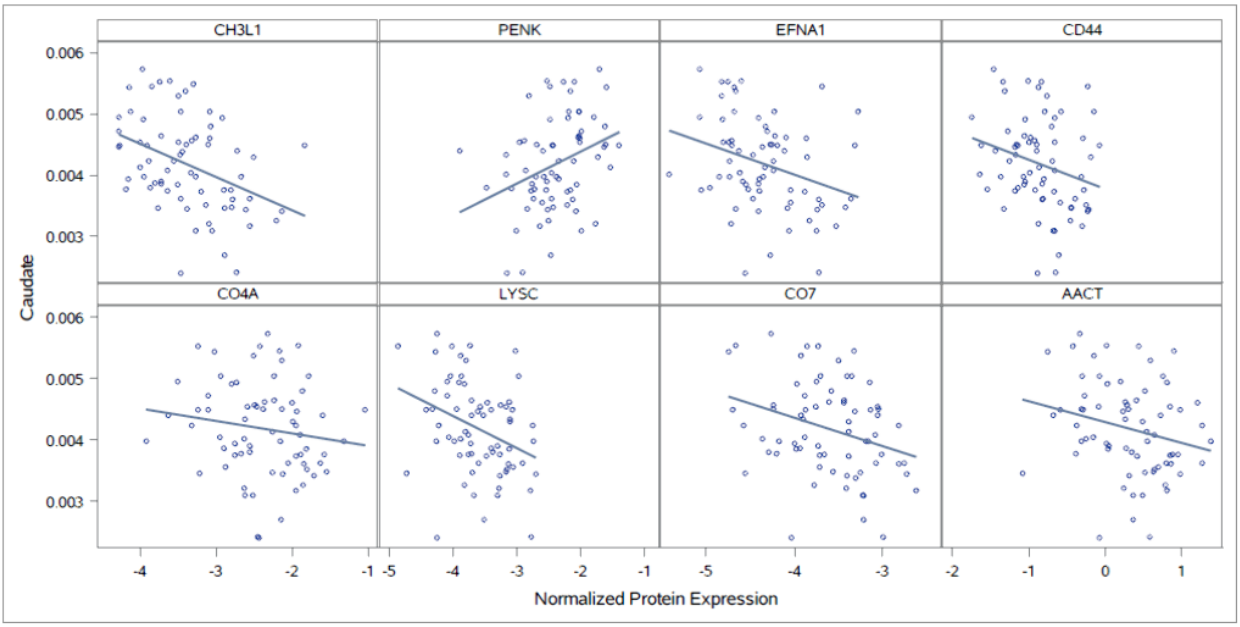
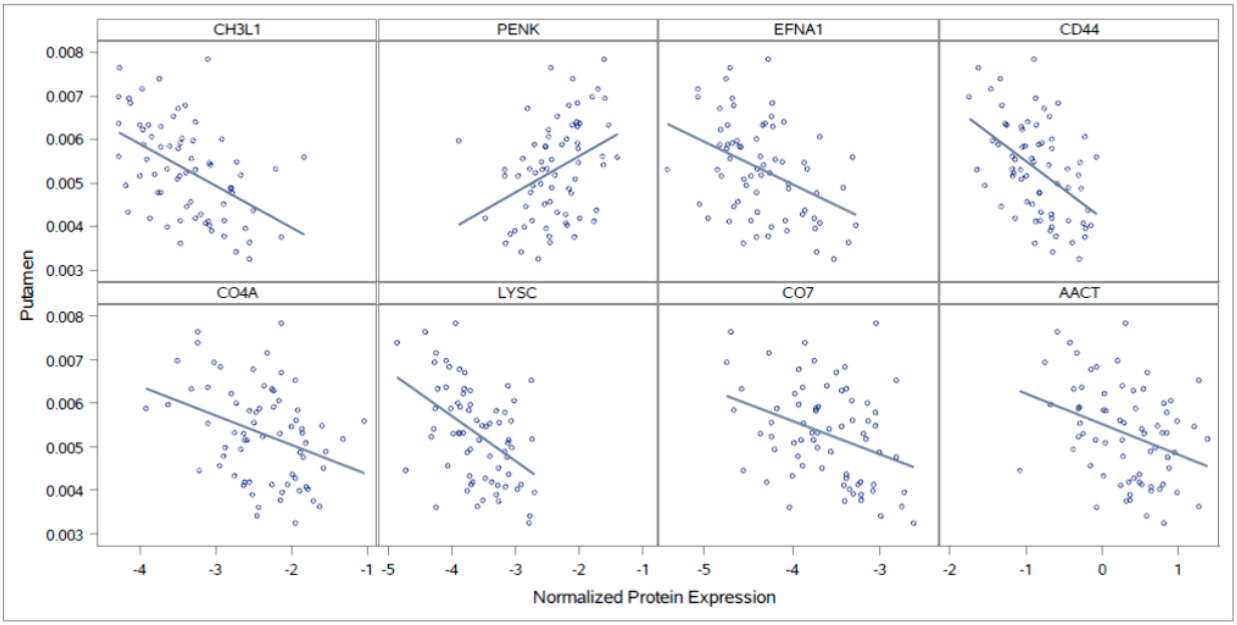
BIOFLUID AND NEUROIMAGING MARKERS IN PRODROMAL HUNTINGTON'S DISEASE MAY REVEAL A MULTI-MODAL BIOMARKER FOR TIMING OF DISEASE PREVENTION

POSTERS: G04. IMAGING, BIOMARKERS, DIAGNOSTICS

H. Bockholt[1], Jordan Clemsen[1], Daniel Chelsky[2], Cara Joyce[3], William Adams[3], Michael Newton[4], Vince Calhoun[1], Jane Paulsen[5]
[1]Tri-Institutional Center for Translational Research in Neuroimaging and Data Science (TReNDS), Georgia State University, Georgia Institute of Technology, and Emory University, Neuroinformatics, Atlanta, United States of America, [2]Caprion Proteomics, Proteomics, Montreal, Canada, [3]Loyola University Chicago, Biostatistics, Chicago, United States of America, [4]University of Wisconsin-Madison, Biostatistics And Medical Informatics, Madison, United States of America, [5]University of Wisconsin-Madison, Neurology, Madison, WI, United States of America

Aims: To examine the associations among CSF-based proteomics markers and MRI basal ganglia markers in prodromal Huntington's Disease (HD) and discern consistency among biomarkers for indications of early abnormality.
Methods: A sample of participants with the gene-mutation for HD (n=69) was selected from the PREDICT-HD study based on those with both proteomic and brain imaging volumetric outcomes acquired at a study visit. Proteins associated with disease burden (product of CAG repeat length and age) were selected for evaluation with putamen and caudate volumes. Spearman's rank correlation coefficients were calculated to examine relationships between proteins and imaging measures.
Results:





A sample of 69 patients was included with mean age 41±14 and 64% (n=44) female. Multiple proteins, including Chitinase 3 Like 1 (CH3L1) and proenkephalin (PENK), had moderate and statistically significant associations with volumetrics. Higher expression was associated with lower putamen and caudate volumes for all proteins except for PENK where the inverse was observed.

Conclusions: The proteins demonstrated a strong relationship to the MRI biomarkers. However, the direction of the relationship was not ubiquitous across proteins. Nearly all proteins associated with inflammation and apoptosis were upregulated as caudate and putamen volumes decreased. In contrast to the protein elevations expressed in most of these findings, PENK was downregulated and was associated with volumetric loss. Strong associations validate HD pathology models indicating the prominence of the medium spiny neuron in the indirect corticostriatal circuits of the basal ganglia. Future research with larger sample sizes would examine multi-modal biomarkers to determine the best prognostic model for time for intervention in clinical trials for prevention of HD.

USING PAIRED-PULSE TMS-EEG TO INVESTIGATE CEREBELLAR-CORTICAL CONNECTIVITY

POSTERS: G04. IMAGING, BIOMARKERS, DIAGNOSTICS

Po-Yu Fong[1,2], Danny Spampinato[3], Lorenzo Rocchi[4], Anna Latorre[1], John Rothwell[1]
[1]UCL Queen Square Institute of Neurology, Department Of Clinical And Movement Neurosciences, London, United Kingdom, [2]Chang Gung Memorial Hospital at Linkou, Division Of Movement Disorders, Department Of Neurology And Neuroscience Research Center, Taoyuan City, Taiwan, [3]IRCCS Santa Lucia Foundation, Non-invasive Brain Stimulation Unit, Rome, Italy, [4]University of Cagliari, Department Of Medical Sciences And Public Health, Cagliari CA, Italy

Aims: The combined technique of TMS (transcranial magnetic stimulation) and EEG co-registration has been extensively applied to explore cortico-cortical connectivity. Here, we explore its use in probing cerebello-cortical connections.
Methods: Twenty-five healthy subjects received the cerebellar-brain Inhibition (CBI) protocol, consisting of a subthreshold cerebellar conditioning stimulus preceding a suprathreshold test stimulation over the contralateral motor cortex by 5ms. Motor-evoked potentials (MEPs) and EEG were recorded simultaneously. CBI over both hemispheres was tested, together with an active control condition on twenty subjects using low-intensity cerebellar conditioning stimuli. During EEG recording, white noise was played via earphones to minimise auditory input from TMS coil activation, and the residual auditory evoked potential (AEP) was removed in pre-processing. Results were analysed in both time and frequency domains.
Results: As expected, conditioned MEPs were significantly reduced; on average left CBI (LCBI) was more effective than right CBI (RCBI). The EEG data showed that during LCBI, TMS-evoked potentials over left M1 (M1 TEP) were suppressed from very early to late latencies. Results from RCBI were similar to LCBI, except that the N100 was unchanged. The active control condition showed that a low-intensity cerebellar conditioning stimulus had no effect on the M1 TEP. A frequency domain analysis revealed desynchronisation in multiple frequency bands, consistent with dis-facilitation on the dentate nucleus by active Purkinje cells.
Conclusions: CBI explored with TMS-EEG produces clear effects on cerebellar-evoked TEPs in healthy subjects, and could be a potential clinical tool for investigating cerebello-motor cortex connectivity in patients with cerebellar dysfunction.

PARKINSONISM AS A MANIFESTATION OF SPS

POSTERS: G04. IMAGING, BIOMARKERS, DIAGNOSTICS

Mohammad Golzarian, Mehri Salari
shahid beheshti university, Medicine School Of Shahid Beheshti University, tehran, Iran

Aims: We investigate the relationship between anti-amphiphysin antibody with parkinsonism and cortical ribbon sign by reporting 2 cases. Our case series expand the phenotypic spectrum of antiamphyphisin related disorders. We report 2 antiamphiphysin positive cases with parkinsonism. One of them manifested with cortical ribbon's sign beside parkinsonism which has not been reported yet.
Methods: We conducted a systematic review of papers in English indexed in PubMed with no time restriction reporting cases of positive antiamphyphisin. We used the following search terms, either as plain text or as MeSH terms: ("amphyphisin) AND ("parkinsonism" OR "parkinsonian disorder*) , "Autoimmune Diseases of the Nervous System" AND "amphiphysin" , ("stiff-man syndrome" OR "stiff-person syndrome") AND ("anti amphiphisin antibody") , "ribbon sign" AND "antiamphyphisin" , "cortical ribboning" AND "antiamphiphysin" , "cortical diffusion restriction" AND "amphiphysin" , "movement disorder*" AND "antiamphiphysin" , "movement disorder*" AND "neuronal antibod*" , ("parkinsonian disorder" OR "parkinsonism") AND ("neuronal antibod") and "antiamphyphisin". All results of the literature search were reviewed and relevant information was extracted and summarized. References of the included articles were also screened for eligible studies. Finally with duplication a total of 74 records were identified and assessed for eligibility, with 32 articles included in the review, some of these studies reviewed several cases retrospectively 1 additional article was identified via screening of references of articles, with 33 studies finally included in the review.
Results: We ruled out all of differential diagnosis of parkinsonism and cortical ribbon sign and realized that there might be a novel relationship between anti-amphyphisin antibody with parkinsonism and cortical ribbon sign.
Conclusions: Prkinsonism and cortical ribbon sign should be considered as new manifestations in the phenotypic spectrum of antiamphyphisin antibody-related disorders.

DIGITAL MEASUREMENT OF OCULAR MICROTREMOR IN PARKINSON'S DISEASE: PRELIMINARY RELIABILITY AND CLINICAL VALIDATION EVIDENCE

POSTERS: G04. IMAGING, BIOMARKERS, DIAGNOSTICS

Lisa Graham[1,2], Rodrigo Vitorio[2], Patrick Tait[2], Claire Mcdonald[1], Richard Walker[3], Alan Godfrey[4], Rosie Morris[2,3], Samuel Stuart[2,3,5]
[1]Gateshead Health NHS Foundation Trust, Qe Hospital Gateshead, Gateshead, United Kingdom, [2]Northumbria University, Sports, Exercise And Rehabilitation, Newcastle upon Tyne, United Kingdom, [3]Northumbria NHS Foundation Trust, North Tyneside General Hospital, North Shields, United Kingdom, [4]Northumbria University, Computer And Information Sciences, Newcastle upon Tyne, United Kingdom, [5]Oregon Health & Science University, Neurology, Portland, United States of America

Aims: Ocular microtremor (OMT) is a fixational eye movement linked to brainstem activity. OMT frequency is typically 70-80Hz in healthy adults and research suggests that this is reduced neurological diseases like Parkinson's Disease (PD) making it a potential biomarker. This study aimed to; 1) examine the reliability of the novel iTremor ONE device (Head Diagnostics Ltd., Dublin, Ireland) in measuring OMT frequency (Hz) in people with PD (PwPD); and 2) investigate the clinical validity of OMT as a relevant disease measure through relationship with traditional clinical rating scales.
Methods: 16 PwPD participated in a home-based assessment involving cognitive (Montreal Cognitive Assessment, MoCA), motor (motor section of the Unified Parkinson's Disease Rating Scale, UPDRS-III) and OMT measures (three readings taken from each eye to get an average). PwPD completed a test-retest reliability assessment at the same time, exactly one week apart. Interclass correlation coefficients (ICC) and paired samples t-tests were used to assess reliability. Pearson's correlations were used to compare OMT frequency to relevant clinical rating scales (MoCA, UPDRS-III).
Results: OMT frequency was 64.75Hz (SD 4.1) in the right, 64.05Hz (SD 4.6) in the left, and 64.38Hz (SD 4.3) for both eyes together. The iTremor ONE device reliably measured OMT in in PwPD. OMT frequency showed good agreement in the right (ICC 0.81), left (ICC 0.88), and both eyes averaged (ICC 0.89). Average OMT frequency was positively correlated with MoCA (r = 0.583, *p*= .018), and negatively correlated with UPDRS-III score (r= -0.564, *p*= .036). Highlighting that reduced OMT frequency relates to worse cognitive ability and increased disease severity.
Conclusions: These preliminary findings show the iTremor ONE device reliably measures OMT frequency in PwPD, and OMT frequency is associated with cognition and disease severity in PwPD.

TRANSCRANIAL MAGNETIC STIMULATION (TMS) EVOKED POTENTIALS (TEP) FOR PREDICTION OF RESPONSE TO VENTRICULO-PERITONEAL SHUNT (VPS) IN NORMAL PRESSURE HYDROCEPHALUS (NPH)

POSTERS: G04. IMAGING, BIOMARKERS, DIAGNOSTICS

Sharon Hassin-Baer, Tal Davidy, Saar Anis, Alexandra Suminski, Yakov Zauberman, Orit Lesman-Segev, Tsvia Fay-Karmon
Sheba Medical Centre and Tel Aviv University, Neurology, Ramat Gan, Israel

Aims: To assess the utility of a TEP-based evaluation, for prediction of response to VPS in NPH, as an alternative for the CSF tap test (CTT).
Methods: 37 "possible iNPH" patients and 16 age-matched healthy controls underwent a neurological exam, cognitive evaluation and brain MRI scans. All subjects performed Delphi, a TMS-EEG based evaluation, measuring TEPs using proprietary algorithm. All probable iNPH patients underwent a CTT (removal of 30-50 ml of CSF while measuring change in the "Timed Up and Go ", TUG test) and 17 patients underwent VPS and were evaluated for their symptoms after 3-4 months. Response was rated using the CGIC scale and a repeated TUG, by a multidisciplinary team of movement disorders neurologists and a neurosurgeon.
Results: Gait improved in 14 operated patients; these responders had a significantly earlier 'early phase latency' (P60, p=0.0044) compared to HC. Furthermore, their TEP's early and late phase slopes were highly associated with the degree of response to VPS. Additionally, both the late phase slope ($N100\text{-}P180_{Mo}$, r=0.79, p=0.0033) and the early phase slope ($P60\_N100_{Fr}$, r=-0.88, p=0.0003) were correlated to the change in TUG after VPS. CTT was not significantly correlated with VPS response (r=0.35, p=0.198).
Conclusions: The results suggest that TEPS, measured by Delphi, may be an alternative for CTT, in prediction of response to VPS in patients suspected as iNPH, exhibiting higher efficacy with reduced patient discomfort and risks.

DOPAMINERGIC ALTERATIONS IN PATIENTS WITH ALZHEIMER'S DISEASE

POSTERS: G04. IMAGING, BIOMARKERS, DIAGNOSTICS

Rao Nargis Jahan[1], Mohammad Azharuddin[2]
[1]School of Pharmaceutical Education and Research, Jamia Hamdard, Pharmaceutics, New Delhi, India, [2]School of Pharmaceutical Education and Research, Jamia Hamdard, Pharmacology, New Delhi, India

Aims: Low levels of Dopamine may contribute to Alzheimer's disease. However, the relationship between Alzheimer's disease and dopaminergic measures remains unclear.
This study aimed to perform a meta-analysis to calculate the pooled mean difference (MD) of dopaminergic measures between Alzheimer's disease and control groups.
Methods: A systematic search on, MEDLINE/PubMed and Cochrane Central Register of Controlled Trials was performed from inception to June 2023. Eligible studies measuring the dopaminergic levels in patients with Alzheimer's disease. Subgroup analysis was performed by the stratification of the dopamine receptors. Heterogeneity was assessed by using the Cochrane Q test statistic and inconsistency index (I^2). A random effects model was used to calculate the MD with a 95% confidence interval (CI) to assess differences in the levels of dopaminergic neurometabolites.
Results: A total of 10 studies were included in this meta-analysis. Results from the meta-analysis showed significantly lower levels of dopamine 1 receptor, dopamine 2, and dopamine 3 receptor in patients with Alzheimer's disease compared with controls (MD = -22.78, 95% CI: -35.03, -10.54; $p < 0.003$), (MD = -15.81, 95% CI: -29.03, -2.58; $p < 0.002$), and (MD = -10.50, 95% CI: --20.09, -0.92; $p < 0.03$) respectively. However, there was no significant differences were observed in dopamine 4 and dopamine 5 receptor in patients with Alzheimer's disease compared with controls (MD = -30.32, 95% CI: -109.70, 49.06; $p= 0.45$), and (MD = 17.62, 95% CI: -15.70, 50.94; $p= 0.30$).
Conclusions: The current finding suggests that low dopaminergic levels were associated with the risk of Alzheimer's disease. Moreover, further study is needed to robust the present finding.

LC-MS/MS-BASED ANALYSIS OF N-GLYCAN CHANGES IN POST-MORTEM BRAIN TISSUE OF PARKINSON'S DISEASE

POSTERS: G04. IMAGING, BIOMARKERS, DIAGNOSTICS

Yehia Mechref, Oluwatosin Daramola, Andrew Bennett, Judith Nwaiwu, Mojibola Fowowe, Sherifdeen Onigbinde, Hanh Minh Nguyen
Texas Tech University, Dept. Of Chemistry And Biochemistry, Lubbock, United States of America

Aims: This research aims to find unique Parkinson's Disease (PD) glycome and glycosite specific biosignatures indicative of PD progression.
Methods: In this study, LC-MS/MS analysis of *N*-glycomics of 10 post-mortem human brain tissues from PD patients and 19 healthy controls was done. The tissue samples were lysed and then digested using PNGase F enzyme before they were analyzed with LC-MS/MS. We identified 90 *N*-glycans in the 29 brain tissue samples using Multiglycan software, X-Calibur, and quantified using Skyline MS.
Results: All the identified *N*-glycans were grouped into sialylated, fucosylated, sialofucosylated, oligomannose, NeuGc, and others (*N*-glycans without the sialic acid, fucose, and are not oligomannose). We observed that there was a significant decrease in the abundance of the fucosylated, and sialofucosylated *N*-glycans in the PD samples compared to the control while the high mannose *N*-glycans increased significantly in the PD samples compared to the control ($p<0.05$). Typically, a decrease in sialylated and fucosylated *N*-glycan, as well as an increase in the concentrations of high mannose in the PD can be autonomously associated with neuroinflammation and brain disorder critically affecting function and recovery. Furthermore, we observed 23 statistically significant *N*-glycans ($p<0.05$) of which 12 were observed to be downregulated in PD, while 11 were upregulated.
Conclusions: Notably, the dysregulated *N*-glycans observed in PD include fucosylated, sialylated, and bisecting *N*-glycans which have been linked to unique brain functions and implicated in various brain-related diseases, including Traumatic Brain Injury, Mild Cognitive Impairment, and Alzheimer's disease. Furthermore, the isomeric changes in the *N*-glycans will be further investigated and the glycosite related to the observed changes will be investigated as well.

FRONTOTEMPORAL DEMENTIA IN ASSOCIATION WITH INCLUSION BODY MYOPATHY AND PAGET'S DISEASE: A CASE REPORT WITH THE VCP GENE MUTATION (C.383G>C)

POSTERS: G04. IMAGING, BIOMARKERS, DIAGNOSTICS

Vuk Milošević[1], Radomir Damjanović[1], Eva Antić[1], Marina Malobabić[1], Jelena Bašić[2], Stojan Perić[3]
[1]University Clinical Center Niš, Clinic Of Neurology, Niš, Serbia, [2]Faculty of Medicine, University of Niš, Department Of Biochemistry, Niš, Serbia, [3]University Clinical Center of Serbia, Clinic Of Neurology, Belgrade, Serbia

Aims: This paper aimed to present a case of Inclusion Body Myopathy associated with Paget's disease of bone and Frontotemporal Dementia (IBMPFD), a rare autosomal dominant multisystem disorder caused by mutations in the valosin-containing protein (VCP) gene.
Methods: We presented a comprehensive clinical evaluation of a 62-year-old male with a missense mutation in the VCP gene, highlighting the diverse clinical manifestations of this complex disorder.
Results: The patient initially presented with progressive behavioral changes characterized by socially inappropriate behavior, repetitive movements, apathy, and altered food preferences, which began two years ago. The patient had been treated for unspecified myopathy seven years prior to the first reported behavioral changes. Neurological examination revealed proximal muscle weakness, generalized rigidity, and marked muscle atrophy. Laboratory tests were unremarkable except for elevated alkaline phosphatase levels. Brain MRI demonstrated global cortical atrophy, while arterial spin labeling (ASL) revealed decreased perfusion in the left frontal, temporal, and parietooccipital regions. Electromyography showed fibrillation, positive sharp waves at rest, and myopathic motor unit potentials during contraction. Subsequent skull imaging identified cranial bone thickening and sclerosis, consistent with Paget's disease. The behavioral and cognitive assessment led to a diagnosis of probable behavioral variant frontotemporal dementia (bvFTD). Genetic testing identified a likely pathogenic VCP gene mutation (c.383G>C), confirming IBMPFD. Treatment included escitalopram and atypical antipsychotics, resulting in a modest reduction in behavioral symptoms.
Conclusions: This case highlights the importance of considering IBMPFD in patients presenting with a constellation of symptoms, including behavioral changes, muscle weakness, and Paget's disease.

POLYGENIC RISK FOR ESSENTIAL TREMOR IS ASSOCIATED WITH MICROSTRUCTURAL DIFFERENCES IN GREY AND WHITE MATTER

POSTERS: G04. IMAGING, BIOMARKERS, DIAGNOSTICS

Alexandre Pastor-Bernier[1], Miranda Medeiros[2], Houman Azizi[1], Zoe Schmilovich[2], Patrick Dion[2], Alain Dagher[1], Guy Rouleau[2]
[1]Montreal Neurological Institute and Hospital, McGill University, Neurology And Neurosurgery, Montreal, Canada, [2]McGill University, Department Of Human Genetics, Montreal, Canada

Aims: Elucidation of essential tremor neuroanatomical vulnerabilities by investigating the associations between polygenic risk and brain magnetic resonance images (MRI).
Methods: We paired genetic and imagining data from the UK Biobank (UKBB) to model the associations of essential tremor (ET) polygenic risk scores (PRS) and brain structure. Individual-level genotyping and neuroimaging measures on 31,386 adults were used to correlate ET-PRS to brain morphometry. PRS-CS was used to infer SNP posterior effects and a PRS for each subject was obtained with PLINK. Principal component analysis (PCA) was performed to correct for population stratification. White matter tractography (WM DTI), mean diffusivity (MD), Free Water (FW) and NODDI models derived from diffusion weighted MRI (dMRI) were used to map WM integrity. Grey matter dMRI, along with cortical and subcortical anatomical data were also used.
Results: Our results indicate significant associations between ET-PRS in WM DTI cerebellar microstructure. We found positive associations of ET-PRS with MD in the corticospinal tract, external capsule, corpus callosum, middle cerebellar peduncle, intracerebellar-input and purkinje tract, superficial-frontal and uncinate fasciculus tracts. We also found extensive positive associations between ET-PRS and MD in several GM structures including the cerebellum, hypothalamus, caudate, putamen, thalamus and pedunculopontine nucleus. Also, the MD in thalamic deep brain stimulation hotzones VPL, VPM and VIM were positively associated with ET-PRS.We found ET-PRS negative associations with cortical volume in superior parietal and superior frontal areas. The subcortical volumes in the caudate, putamen, ventral diencephalon, midbrain, pons and medulla oblongata were all found to be negatively associated with ET-PRS.
Conclusions: Brain structural vulnerabilities in healthy subjects at risk of developing ET correspond to WM and GM areas that are also known to be involved in the rythmogenesis and pathology of ET.

Aims: Primary brain calcification (PBC; formerly Fahr's syndrome; primary familial brain calcification (PFBC) in inherited cases) is an often-genetic disease that is characterized by calcifications most often in the basal ganglia but also cerebellum, thalamus or cerebral cortex. It causes a broad clinical syndrome involving neurological and psychiatric deficits. Mutations in several genes, including PDGFB, PDGFRB, SLC20A2, MYORG and XPR1, can cause autosomal-recessively or -dominantly inherited PBC/PFBC. However, sporadic brain calcifications are frequently observed also in healthy, often elderly individuals. PBC/Fahr's syndrome has therefore been questioned as a disease entity, and the role of less extended calcification at higher ages remained elusive. The aim of this study is to better understand the differences between symptomatic and asymptomatic PBC.
Methods: We subjected individuals with various degrees of PBC from the German *Fahr-NET* patient register to an extensive study protocol including neurological, neuropsychological, imaging, genetic and laboratory biomarker assessment. Furthermore we tested several established serum markers linked to neurodegeneration and glial activation.
Results: The data show that almost all individuals with calcifications going beyond the putamen were symptomatic. In addition, we found that Serum GFAP was significantly increased in individuals with PBC, in line with the predominant expression of PBC genes in cells forming the blood-brain-barrier, including astrocytes.
Conclusions: Our results define a clinically relevant imaging cut-off indicating the presence of PBC-related symptoms. Moreover, an increase in serum GFAP indicates pathology in the sense of glial reactivity in PBC.

ANALYSIS OF THE GGC REPEAT LENGTH OF THE NOTCH2NLC GENE RESPONSIBLE FOR NEURONAL INTRANUCLEAR INCLUSION DISEASE IN A JAPANESE PSYCHIATRIC DEMENTIA COHORT

POSTERS: G05. GENETICS, EPIDEMIOLOGY

Tesshin Miyamoto[1], Kohji Mori[1], Shoshin Akamine[1], Ryota Uozumi[1], Shiho Gotoh[2], Shizuko Kondo[2], Sumiyo Umeda[2], Yuto Satake[2], Takashi Suehiro[2], Hideki Kanemoto[2], Kenji Yoshiyama[2], Takashi Morihara[2], Manabu Ikeda[2]
[1]Osaka University, Department Of Psychiatry, Osaka, Japan, [2]Osaska University, Department Of Psychiatry, Osaka, Japan

Aims: A GGC repeat expansion in the 5' untranslated region of the *NOTCH2NLC* is a genetic cause of Neuronal Intranuclear Inclusion Disease (NIID). Although proving the presence of intranuclear inclusion body by skin biopsy facilitated clinical identification of *NOTCH2NLC*-NIID patients, it is only performed in a few cases because of its invasive nature. Since patients with *NOTCH2NLC*-NIID heterogeneously exhibit cognitive, motor and autonomic dysfunction, it is difficult to diagnose it based on symptoms alone. Therefore, there may be a significant number of undiagnosed *NOTCH2NLC*-NIID cases.
Methods: We performed a comprehensive genetic screening of *NOTCH2NLC* GGC repeat expansion by Repeat-Primed PCR and Amplicon-Length PCR in a total of 745 cases of our psychiatric dementia cohort including non-demented cases with suspected cognitive dysfunction. All cases were clinically classified according to the International Classification of Diseases (ICD)-10 system and cases of organic, including symptomatic, mental disorders (F0) were further subclassified into dementia subtypes. This study was approved by the Ethics Committee of Osaka University. Genomic DNA has been collected from patients of Psychiatric clinic of Osaka University Medical Hospital under written informed consent.
Results: Two of the 745 cases were confirmed to have aberrant GGC repeat expansion in *NOTCH2NLC*. Subsequent skin biopsy revealed that both cases were positive for ubiquitin- and p62-positive intranuclear inclusion. One case of *NOTCH2NLC*-NIID showed anxiety and food intake disturbances with mild cognitive dysfunction, without MRI findings characteristic of NIID.
Conclusions: *NOTCH2NLC*-NIID is one potential cause of cognitive dysfunction in our Japanese psychiatric dementia cohort.

Aims: In Parkinson's disease (PD) the dopamine neurons containing neuromelanin (NM) are lost in the substantia nigra (SN), resulting in decreased NM and increased Fe concentrations. In Alzheimer's disease (AD) neurons are lost in cortical regions where an increase of Fe occurs. We aimed to measure NM and Fe concentrations in human midbrain subregions of PD and AD subjects and to investigate the effect of NM and Fe on NM-sensitive magnetic resonance imaging (NM-MRI) signal, in order to evaluate the reliability of MRI in detecting the loss of dopamine neurons in PD.
Methods: We imaged NM and Fe in slices of PD (n = 4) and AD (n = 7) subjects using NM and T_2-weighted MRI sequences. Results were then compared with a precise measurement of NM and Fe concentrations in the same midbrain slices, then imaging maps were calculated for each subject.
Results: Compared to AD, the PD subjects showed increased NM-MRI values in superior colliculus and periaqueductal gray matter, and higher Fe concentration in substantia nigra. Both NM and Fe concentrations had unique significant contributions to the NM-MRI signal (mixed-effects model controlling for diagnosis, 163 grid sections, 11 specimens).
Conclusions: Our results support the use of NM-MRI to study NM in the SN and midbrain regions like superior colliculus and periaqueductal gray matter for better monitoring of neuropathological damage in patients with PD and possibly in patients at risk of developing this disease.

ASSOCIATION OF C12ORF65 GENE MUTATION IN PATIENT WITH NOONAN SYNDROME

POSTERS: G05. GENETICS, EPIDEMIOLOGY

Gomathi Mohan, Kalaivanan Gokul
Karpagam Academy of Higher Education, Biotechnology, Coimbatore, India

Aims: Pathogenic mutations in C12orf65 gene leads to cause optic atrophy and progressive encephalomyopathy. This mutation was implicated in spastic paraplegia 55. In this study, we delineate and expand the clinical manifestation of C12orf65 mutation from an Indian case.
Methods: Whole exome sequencing, deletion or duplication analysis and mitochondrial genome sequencing were done.
Results: A 6 year old girl with global developmental delay, microcephaly, hypertelorism, epicanthic fold, webbed neck, camptodactyly of bilateral little finger, laterally placed nipples, and tongue tie. The clinical characteristics of the child made us to suspect mutation in Noonan syndrome related genes. But, WGS resulted in pathogenic mutation in C12orf65 gene at NM_152269.5; c.346del, deletion of one nucleotide at position c.346 leads to loss of normal protein function either through protein truncation or non-sense mediated mRNA decay. This homozygous mutation was found to be autosomal recessive in nature.
Conclusions: This study confirms the clinical and genetic spectrum of Noonan syndrome patient from India.

Aims: The Glass Syndrome is a rare neurogenic multisystem disorder that occurs due to the mutation in *SATB2* (OMIM-608148 and PMIM:612313). The clinical features of this syndrome include, delay in development and speech, hypotonia, abnormal dental features and cleft palate, difficulty in behavior, seizures and bone abnormalities. The present study aims in the identification of genetic background behind the patient present with features of cleft palate and developmental delay.
Methods: The Whole exome sequencing and targeted sequencing analysis was performed to the Index patient and to her daughter exhibiting the same clinical conditions respectively
Results: On the genetic analysis through whole exome sequencing, it was found that index had a mutation in the SATB2 gene with a rare variant c.1741-2A>C; p.R239X variant at intron 11. This is a substitution of base A at the place of C, two nucleotides before the initiation of the exon. This variant is reported to be pathogenic and causative of the Glass syndrome. There were also other uncertain significant mutations found in the CDCD42BP and SMARCC2 with variants c.3658C>T and c.2527G>A subjective of Chilton-Okur-Chung neurodevelopmental syndrome and Coffin-siris syndrome 8 respectively.
Conclusions: The whole exome exome sequening identifies the rare pathogenic variant of Glass syndrome and its association with neurodevelopmental disorders

Aims: Huntington's disease (HD) is an autosomal dominant condition causing severe neurodegeneration in the striatum and the entorhinal cortex (EC). An epigenome wide association study of DNA methylation in HD by our group, identified potential hypomethylation at the *PTGDS* gene in the striatum. We aimed to validate this result through pyrosequencing, examining the locus in fine detail, and to assess the signal specificity by profiling multiple neurodegenerative diseases.
Methods: 379 EC and striatal DNA samples from 85 control, 73 Alzheimer's disease (AD), 90 dementia with Lewy bodies (DLB), 20 HD, 34 Parkinson's disease (PD) and 24 vascular dementia (VaD) subjects were matched for sex and age. DNA was bisulfite converted, before *PTGDS* target region amplification and subsequent pyrosequencing. Samples were analysed using linear models comparing the control group to each disease, controlling for sex, age, and batch effects. Average methylation levels across the amplicon were also compared. Additional analysis stratifying DLB and VaD cases by co-existing AD pathology was also performed.
Results: We confirmed our previous findings of DNA hypomethylation at *PTGDS* in the striatum in HD. Furthermore, we found significant hypomethylation in the targeted region, both at the level of individual CpG sites, and across the amplicon in the EC. We also observed nominally significant changes in PD and DLB with co-existing AD pathology across the amplicon, but these did not pass multiple correction.
Conclusions: This study validates our previous findings of *PTGDS* hypomethylation in HD in the striatum and presents novel associations at the EC. Together, these findings suggest further investigation of *PTGDS*, given others report differential expression in HD oligodendrocytes. Future studies should address the cell-specific profile of *PTGDS* methylation and its transcriptional regulation in HD through fluorescent activated cell sorting.

DEFICIENT DIETARY FOLIC ACID AND SYSTEMIC DSP-4 INDUCED LOCUS COERULEUS LOSS ASSESSED AS NEURODEGENERATIVE COGNITIVE MODEL IN ADULT CB57/J6 MICE

POSTERS: G06. CELL, MOLECULAR AND SYSTEMS BIOLOGY

Susan Helm[1], Gabriel Kong[1], Aristotle Zeng[2], Theodore Helm[3], Simon Khorani[1], Rohan Rampal[2], Smayana Kurapati[2], Riva Rainier[2]
[1]Pepperdine University, Nutritional Science, Malibu, United States of America, [2]Pepperdine University, Biology, Malibu, United States of America, [3]Pepperdine University, Computer Science/math, Malibu, United States of America

Aims: Assessment of a potential neurodegenerative cognitive mouse model subjected to a dietary deficiency of folic acid (FA) by using DSP-4 to knockout the locus coeruleus (LC), notably, a major norepinephrine source in the DG and frontal cortex (FC).
Methods: For 16 weeks, adult CB57/J6 mice (N=66) were provided 4 dietary/DSP-4 treatments: NFCS (n=16, normal FA control, saline injected [0.2 mg FA/kg BW]); NFCD (n=18, normal FA, DSP-4 injected (50 mg DSP-4/kg BW); FADS (n=16, FA deficient, saline injected); and, FADD (n=16, FA deficient, DSP-4 injected). NE in FC was measured in addition to significant loss of LC neurons; astrocytes, calcium signaling, and embryonic neurons using, respectively, immunohistochemical methods for tyrosine hydroxylase (TH), GABA fibrillary acidic protein (GFAP), parvalbumin (PV), doublecortin (DCX) were analyzed.
Results: Confirmation of phenotypic cognitive behavior with Nesting Behavior; decreased distance traveled with Novel Object Recognition (NOR); and, decreased rearing and latency to explore to the center of the field in Open Field Testing (OFT) were enumerated between NFCS and FADD ($p<0.05$). Elevated plasma homocysteine (Hcy) and decreased methyltransferase activity ($p<0.05$) established folic acid deficiency between NFCS and FADS/FADD.
Conclusions: Results support that grievous injury to the LC noradrenergic system via systemic NE specific neurotoxin DSP-4 disrupts motor activity, contextual learning and memory, and perhaps significantly, the supportive cellular environment for the LC and efficient dispersion of NE. Understanding the molecular mechanisms underlying LC degeneration during disease progression or aging is yet to be fully understood.

IDENTIFICATION OF DISEASE CAUSING VARIANTS IN A COHORT OF 60 INDIVIDUALS WITH PRIMARY FAMILIAL BRAIN CALCIFICATION

POSTERS: G05. GENETICS, EPIDEMIOLOGY

Rüstem Yilmaz[1], Janine Schwahn[1], Sophie Hebestreit[1], Olivia Kosche[1], Vesile Sandikci[2], Mate E Maros[3], Ivan Valkadinov[1], Jasper Hesebeck-Brinckmann[1], Marvin Spreyer[1], Lukas Eckrich[1], David Brenner[4], Holger Wenz[3], Anne Ebert[2], Julian Conrad[1], Jochen Weishaupt[1]
[1]Division of Neurodegenerative Disorders, Mannheim Center for Translational Neurosciences, Medical Faculty Mannheim, Heidelberg University, Neurology, Mannheim, Germany, [2]Medical Faculty Mannheim, Heidelberg University, Neurology, Mannheim, Germany, [3]Medical Faculty Mannheim, Heidelberg University, Neuroradiology, Mannheim, Germany, [4]University Hospital Ulm, Neurology, Ulm, Germany

Aims: Primary familial brain calcification (PFBC), also known as familial idiopathic basal ganglia calcification or Fahr's disease, is a rare neurodegenerative disorder characterized by calcium deposits mainly in the basal ganglia, cerebellum, thalamus, and subcortical white matter. The disorder manifests with a wide range of neuropsychiatric symptoms and movement abnormalities. There are several genes linked to PFBC: autosomal dominant mutations in *PDGFB*, *PDGFRB*, *SLC20A2*, and *XPR1*, and biallelic mutations in *MYORG* and *JAM2* are causative. In this study, we set out to investigate the genetic causes of our PFBC study cohort from the German Fahr-NET register, evaluate pathogenicity of the variants, and analyze phenotype-genotype correlation.
Methods: We performed whole-exome sequencing in 60 patients affected with PFBC as confirmed by brain imaging and neurological as well as neuropsychological examination. We filtered for rare variants affecting a splice site, or causing missense, nonsense, stop-loss, and/or frameshift alteration. The patients were examined thoroughly in our clinics.
Results: In 18 patients from 16 unrelated families, we identified rare variants in the known PFBC genes: six in *SLC20A2*, six in *MYORG*, three in *PDGFB*, and one in *PDGFRB* and *XPR1* each. While a minority of these variants have been previously reported as pathogenic, most of those detected in our cohort are novel. Moreover, we identified two rare variants in *XPR1* and one in *PDGFRB* in our control cohort, which are not pathogenic according to brain imaging. We identified a rare variant in *JAM2* in heterozygous state.
Conclusions: In 30% of our patients, we identified a potentially causative variant in a known PFBC gene. As expected, variants in *SLC20A2* were more frequent than in other genes; whereas variants in MYORG (33%) were more frequent than expected.

DEFINING THE MECHANISMS BY WHICH MUTATIONS IN DNAJC7 INCREASE SUSCEPTIBILITY TO ALS/FTD

POSTERS: G06. CELL, MOLECULAR AND SYSTEMS BIOLOGY

Andrew Fleming
Northwestern University, Neurology, Chicago, United States of America

Aims: Aim 1: Identify endogenous interacting partners of DNAJC7 in human neurons and develop genetic tools to study DNAJC7-ALS/FTD. Aim 2: Define the mechanistic role of DNAJC7 in the neuronal stress response. Aim 3: Determine the contribution of pathogenic DNAJC7 on RNA metabolism.
Methods: We used mutant DNAJC7 cellular models, patient induced pluripotent stem cell (iPSC)-derived spinal motor neurons (MNs) and CRISPR/Cas9 gene-editing, in combination with mass spectrometry (MS)-based quantitative proteomics and RNA-Sequencing to elucidate how ALS/FTD-associated mutations in *DNAJC7* contribute towards neuronal dysfunction and degeneration.
Results: DNAJC7 interactome is highly enriched for genes involved in both the stress response and RNA metabolism. Introduction of ALS/FTD-causative mutation in neurons negatively impacted multiple levels of RNA processing at basal conditions. Furthermore, mutant neurons displayed a marked reduction in response to molecular insults, ultimately resulting in neurotoxicity.
Conclusions: Taken together, our work suggests DNAJC7 plays a critical role in function of its interacting partners, highlighting critical neuronal homeostasis pathways that may be perturbed in ALS/FTD. This study contributes towards the understanding of heat shock protein-dependent proteostasis mechanisms in human neurons as well as to how rare ALS/FTD genetic mutations lead to neuron dysfunction and loss.

MITOCHONDRIAL FRAGMENTATION IN HUNTINGTON'S DISEASE IS INDEPENDENT OF HUNTINGTIN FUNCTION AND IS DISTINCT FROM TRAUMATIC BRAIN INJURY (TBI)-MEDIATED FRAGMENTATION.

POSTERS: G06. CELL, MOLECULAR AND SYSTEMS BIOLOGY

Shermali Gunawardena
SUNY at Buffalo, Department Of Biological Sciences, Hochstetter Hall Rm 540, Buffalo, United States of America

Aims: Mitochondrial dysfunction has been reported in several Huntington's disease (HD) models with altered levels of the fission protein DRP1 and fusion protein MFN2. Impaired calcium homeostasis with increased cytoplasmic calcium and depletion of mitochondrial calcium stores have also been reported in HD. However, the mechanistic details of how mitochondrial dysfunction occurs in HD are unknown. Here we test the hypothesis that disruption of HTT function in the context of pathogenic HTT contributes to mitochondrial dysfunction.
Methods: To test this hypothesis we use humanized *Drosophila* models of HD, polyQ disease, or mechanically induced traumatic brain injury (TBI), together with pharmacological inhibitors and in vivo mitochondrial health reporters to examine mitochondrial defects.
Results: Expression of pathogenic HTT caused fragmented mitochondria compared to normal HTT, but HTT did not co-localize with mitochondria under normal or pathogenic conditions. Expression of pathogenic polyQ (127Q) alone or in the context of Machado Joseph Disease (MJD) also caused fragmented mitochondria. While mitochondrial fragmentation was not dependent on the cellular location of polyQ accumulations, expression of a chaperone protein, excess of mitofusin (MFN), or depletion of dynamin-related protein 1 (DRP1) rescued fragmentation. Intriguingly, a higher concentration of nitric oxide (NO) was observed in polyQ-expressing larval brains, and inhibiting NO production rescued polyQ-mediated fragmented mitochondria, postulating that DRP1 nitrosylation could contribute to excess fission. Further, while excess PI3K which suppresses polyQ-induced cell death did not rescue polyQ-mediated fragmentation, it did rescue fragmentation caused by mechanical stress/TBI.
Conclusions: Our observations suggest that pathogenic polyQ alone is sufficient to cause DRP1-dependent mitochondrial fragmentation upstream of cell death. Conversely, mechanical stress/TBI-mediated mitochondrial fragmentation is likely caused by cell death. Our work uncovers distinct physiological mechanisms for mitochondrial dysfunction in polyQ disease and under mechanical stress.

VGAMMA1 AND VGAMMA4 GAMMA-DELTA T CELLS PLAY OPPOSING ROLES IN THE IMMUNOPATHOLOGY OF TRAUMATIC BRAIN INJURY IN MALES

POSTERS: G06. CELL, MOLECULAR AND SYSTEMS BIOLOGY

Hadi Abou-El-Hassan[1], Rafael Machado Rezende[1], Saef Izzy[1], Taha Yahya[1], Zhuoran Yin[1], Marilia Garcia De Oliveira[1], Laura Michelle Cox[1], Oleg Butovsky[1], Howard Weiner[2]
[1]Brigham and Women's Hospital, Harvard Medical School, Neurology, Boston, United States of America, [2]Brigham and Women's Hospital, Neurology, Boston, United States of America

Aims: To investigate the role of γδ T cells in a model of traumatic brain injury (TBI) in mice, a model that shares features with AD.
Methods: TBI was induced to 8-12 weeks old TCRγδ knockout and wild-type mice. Rotarod, Morris water maze and probe tests were performed. Flow cytometry was performed to quantify total γδ T cells and Vγ4 subset. APP and pTau expression were shown by bright field staining. Cytokines and other factors were measured by qPCR. Microglia were sorted and sequenced. Vγ1 and Vγ4 subsets were depleted by the administration of monoclonal antibodies.
Results: After TBI, γδ-/- mice showed improvement in motor (Fig. 1A), and memory function (Fig. 1B-F). γδ T cell were increased in WT brain (Fig. 1G), mainly Vγ4 subset (Fig. 1H). WT mice had increased APP and pTau immunoreactivity compared to γδ-/- mice (Fig. 2A). γδ-/- mice showed reduction of brain inflammatory cytokines whereas Foxp3 was increased (Fig. 2B). 2,437 genes were differentially expressed (DEGs) in microglia from young WT-TBI vs. WT-Sham mice (Fig. 2C-E). 1,062 microglial DEGs from young WT-TBI compared to γδ-/-TBI mice (Fig. 2E). Homeostatic genes were increased in microglia from γδ-/- mice whereas inflammatory genes were reduced (Fig. 2C-E). In the chronic phase of TBI, 1,376 and 59 microglial DEGs from aged WT-TBI vs. WT-Sham and vs. γδ-/-TBI mice (Fig. 2F-H). Vγ4 and total γδ T cell-blocked mice displayed a greater reduction of CNS inflammatory cytokines whereas Vγ1-blocked mice had less regulatory cytokine (Fig. 3B). Microglia isolated from Vγ4 or total γδ T cell depleted mice had downregulation of inflammatory genes compared to Vγ1-depleted mice (Fig. 3C, D).
Conclusions: Taken together, these findings indicate that γδ T cells play a critical role in TBI.

NEUROTOXIC EFFECT OF SALSOLINOL ON NE-4C NEURAL STEM CELL MEDIATED THROUGH MTOR PATHWAY

POSTERS: G06. CELL, MOLECULAR AND SYSTEMS BIOLOGY

Rhun Yian Koh[1], Salini Mohan Kumar[1], Yiing Jye Yap[2], Soi Moi Chye[1], Kenny Gah Leong Voon[3], Khuen Yen Ng[4], Anna Pick Kiong Ling[1]
[1]International Medical University, Division Of Applied Biomedical Science And Biotechnology, Bukit Jalil, Malaysia, [2]Monash University Malaysia, School Of Medicine, Subang Jaya, Malaysia, [3]University of Nottingham Malaysia, Division Of Biomedical Science, Semenyih, Malaysia, [4]Monash University Malaysia, School Of Pharmacy, Subang Jaya, Malaysia

Aims: Parkinson's disease is a common neurological disease characterised by motor and non-motor symptoms. Cell therapy is a promising alternative therapeutic strategy in Parkinson's disease. It restores the damaged neurons in the nigrostriatal pathway. Transplanted neuronal stem cells are multipotent and are capable of differentiating to several types of cells in the central nervous system, including neurons and other brain cells. However, salsolinol, a neurotoxin exerts substantial toxicity on the transplanted neuronal stem cells. Salsolinol has diverse neuropharmacological effects including inducing oxidative stress besides being able to inhibit the mitochondrial energy supply. Salsolinol also inhibits some key enzymes involved in the production of dopamine such monoamine oxidase, tyrosine hydroxylase and catechol-O-methyltransferase. Additionally, salsolinol also prevents the uptake of catecholamines. This study aims to evaluate neurotoxicity and apoptogenic effect of salsolinol on NE-4C neuronal stem cells through mammalian target of rapamycin signalling pathway.
Methods: Salsolinol was added to NE-4C cells. Cell viability and apoptosis were evaluated by using trypan blue exclusion method and mitochondrial membrane potential staining assay, respectively. Additionally, some key regulatory proteins that could mediate cell apoptosis through mTOR signalling pathway was analysed. The relative expressions of mTOR, phospho-mTOR, raptor and GßL proteins were determined using enzyme- linked immunosorbent assay.
Results: revealed that when NE-4C cells were treated with salsolinol (0-100µM) for 24, 48 and 72 hours, salsolinol induced death in NE-4C cells mainly by alteration of mitochondrial membrane potential. Additionally, the change of the level of phospho-mTOR indicates the contribution of this protein in the death of the NE-4C cells.
Conclusions: In conclusion, salsolinol induced neuronal cell death via mitochondrial membrane potential alteration and down-regulation of phospho-mTOR protein.

COMPREHENSIVE CROSS-PATHOLOGIES STUDY AND NEURONAL SUBTYPE ANALYSIS REVEALS MOLECULAR SIGNATURES OF NEURODEGENERATIVE DISORDERS

POSTERS: G06. CELL, MOLECULAR AND SYSTEMS BIOLOGY

Zhaohui Man
Duke University, Neurology, Durham, United States of America

Aims: Late-onset Alzheimer's Disease (LOAD), Parkinson's Disease (PD), and Dementia with Lewy Bodies (DLB) represent three neurodegenerative disorders with overlapping clinical characteristics. Disentangling their molecular subtypes and identifying distinct biomarkers remains challenging. In this study, we conducted a comprehensive cross-pathologies investigation utilizing single-cell RNA sequencing (scRNA-seq) data derived from post-mortem brain tissues of individuals affected by these three debilitating conditions. Our study encompassed three pivotal comparisons: LOAD vs. PD, PD vs. DLB, and DLB vs. LOAD, aimed at identifying differentially expressed genes (DEGs) crucial to understanding the unique molecular signatures of each disorder.
Methods: Pathway analysis of the DEGs from these comparisons unveiled intricate molecular networks, emphasizing the convergence of neuroinflammatory, synaptic, and protein homeostasis pathways as common denominators across these disorders. This collective insight into shared pathways deepens our comprehension of their overlapping pathogenic mechanisms.Furthermore, our research aspired to uncover biomarkers capable of distinguishing subtypes within the spectrum of neurodegenerative diseases. Leveraging the scRNA-seq data, we deployed the MASC (Marker Gene Analysis with Single-Cell RNA-Seq) method to pinpoint depleted or vulnerable neuronal subtypes and signature/marker genes. Our analysis focused on PD vs. Normal, LOAD vs. Normal, and DLB vs. Normal comparisons, providing novel insights into the distinct neuronal vulnerabilities associated with each disorder.
Results: This multi-faceted investigation harnesses the potential of single-cell transcriptomics and MASC analysis to not only delineate the intricate molecular landscapes of AD, PD, and DLB but also to uncover unique neuronal vulnerabilities and potential biomarkers. Our findings advance our understanding of these neurodegenerative diseases, opening avenues for more precise diagnoses and targeted therapies tailored to distinct subtypes within this challenging clinical landscape.
Conclusions: Subtypes of NDD have their shared pathways and unique molecular signatures.

NOVEL PLATFORMS TO INVESTIGATE CENTRAL NERVOUS SYSTEM DISEASES FOR DISCOVERY PURPOSES

POSTERS: G06. CELL, MOLECULAR AND SYSTEMS BIOLOGY

Matteo Zanella[1], Malika Bsibsi[1], Blanca Torroba[1], Marta Da Silva[1], Laila Ritsma[1], Dario Magnani[2], Mariangela Iovino[2], Roxana Redis[1], Maria Herva Moyano[2], Ludovico Buti[1], Marijn Vlaming[1]
[1]Charles River Laboratory, Early Discovery, Leiden, Netherlands, [2]Charles River Laboratory, Early Discovery, Saffron Walden, United Kingdom

Aims: There is an urgent need for reproducible and up scalable platforms for discovery of modifiers of Central Nervous System (CNS) diseases in high throughput formats. Recent advances in the areas of 2D and 3D stem cell research and gene/RNA editing have translated into opportunities to better understand brain diseases. Application within a drug discovery setting enables discovery of potential treatments using the most relevant cell models.
Methods: Both induced pluripotent stem cells (iPSCs) and organoids represent promising resources for modeling CNS diseases. iPSCs can be used to generate patient-specific neurons or glial cells either as single cell types or in co-cultures. Organoids offer a three-dimensional representation of the brain, enabling the investigation of CNS architecture, connectivity and function; thus allowing *in-vivo* conditions to be simulated.
Results: Our recent results confirm that iPSC-derived neurons and microglia are robust platforms for the study of neurodegenerative disorders, such as Amyotrophic Lateral Sclerosis (ALS) and Alzheimer's Disease (AD). We demonstrate that these models possess phenotypical and functional properties similar to those observed in the human body, both in mono- and co-culture experiments, including electrical activity (neurons) and cytokine release (microglia). Differences can be observed between healthy and diseased cell lines which mimic pathological conditions, such as reduced firing activity in neurons with mutations in ALS causative genes. Additionally, we demonstrate downregulation of target genes in these cell types using either a siRNA- or ASO-based approach.
Conclusions: Together, these platforms can help identify novel therapeutic targets and improve our understanding of disease mechanisms, with the goal of establishing effective treatments for CNS diseases.

BAICALIN PREVENTS CEREBRAL ISCHEMIA-INDUCED NEUROBEHAVIORAL DISORDERS AND BRAIN DAMAGE

POSTERS: G07. ANIMAL MODELS

Phil-Ok Koh, Hyun-Kyoung Son
Gyeongsang National University, College Of Veterinary Medicine, Jinju, Korea, Republic of

Aims: Cerebral ischemia is known that causes neurological disorder, neuronal cell death, and permanent disability. Baicalin has antioxidant and anti-apoptotic properties. The aim of this study was to investigate the neuroprotective effect of baicalin in animal models of stroke.
Methods: Middle cerebral artery occlusion (MCAO) was performed to induce focal cerebral ischemia and baicalin (30 mg/kg) or vehicle was injected intraperitoneally just before MCAO surgery. Neurological behavior tests including neurobehavioral scores, corner test, adhesive removal test, and vibrissae-evoked forelimb placing test were performed 24 h after MCAO. Brain edema and infarct volume were measured. To investigate the antioxidant effect of baicalin, reactive oxygen species (ROS) and lipid peroxidation (LPO) levels were measured. Hematoxylin and eosin staining and terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) histochemical staining were performed.
Results: There were significant neurobehavioral defects in MCAO-treated animals. However, in the presence of baicalin, neurobehavioral defects due to MCAO surgery were significantly attenuated. MCAO damage causes severe cerebral edema and increases infarct volume, and baicalin treatment alleviates these changes caused by MCAO. The cerebral cortex of MCAO animals showed histopathological changes with condensed nuclei and expanded cytoplasm and increased TUNEL positive responses. However, administration of baicalin attenuated histological lesions caused by MCAO. In addition, baicalin treatment alleviated MCAO-induced increases in ROS and LPO levels.
Conclusions: We showed that MCAO damage caused severe neurobehavioral impairment and brain tissue damage, and baicalin exerted neuroprotective effects by regulating apoptosis and oxidative stress. Therefore, these results suggest that baicalin acts as a neuroprotective agent in stroke animal models.

FERULIC ACID'S AMELIORATE MYCOTOXIN-INDUCED NEUROTOXICITY IN RATS

POSTERS: G07. ANIMAL MODELS

Puneet Kumar[1], Surbhi Singh[2]
[1]Central University of Punjab, Pharmacology, bathinda, India, [2]Central University of Punjab, Pharmacology, Bathinda, India

Aims: Huntington's disease (HD) is a neurological ailment marked by chorea, aberrant movement patterns, cognitive and mental challenges. Few therapies are available for the management of HD, and the majority of these drugs have side effects affecting patient compliance and treatment outcomes. Plant and their phytoconstituents have long been a hub for identifying novel and alternative drug compounds. It has been hypothesized that ferulic acid (FA), a polyphenolic molecule with antioxidant properties, can reduce oxidative stress, contributing to CNS disorders' pathophysiology, including Huntington's disease.
Methods: In this study, 3-NP a mycotoxin that inhibits mitochondrial complex 2 was used to induce Neurotoxicity in rats to assess the neuroprotective potential of ferulic acid (FA). Wistar rats were given FA (25,50 and 100 mg/kg) p.o. one hour before 3-NP treatment (10 mg/kg) i.p., for 21 days. Body weight and physical qualities (activity, muscular coordination, and gait abnormalities) were assessed every 7 days. Animals were euthanized on the 22nd day, brain cells extracted, and striatal sections excised to determine oxidative stress indicators and inflammatory cytokines. The level of proapoptotic proteins was evaluated using Western blot.
Results: 3-NP administration affected experimental animals' body weight, motor coordination, and biochemical indicators. Compared to the 3-NP groups, FA (50 and 100 mg/kg) mitigated abnormalities in behavioral, oxidative, inflammatory, and apoptotic markers.
Conclusions: In conclusion, FA could exert its neuroprotective effect via its antioxidant, anti-inflammatory, and anti-apoptotic properties. **Acknowledgement:** The authors would like to thank Central University of Punjab for providing Research Seed Money and animal house facilities.

SELECTIVE RNAI-SILENCING OF SCHWANN CELL PIEZO1 ALLEVIATES MECHANICAL HYPERSENSITIZATION FOLLOWING PERIPHERAL NERVE INJURY

POSTERS: H01. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Hongwei Yu[1], Brandon Itson-Zoske[1], Uarda Gani[1], Chensheng Qiu[1], Fan Fan[2], Quinn Hogan[1], Seung Min Shin[1]
[1]Medical College of Wisconsin, Anesthesiology, MIlwaukee, United States of America, [2]Augusta University, Physiology, Augusta, United States of America

Aims: We previously reported functional mechanosensitive Piezo1 expression in Schwann cells of the peripheral nervous system, which plays a role in the regulation of myelination. The present study is designed to further investigate the role of Schwann cell Piezo1 in peripheral nociception.
Methods: We first developed an adeno-associated viral (AAV) vector that has primary Schwann cell tropism after delivery into the sciatic nerve. This was achieved by packing AAV-GFP transcribed by a hybrid CMV enhancer/chicken β-actin (CBA) promoter using a capsid AAVolig001 to generate AAVolig001-CBA-GFP. Five weeks after intrasciatic injection of AAVolig001-CBA-GFP in naïve rats, GFP expression was detected selectively in the Schwann cells of the sciatic nerve. A short hairpin RNA against rat Piezo1 (PZ1shRNA) was designed that showed efficient physical and functional knockdown of Piezo1 in NG108 neuronal cells. A dual promoter and bidirectional AAV encoding a U6-driven PZ1shRNA and CBA-transcribed GFP was packed with capsid olig001 (AAVolig001-PZ1shRNA), and AAV was injected into unilateral sciatic nerve immediately after induction of common peroneal nerve injury (CPNI).
Results: showed that the development of mechanical hypersensitivity in the CPNI rats injected with AAVolig001-PZ1shRNA was mitigated, compared to rats subjected with AAVolig001-scramble. Selective *in vivo* Schwann cell transduction and functional block of Piezo1 channel activity of primary cultured Schwann cells was confirmed.
Conclusions: Our data demonstrate that 1) AAVolig001 has unique and selective primary tropism to Schwann cells via intrasciatic delivery, which provides a useful tool in studying demyelinating disorders, and 2) Schwann cell Piezo1 contributes to mechanical hypersensitivity following nerve injury.

DHCB ALLEVIATE MOUSE EAE MODEL IN GUT MICROBIOTA DEPENDENT MANNER

POSTERS: H01. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Haoran Wang, Zhou Jiawei
Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Laboratory Of Development And Degeneration Of Basal Ganglia, Shanghai, China

Aims: Multiple sclerosis is an inflammatory demyelinating disease of the CNS which specific nosogenesis remains unkonwn. We intented to study MS by using mouse EAE model and tried to alleviate this disease in the context of regulating gut microbiota.
Methods: The main methods we used is mouse EAE model. The mouse experimental autoimmune encephalomyelitis (EAE) model is widely used to study multiple sclerosis (MS), an autoimmune disease that affects the central nervous system. In this model, mice are immunized with myelin antigens, such as myelin basic protein (MBP) or proteolipid protein (PLP), to induce an immune response against their own myelin. This leads to the development of inflammation and demyelination in the central nervous system, similar to what is observed in MS patients.
Results: We gavage DHCB to mice following EAE model and found that DHCB could significantly reduce the severity of the EAE. By using16s rRNA sequencing technology, we found that gut micobiota were dramatically changes after gavage of DHCB which is critical for the neuroprotective role of DHCB.
Conclusions: In conclusion, we found that Chinese herb extracts, DHCB could prevent experimental autoimmune encephalomyelitis.

UNTANGLING LONG-TERM EFFECTS OF BOTULINUM TOXIN AS THERAPY FOR MOTOR SYMPTOMS

POSTERS: G07. ANIMAL MODELS

Petra Šoštarić Mužić[1], Patrik Meglić[2], Ivica Matak[1]
[1]University Of Zagreb School Of Medicine, Department Of Pharmacology, Zagreb, Croatia, [2]School of Medicine University of Zagreb, Pharmacology, Zagreb, Croatia

Aims: Botulinum toxin A (BoNT-A) is often used as therapy for various motor disorders, including motor symptoms in Parkinsons disease and Parkinsonian syndromes. Its therapeutic effects are mostly associated with neuroparalysis of muscular motor terminals, but recent studies revealed that lasting effects on focal muscle hypertonia, are at least in part due to the toxin's central transcytosis. Here we examined action of botulinum toxin and its relative contribution of peripheral and central effects on normal and hyperactive muscles by implying neutralizing antitoxin and evoked focal spasticity by i.m. tetanus injection.
Methods: Male Wistar rats were unilaterally injected into gastrocnemius muscle with BoNT-A (Clostridium botulinum type A neurotoxin complex, 5 U/kg). After 24 hours, BoNT-A-neutralizing antitoxin (5 I.U.) was administered intrathecally to prevent the toxin's central transcytosis. Motor tests such as gait ability test, digit abduction score (DAS) and electrophysiological measurements were repeatedly performed to assess motor performance recovery. After the animals recovered, unilateral injection of TeNT (1,5 ng) was administered to gastrocnemius to induce spastic paralysis and assessed by ankle dorsiflexion resistance test, Basso–Beattie–Bresnahan locomotor rating scale (BBB) and monosynaptic H-reflex measurements.
Results: The BoNT-A induced lasting and reversible impairment of examined motor functions, which mostly recovered by day 70 post i.m toxin injection. The TeNT increased monosynaptic H-reflex was not decreased by BoNT-A. TeNT-evoked spastic paralysis was affected by BoNT-A central and peripheral effects showed during dorsiflexion test and BBB score.
Conclusions: This data suggest that combined peripheral and central effects of the peripherally administered BoNT-A are responsible for its lasting action in hyperactive muscle, while peripheral toxin effect are more important in motor performance impairment and lasting muscle atrophy. Funding: CSF-UIP-2019-04-8277

CORPUS CALLOSUM MYELIN AND VOLUME PRESERVATION IN PARTICIPANTS WITH ALZHEIMER'S DISEASE: MRI OUTCOMES FROM THE OVERTURE STUDY

POSTERS: H01. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Xiao Da, Mihaly Hajos, Ralph Kern, Aylin Cimenser
Cognito Therapeutics, R&d, Cambridge, United States of America

Aims: In the OVERTURE study, 1-hour daily treatment of Alzheimer's Disease (AD) participants with Cognito Therapeutics' medical device preserved function, cognition, reduced brain atrophy, and preserved white matter volume and myelin content compared to sham treatment over 6 months (Da et al, 2023). We evaluated the effect of treatment on corpus callosum (CC) volume and myelin content.
Methods: OVERTURE (NCT03556280) participants across the AD spectrum were randomized 2:1 (Active:Sham) to receive daily, 1-hour, 40-Hz gamma sensory stimulation or sham treatment for six months. Structural MRI data from 50 participants were analyzed using DRAMMS (Ou et al, 2011) and MRTool (Ganzetti et al, 2014) to evaluate longitudinal changes in the CC (Mori et al, 2005). T1w and T1w/T2w ratio were used for volumetric and myelin content assessment, respectively. Bayesian linear mixed-effects modeling was used for statistical analysis.
Results: After 6 months, active treatment showed preserved corpus callosum myelin content (T1w/T2w ratio) and volume (T1w) compared to the sham treatment with a lower % change from baseline of myelin content in CC-total (4.14±1.50%, $p<.008$), CC-Body (4.21±1.60%, $p<.01$), CC-Genu (6.32±1.84%, $p<.001$) and CC-genu volume (2.94±0.93%, $p<.003$). We did not observe significant changes in the CC-splenium.
Conclusions: Six months of active treatment with Cognito Therapeutics' medical device preserved CC myelin content and volume compared to sham treatment in participants with AD. Myelin and white matter are important AD biomarkers that will be evaluated in the ongoing phase 3 HOPE study (NCT05637801).

MENINGEAL LYMPHATIC DRAINAGE REGULATES OLIGODENDROCYTE SURVIVAL AND BRAIN MYELINATION

POSTERS: H01. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Sandro Da Mesquita
Mayo Clinic, Department Of Neuroscience, Jacksonville, United States of America

Aims: The meningeal lymphatic vessels are constantly draining cerebrospinal fluid content to the cervical lymph nodes, and functional defects in this previously unappreciated brain lymphatic cleansing pathway have been linked to accumulation of toxic protein aggregates, exacerbated neuroinflammation, and poor cognitive function. However, the impact of impaired meningeal lymphatic drainage on the function of specific brain cells and on the regulation of particular brain molecules, namely lipids, is still unknown. The main purpose of this study was to test whether and how decreased meningeal lymphatic drainage alters brain lipid composition and myelination.
Methods: To test the effect of meningeal lymphatic vessel ablation on brain myelination, we took advantage of two different mouse models, the VEGF-C/D trap and a genetic model that relies on the conditional deletion of *Prox1* from endothelial cells. Additionally, the cuprizone model was used to investigate the role of meningeal lymphatic drainage during the process of brain remyelination.
Results: Meningeal lymphatic vessel ablation resulted in altered oligodendrocyte gene expression, reduced myelin integrity, loss of specific lipid classes and decreased numbers of oligodendrocytes. Most of these results were recapitulated in a genetic model of meningeal lymphatic endothelial cell loss. Importantly, the loss of oligodendrocytes was not recapitulated in models with compromised adaptive or innate immune responses. Additionally, we observed that animals with impaired meningeal lymphatic function show a delay in the spontaneous remyelination process that occurs after cuprizone withdrawal.
Conclusions: Decreased meningeal lymphatic drainage is associated with a marked changes in mature oligodendrocytes, brain demyelination, and delayed remyelination.

6-PYRUVOYL-TETRAHYDROPTERIN SYNTHASE MODULATES THE FUNCTION OF OPCS IN MULTIPLE SCLEROSIS

POSTERS: H01. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Hui Xiao[1], Zhou Jiawei[2]
[1]Center for Excellence in Brain Science and Intelligence Technology, Laboratory Of Development And Degeneration Of Basal Ganglia, Shanghai, China, [2]Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Laboratory Of Development And Degeneration Of Basal Ganglia, Shanghai, China

Aims: During multiple sclerosis (MS), remyelination is occurred at the early stage of the disease but is finally failed. The most likely reason is the dysfunction of oligodendrocyte precursor cells (OPCs). Therefore, maintaining the function of OPCs has been proposed as a potential therapeutic approach for MS. Patients with deficiency of 6-Pyruvoyl-tetrahydropterin synthase (PTS) exhibited abnormal myelination, which indicated the correlation of PTS and myelination. We investigated the role of PTS in OPCs during the process of experimental autoimmune encephalomyelitis (EAE), an animal model of MS.
Methods: Mice lacking PTS in OPCs (*Pts*^{pdgfra} cKO mice) were used to investigate the impact of *Pts* in OPCs on the process of EAE. The number of oligodendrocyte lineage cells were evaluated by immunohistochemistry, Western blot, and quantitative PCR. RNA sequencing analysis was carried out to identify differentially expressed genes in spinal cord of *Pts*^{pdgfra} cKO mice with EAE. Primary OPCs and oli-neu cells were used to examine the regulation of PTS to OPCs.
Results: We show the upregulation of PTS in MS brain. Mice lacking PTS in OPCs exhibit a delay in the onset of EAE and decreased demyelination. The proliferation of OPCs and the level of *Mbp* was increased in spinal cord of PTS deletion mice. Mechanistically, PTS regulates the expression of hydroxy-3-methylglutary-coenzyme-A synthase 1 (HMGCS1), which is the first enzyme catalyze cholesterol de novo synthesis. In OPCs, knockdown of PTS and overexpress HMGCS1 both increased the expression of *Cspg4*, which regulates the proliferation of OPCs.
Conclusions: Our findings suggest that PTS modulates the proliferation of OPCs and demyelination during EAE, and provide a new drug target to regulate the proliferation of OPCs to treat demyelinating diseases.

INHIBITION OF ASTROCYTIC DRD2 SUPPRESSES CNS INFLAMMATION VIA PTS IN AN ANIMAL MODEL OF MULTIPLE SCLEROSIS

POSTERS: H01. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Guo Yongshun, Lu Shenzhao, Wu Yue, Zhou Jiawei
Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Laboratory Of Development And Degeneration Of Basal Ganglia, Shanghai, China

Aims: Astrocytes, which are the most abundant type of glial cell in the central nervous system, play essential roles in the maintenance of central nervous system homeostasis and contribute to the pathogenesis of neurodegeneration diseases. Dopamine is one of the abundant neurotransmitters, regulating multiple important physical processes. Although dopamine receptors are expressed in astrocytes, the impact of dopamine on glial cells is largely unknown. In this study, we investigated the function of astrocytic dopamine D2 receptor (Drd2) and its downstream signaling pathway in the pathogenesis of multiple sclerosis (MS).
Methods: Astrocytic Drd2 conditional knockout mice were used to investigate the their role in experimental autoimmune encephalomyelitis (EAE), an animal model of MS. RNAseq was perform to explore the downstream pathway of Drd2 to regualte the inflammation. Drd2 antagonists were also screened to verify whether it could be used as a new target for the treatment of MS.
Results: We showed the upregulation of Drd2 in reactive astrocytes in MS brain. Mice deficient in astrocytic Drd2 exhibited a remarkable suppression of reactive astrocytes and inflammation which were correlated with the amelioration of EAE. Comparison of the transcriptional profiles between mice deficient in astrocytic Drd2 and control revealed that astrocytic Drd2 regulated the expression of 6-pyruvoyl-tetrahydropterin synthase (PTS) which modulated NF-κB activity through protein kinase C delta. Pharmacological blockade of astrocytic Drd2 with Drd2 antagonist dehydrocorybulbine remarkably inhibited the inflammatory response in vitro and in vivo.
Conclusions: Our findings reveal a crucial role of astrocytic Drd2, and its downstream signaling pathway in the modulation of inflammatory response in astrocytes during MS pathogenesis. This study also provides new insights into the role of astrocytes in neurodegenerative processes and development of potential therapeutics for treatment of neurodegeneration diseases.

MULTIPHASIC ADEM IN A 14 YEAR OLD BOY

POSTERS: H01. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Pratyush Kumar
HIMALAYAN INSTITUTE OF MEDICAL SCIENCES, Department Of Neurology, DEHRADUN, India

Aims: To explore the clinical features and prognostic factors for relapse of acute disseminated encephalomyeltis (ADEM) in an adolescent .
Methods: A 14 year old boy was prospectively analyyzed on the basis of clinical manifestations , laboratory features , magnetic resonance imaging (MRI) , treatment and prognosis .
Results: A 14 year old boy presented to us with recurrent episodes of focal neurological deficit .The patient was apparently alright until June 2022 when he developed fever followed by quadriparesis. Mri was suggestive of focal hyperintensities in left frontal lobe and subcortical and periventricular white matter. Similar signals were seen were also seen in splenium of corpus callosum and on pons in the right side . T2 weighted images showed with hyperintense signal involving long segment of cervical cord from . Csf analysis revealed albuminocytological dissociation .Oligoclonal band cells were negative in Csf . Serum anti mog and anti aquaporin 4 antibody in were also negative. VEP was b/l abnormal. Patient was given pulse methylprednisolone for 5 days after which he recovered with residual weakness. This episode was followed by similar episodes of neurological deficit at 6 months and 12 months respectively with new lesions on MRI.
Conclusions: Multiphasic ADEM involves two or more episodes that are separated by at least 3 months.It is a rare entity. The treatment of multiphasic ADEM is aimed at reducing inflammation and preventing further damage to myelin .The main treatment is high dose corticosteroids which are usually given intravenously for a few days . Other immunosuppressive or immunomodulatory drugs may be used like IVIG ,Plasmapharesis, rituximab or cyclophosphamide.

LOWER MYELIN CONTENT IS ASSOCIATED WITH STEEPER LONGITUDINAL DECLINE IN MOTOR FUNCTION: NEW INSIGHTS USING ADVANCED MAGNETIC RESONANCE PHYSICS

POSTERS: H02. IMAGING, BIOMARKERS, DIAGNOSTICS

Mustapha Bouhrara, Siddique Akhonda, Mary Faulkner, John Laporte, Zhaoyuan Gong
National Institutes of Health, National Institute On Aging, Baltimore, United States of America

Aims: Mounting evidence indicates that myelin breakdown is a major hallmark of Alzheimer's and Parkinson's diseases. We previously have provided evidence of the role of myelination in cognitive changes (PMC10387505). We also showed that lower myelin content is associated with lower gait speed (GS) (PMC10395567). Here, we expanded our work to provide original results linking myelin content to changes in motor function.
Methods: Our study cohort included 123 cognitively unimpaired participants. For each participant, myelin content was probed using our advanced MRI method of myelin water fraction (MWF), a direct measure of myelin content. Rapid and Usual gait speeds (UGS, RGS), two integrative measures of motor function, were measured longitudinally over a long time period. Voxel-wise linear mixed-effects models were used to assess the associations between MWF and longitudinal changes in UGS and RGS. Statistical significance was defined as $p < .001$ with a cluster size > 400 voxels.
Results: Our results showed regional associations between MWF and UGS or RGS, with lower myelin content, that is, lower MWF, associated with steeper declines in gait speeds. These associations were significant in various cerebral white matter structures investigated.
Conclusions: For the first time, we showed a strong and significant relationship between myelin content and the rate of changes in motor function in cognitively normal individuals. These findings advance our understanding on the implication of myelination in gait impairment among cognitively unimpaired adults, providing further evidence of the interconnection between white matter integrity and motor function. Finally, MWF may serve as a potential sensitive and specific imaging biomarker for predicting motor changes in normative aging and cognitive impairments, including Alzheimer's and Parkinson's diseases.

BIG-TAU AND BRAIN-DERIVED TAU DYNAMIC IN GUILLAIN-BARRÉ SYNDROME AND ALZHEIMER'S DISEASE

POSTERS: H02. IMAGING, BIOMARKERS, DIAGNOSTICS

Fernando Gonzalez-Ortiz[1], Kaj Blennow[2], Thomas Karikari[3], Hlin Kvartsberg[4], Henrik Zetterberg[2], Luis Querol Gutierrez[5], Lorena Martin Aguilar[5]
[1]Gothenburg University, Psychiatry And Neurochemistry, Göteborg, Sweden, [2]University of Gothenburg, Department Of Psychiatry And Neurochemistry, Molndal, Sweden, [3]University of Gothenburg, Psychiatry And Neurochemistry, Göteborg, Sweden, [4]Sahlgrenska University Hospital, Psychiatry And Neurochemistry, Göteborg, Sweden, [5]hospital sant pau, Neuromuscular Unit, Barcelona, Spain

Aims: Biomarkers for monitoring disease activity and treatment outcomes in patients with neuropathies are lacking. A high-molecular-weight isoform of tau protein, called big-tau, is predominantly expressed in PNS. Our objective is to study the dynamic of big-tau and brain-derived tau (BD-tau) in blood in patients with Guillain-Barré syndrome (GBS), including the Miller-Fisher syndrome (MFS) variant, and Alzheimer's disease (AD).
Methods: We measured big-tau and BD-tau in serum samples from 101 GBS patients, 89 of them prospectively included in the IGOS study (at baseline and at different timepoints), 12 MFS patients, 41 healthy controls (HC) and 20 AD patients.
Results: GBS patients had significantly higher big-tau levels than AD (11.43 vs 2.77pg/ml, p<0.001). BD-tau levels were higher in AD compared to the GBS group (11.29 vs 3.29 pg/ml, p<0.001). Big-tau levels increased at week 1 and 2 to subsequently decrease up to 1 year. BD-tau levels maintained stable or with a slight increase at follow-up in most GBS patients. Patients with MFS had higher BD-tau levels than other forms of GBS (12.72 vs 3pg/ml, p=0.003) and lower big-tau levels (5.39 vs 11.43pg/ml, p=0.002). GBS patients with ganglioside antibodies had higher levels of both biomarkers (for BD-tau 3.76 vs 2.51pg/ml, p=0.01 and for big-tau 13.23 vs 8.26 pg/ml, p=0.001).
Conclusions: Big tau is a potential new marker in GBS. Patients with GBS had higher big-tau levels than AD and HC. Patients with MFS had higher levels of BD-tau and lower levels of big-tau compared to other forms of GBS, supporting the role of CNS involvement in those patients. The dynamic Big tau/BD-tau in blood may help to determine the magnitude of CNS or PNS affection in different pathologies.

INVESTIGATION OF MOTOR COORDINATION AND MEMORY PROCESSES DURING THE DEMYELINATION AND REMYELINATION PERIODS IN A CUPRIZONE MODEL OF MULTIPLE SCLEROSIS

POSTERS: H03. ANIMAL MODELS

Ivalina Valchinkova[1], Ivanka Kostadinova[2], Aleksandar Iliev[3], Stancho Stanchev[4], Nikola Stamenov[3], Lyubomir Gaydarski[3], Boycho Landzhov[3]
[1]Faculty of pharmacy, Medical university-Sofia, Pharmacology, Pharmacotherapy And Toxicology, Sofia, Bulgaria, [2]Faculty of pharmacy, Medical university of Sofia, Pharmacology, Pharmacotherapy And Toxicology, Sofia, Bulgaria, [3]Faculty of Medicine, Medical university of Sofia, Anatomy, Hystology And Embryology, Sofia, Bulgaria, [4]Faculty of Medicine, Medical university ot Sofia, Anatomy, Hystology And Embryology, Sofia, Bulgaria

Aims: The aim of this study was to determine the changes in the body weight, motor coordination and memory processes in the context of a cuprizone model of multiple sclerosis in mice.
Methods: The neurotoxicant, cuprizone, was administered to 8-week-old C57BL/6 mice with the drinking water at a concentration of 0.2% for 5 weeks in order to induce demyelination. After 5 weeks, cuprizone intake was discontinued and the mice received only drinking water for the next 5 weeks to allow remyelination. The body weight of the mice was measured daily during the first week and then once a week for the entire period of the experiment. Motor coordination and passive avoidance experiments were conducted at the end of each week. After the period of demyelination and remyelination, an immunohistochemical study with antibodies for apelin receptor and progenitor oligodendrocytes was also performed.
Results: The body mass of the mice did not change significantly throughout the experiment. During the remyelination period, a gradual improvement in balance and memory processes in the mice was observed.
Conclusions: 5-week administration of the neurotoxicant cuprizone did not result in a significant change in the body mass of the mice. Compared to the demyelination period, the removal of cuprizone from the drinking water lead to an improvement in mice's gait, coordination, and memory. **Funding: The investigations were conducted with the financial support from Grant 2023, Contract №: D-178/03.08.2023 to the Council of Medical Science of the Medical University of Sofia, Bulgaria**

QUANTITATIVE ANALYSIS OF S1PR1 EXPRESSION IN THE BRAIN OF MS PATIENT USING [3H]CS1P1

POSTERS: H02. IMAGING, BIOMARKERS, DIAGNOSTICS

Zhude Tu[1], Jiang Hao[1], Charles Zhou[1], Lin Qiu[1], Stephen Moerlein[1], Robert Gropler[1], Matthew Brier[1,2], Gregory Wu[2], Anne Cross[2], Joel Perlmutter[1,2], Tammie Benzinger[1,2]
[1]Washington University School of Medicine in Saint Louis, Radiology, Saint Louis, United States of America, [2]Washington University School of Medicine in Saint Louis, Neurology, Saint Louis, United States of America

Aims: Multiple sclerosis (MS) is an immune-mediated disease characterized by demyelination and inflammation in the central nervous system (CNS). Previous studies demonstrated sphingosine-1-phosphate receptor (S1PR) modulators effectively reduce expression of S1PRs, especially S1PR1, from the surface of most lymphocytes, thereby reducing immune cell trafficking out of secondary lymphoid tissues and reducing entry of pathogenic cells into CNS. Studies have also implicated direct CNS effects of S1PR modulators in MS with several lines of evidence suggesting a non-immune, inflammatory role of S1PR1 within the CNS.
Methods: In this study, we explored the role of S1PR1 in the development and progression of demyelinating pathology of MS by quantitative assessment of S1PR1 expression using our S1PR1 specific radioligand, [^{3}H]CS1P1, in post-mortem CNS tissues including cortex, cerebellum, and spinal cord of MS and neurologically healthy cases. Immunohistochemistry and whole slide scanning of S1PR1 along with various myelin proteins were also performed.
Results: Autoradiography analysis using [^{3}H]CS1P1 showed the expression of S1PR1 was significantly elevated in lesions compared to non-lesion tissue in MS cases, as well as neurologically healthy controls. Gray and non-lesion white matter did not significantly differ between controls and MS CNS tissues. Saturation autoradiography analysis showed an increased binding affinity (K_d) of [^{3}H]CS1P1 to S1PR1 in both gray matter and white matter of MS brains compared to healthy brains. Our findings demonstrated the activation of S1PR1 and an increased uptake of [^{3}H]CS1P1 in the lesions of MS CNS. The elevated binding affinity [^{3}H]CS1P1 to S1PR1 in MS brains suggested physical or biochemical changes of S1PR1 in MS brains that can impact ligand-receptor binding.
Conclusions: Our quantitative autoradiography analysis using [^{3}H]CS1P1 on human postmortem tissues demonstrates the feasibility of novel diagnostic strategies for MS by targeting S1PR1.

INVESTIGATING THE ROLE OF LYSOSOMAL HYDROLASES IN ALZHEIMERS DISEASE: FROM ZEBRAFISH TO HUMAN.

POSTERS: I01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

George Sigalas[1], Anders Wallin[1,2], Petronella Kettunen[1,2]
[1]University of Gothenburg, Neuroscience And Physiology, Gothenburg, Sweden, [2]Sahlgrenska University Hospital, Psychiatry, Cognition And Old-age Psychiatry, Mölndal, Sweden

Aims: Cathepsin B and D are lysosomal hydrolases that are implicated in Alzheimer's disease (AD). During the past years, research has produced contradictory results regarding their role in pathological processes, some of which show an increase in the expression levels of cathepsins in AD, while others show a decrease. Hence, the exact mechanism underlying their function and correlation with AD pathology remains unclear. In this study, we aimed at investigating their role in lysosomal function by using the zebrafish and compare our results to CSF biomarker analysis of control and AD patients from the Gothenburg Mild Cognitive Impairment study at the Memory Clinic in Gothenburg, for which brain imaging data, neuropsychological tests, as well as the core AD CSF biomarkers are available.
Methods: To manipulate cathepsin signaling we used Pepstatin A and CA-074, two drugs that inhibit cathepsin D and B respectively, in transgenic ApoE:GFP zebrafish marking microglia. Moreover, the cathepsin levels were analyzed in CSF of control, as well as AD patients.
Results: We explored cathepsin function in live zebrafish, focusing on microglia function. In short, microglia morphology, phagocytosis, as well as lysosomal function were investigated in vivo using confocal microscopy. Moreover, cathepsins were measured in human CSF and data were correlated to other patient variables, such as the core AD CSF biomarkers indicating disease progression.
Conclusions: Our study combining an innovative new model for microglia function in neurodegenerative diseases, with analysis in well-characterized human samples helps unravel the function of cathepsins in AD pathology.

DEMENTIA WITH LEWY BODIES IN A PATIENT WITH GAUCHER DISEASE

POSTERS: I01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Marta Villa Lopez[1], Oksana Suchowersky[2,3], Shailly Jain[3]
[1]University of Alberta, Medical Genetics, Edmonton, Canada, [2]University of Alberta, Department Of Neurology, Edmonton, Canada, [3]University of Alberta, Medical Genetics, EDMONTON, Canada

Aims: This clinical case report aims to deepen our understanding of the relationship between GBA1 mutations and synucleinopathies. Biallelic GBA1 mutations typically result in Gaucher disease (GD). Not only patients with GD, but patients with GBA1 heterozygous mutations have an increased risk of Parkinson's disease (3.5-6 times) and dementia with Lewy bodies (8.28 times).
Methods: We conducted a comprehensive evaluation of a 67-year-old male with a history of Gaucher disease type 1 who exhibited a two-year decline in cognition and parkinsonism. Our assessment involved cognitive testing, neurological examination, neuroimaging, analysis of genetic history related to GBA1 mutations, and documentation of the response to dopamine replacement therapy, along with a literature review.
Results: Cognitive assessments revealed notable decline, especially in attention and visuospatial domains. The physical examination indicated mild symmetric parkinsonism, and MRI showed mild generalized atrophy. The patient experienced improved motor symptoms with levodopa, but higher doses were intolerable due to cognitive issues.
Conclusions: With the increasing use of enzyme replacement therapy in Gaucher disease, more patients are reaching ages at which they may develop parkinsonism. While the association between Parkinson's disease and Gaucher disease has been extensively studied, there is limited literature on the connection between Lewy body dementia and Gaucher disease. Thus, it is crucial to consider this diagnosis in GBA1 mutation carriers experiencing cognitive decline, as it could have significant implications for their clinical management in the future.

THE EFFECTS OF MELATONIN ON CLINICAL SEVERITY IN EXPERIMENTAL AUTOIMMUNE ENCEPHALOMYELITIS MODEL OF MULTIPLE SCLEROSIS; A SYSTEMATIC REVIEW AND META-ANALYSIS

POSTERS: H03. ANIMAL MODELS

Reza Mosaddeghi-Heris[1], Hadis Razmaray[2], Ehsan Nasiri[2], Pouya Vakilipour[2], Soroush Morsali[2], Afshin Moradi[2], Asal Ebrahimian[2], Sahel Rashidi[2], Amirreza Naseri[2], Saeed Sadigh-Eteghad[1]
[1]Tabriz university of medical sciences, Neurosciences Research Center (nsrc), Tabriz, Iran, [2]Tabriz university of medical sciences, Student Research Committee, Tabriz, Iran

Aims: Through the antioxidant and anti-inflammation pathways, melatonin is proposed as a safe and effective intervention in neurological diseases. This study aims to evaluate the effects of melatonin supplementation on the clinical outcomes in the experimental autoimmune encephalomyelitis (EAE) model, which is the most common animal model for MS.
Methods: This study was conducted following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement. Animal studies that reported the effects of melatonin in preclinical EAE models are included in this study. Letters to the editors, conference papers, studies with overlapping data, human studies, reviews, and articles published in languages other than English were excluded. A systematic search in PubMed, Web of Science, Embase, and Scopus up was conducted in April 2023. The collaborative Approach to Meta-Analysis and Review of Animal Experimental Studies (CAMARADES) critical appraisal tool was used for the quality assessment of the studies and the quantitative synthetizes were conducted using the comprehensive meta-analysis software.
Results: Out of 542 studies, finally 10 studies were included in this study. The route of administration was intraperitoneal in 7 studies, oral in 2 studies, and subcutaneous in 1 study. The quantitative synthesis of the EAE clinical severity scale was associated with significant differences (standardized mean difference [SDM]: -2.52; -3.61 to -1.42; p-value<0.01). In subgroup analyses, the difference was statistically significant in the mouse subgroup (p-value<0.01) but not in the rat subgroup (p-value=0.39). Partially, in two studies, melatonin treatment was not effective, but in 8 other studies, it was reported to be effective.
Conclusions: This study encountered that melatonin may be associated with improved clinical outcomes of the preclinical EAE model, which suggested future well-designed clinical studies on this topic.

PLASMA P-TAU217 AS A BIOMARKER OF SEVERITY AND DISEASE PROGRESSION IN NIEMANN-PICK DISEASE TYPE C, A TANGLE PATHOLOGY WITHOUT AMYLOIDOSIS.

POSTERS: I01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Fernando Gonzalez-Ortiz[1], Kaj Blennow[1], Thomas Karikari[2], Tormod Fladby[3], Bjørn-Eivind Kirsebom[4], Frances Platt[5], Dawn Shepherd[5], Danielle Te Vruchte[5]
[1]Gothenburg University, Psychiatry And Neurochemistry, Göteborg, Sweden, [2]Gothenburg University, Psychiatry And Neurochemistry, Gothenburg, Sweden, [3]Akerhus University Hospital, Neurology, Oslo, Norway, [4]Akerhus University Hospital, Neurology, Lørenskog, Norway, Norway, [5]Oxford Univeristy, Lysosomal And Sphingolipid Disorders, Oxford, United Kingdom

Aims: Niemann-Pick disease type C (NPC) is a genetic condition primarily characterized by the accumulation of cholesterol and sphingolipids within cellular compartments, leading to neurodegeneration and cognitive impairment. Unlike Alzheimer's disease (AD), NPC does not exhibit amyloid β (Aβ) plaques. However, both conditions present neurofibrillary tangles (NFT) of hyperphosphorylated tau. Moreover, NFT in AD and NPC have the same pattern of phosphorylation and seem to be almost identical. Plasma p-tau correlations with amyloid deposition, established either by PET or CSF positivity, have led to the idea that p-tau reflect amyloid pathology more than tau. Amid of this speculation, we decided to investigate the role of plasma p-tau217 in NPC.
Methods: We measured plasma p-tau217 in a multicentre cohort (n=180), consisting of healthy controls (n=60), NPC patients (n=60) and AD patients (n=60). Furthermore, we investigated plasma p-tau217 associations with age, annual severity increment score (ASIS) and magnitude of lysosomal dysfunction in NPC and compared levels in NPC and AD.
Results: Plasma p-tau217 was significantly higher in the NPC group compared to controls (2.52 pg/ml ±1.93 and 1.02 ± 0.34, respectively, $p<0.001$, AUC: 0.85). P-tau217 levels correlated inversely with age at baseline ($R= -0.57$, $p<0.001$) and positively with longitudinal increases in lysosomal enlargement and ASIS ($R=0.26$, $p<0.001$ and $R=0.46$, $p<0.001$, respectively). Mean concentrations of plasma p-tau217 in AD were higher than levels in the NPC group (2.97 pg/ml ±1.30 and 2.52 pg/ml ±1.93, respectively).

Conclusions: Our findings indicate that plasma p-tau217 can reflect tau pathology independently of brain amyloid. However, joint amyloid and tau pathologies, as in AD, have stronger effects on this marker. High

levels of plasma p-tau217 in NPC were associated with disease severity and rapid progression, supporting its use as a prognostic/monitoring marker.

INFLAMMATION AND AUTOPHAGY DYSFUNCTION IN METACHROMATIC LEUKODYSTROPHY: MTOR AS A NOVEL THERAPEUTIC TARGET?

POSTERS: I02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Daniel Erskine[1], Zoe Catchpole[1], Annabelle Eleana Hartanto[1], Tetsushi Kataura[2], Kate Madden[1], Viktor Korolchuk[2]
[1]Newcastle University, Translational And Clinical Research Institute, Newcastle upon Tyne, United Kingdom, [2]Newcastle University, Biosciences Institute, Newcastle upon Tyne, United Kingdom

Aims: Metachromatic leukodystrophy (MLD) is a rare lysosomal storage disorder characterised by the accumulation of sulfated cerebrosides (sulfatide) that underlies the striking white matter degeneration that underlies cognitive and motor impairment in MLD. The aim of the present study was to investigate disease mechanisms in MLD, with a view to developing novel therapies for patients for whom gene therapy is not indicated.
Methods: *Post-mortem* tissue was obtained from the globus pallidus and dentate nucleus of MLD cases (N=5) and age-, sex- and ethnicity- matched controls for discovery proteomics analysis, combined with histological validation. Pathways identified from the neuropathology study were then further studied by exposing HMC3 microglial cells and MLD fibroblasts to sulfatide *in vitro* and characterising the cellular phenotype. Drugs based on pathways identified from the neuropathology were then tested in MLD fibroblasts to determine whether they rescue the phenotype.
Results: Discovery proteomics identified up-regulation of inflammatory pathways and the mTOR nutrient-sensing pathway in MLD cases. Imunoblotting of MLD tissue identified accumulation of autophagosomes, consistent with deficient autophagy in the context of mTOR activation. Sulfatide exposure led to changes in HMC3 microglia consistent with activation, including morphological changes and increased production of reactive oxygen species. Screening of the mTOR inhibitor, rapamycin, in MLD fibroblasts is on-going.
Conclusions: These findings suggest that MLD is characterised by widespread inflammation and deficient autophagy, both potentially resulting from activation of the mTOR pathway as a result of lysosomal dysfunction. As mTOR inhibition has been demonstrated to attenuate inflammation and white matter loss in the related condition, Krabbe disease, these findings may indicate mTOR is a key mechanistic target in ameliorating lysosomal storage disorders characterised by accumulated sphingolipids.

THERAPEUTIC POTENTIAL OF HUMAN MICROGLIAL TRANSPLANTATION FOR THE TREATMENT OF SANFILIPPO SYNDROME (MPS-IIIA)

POSTERS: I02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Alina Lahian[1], Jean Paul Chadarevian[1], Johannes Schlachetzki[2], Jonathan Hasselmann[3], Sepideh Kiani Shabestari[1], Christina Tu[3], Lauren Le[3], Chris Glass[2], Jeffrey Esko[2], Philip Gordts[2], Hayk Davtyan[1], Mathew Blurton-Jones[1]
[1]University of California Irvine, Department Of Neurobiology And Behavior, Irvine, United States of America, [2]University of California, Department Of Cellular And Molecular Medicine, San Diego, United States of America, [3]University of California Irvine, Institute For Memory Impairments & Neurological Disorders, Irvine, United States of America

Aims: Sanfilippo Syndrome(MPSIIIA) is a devastating pediatric lysosomal storage disease that leads to progressive neurodegeneration and greatly shortened life span. MPSIIIA results from loss of function mutations in N-Sulphoglucosamine Sulphohydrolase(SGSH), a lysosomal enzyme critical for the degradation and recycling of heparan sulfate(HS) glycosaminoglycans(GAG). Recent evidence suggests that microglia express the highest levels of SGSH within the brain. Therefore, correction of SGSH mutations within microglia, or the transplantation of healthy microglia, could potentially increase levels of this enzyme, enhancing the degradation and clearance of HS-GAGs, and slowing or even preventing further neurodegeneration.
Methods: To explore the potential for human microglia transplantation, we generated a novel xenotolerant mouse model of MPSIIIa via CRISPR-deletion of SGSH. Following histochemical and biochemical validation, SGSH KO pups(P1-P2) were transplanted with saline or human iPSC-microglia progenitor cells. After 4months, mice were sacrificed, peripheral blood and liver collected and hemibrains dropfixed for immunohistochemical analysis and flash frozen for biochemistry and single nuclei RNA sequencing.
Results: Initial analysis of 4-month old SGSH-KO mice reveals a dramatic increase in lysosomal content, gliosis, lipid accumulation, and greatly elevated levels of nonreducing end heparan sulfates(HS-NRE). Remarkably, transplantation of human microglial progenitors significantly lowers lysosomal accumulation and suggests preliminary evidence of cross-correction by reducing lysosomal content within murine neurons adjacent to engrafted human microglia. Biochemical analysis further revealed that microglia transplantation partially restores enzymatic function leading to a significant reduction in disease-specific HS-NRE. Ongoing experiments will further examine mRNA and protein expression levels to elucidate the impact of human microglial transplantation on neuronal and other cell populations within the brain.
Conclusions: Taken together, these results provide the first evidence that iPSC-microglia could potentially be developed as a novel therapy for MPSIIIA and likely other lysosomal storage diseases.

EVIDENCE FOR APOER2-DAB1 PATHWAY DISRUPTION IN THE AMYGDALA IN SPORADIC ALZHEIMER'S DISEASE

POSTERS: J01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Christopher Ramsden[1], Mark Horowitz[1], Daisy Zamora[1], Dragan Maric[2]
[1]National Institutes of Health, Nia/lci/lpu, Bethesda, United States of America, [2]National Institute on Neurological Diseases and Strokes, Ninds/nih, Bethesda, United States of America

Aims: Neuropsychiatric symptoms are common early manifestations of sporadic Alzheimer's disease (sAD) that are associated with more rapid progression to severe dementia and death. Degeneration of the amygdala, a hub for emotional regulation and fear memory, may contribute to neuropsychiatric and cognitive manifestations of sAD. The ApoE receptor 2-Disabled homolog-1 (ApoER2-Dab1) pathway suppresses Tau phosphorylation as part of a multi-arm pathway that regulates cytoskeletal and synaptic integrity. Our group previously showed that multiple ApoER2-Dab1 components accumulate together with hyperphosphorylated Tau (pTau) in the hippocampus in mild cognitive impairment (MCI) and sAD cases. Here, we sought to assess whether ApoER2-Dab1 pathway components accumulate in amygdala in MCI and sAD.
Methods: Imunohistochemistry (IHC) was used to label ApoER2-Dab1 components in coronal amygdala sections from 30 rapidly autopsied cases spanning the clinicopathological spectrum of AD. IHC images were uploaded into HALO image analysis software (Indica Labs, Corrales, NM). Stain positive area was quantified and compared to a standard battery of neuropathological, cognitive, and neuropsychiatric endpoints. Multiplex-IHC was used to provide spatial and cytoarchitectural context for ApoER2-Dab1 pathway marker accumulation.
Results: Two ApoER2 ligands (ApoE and ApoJ) and five intraneuronal ApoER2 signaling partners (Dab1, pP85α$_{Tyr607}$,pLIMK1$_{Thr508}$, pTau $_{Ser202/Thr205}$ and pPSD95$_{Thr19}$) were higher in MCI and sAD cases than non-sAD controls and correlated with histological progression and cognitive and/or neurobehavioral manifestations of sAD. Multiplex-IHC revealed that Dab1, pP85α$_{Tyr607}$,pLIMK1$_{Thr508}$, pTau $_{Ser202/Thr205}$ and pPSD95$_{Thr19}$ accumulated together within MAP2-labeled dystrophic dendrites and soma of ApoER2-expressing neurons in the vicinity of ApoE/ApoJ-enriched extracellular plaques.
Conclusions: Findings add to growing evidence that ApoER2-Dab1 disruption contributes to pTau-related neurodegeneration in humans, and suggests that ApoER2-Dab1 disruption in amygdala may contribute to the neuropsychiatric manifestations of sAD.

BEHAVIOURAL AND PSYCHOLOGICAL SYMPTOMS IN DEMENTIA, OFTEN REVERSIBLE CONDITIONS

POSTERS: J01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Maria Roberta Vazzana[1], Antonia Nucera[2], Michela Papa[3]
[1]grande ospedale metropolitano, Urgency Medicine, reggio di calabria, Italy, [2]f. spaziani hospital, Urgency Medicine, frosinone, Italy, [3]moscati asl ce, General Medicine, aversa, Italy

Aims: Introduction:In the later stages of dementia some people with develops what's known as behavioural and psycological symptoms of dementia(BSPD). Symptoms of BPSD can include increased agitation, aggression,delusions,hallucinations, sleep disturbance and night-time waking.Behaviour changes could be caused by brain-related issues or from changes to someone's environment, health or medication.
Methods: Dementia is an umbrella term used to describe a group of symptoms that affect brains work. Many conditions, such as stroke, depression, infections, as well as normal ageing, can cause dementia-like symptoms.We decribe 120 patients than have been admitted in the emergency setting because of acute symptoms.We examinated the patients to see if they have any infection, pain constipation, depression or side-effects of their medicine that could be contributing to or causing the behavior change.
Results: :The mean age was 81, 68 women and 52 men. Hypertension was present in 96 and vascular changes in the brain were found in the neuroimaging. 78 patients had reversibile symptoms of dementia due to such conditions: urinary infection , hydrataion, costipation, fever and Covid-19 infection.
Conclusions: Conclusion:Dementia is always changing and unique for each person. Everyday life can be a stressful ordeal for a person with a dementia-related disorder. As the disease progresses, behaviors changes can occur .The pandemic worsened such situation. It is important in the acute setting to rule out any concomitant illness that can cause or worsen behavioral and psychological symptoms in dementia.

Aims: In previous work, we showed iron accumulation was located in lysosome of patient derived cells with NBIA (Neurodegeneration with brain iron accumulation), and Lysosome's functional disorder in these cells was observed in activity test. Our current research aims to investigate ultrastructural changes of lysosomes in NBIA patient derived cell and lysosomal storage disorder.
Methods: We used mainly electron microscopy including Cryo-EM, Correlative light and electron microscopy, and 3DEM to investigate lysosomal structural changes. Correlative light-electron microscopy (CLEM) is a combination of light and electron microscopies, and thin lamella was made by Cryo-FIB for Cryo-tomography.
Results: In our results, patient's derived cells showed abnormal autophagy, mitochondria or excess lipid by confocal microscopy. Ultrastructure analysis by transmission electron microscopy (TEM) showed abnormal vesicles and shorten mitochondria. Specially, lipid or protein accumulations were shown in specific lysosome including lamellar structures through Correlative light and electron microscopy (CLEM) and Cryo-CLEM and tomography.
Conclusions: Those data showed the functional and structural changes in lysosome induced lysosomal disorders, which suggested how related lysosome's function and specific protein or lipid accumulations.

MULTIPLE LIMBIC PROTEINOPATHIES CORRELATE TO PSYCHOTIC AND HYPERACTIVE BEHAVIOURAL SYMPTOMS: DATA FROM THE ABBIATEGRASSO BRAIN BANK

POSTERS: J01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Giulia Negro[1], Valentina Medici[2], Michele Rossi[2], Xhulja Profka[2], Annalisa Davin[3], Riccardo Ferrari[3], Valeria Terzoli[2], Arcangelo Ceretti[2], Mauro Ceroni[2], Antonio Guaita[4], Tino Poloni[2]
[1]University Milano-Bicocca, Neurology, School Of Medicine And Surgery, Monza, Italy, [2]Golgi-Cenci Foundation, Neurology-neuropathology And Abbiategrasso Brain Bank, Abbiategrasso, Italy, [3]Golgi-Cenci Foundation, Neurobiology And Neurogenetics, Abbiategrasso, Italy, [4]Golgi-Cenci Foundation, Research Center For Brain Aging And Related Diseases, Abbiategrasso, Italy

Aims: Psychotic and hyperactive behavioural symptoms are the most considerable challenges in the clinical-therapeutic management of patients with dementia. The limbic system is primarily responsible for emotional processes strictly related to behaviour, and the presence of neuroinflammation could exacerbate behavioural symptoms. In our series of pathologically defined demented patients, we investigate the correlation of multiple limbic lesions with the aforementioned behavioural symptoms and microglial activation in specific limbic regions.
Methods: Twenty-four subjects from the Abbiategrasso Brain Bank underwent serial neurological and neuropsychological evaluations. At death, they all had a diagnosis of major neurocognitive disorder. According to the donation program, their brains underwent a complete vascular and degenerative neuropathological characterization. Further, microglial activation was assessed in four limbic regions (hippocampus, amygdala, gyrus cinguli, orbitofrontal cortex) through a semi-quantitative method. The Fisher's exact test and the Mann-Whitney test were used for statistical analysis.
Results: Clinical diagnosis includes Alzheimer's Disease (AD; n=10), multiple etiologies (n=8), Lewy body disease (n=2), vascular dementia (n=2) and frontotemporal lobar degeneration (n=2). Additional unexpected neuropathology was found in 19 cases, including Lewy Type Synucleinopathy (LTS), and TDP-43 pathology (TDP). Sixteen cases had psychotic and hyperactive behavioural symptoms; 12 of them exhibited additive limbic pathology (1 LTS; 8 TDP-43; 3 TDP-43/LTS). The presence of multiple limbic proteinopathies (LTS and/or TDP-43 pathology) significantly correlates with psychotic and hyperactive symptoms ($p = 0.032$), the latter also significantly correlates with microglial activation in the dentate gyrus, amygdala and orbitofrontal cortex. Moreover, multiple limbic proteinopathies significantly correlate with microglial activation in the hippocampus.
Conclusions: Frequently, limbic LTS and TDP-43 lesions are concomitant suggesting a possible synergistic role of these proteinopathies, promoting neuroinflammation, causing limbic dysfunction and influencing the clinical phenotype.

DYSREGULATED RIBOSOME GENE EXPRESSION AND ASTROCYTE-DOPAMINERGIC NEURONAL SIGNALING IN THE PREFRONTAL CORTEX OF ELDERLY MAJOR DEPRESSIVE DISORDER PATIENTS.

POSTERS: J01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Ashlesh Patil[1], Ansh Malik[2], Gunjan Sharma[2], Satyendra Tripathi[3], Vishwajit Deshmukh[4]
[1]AIIMS Nagpur India, Physiology, Nagpur, India, [2]AIIMS Nagpur, Mbbs Student, Nagpur, India, [3]AIIMS Nagpur, Biochemistry, Nagpur, India, [4]AIIMS Nagpur, Anatomy, Nagpur, India

Aims: Aging is known to be associated with major depression (MDD), it is not yet fully understood how depression may differ in older patients. This bioinformatic study aims to identify dysregulated genes in the prefrontal cortex focusing on two age groups: working-age individuals and senior individuals.
Methods: For this bioinformatic study, we utilized the GSE208338 dataset obtained from the Gene Expression Omnibus (GEO) database. The dataset contains gene expression data obtained from post-mortem brain tissue of dorsolateral prefrontal cortex. Four groups were compared, including working-age individuals with MDD, senior individuals with MDD, working-age healthy controls, and senior healthy controls. Gene pathway analysis and protein-protein interaction analysis of differentially expressed genes were investigated.
Results: We found that 190 genes were up/downregulated by at least 1.2 log fold times in senior healthy controls as compared to working-age healthy controls ($p<0.05$). Additionally, 33 genes were up/downregulated by at least 1.2 log fold times in senior MDD as compared to working-age MDD. Among these, 6 genes (TMEM176A, FZD, FBXO5, VIM, EPHX1, SP1005) were increased in senior MDD compared to working-age MDD, while 7 genes (ADCK5, S100A1, COL4A4, PWP1, PKNOX2) were decreased in senior MDD compared to working-age MDD but not in senior healthy controls compared to working-age healthy controls. Protein-protein interaction analysis showed dysfunctional ribosome biogenesis and astrocyte-dopaminergic neuron signaling.
Conclusions: This study suggests that senior individuals with depression may differ from working-age depressed individuals. Dysregulation of S100 proteins and ribosomal gene expression has been observed in older patients on electroconvulsive therapy or antipsychotic drugs, indicating that the treatment of depression or the disease itself may be altering the genes. Additionally, the astrocyte-dopaminergic system, which is implicated in depression, worsens in senior depressed individuals.

THE REGULATION OF MICROGLIAL POLARIZATION BY INHIBITION OF TOLL-LIKE RECEPTOR 2

POSTERS: J02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Kyoung Ja Kwon[1,2], Seol-Heui Han[2], Ryeong-Eun Kim[1]
[1]Konkuk University, Neuroscience, Seoul, Korea, Republic of, [2]Konkuk University Medical Center, Neurology, Seoul, Korea, Republic of

Aims: Neuroinflammation holds a vital role in neurodegenerative diseases and neuropsychiatric disorders and that microglia and astrocytes chiefly modulates inflammatory responses in the central nervous system (CNS). Toll-like receptors (TLRs), is critical in innate immune responses, regulation in microglia can be a potential therapeutic strategy for neurological disorders. In this study, we examined the protective effects of GSP1-111, a novel synthetic peptide for inhibiting TLRs signaling, on neuroinflammation and depression-like behavior.
Methods: In this regard, we examined 1) the mRNA expression of inflammatory mediators including iNOS, IL-1b, TNFa, TGFb and COX-2, 2) nitric oxide (NO) production, 3) the protein expression of TLR2 and TLR4 in the BV2 microglial cells and the brain of LPS-injected mice, and 4) depressive-like behaviors in the mice.
Results: GSP1-111 decreased TLR2 expression and remarkably reduced mRNA expression of inflammatory M1-phenotype markers, including tumor necrosis factor (TNF)-a, interleukin (IL)-1b, and IL-6, while elevating that of M2 phenotype markers, Arg-1 and IL-10. In vivo GSP1-111 administration significantly decreased depression-like behavior induced by lipopolysaccharide (LPS) in forced swim test and significantly reduction brain levels of M1-specific inflammatory cytokines. GSP1-111 could prevent depression-like behavior by inhibiting TLR2.
Conclusions: Our results suggest that TLR2 pathway is a promising therapeutic target for depression, and GSP1-111 could be a novel therapeutic candidate for various neurological disorders.

Aims: Cocaine addiction, gambling and dopaminergic dysregulation syndrome in patients with Parkinson's disease, despite their clinical diversity, contain neurobiological circuits in common which allow us to adopt a perspective of shared rehabilitation strategy.
Methods: In this project, we propose a multidisciplinary rehabilitative approach for 30 patients affected of cocaine addiction, pathological gambling and l-dopa addiction in people with Parkinson's disease,through a psychoeducational path combined with 12 neuromodulation sessions through transient current dirrect stimulation (TDCS) with 20 minutes of anodic right/cathodic left stimulation on the dorsolateral prefrontal cortex The selection criteria for the various categories of patients were: for cocaine addiction and for pathological gamblers diagnosis of according to DSM 5 criteriaand active addiction ; for patients with Parkinsons ' s disease a positive Quiprs Questionnaire score for Dopamine dysregulation syndrome and a Levodopa Equivalent Daily Dosage over 600 mg/die. The psychoeducational path consists in focusing on the most dangerous individual trigger situations without implementing the addictive behavior, replacing it withpersonal and social resources. The integrated method is based on the Cognitive-Behavioral Therapy approach and in particular the exposure with prevention of the response (Exposure/Prevention) in imagination.
Results: All three categories of patients reported a high frequency of non-motor symptoms (Patients with Parkinson's disease) and clinical symptoms related to craving.
Neuromodulation treatment was terminated by all patients without side effects with a decrement of craving sintomatology.
Conclusions: Parkinson's disease patients affected by dopaminergic dysregualtion syndrome , pathological gamblers and cocaine addicters may show similar clinical picture concerning craving symptomatology, which may be considered a clinical aim to reduce addiction behavior. Neuromodulation combined with psychoeducational effect may be proposed as approach .

Sheps Center For Health Services Research, Chapel Hill, United States of America, [7]University of California, San Francisco, School Of Medicine, San Francisco, United States of America

Aims: The aim of this study is to determine underlying factor structures of psychiatric syndromes associated with the degeneration of specific brain networks in humans with ADRD.
Methods: We pursue this objective through the collection of neuropsychiatric assessments from patients and their caregivers including: Structured Clinical Interview for DSM-5 Research Version, DSM-5 Cross-Cutting Measures, NPI, GDS, and SCL_90R. Specific aims include: 1. Identifying psychiatric factors previously recognized in other patient groups and discover additional factors specific to these patients. We will use multiple group factor analysis to assess the similarity of the factor structure between a test group (n=300) of mild AD and a generalizability group including diverse neurodegenerative diseases (n=300; MCI, bvFTD, PPA, DLB, HD, PDD). We will utilize the most informative items from this factor analysis to create a new instrument that is tailored to patients diagnosed with ADRD. 2. Replicating and expanding upon associations between specific brain networks and neuropsychiatric factors previously observed in patients with penetrating traumatic brain injury. These analyses will be performed on neuropsychiatric symptoms (NPS) and MRI data collected from our test and replication groups, focusing on patients with mild AD and NPS. 3. Comparing the effectiveness of three measures of NPS (DSM-5 Cross-Cutting, NPI, GDS) in explaining the variance in sMRI regional volume and the outcomes of integrative MRI analyses in networks related to NPS factors.
Results: Anticipated outcomes include the identification of brain regions associated with specific psychiatric symptoms, which will provide insights into potential targets for symptom treatment, especially anatomically-based treatments, among individuals with neurodegenerative disorders.
Conclusions: This study will enhance our understanding of the neuroanatomy of psychiatric symptoms in patients with neurodegenerative illnesses and help develop new treatments for these symptoms.

FUNCTIONAL MOVEMENT DISORDERS - A MOSAIC OF NON-STEREOTYPICAL MANIFESTATIONS

POSTERS: J01. DISEASE MECHANISMS, PATHOPHYSIOLOGY

Darshana Vijaywargiya[1], Tinatin Chabrashvili[2]
[1]SUNY Upstate Medical University, Neurology, Syracuse, United States of America, [2]SUNY Upstate Medical University, Neurology And Neuroscience, Syracuse, United States of America

Aims: Functional movement disorders (FMD) are complex neuropsychiatric conditions with a motor-dominant phenotype. The objective of this case report is to present a case that started with neuromuscular symptoms and evolved as a FMD, a potentially novel FMD phenotype combining movement and neuromuscular presentations including somatic symptoms and psychiatric diagnoses.
Methods: In July 2022, a 24-year-old male enlisted in the military while deployed in the Middle East, developed a constellation of symptoms including urinary retention, progressive bilateral lower extremity weakness and paresthesias causing walking difficulties (without falls) requiring use of a cane by November 2022. Around mid-November 2022, he started manifesting involuntary, jerky movements in head, neck and extremities. Neurological exam revealed non-stereotypical, hyperkinetic, choreiform movements of head, neck and extremities, upper greater than lower, appearing randomly, suppressible on distraction and exaggerated on direct observation and testing of individual muscles. Gait was normal based, irregular amplitude, slow marching type with normal speed and cadence. On subsequent visits, while the aforementioned movements decreased, additional movements like low amplitude finger tapping, neck jerking similar to shivering, lip smacking, irregular hand movements appeared. None of these movements were associated with an urge to move.
Results: Normal MRI of the neuraxis, EMG, EEG, ceruloplasmin, metabolic, urological work-up. Negative heavy metal screen, connective tissue panel, lyme, and sickle cell screens. Whole exome sequencing with mitochondrial DNA testing revealed no pathological genetic variants. KF rings were not detected on ophthalmologic exam. He was diagnosed with FMD after extensive workup. On subsequent visits, abnormal movements resolved with physical therapy coupled with cognitive behavioral therapy.
Conclusions: This case exemplifies the importance of functional movement disorders as a differential while evaluating non-stereotypical, inconsistent movements associated with neuromuscular phenotypes.

SUB THALAMIC NUCLEUS VERSUS GLOBUS PALLIDUS INTERNUS: EFFECTIVE TARGET FOR REDUCING DEPRESSION AFTER DEEP BRAIN STIMULATION

POSTERS: J02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Tulika Gupta, Rafika Munawara
Post Graduate Institute of Medical Education and Research, Anatomy, Chandigarh, India

Aims: Background: Deep Brain Stimulation of the subthalamic nucleus (STN) or Globus Pallidus Internus (GPi) is a standard treatment for Parkinson's disease, with both regions exhibiting comparable treatment effectiveness. Post-treatment neuropsychiatric side effects includes severe depression. Loss of serotonergic neurons is thought to be the primary cause of depression. Identification of a region with lesser number of serotonergic neurons may reduce these side effects. There is a lack of molecular evidence comparing the choice of STN and GPi in this regard. This study aimed to quantify the number of serotonergic neurons and semi-quantify the serotonin levels in the STN and GPi.
Methods: The STN and GPi regions were studied histologically in 15 human brain specimens; ethical clearance was taken at the time of body donation. Serotonergic neurons were identified immunohistochemically using tryptophan hydroxylase 2 antibody. Semi-quantification of the Immunoreactivity was performed by calculating the histo-score.
Results: The number of immunopositive cells was, 80 in the STN and 16 in the GPi, per 10 high power fields. GPi had a significantly lesser number of serotonergic neurons than STN. Three types of neurons were observed. In the STN, large cells were concentrated in the center and small cells in the periphery. While in GPi only small neurons were present. Two patterns of serotonergic granule distribution were observed; the majority of the cells had a fine granular pattern. In STN, variability in the number of Serotonergic neurons and in the histo-score was observed more in the cells in the medial half of the nucleus, than in the lateral half.
Conclusions: GPi could be a safer target region, for considerably lowering the incidence of post-DBS depression.

5-HT2A AND 5-HT2C DUAL INVERSE AGONIST FOR THE TREATMENT OF PSYCHOSIS IN DEMENTIA.

POSTERS: J02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Kohei Jino[1], Ken Koda[1], Nozomi Takai[1], Takuya Oguma[2], Kana Hyakkoku[1], Ken-Ichi Kusakabe[2], Naotaka Horiguchi[1]
[1]Shionogi & Co., Ltd., Neuroscience, Drug Discovery & Disease Research Laboratory, Osaka, Japan, [2]Shionogi & Co., Ltd., Laboratory For Medicinal Chemistry Research, Osaka, Japan

Aims: People with dementia experience psychosis, which is a distressing factor for both patients, their family, and caregivers. Pimavanserin is the only drug approved for the psychosis associated with Parkinson's disease, but it has also demonstrated efficacy for dementia-related psychosis in clinical trials. Pimavanserin is known as a 5-HT_{2A} receptor inverse agonist. However, it also has suboptimal affinity to 5-HT_{2C} receptor. Based on its clinical outcomes, we hypothesized that the antipsychotic effect of pimavanserin has been exerted by simultaneous inhibition of both 5-HT_{2A} and 5-HT_{2C} receptors. The objective of the study is to verify the hypothesis from engagements with those targets and non-clinical behavioral models.
Methods: MK-801 (NMDA receptor antagonist) induced locomotor hyperactivity in Wistar rats (6 or 7-weeks-old) was conducted, evaluating antipsychotic effect. The receptor occupancy study and microdialysis study (medial prefrontal cortex, dopamine) were performed to assess with 5-$HT_{2A/2C}$ receptors.
Results: Pimavanserin exhibited a dose-dependent efficacy in a rodent psychobehavioral model. At effective doses, saturated occupancy for 5-HT2A receptors and increased DA flux were observed, indicating engaging both receptors. On the other hand, doses occupying only 5-HT2A receptor did not reduce MK-801 induced hyperactivity in rats. In addition, no significant efficacy was observed when SB242084, a selective 5-HT_{2C} inhibitor, was administered alone, albeit DA flux increased.
Conclusions: We demonstrated that simultaneous inhibition of both 5-HT_{2A} and 5-HT_{2C} are pivotal to reduce MK-801 induced hyperactivity in rats. Our findings highlight that a 5-HT2A and 5-HT2C dual inverse agonist would be a promising therapy mitigating dementia-related psychosis.

Sheps Center For Health Services Research, Chapel Hill, United States of America

Aims: This study investigates the impact of neurodegeneration on emotional systems by using the Research Domain Criteria (RDoC) Paradigms as categorized by the National Institute of Mental Health, with a particular emphasis on the Negative Valence (NV) and Positive Valence (PV) Systems and their relevance to Alzheimer's disease and related dementias (ADRD). Applying these RDoC paradigms will help us gain a deeper insight into the development of neuropsychiatric symptoms (NPS) in neurodegenerative disease.
Methods: RDoC behavioral tasks spanning both NV and PV systems are administered to participants with a diagnosis of mild (CDR=1) AD, bvFTD, svPPA, or HD, and age matched controls. NV tasks include: Behavioral Approach Task (fear), NPU-Threat Task (anxiety), and Cold Pressor Task (pain processing). PV tasks include the Probabilistic Learning Task (reward learning) and a Habit Learning Task. We will analyze data derived from these tasks in conjunction with neuropsychiatric and imaging data collected from the broader Neurodegeneration-Associated Psychiatric Syndromes (R01AG062268) project. Our analytical framework encompasses correlations between our RDoC paradigm, MRI findings, and NPS outcomes, as well as an integrative assessment of behavioral and MRI data.
Results: We hypothesize that individuals with neurodegenerative diseases will have impaired processing within the PV and NV domains, displaying correlations with NPS and regional brain atrophy. We anticipate that the degeneration of the vmPFC will be associated with low NV scores, internalizing NPS (such as anxiety and depression), and apathy. Furthermore, we predict that degeneration in NV Circuit Elements will be linked to high NV and Internalizing NPS.
Conclusions: Our project represents a comprehensive examination of NPS mechanisms in order to advance our understanding of these crucial aspects of ADRD and inform the development of novel treatments to enhance patients' quality of life.

EVALUATION OF PHARMACOLOGICAL SAFETY AND MECHANISM OF ACTION OF AN ANTIPARKINSONIAN PEPTIDE.

POSTERS: J02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Gabriela Pinheiro[1], Isabela Guedes[2], Victória Dos Santos[2], Danilo Rodrigues De Oliveira[1], Jair Goulart[1], Márcia Renata Mortari[3]
[1]University of Brasilia, Institute of Biological Sciences, Department Of Physiological Sciences, Laboratory Of Neuropharmacology, Asa Norte, Brasília, Brazil, [2]University of Brasilia, Physiological Sciences, Brasilia, Brazil, [3]Institute of Biological Science, Department Of Physiology, Brasília, Brazil

Aims: The present study aims to evaluate the toxicity, pharmacological security, and mechanism of action of Occidentalina-1202, a wasp venom peptide with antiparkinsonian and neuroprotective effects.
Methods: The experimental design for the toxicity evaluation consisted on a 14-day and 30-days observation period in the acute and chronic models respectively. The peptide was administrated in three different doses (4mg/kg, 20 mg/kg and 40mg/kg) once in the acute model and 1x/day in the chronic model, and the mice were subjected to the Open Field test. At the end of the observation period, animals were euthanized and had brain, liver, lungs, kidney, and heart collected. The organs were weighted and measured, and further processed for preparation of histology slides. To access the mechanism of action, synaptosomes were prepared from cerebral cortices, the binding assay was performed with H^3-GABA, H^3-Glutamate, and a range of six different concentrations of the peptide.
Results: In the evaluation of the histology slides, no alterations were observed in any of the tissues analyzed, in any of the groups (vehicle, Diazepam, 4mg/kg, 20 mg/kg and 40mg/kg). No pronounced weight loss was observed in the animals during the observation period (both acute and chronic model), as well as in the weight and volume of the organs. Regarding food and water consumption in the chronic model, no alterations were detected. The binding assay showed a 15% competition with H^3-Glutamate in the 10nM peptide concentration. The peptide did not show competition with H^3-GABA.
Conclusions: These findings suggest that Occidentalina-1202 is safe to treat Parkinson's disease, being a potential therapeutic alternative and that the peptide might compete with Glutamate. This study was funded by FAPDF, CNPq and CAPES.

QUALITATIVE INTERVIEWS FOR CONCEPT ELICITATION IN CAREGIVERS OF PATIENTS WITH DEMENTIA RELATED APATHY

POSTERS: J03. DRUG DEVELOPMENT, CLINICAL TRIALS

Stella Karantzoulis[1], Betsy Williams[1], Karli Heuer[1], Jianbin Mao[2], Gary Globe[2], Emily Ruzich[1], Rahul Sasane[2]
[1]IQVIA, Patient Centered Solutions, New York, United States of America, [2]Cerevel Therapeutics, Heor, Cambridge, United States of America

Aims: Diagnostic criteria for dementia-related apathy (DRA) includes diminished initiative, diminished interest, and diminished emotional expression/responsiveness. The development of existing instruments measuring DRA did not involve patients nor caregivers. This study aims to fill this void by characterizing the patient experience with DRA using 1:1 concept-elicitation interviews with caregivers of patients with DRA. Patients with dementia were not interviewed given their anosognosia.
Methods: Caregivers of patients with clinically significant DRA and with mild/moderate dementia were recruited through advocacy groups, clinician referral, and social media. Physician confirmation of DRA diagnosis was required; study materials were IRB approved. Caregiver interviews were conducted by trained interviewers using a semi-structured discussion guide; interviews were recorded and transcribed with caregiver permission, and transcripts were coded and analyzed. Caregivers were asked open-ended questions to characterize the patient's experience with DRA. Concepts for DRA were presented to caregivers during the interview for feedback.
Results: Fifteen caregivers (n=11 females; mean age=52.9 years; n=6 spouses as caregivers) of patients with DRA (n=6 females; mean age=75.6 years; n=9 moderate dementia, n=6 mild dementia) were interviewed. Most caregivers described lack of motivation, lack of interest, being inactive/sedentary (n=14 each), losing interest rapidly mid-activity (n=13), withdrawing/isolating socially (n=12), and reduced communication, lack of initiative, neglecting instrumental activities of daily living, lack of emotions (n=11 each) as features of DRA. Reported impacts included sleeping a lot (n=11), decreased physical activity, reduced meaningful intimacy (n=9 each), reduced communication (n=8), daytime immobility (n=7), and less interaction with environment (n=7).
Conclusions: No new concepts were identified during these interviews, thus confirming aspects of apathy from the conceptual model developed from literature and clinician interviews.

LINK BETWEEN POST-TRAUMATIC STRESS DISORDER (PTSD) AND MEDIA EXPOSURE IN INDIVIDUALS OVER 65.

POSTERS: J02. THERAPEUTIC TARGETS, MECHANISMS FOR TREATMENT

Anne-Julie Vaillant-Ciszewicz, Laura Lantermino, Alice Cuni, Cassandra Quin, Olivier Guérin
CHU DE NICE, Geriatrics, NICE, France

Aims: Post-Traumatic Stress Disorder (PTSD) is underdiagnosed in the elderly. The clinical expression of the disorder and its prevalence after the age of 65 are challenging to identify in the scientific literature. Currently, there is also no validated screening tool available for this population. Some studies suggest a connection between PTSD and media exposure on PTSD symptoms, but no conclusive findings have been reached to date. The objective of this study is to identify signs of anxiety in residents/patients of nursing homes and long-term care facilities who are exposed to news (continuous news channels, newspapers, etc.) and the potential link with psychological symptoms suggestive of PTSD according to DSM-5 criteria in adults.
Methods: The multicenter exploratory study conducted by the Hospital of Nice (5 nursings homes/long-term care facilities) has obtained approval from the Research Ethics Committee. Fifty inclusions were conducted from December 2022 to September 2023. The first step of our methodology involves identifying patients through the rating of the "Anxiety" item on the Neuropsychiatric Inventory (NPI). Clinical psychologists leading the project then conduct a non-directive interview with the included resident/patient, following the signing of informed consent. The emotional impact of the news on the individual is assessed. If positive responses are obtained, the Traumatic Check List-Specific clinical scale (PCL-S) is administered.
Results: The results are currently being processed and will be presented at the conference.
Conclusions: This study will help determine whether news from the past 24 months (such as the Ukraine War, food shortages, etc.) reactivates traumatic experiences in nursing home/long-term care facility residents. Additionally, it aims to provide an overview of significant life events among residents (with and without cognitive impairments).

AN OVERVIEW STUDY ON PARKINOL TOXICITY

POSTERS: J03. DRUG DEVELOPMENT, CLINICAL TRIALS

Raafat Abdeldayem
Mansoura university, Toxicology, Mansoura, Egypt

Aims: Antiparkinsonian drugs are known to be substances of abuse. This is true both in abusers of other substances and in chronic schizophrenics, the latter being infrequent abusers of other drugs The aim of the study is to determine the extent of the spread of this drug among hospital patients under study
Methods: 924 cases of different signs of poisoning, admitted the poison units of the hospitals under study along the last six years. Five ml of blood are taken without anticoagulant under precautions to prevent contamination. Each sample was placed in labelled sterile polypropylene tube and sealed immediately.1 µl of each extracted sample was injected into GC-MSD (Hewlett Packard 6890 series) of FID (Flame Ionization detector) and examine in Wiley library
Results: Twenty six Parkinson cases were detected by GC/MS of characteristic peak at specific retention time (12.21 min) is appeared and the compatible ion fragments (98, 55,218) from Wiley library are obtained and indicated that the compound is benzhexol.
Conclusions: GC/MS is today the method of choice for systematic toxicological analysis in clinical and forensic toxicology.

PATHWAY ALTERATIONS AND BIOMARKERS FOR NEUROPSYCHIATRIC SYMPTOMS IN OLDER PEOPLE WITH COGNITIVE DECLINE AND ALZHEIMER'S DISEASE

POSTERS: J04. IMAGING, BIOMARKERS, DIAGNOSTICS

Julius Popp[1,2], Miriam Rabl[1], Loïc Dayon[3,4], Christopher Clark[1]
[1]University of Zurich, Department For Psychiatry, Psychotherapy And Psychosomatics, Zurich, Switzerland, [2]Lausanne University Hospital, Old Age Psychiatry, Department Of Psychiatry, Lausanne, Switzerland, [3]Nestlé Research, Nestlé Institute Of Food Safety & Analytical Sciences, Lausanne, Switzerland, [4]Ecole Polytechnique Fédérale de Lausanne, Institut Des Sciences Et Ingénierie Chimiques, Lausanne, Switzerland

Aims: Neuropsychiatric symptoms (NPS) are common in older people with cognitive decline and are associated with worse long-term outcomes. The contribution of systemic and central nervous system (CNS) pathophysiological alterations to the etiology of NPS is not well understood. Furthermore, no biomarkers for early detection of these alterations, and for prediction of further disease progression are available to date.
Methods: Using hypothesis-free untargeted proteomics in a cohort of longitudinally followed-up older people with normal cognition and with cognitive impairment, we identified plasma protein biomarkers predictive of NPS persisting over time and investigated biological pathway alterations underlying NPS. Using targeted approaches, we addressed associations of neuroinflammatory markers and cortisol and DHEAs with NPS and related cognitive decline. Additionally, we related the identified alterations with regional brain volumetry.
Results: We found 15 altered plasma proteins levels in participants with NPS. These proteins additionally predicted both persisting NPS and cognitive decline at follow-up visits. In CSF, gene ontology enrichment showed abundance alterations of proteins related to cell adhesion, immune response, and lipid metabolism, among others, in relation to NPS. The observed associations were independent of the presence of Alzheimer's disease (AD) pathology. NPS were associated with distinct inflammatory profiles in serum and CSF. Furthermore, CSF cortisol predicted persisting NPS. The strongest correlations between regional brain volumes and NPS severity were found for the right temporal lobe, third ventricle, frontal lobe, and right hippocampus.
Conclusions: Our results provide evidence for specific molecular alterations and volumetric changes in NPS. These are at least in part independent of the presence of AD pathology. Blood-based biomarkers may help to identify patients with NPS persisting over time, which may facilitate clinical decision and developing of targeted interventions.

MACROSCALE STRUCTURAL COVARIANCE NETWORK REVEALS THREE DISTINCT SUBTYPES AND ABNORMAL PATTERNS OF NEUROPSYCHIATRIC SYMPTOMS IN ALZHEIMER'S DISEASE CONTINUUM

POSTERS: J04. IMAGING, BIOMARKERS, DIAGNOSTICS

Jiwei Jiang[1], Kun Zhao[2], Jun Xu[1]
[1]Beijing Tiantan Hospital, Capital Medical University, Neurology, Beijing, China, [2]Biomedical Engineering School of Biological Science and Medical Engineering Beihang University, Radiology, Beijing, China

Aims: The current diagnosis of neuropsychiatric symptoms (NPS) highly depends on the clinical scale assessments, affected by the emotions and educational levels of caregivers. This study aimed to identify the subtypes of NPS by using a regional radiomics similarity network (R2SN), and to characterize the abnormality patterns associated with the clinical and multimodal imaging features, and progression of each subtype.
Methods: An individual-level R2SN is constructed for N=550 {healthy controls (HCs)=63, patients without NPS among AD continuum (nNPS)=111, patients with NPS=376}. The R2SN profiles of patients with NPS were clustered into three subtypes using nonnegative matrix factorization. The patterns of brain alterations, clincial manifestations, multimodal neuroimaging, gene expression and clinical progression in each subtype were evaluated.
Results: Patients with NPS were clustered into three goups, severe NPS (sNPS, n=187), moderate NPS (moNPS, n=87), and mild NPS (miNPS, n=102). Significant differences were observed among three subtypes with respect to the following: 1) clinical measures (Patients with sNPS exhibited lower BMI and scores in the MMSE, MoCA and MNA, but higher scores in the NPI, ADL, CBI, and PSQI than nNPS (P<0.05 for all), while there was no significant difference in the MMSE and MoCA scores between patients with miNPS and nNPS.); 2) multimodal neuroimaging (Significant differences in the lateral occipital cortex, inferior temporal gyrus, medioventral occipital cortex, fusiform gyrus, and insular gyrus of the altered morphological connectivity, brain volumes, cortical thickness, and cCBF were found among three subtypes.); 3) the rate of clinical progression was faster in sNPS within 9.87± 3.28 months; 4) enriched genes for inorganic ion transmembrane transport and synaptic transmission.
Conclusions: Identification of NPS subtypes based on brain connectomes and a full understanding of heterogeneity could help clinical early diagnosis and intervention in AD continuum.

THE POTENTIAL OF MEASURING CONSCIOUS STATES VIA EEG CLOSED EYES RECORDINGS AS A DIAGNOSTIC MARKER OF ALZHEIMER'S DISEASE

POSTERS: J04. IMAGING, BIOMARKERS, DIAGNOSTICS

Yuan Ma[1], Gaku Yoshikawa[1,2], Jeffrey Keith Spaneas Bland[1]
[1]K. K. FOVE, Development Division, Tokyo, Japan, [2]Japan Advanced Institute of Science and Technology, ., Tokyo, Japan

Aims: We aim to diagnose Alzheimer's disease (AD) via electroencephalogram (EEG) signals employing the *integrated information theory*, a concept that measures conscious states (in Phi values) based on the amount of mutual information across elements in a system. As a pilot study, this work presents the potential of Phi values calculated by EEG signals obtained from the prefrontal cortex.
Methods: We employed 26 copies of EEG data (13 AD and 13 healthy control) recorded by two electrodes, Fp1 and Fp2. Participants were resting with closed eyes during the data collection. We transformed the first 60s of pre-processed EEG amplitude into Phi values, compared two groups by t-test, and examined the predicting accuracy by the ROC Analysis.
Results: The 13 Phi values of the AD group (M = 3.05, SD = 1.06) compared to the 13 Phi values of the healthy control group (M = 4.17, SD = 0.9) demonstrated significantly lower values, $t(24) = -2.9$, p = 0.008. The ROC analysis revealed an AUC of 0.81, indicating reasonably practical discrimination of the Phi values between the two groups (the ROC curve, see Figure
1).

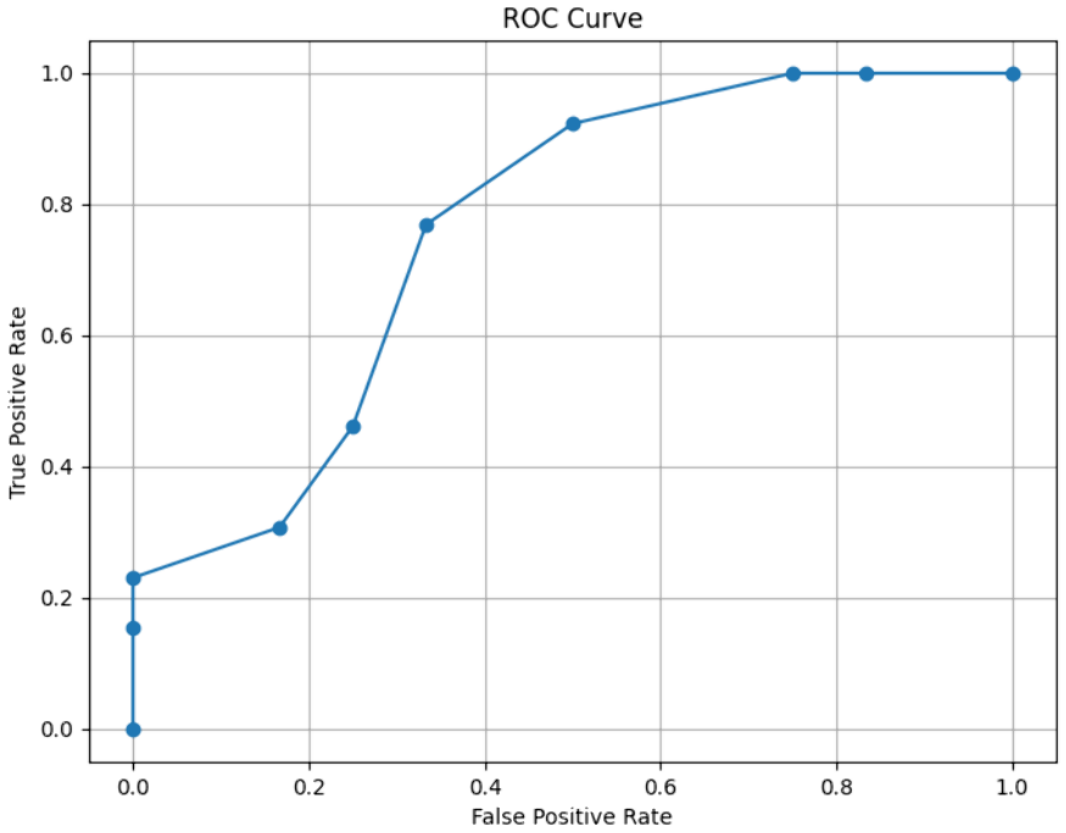

Figure. 1. The ROC curve.

Conclusions: This study found good potential for the Phi value calculated from the mutual information of two EEG electrodes allocated on the prefrontal cortex, contributing a new EEG-based biomarker to diagnosing AD. Our future work will focus on improving the Phi values in predicting accuracy by increasing the complexity of electrode combinations and specifying the EEG frequency domains.

THE PHENOCOPY SYNDROME – A SEPARATE OR CONTINUOUS ENTITY ALONG WITH FRONTOTEMPORAL DEMENTIA?

POSTERS: J04. IMAGING, BIOMARKERS, DIAGNOSTICS

Diana Mortágua, Diana Rafaela
Centro Hospitalar e Universitário de Coimbra, Psychiatry, Coimbra, Portugal

Aims: To present and discuss evidence on the phenocopy syndrome of the behavioral variant of frontotemporal dementia (bvFTD) and its relationship to neurodegenerative disorders.
Methods: Literature review;case description.
Results: Frontotemporal dementia (FTD) is one of the most important causes of early-onset dementia. In the mid-2000, a different group of patients was described, presenting clinical characteristics compatible with bvFTD, without the typical neuroimaging findings and progression over time. These were considered to present a mimetic, or phenocopy, syndrome of bvFTD. Since the term was coined, a substantial body of evidence has allowed to gain some insight that allows to differentiate “true” from phenocopy bvFTD. Although clinically speaking both entities are initially indistinguishable, longitudinally, the phenocopy syndrome shows little or no decline in functioning over time. Besides, phenocopies present with normal brain imaging, or small abnormalities that remain stable over time. Regarding etiology, a group of patients positive to C9Orf72 (most frequent mutation in bvFTD) show slow progression of deficits over time, similar to phenocopies without associated neurodegenerative pathology; besides, patients with this mutation also present with psychiatric pathology more frequently than the bvFTD group and have a higher burden of psychiatric morbidity in their close relatives, once again resembling “idiopathic” phenocopies. Milder forms of Attention Deficit Hyperactivity Disorder (ADHD) and Autism Spectrum Disorder can remain “compensated” throughout adulthood and only later reach medical attention.
Conclusions: Recently, both these studies and similar findings regarding ADHD and synucleinopathies in adulthood have led to the hypothesis of a continuous between neurodevelopmental and neurodegenerative disorders, accounting for the difficulties in establishing definite boundaries between neurodegenerative disorders as well, although while etiology remains, in most cases, undefined, this is still the matter of much debate and a source of controversy.

Aims: The best correlate to cognitive decline in Alzheimer's disease (AD) is synaptic degeneration. Identifying biomarkers capable of quantifying synaptic degeneration that can be used as prognostic biomarkers and to track cognitive decline would be valuable. We have developed several assays for synaptic proteins, including synucleins, neuronal pentraxins, SNAREs, and neurogranin, in CSF for evaluation as potential biomarkers. So far NPTX2 in particular has shown the highest promise in neurodegenerative diseases as a biomarker of cognitive decline but less work has been done in neuropsychiatric diseases.
Methods: Seventeen synaptic proteins were quantified in the Norweigan Dementia Disease Initiation cohort including predementia Alzheimer's disease (AD, n=134), Parkinson's disease with MCI (PD, n=12), late-life depression with normal AD biomarkers (LLD, n=18), and healthy controls (HC, n=41). Stratification of the predementia Alzheimer's disease cases into A/T/N stage was performed using ELISA-determined CSF amyloid beta 42/40 ratio, phosphorylated-tau181, and total-tau. For quantification, micro-high-performance liquid chromatography-mass-spectrometry (triple quadrupole) was used. For group comparisons, linear models adjusted for age and sex were used.
Results: NPTX2 displayed decreased levels in LLD ($p<0.05$) compared to HC as well as at early stages of predementia AD (A+/T-/N- MCI, $p<0.001$) and PD MCI ($p<0.01$) (Figure). The other biomarkers such as 14-3-3 zeta/delta and neurogranin displayed increased levels in late stages of predementia AD (A+/T-/N- MCI, $p<0.001$) and decreased levels in PD MCI (neurogranin only, $p<0.001$), but no changes in the LLD group compared to HC.
Conclusions: NPTX2 is a promising biomarker of cognitive decline not only in neurodegenerative diseases but also in neuropsychiatric diseases such as LLD.

EVALUATING PARTICIPANT BURDEN: ELECTRONIC PATIENT-REPORTED OUTCOME ASSESSMENT COMPLETION TIME IN CLINICAL TRIALS FOR PARKINSON'S DISEASE

POSTERS: J03. DRUG DEVELOPMENT, CLINICAL TRIALS

Laura Khurana, Jessica Emerson
Clario, Ecoa Clinical Science And Consulting, Philadelphia, United States of America

Aims: Patient-reported outcomes (PROs) that measure quality of life and symptom impacts are becoming more important in clinical trials of treatments for Parkinson's Disease (PD). Given the existing symptom and disease burden in PD, participant burden needs to be thoughtfully considered when incorporating PROs into trials. The objective of this analysis was to explore whether PROs present a higher burden to participants with PD as compared to participants without PD by leveraging metadata from an electronic PRO (ePRO) to examine time to completion. The Beck Depression Inventory – Second Edition (BDI-II) was selected; it is a 21-question PRO measure of depression severity, and is commonly used in trials across many different disease areas.
Methods: Operational ePRO metadata from 1 PD trial and 11 non-PD trials were analyzed to determine time to complete the BDI-II. A total of 4806 records were analyzed; 101 records from the PD trial and 4705 records from non-PD trials. Each record represented one completion of the BDI-II on Clario's ePRO device.
Results: The analysis revealed a significant difference whereby participants in PD trials took significantly longer to complete the BDI-II than non-PD trial participants (t=-7.40, p<.001). Mean completion time for the BDI-II was 318s (5.3min) among participants in PD trials and 159s (2.65min) among non-PD trial participants.
Conclusions: This analysis suggests that clinical trial participants with PD take more time to complete the electronic version of the BDI-II than those without PD. This should be considered during protocol design, as the threshold for participant burden in PD trial participants may be lower than for other trial participants. We recommend that this analysis be replicated with other PROs to determine the extent to which these results are generalizable.

EXPLORING IMMERSIVE VIRTUAL REALITY FOR COGNITIVE MONITORING IN HOME CARE: INSIGHTS AND RECOMMENDATIONS FROM EXPERT EVALUATION

POSTERS: J04. IMAGING, BIOMARKERS, DIAGNOSTICS

Angelo Cedric Panganiban[1], Richelle Ann Juayong[1], Jaime Caro[1], Veeda Michelle Anlacan[2]
[1]University of the Philippines Diliman, Department Of Computer Science, Quezon City, Philippines, [2]University of the Philippines Manila, Department Of Neuroscience, Manila City, Philippines

Aims: Mild Cognitive Impairment (MCI) represents a transitional phase preceding younger onset dementia. To expedite early detection of MCI, cognitive function monitoring through long-term routine evaluations in home-care could be implemented and supplement standardized clinical procedures. However, this approach should be meticulously tailored to accommodate specific characteristics of the target population and their unique living environments. Immersive Virtual Reality (VR) presents an innovative solution that could simulate personalized and controlled environments to benefit the target population. **Objectives**: The objectives of this exploratory study were to gather preliminary insights and recommendations concerning the usability of the developed VR prototype, and solicit expert opinions regarding its potential utility as a means of assessing cognition based on user performance during gameplay.
Methods: Methods: Upon acquiring satisfactory VR user experience from alpha testing, the researchers invited four experts from the Alzheimer's Disease Association of the Philippines (ADAP) to experience the prototype. The researchers arranged a two-day demonstration of the VR prototype followed by an online focus group discussion.
Results: Results: The domain experts appreciated the prototype's design, noting its suitability for older persons with some adjustments to enhance safety. They also recognized the prototype's potential for cognitive measurement with suggestions on expanding the range of assessments in future iterations.
Conclusions: Conclusion: This research represented an initial exploration to utilize immersive VR-based interventions for monitoring cognitive function in home-care. It intended to lay the groundwork for future developments and improvements in immersive VR tools. As VR technology continues to evolve, older persons could benefit from this emerging technology.

Aims: This study investigates the longitudinal association between amyloid status and depressive/anxiety symptoms in individuals with subjective cognitive decline (SCD), while also exploring potential modifying roles of personality traits and education.
Methods: We included 329 individuals with SCD from the SCIENCe cohort (follow-up: 3.80±2.10), including 88 amyloid-positive (66.2±7.0) and 241 amyloid-negative participants (61.4±7.5). Amyloid status was determined by amyloid PET/CSF biomarkers according to visual read or established cut-points. Depressive/anxiety symptoms were assessed using the Geriatric Depression Scale (GDS), Center for Epidemiological Studies-Depression (CES-D), and Hospital Anxiety and Depression Scale-Anxiety (HADS-A). We used linear mixed models to assess the association between amyloid status and depressive/anxiety symptoms over time, and its interaction with neuroticism (Dutch Personality Questionnaire), somatization, (Four-Dimensional Symptom Questionnaire), and education (Dutch Verhage scale).
Results: In univariate analyses amyloid status was not associated with GDS, CES-D and HADS-A at baseline or over time. Using a three-way interaction model, we found that neuroticism modified the association between amyloid status and GDS over time ($p<0.10$), with a stronger association in individuals with lower neuroticism (β:0.10±0.08), than in individuals with higher neuroticism (β:-0.03±0.12). Similarly, somatization modified the association between amyloid status and CES-D over time ($p<0.05$), with a stronger association in individuals with lower somatization (β:0.65±0.23), compared to individuals with higher somatization (β:-0.08±0.29). Additionally, education levels modified the association between amyloid status and CES-D & HADS-A over time ($p<0.05$; $p<0.10$), with stronger associations in individuals with lower education (β:0.75±0.34; β:0.34±0.16), compared to individuals with higher education (β:0.14±0.23; β:-0.04±0.10).
Conclusions: Neuroticism, somatization and education modify the association between amyloid status and depressive/anxiety symptoms over time. This emphasizes the importance of considering individual characteristics when examining the association between amyloid status and depressive/anxiety symptoms in individuals with SCD.

IMPAIRED INSIGHT AND OVERESTIMATION OF ABILITY AS PREDICTORS OF BRAIN CHANGES ACROSS TIME IN MILD COGNITIVE IMPAIRMENT AND ALZHEIMER'S DISEASE

POSTERS: J04. IMAGING, BIOMARKERS, DIAGNOSTICS

Jacob Wilkins[1,2], Li Su[1,2,3], Carlos Muñoz-Neira,[1,2,3]
[1]Sheffield Institute of Translational Neuroscience, Artificial Intelligence And Computational Neuroscience Group, Sheffield, United Kingdom, [2]University of Sheffield, School Of Medicine And Population Health, Sheffield, United Kingdom, [3]University of Cambridge, Old Age Psychiatry Research Group, Cambridge, United Kingdom

Aims: Impaired insight can be understood clinically as a loss of ability to appropriately recognise one's own disease status. The study aimed to examine how the character of insight changes with disease stage and assess whether baseline levels of impaired insight can predict rate of brain atrophy across a period of 30 months in a cohort of subjects consisting of: subjective memory complaint (SMC), mild cognitive impairment (MCI), Alzheimer's disease (AD) and cognitively healthy controls (CN).
Methods: Data from 794 eligible participants was extracted from the Alzheimer's Disease Neuroimaging Initiative (ADNI) dataset. Insight levels were estimated using self-administered and informant responses to the Measurement of Everyday Cognition (ECog). Impairment was further categorised into overestimation or underestimation of ability. Brain atrophy rates were estimated for the whole brain and subregions associated with early atrophy in AD disease course. Atrophy rates were measured by change in brain volume calculated from 3 Tesla brain scans undertaken within 30 months.
Results: Insight impairment worsened with disease stage, from minor failures of insight in CN and SMC to more pronounced impairment in MCI and AD. Overestimating ability was significantly correlated with increased whole-brain atrophy rates ($p<0.001$) independent of general cognitive decline. Overestimation of ability exhibited significant correlations with increased atrophy in specific regions of the brain: the medial temporal lobe, fusiform gyrus, and hippocampus.
Conclusions: The present results suggest a significant correlation between overestimation of ability and increased rates of subsequent brain atrophy, highlighting insight as a possible neuropsychological prognostic marker. This is particularly seen in regions of the brain such as the hippocampus. However, further study into the phenomenon of insight and its progression over the disease course is required before predictive ability can be fully assessed.

RELATIONSHIP BETWEEN BRAIN ATROPHY AND NEUROPSYCHIATRIC SYMPTOMS IN ALZHEIMER'S DISEASE

POSTERS: J04. IMAGING, BIOMARKERS, DIAGNOSTICS

Hyon Ah Yi[1], Hyung Lee[1], Hae Won Kim[2], Kyung Sook Won[2]
[1]Keimyung University School of Medicine, Neurology, DAEGU, Korea, Republic of, [2]Keimyung University School of Medicine, Nuclear Medicine, DAEGU, Korea, Republic of

Aims: Neuropsychological symptoms(NPS) are commonly found in Alzheimer's disease(AD) and believed to appear in middle or late stages of AD. However, NPS can be found in early AD and the anatomical localizations of NPS are not completely understood. We aimed to investigate the relationship between structural brain changes and NPS, and between congition and NPS in cognitively impairment patients(CI).
Methods: We enrolled 50 controls, 49 mild cognitive impairment(MCI) and 64 mild to moderate AD. All participants underwent brain MRI, neuropsychological evaluations including Neuropsychiatric inventory(NPI), and amyloid PET. NPI score was classified into 1)NPI-behavioral score(NPI-behav), which included agitation/aggressiveness, disinhibition, irritability and aberrant motor behavior, 2)NPI-psychosis, included delusions and hallucinations, 3)mood disturbance(NPI-mood), included depression, anxiety, sleep, appetite and apathy 4)euphoria. All of them were scored using NPI. We evaluated subcortical change with FIRST.
Results: ANOVAs, adjusted for age, sex and education, showed that NPI-total and NPI-mood scores differed between groups with a tendency to be severe from controls to MCI and further to AD. Comparing controls and cognitively impaired patients(CI) showed lower NPI-total, -behav, -psychosis and mood scores in controls besides euphoria. Correlation analyses revealed that there was significant negative correlation between all of NPI scores except euphoria with MMSE scores. There were correlations between cortical thickness of parts of the lobes and NPI scores besides euphoria after adjusting for age, education and MMSE($p<0.05$). For subcortical analysis, the lower volumes of caudate nucleus and putamen were negatively correlated with NPI-behav and NPI-psychosis, euphoria was related to the lower volumes of hippocampus and amygdala.
Conclusions: NPS were related to the cognitive deterioration and volume loss of focal subcortical regions in early AD and MCI. Our results support previous suggestion of disrupted frontal-subcortical circuit as the mechanisms of NPS.

Aims: To uncover distinct clinical phenotypes within "typical" Alzheimer's disease (AD) based on cognitive and neuropsychiatric markers, track their longitudinal progression, and identify their corresponding pathological and neuroanatomical correlates.
Methods: We employed K-modes clustering on 2483 cognitively impaired (CI) individuals across the AD spectrum, excluding atypical AD and other CI etiologies, from five cohorts: TRIAD, ADNI, BICWALZS, OASIS-III, and Pittsburgh. Cluster-specific clinical and pathological profiles were established through comparison with 2670 cognitively unimpaired (CU) participants across plasma biomarkers (Ptau-181, Ptau-217, GFAP, Nfl, AB42/40 ratio) and neuroimaging (amyloid and tau PET, MRI-derived degeneration maps). Symptom trajectories were assessed using longitudinal follow-up, revealing whether the phenotypes represent sequential or parallel disease forms. Proportional Cox hazards models quantified functional decline rate using CDR-SB, and longitudinal symptom rate of change were also computed for each phenotype.
Results: We identified five distinct clinical phenotypes: pure amnestic syndrome, global cognitive impairment without NPS, global cognitive impairment with NPS, CI with predominant affective symptoms, and CI with predominant hyperactive symptoms (**Figure 1**). Each phenotype displayed a unique neuropathological and neurodegeneration topographical profile (**Table 2, Figure 2**). Three-year longitudinal data showed that these phenotypes represent parallel rather than sequential disease forms (**Figure 3**). The phenotypes exhibited significantly different rates of functional decline, as well as varied rates of change in cognitive symptoms (**Figure 4**).

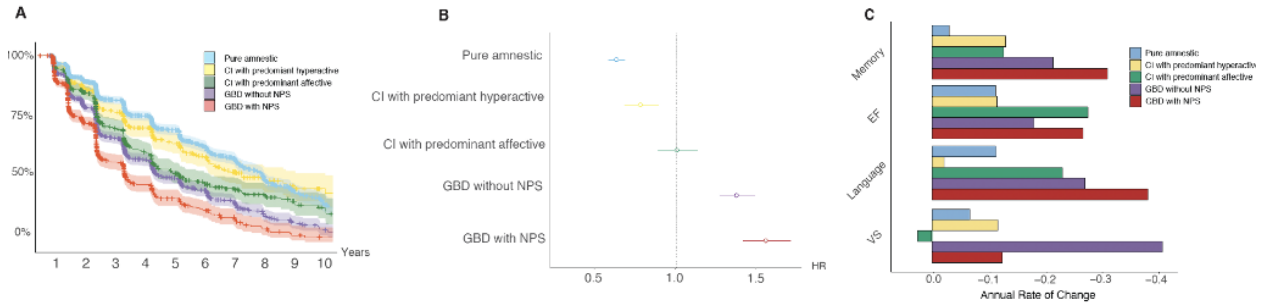

Figure 4: Longitudinal Analysis of the Five Identified Phenotypes. **A**: Survival curves over a 10-year period, controlled for sex, age, and diagnosis using a Proportional Cox Hazards model. **B**: Hazard ratios for each cluster, adjusted for relevant factors, in comparison to the broader CI population for predicting cognitive decline. **C**: Annual rate of symptom progression across the four cognitive domains within each cluster.

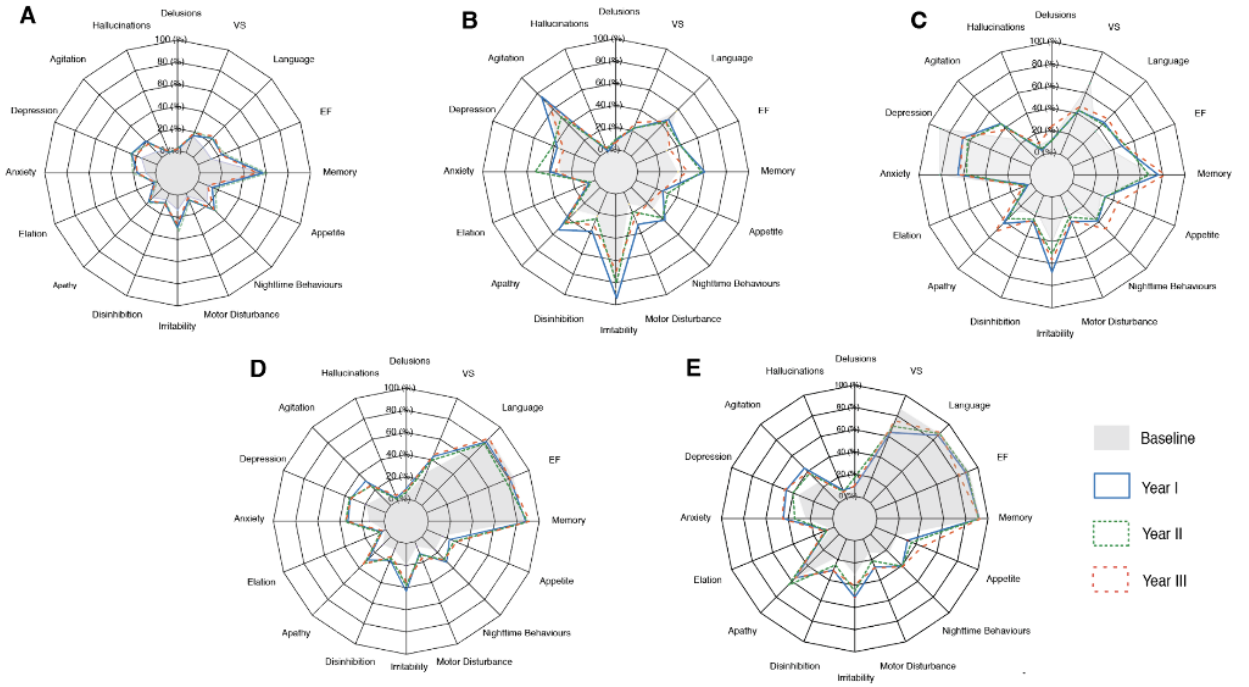

Figure 3: **Longitudinal Radar Chart of Symptom Prevalence Within Each Cluster at Baseline and Annual Follow-Ups (Years 1, 2, 3)**. Subtypes: **A**) Purely Amnestic Syndrome, **B**) CI with Predominant Hyperactive Symptoms, **C**) CI with Predominant Affective Symptoms, **D**) GBD Without NPS, **E**) GBD With NPS. Symptom Structure Within Each Cluster Remains Consistent Over Time.

Conclusions: Our results suggest the existence of robust and replicable sub-phonotypes in "typical" AD by revealing with divergent neuropathological profiles and clinical characteristics. These results highly the importance of personalized medicine to provide a more tailored dementia care in the context of the emerging AD treatments.

CHAIN MEDIATION ANALYSIS OF THE EFFECTS OF NUTRITION AND COGNITION ON THE ASSOCIATION OF APOLIPOPROTEIN E ALLELE 4 WITH NEUROPSYCHIATRIC SYMPTOMS IN ALZHEIMER'S DISEASE

POSTERS: J05. GENETICS, EPIDEMIOLOGY

Jiwei Jiang, Wenyi Li, Jun Xu
Beijing Tiantan Hospital, Capital Medical University, Neurology, Beijing, China

Aims: Apolipoprotein E (*APOE*) is the most recognized risk gene for cognitive decline and clinical progression of late-onset Alzheimer's disease (AD); nonetheless, its association with neuropsychiatric symptoms (NPSs) remains inconclusive. To investigate the association of *APOEε4* with NPSs and explore nutritional status and cognition as joint mediators of this association.
Methods: Between June 2021 and October 2022, patients with amnestic mild cognitive impairment (aMCI) or AD were recruited from the Chinese Imaging, Biomarkers, and Lifestyle Study. NPSs were assessed using the Neuropsychiatric Inventory, while global cognition and nutritional status were evaluated using the Mini-Mental State Examination (MMSE) and Mini-Nutritional Assessment (MNA), respectively. Simple mediation and multiple chain mediation models were developed to examine the mediating effects of the MNA and MMSE scores on the relationship between *APOEε4* and specific neuropsychiatric symptom.
Results: Among 310 patients, 229 (73.87%) had NPSs, and 110 (35.48%) carried APOEe4. Patients with APOEe4 were more likely to have hallucinations (P=0.014), apathy (P=0.008), and aberrant motor activity (P=0.018). MNA and MMSE scores mediated the association between APOEe4 and hallucinations (17.97% and 37.13%, respectively), APOEe4 and apathy (30.73% and 57.72%, respectively), and APOEe4 and aberrant motor activity (17.82% and 34.24%), respectively. Chain-mediating effects of MNA and MMSE scores on the association of *APOEe4* with hallucinations, apathy, and aberrant motor activity after adjusting for confounding factors were 6.84%, 11.54%, and 6.19%, respectively.
Conclusions: Nutritional status and cognition jointly mediate the association between *APOEe4* and neuropsychiatric symptoms in patients with aMCI or AD. Considering the limitations of NPSs therapy in the AD continuum, this study offers novel valuable insights into the role of targeted nutritional interventions in reducing the negative effect of *APOEe4* on the onset and development of NPSs.

COMPETING RISK ANALYSIS OF THE ASSOCIATION BETWEEN DEMENTIA AND THE RISK OF MAJOR DEPRESSIVE DISORDER IN TAIWAN: A NATIONWIDE POPULATION-BASED COHORT STUDY

POSTERS: J05. GENETICS, EPIDEMIOLOGY

Chih-Ching Liu[1], Chien-Hui Liu[2]
[1]College of Medical and Health Science, Asia University, Department Of Healthcare Administration, Taichung, Taiwan, [2]National Yang Ming Chiao Tung University, Institute Of Biomedical Informatics, Taipei, Taiwan

Aims: Major depressive disorder (MDD) and dementia are both major contributors to the global burden of disease. Despite existing literature on the association between dementia and the risk of MDD, there is a lack of a nationwide longitudinal cohort study that considers the competing risk of death. Therefore, this cohort study assessed the association between dementia and the risk of MDD over an 11-year period in population-based settings of Taiwan, accounting for death as a competing risk.
Methods: We conducted a population-based retrospective cohort study based on Taiwan's National Health Insurance Database. We identified 80,108 patients diagnosed with dementia in 2009–2010 and matched them with patients without dementia by sex, age, and year of diagnosis to assess the relative risk of MDD. All patients were followed until they received a diagnosis of new onset MDD, their death, or the end of 2019. Cause-specific hazards models were used to estimate adjusted hazard ratios (aHRs).
Results: Our results showed the incidence density of MDD was higher in patients with dementia than in patients without dementia (12.77 vs. 4.69 per 1000 person-years), with an aHR of 2.47 (95% CI: 2.35–2.59). Also, the association between dementia and MDD was observed in the strata of follow-up periods. Among them, the association was strongest within 1-year of follow-up, then reduced rapidly but persisted over follow-up of more than 10 years.
Conclusions: This study found an association between dementia and the risk of MDD. Our findings suggest the need to identify MDD in patients with dementia.

TFINDER: A PYTHON WEB TOOL PREDICTING NEURODEGENERATIVE-LINKED TRANSCRIPTION FACTOR BINDING SITES

POSTERS: J06. CELL, MOLECULAR AND SYSTEMS BIOLOGY

Julien Minniti
CNRS UMR 7275 Institut de Pharmacologie Moléculaire et Cellulaire, Biologie Cellulaire & Moléculaire Du Vieillissement Cérébral Normal & Pathologique, Valbonne, France

Aims: Transcription factors (TFs) bind to the regulatory regions of genes and regulate their expression. Dysregulation or mutations of TFs lie at the core of neurodegenerative diseases pathophysiology. Notable among these TFs are p53, a key regulator of apoptosis; NFkB, involved in the neuroinflammatory response; and the less-documented Parkin, which has a neuroprotective function against Alzheimer's disease, Parkinson's disease, and glioblastoma development. Experimental validation of TF-regulated genes typically involves ChIP and EMSA assays. However, identifying Transcription Factor Binding Sites (TFBSs) in-silico is a fundamental step. Many tools recover regulatory regions but lack user-friendliness. TFBS analysis leans heavily on databases, often lacking data about recent TFBS. Consequently, databases fail to uncover unpublished TFBSs, and some tools require payment. TFinder offers an all-encompassing solution. It allows users to retrieve regulatory regions by providing only the gene name and promptly search for TFBSs, irrespective of their database status. TFinder is fast, accessible, user-friendly and open source.
Methods: We investigated the regulation of TP53, PSEN1, PSEN2, CCNA2, CCNB1, SNCA, and GBA at the protein and mRNA levels under conditions of Parkin overexpression or knockout using Western Blot and RT-qPCR. TFinder expedited the extraction of these genes' promoter regions and identified Parkin-recognized TFBSs, particularly GCCGGAG. We cross-referenced TFinder-predicted TFBSs with validated ones from promoter activity assays, EMSA, and ChIP.
Results: TFinder efficiently extracted the sequences and pinpointed TFBSs, which we subsequently validated functionally. Our findings indicate that Parkin directly and transcriptionally regulates TP53, PSEN1, PSEN2, CCNA2, CCNB1, SNCA, and GBA.
Conclusions: TFinder is a powerful and user-friendly tool for discovering TFBSs. It proves to be a valuable time-saving resource, especially for studying non-referenced TFs.

CONSEQUENCES OF PATHOGENIC TAU EXPRESSION IN MOUSE LOCUS COERULEUS

POSTERS: J07. ANIMAL MODELS

Anuradha Korukonda, Jake Atallah, David Weinshenker
Emory University, Department Of Human Genetics, Atlanta, United States of America

Aims: During early stages of Alzheimer's disease (AD), patients often suffer from prodromal symptoms such as anxiety, depression, agitation, and sleep disturbances prior to the onset of cognitive impairment. Incidentally, the brainstem noradrenergic locus coeruleus (LC) is the first structure to develop hyperphosphorylated 'pretangle' tau pathology in the brain, and norepinephrine (NE) influences several of these physiological processes. It is critical to evaluate if early tau accumulation in the LC and the manifestations of prodromal behaviors are causally linked. We thus developed a translationally-relevant tau mouse model that recapitulates the 'LC first' phenomena commonly observed in humans.
Methods: Adult male and female tyrosine hydroxylase (TH)-Cre mice (3 months) underwent intra-LC infusions with a Cre-dependent adeno-associated virus expressing EYFP or P301S mutant human tau (n=5-8/group). 3 months post-infusion, mice underwent behavioral tests to assess sleep latency, locomotor activity, compulsivity, stress-induced anxiety-like behavior, and association memory deficits. Following behavioral tests, brain sections comprising the LC and hippocampus were immunostained with TH to assess for LC integrity, AT8 to detect pretangle tau, NE transporter (NET) to evaluate NE fiber intensity in projection regions, and GFAP and IBA1 as neuroinflammatory markers. Immunoreactivity (IR) was calculated as a measure of fluorescence via ImageJ.
Results: At 3 months, hyperphosphorylated tau was detected in cell bodies and somatodendritic compartments of LC neurons. These mice showed hypersomnia or decreased latency to fall asleep, anxiety-like behavior, and deficits in contextual memory. In tandem, tau accumulation in the LC provoked robust astrocyte inflammatory responses in the LC and dentate gyrus, without significantly affecting NET or TH levels.
Conclusions: Tau pathology in the LC contributes to manifestations of prodromal symptoms. Further studies will address molecular mechanisms underlying tau-mediated LC dysfunction in early AD.

VALIDATING PINK1-/- RATS AS SUITABLE MODELS FOR EXPLORING THE IMPACTS OF GLUCOCEREBROSIDE DYSREGULATION ON NON-MOTOR DEFICITS IN PARKINSON'S DISEASE

POSTERS: J07. ANIMAL MODELS

Mary Kritzer, Markus Riessland, Taylor Russo, Kelly Ng, Elliot Paimany
Stony Brook University, Department Of Neurobiology And Behavior, Stony Brook, United States of America

Aims: Dysregulation in lipid metabolism in Parkinson's disease (PD) is associated with increased risk and/or greater severity of non-motor deficits, including autonomic dysregulation, neuropsychiatric symptoms and cognitive deficits. Our objective is to validate rats with knockout of the PTEN-induced putative kinase1 gene (*Pink1*-/-) as models for exploring PD-relevant lipid pathologies and their roles in predicting, contributing to and/or mitigating non-motor deficits in PD.
Methods: Male and female control and *Pink1*-/- rats were behaviorally tested every two months from 3-12 months old on tasks measuring cognition/memory, affect/anxiety and motor function. This was interleaved with ECG analysis and assessments of glucocerebroside (GluCer) extracted from animals' fur and measured in dot blot assays using an antibody specific for GluCer (Glycobiotech).
Results: Male *Pink1*-/- rats developed significant object recognition memory deficits (Novel Object Recognition, Object Location, Object-in-Place) by 5 months old. *Pink1*-/- females showed little memory impairment but did show significant deficits in sensorimotor gating and worsening anxiety, e.g., in elevated plus maze, from 3 months on. *Pink1*-/- rats of both sexes also had significantly increased heart rates and significantly reduced heart rate variability. These and all non-motor impairments were expressed months before the onset of motor signs. Finally, significantly increased GluCer levels were seen in *Pink1*-/- males from 3 months of age on. However, in females no significant effects of the *Pink1*-/- genotype on GluCer were seen.
Conclusions: Our data show that *Pink1*-/- rats develop prodromal, non-motor deficits in multiple domains; emulate male susceptibility to cognitive deficits, female vulnerability to affective disturbance and sex differences in GluCer dysregulation similar to those observed in PD. Together, these findings identify *Pink1*-/- rats as well suited for deeply exploring the impacts of brain lipid metabolism in PD in sex-specific ways.

SHORT-TERM HIGH-FAT DIET FEEDING INDUCES COGNITIVE DECLINE, AGGRESSIVENESS AND ANXIETY-LIKE BEHAVIOR IN ADULT ZEBRAFISH (DANIO RERIO)

POSTERS: J07. ANIMAL MODELS

Victor Luna Picolo, Andreza De Bem
Universidade de Brasília, Physiology, Brasília, Brazil

Aims: Obesity is a high- prevalence (13% of adult population in 2016), global health concern defined by a high body mass index (BMI). Several comorbidities are associated, including some affecting central nervous system (CNS), i.e. neurodegenerative diseases, cognitive deficit and psychobehavioral disturbs. Zebrafish has raised as a versatile and cheap model widely used to study human diseases, including obesity and neurological diseases. Therefore, our objective is verify the impact of a high-fat diet on the central nervous system (CNS) using well- stablished behavioral tests.
Methods: Animals was feed according with three dietary groups. The standard diet group (SD) received only 7.5 mg/fish of dry food, while the high-fat diet groups received 5 mg/fish dry food plus 7.5 (HFD-7.5) or 15 mg/fish (HFD-15) of chicken egg yolk. Dietary fat content (w/w) was approximately 6.5%, 16.9% and 21.1%, respectively. After two weeks of diets ingestion, behaviors were assessed.
Results: Both HFD groups had obesogenic effects, indicated by increase on BMI, abdominal length and body weight compared with SD group. We show a HFD ingestion induced aggressive and anxiety-like behavior on zebrafish, as measured by mirror-induced aggression and novel tank diving test, respectively. Also, the higher concentration of HFD (HFD-15) elicited cognitive deficit on inhibitory avoidance test while sociability was unaffected, as determined by the social preference test.
Conclusions: Our results are in accordance with evidences in obese human and rodent models, suggesting similar effects of fat intake. Therefore, we highlight the unexplored potential of zebrafish to elucidate this study field.

CARE GIVER BURDEN IN DEMENTIA

POSTERS: K01.A. DEMENTIA AND COGNITIVE DYFUNCTION: CAREGIVER SUPPORT

Sai Teja, Karthik Vinay Mahesh
PGIMER, Neurology, chandigarh, India

Aims: Our Aim was to study the clinical profile of patients presenting with major neurocognitive disorder and to study care giver burden.
Methods: All confirmed cases attending neurology and psychiatry outpatient department or admitted inpatients and fulfilling inclusion criteria was included instudy. Total sample size includes 91.
• Written informed consent would beobtained
• Detailed history as well as neurological examination was carried out in all patients eligible forstudy • Severity of dementia is assessed by Dementia ratingscale
• Care giver burden is assessed by family burden interview Pai andKapoor
Results: The current study included 91 patients with a mean (SD) age of presentation is 63.36 (8.73) Males constituted 54 patients (59.3%) and females 37 (40.7%).
Among subtypes of Major neurocognitive disorder most common was FTD group 40 (44%) followed by AD 22 (24.2%), VD 10(11%), CBS 6 (6.6%), and least CJD 4(4.4%).
Among primary caregivers' spouses constituted 39, children including both son and daughter constituted 40 members
The mean (SD) MMSE was 11.78 (9.47) in our group and the Mean (SD) MOCA score is 9.59.
The family burden score assessed by the Pai and Kapur scale is 6.93(5.03) with a maximum score of 23
The highest Burden was noted in the financial domain and disruption of family routine activities.
Caregiver burden was maximum in CJD with a score of 11 (4.16) followed by FTD 7.88(5.65) and VD 7.20(3.71) with the least in AD 4.68(4.24) group.
Conclusions: Caregiver burden was maximum in Major Neurocognitive disorder with higher neuropsychiatric symptoms like CJD followed by FTD, vascular dementia, with the least burden in AD. Financials and disruption of routine family activities lead to a major burden for caregivers compared to the physical and emotional component

IMPACT OF CAREGIVER BURDEN ON SLEEP PATTERNS AND CIRCADIAN RHYTHMS OF THE HEART RATE IN SPOUSAL CAREGIVER OF COGNITIVE IMPAIRMENT PATIENTS: A FITBIT-BASED STUDY

POSTERS: K01.A. DEMENTIA AND COGNITIVE DYFUNCTION: CAREGIVER SUPPORT

Shin Young Park[1], Jung Been Lee[2], Taek Lee[2], So Yeon Jeon[3]
[1]Chungnam National University Hospital, Daejeon, Republic of Korea, Department Of Psychiatry, Daejeon, Korea, Republic of, [2]Sun Moon University, Division Of Computer Science And Engineering, Asan, Korea, Republic of, [3]Chungnam National University Hospital, Psychiatry, Daejeon, Korea, Republic of

Aims: Numerous studies have established associations between caregiver burden and various aspects of circadian rhythms (heart rate, sleep pattern), primarily relying on subjective measures. In this study, we examined the impact of caregiver burden on spousal caregivers (SCGs) and their circadian rhythms, utilizing Fitbit technology.
Methods: A total of 49 SCGs participated in the study(mean age of 71.9±6.3 years). Participants underwent clinical assessments, including the Pittsburgh Sleep Quality Index (PSQI) and Zarit Burden Interview (ZBI), to evaluate global cognition. They also wore daily activity trackers(Fitbit) for 14 consecutive days.
Results: Elevated ZBI scores in SCGs with cognitive impairment were associated with earlier wake times($p=0.003$), increased daytime sleep($p=0.018$), and reduced nocturnal sleep duration($p=0.002$) based on Fitbit data. This trend was consistent among all patient spouses, regardless of cognitive impairment, and ZBI scores linked to reduced overall sleep duration($p=0.021$) and time in bed(TIB, $p=0.022$). However, no significant relationship was found between ZBI scores and sleep efficiency or PSQI scores. Furthermore, higher ZBI scores were associated with reduced circadian rhythm amplitude($p<0.001$) and goodness-of-fit($p<0.001$).
Conclusions: These findings emphasize the significant impact of caregiver burden on sleep pattern and circadian rhythms of heart rate, suggesting that PSQI may overestimate sleep quality compared to actigraphy. Many SCGs may experience unrecognized sleep disturbances, highlighting the need for interventions. Additionally, cosinor analysis indicates that higher ZBI scores are associated with more static activity(reduced amplitude) and irregular fluctuations in sleep duration, rest periods, and activity times(reduced GoF).

PRELIMINARY EVIDENCE OF BURDEN EFFECT ON BRAIN MORPHOMETRY IN INFORMAL CAREGIVERS OF PATIENTS WITH ALZHEIMER'S DISEASE

POSTERS: K01.A. DEMENTIA AND COGNITIVE DYFUNCTION: CAREGIVER SUPPORT

Giulia Quattrini[1], Claudio Singh Solorzano[1], Roberto Gasparotti[2], Francesca Morganti[3], Orazio Zanetti[4], Cristina Festari[1], Michela Pievani[1]
[1]IRCCS Istituto Centro San Giovanni di Dio Fatebenefratelli, Laboratory Of Alzheimer's Neuroimaging And Epidemiology, Brescia, Italy, [2]University of Brescia, Neuroradiology Unit, Brescia, Italy, [3]University of Bergamo, Department Of Human And Social Sciences, Bergamo, Italy, [4]IRCCS Istituto Centro San Giovanni di Dio Fatebenefratelli, U.o. Alzheimer, Brescia, Italy

Aims: Informal caregivers (iCG) of patients with Alzheimer's disease (AD) generally experience burden and stress; however, whether these chronic conditions have an effect on the brain is unclear. Stress may have neurotoxic effects on brain regions modulating behavior and distress such as the anterior hypothalamus, hippocampus, amygdala, and prefrontal cortex. In this study, we tested the association between caregiver burden and stress and brain morphology in iCG of AD patients.
Methods: Twenty iCG (age=52.6±9.1 years, 90% females) underwent clinical evaluation, including the Zarit Caregiver Burden Interview (ZBI) and the Perceived Stress Scale (PSS), and 3T MRI exam. Structural 3D T1-weighted images were processed using FreeSurfer v7.2.0 to assess cortical thickness and subcortical volumes (mean prefrontal cortex thickness, mean volumes of the hypothalamus, hippocampus, amygdala, and their subregions). Spearman correlations were conducted between ZBI, PSS and MRI measures controlling for age.
Results: A negative correlation emerged between ZBI score and the anterior hypothalamic volume (whole, *rho*=-0.648, *p*=.003; left, *rho*=-0.540, *p*=.017; right, *rho*=-0.649, *p*=.003). No significant correlations emerged between PSS and MRI features.
Conclusions: Our preliminary results showed an association between iCG burden and lower volume of the anterior hypothalamus. Further studies are needed to clarify the possible mechanisms underlying these associations.

"IF I KEEP CALM AND USE A SOFT VOICE AND SMILE AND LOOK AT HIM … IT WORKS MUCH BETTER"

POSTERS: K01.A. DEMENTIA AND COGNITIVE DYFUNCTION: CAREGIVER SUPPORT

Dympna Casey, Barbara Whelan, Priscilla Doyle, Niamh Gallagher, Siobhán Smyth
University of Galway, School Of Nursing And Midwifery, Galway, Ireland

Aims: A carer education programme was developed as part of a pilot comprehensive resilience-building psychosocial intervention (CREST) for people with dementia living in the community. The aim of the programme was to enable carers to respond more confidently to the needs of the person with dementia, to provide them with an opportunity to focus on their own health needs and to meet other carers and share experiences. We explore the carers' experience of the programme consisting of six weekly 2-hour sessions with each week covering a different topic.
Methods: Qualitative group and individual interviews were conducted with the carers during the education programme and at the end of the CREST intervention. Attendance rates were recorded and evaluation forms completed by carers at the end of each session. Qualitative data were analysed using thematic analysis and descriptive statistics used for quantitative data.
Results: Nine carers completed the intervention with an average of 91% attendance (range: 67-100%). Evaluations were very positive with all agreeing that the content of each session was helpful and met their expectations. A key motivation to participate was to gain more knowledge and understanding about dementia and learning communication strategies were particularly useful. The support and learning that carers got from other group members, the social interaction and the emphasis on self-care were important elements of the programme.
Conclusions: Carers of people with dementia need good support to enable them to manage the demands of caregiving. The carer education programme of the CREST intervention helped to support carers to manage stresses through better communication strategies, to build a support network of other carers and to focus on their own needs to better enable them in their role.

THE CAREGIVER BURDEN OF DEMENTIA

POSTERS: K01.A. DEMENTIA AND COGNITIVE DYFUNCTION: CAREGIVER SUPPORT

Wei-Pin Hong[1], Ming-Chyi Pai[2]
[1]National Cheng Kung University Hospital, Department Of Neurology, Tainan City, Taiwan, [2]Medical College and Hospital, National Cheng Kung University, Neurology (behavioral Neurology), Tainan, Taiwan

Aims: Dementia causes considerable caregiver burden to caregivers. In this study, our first aim is to qualify the caregiver burden and the second aim is to reveal the need of caregivers in different types of dementias and different stages.
Methods: Each patient with dementia coming to visit dementia clinic in National Cheng Kung University Hospital, Tainan, one of the medical centers in Taiwan has comprehensive survey and records of dementia from the first visiting and the after follow-up, including basic demographic data, cognitive function, Zarit burden interview scale, and Neuropsychiatric inventory scale, etc. We enrolled the patients with dementia in recent 5 years. The patients were categorized into Alzheimer's disease, Lewy body dementias, vascular dementias, and other type of dementia according to the diagnosis and clinical dementia rating. Subjective cognitive decline, mild cognitive impairment, and patients living in long-term care facilities were excluded. Analysis of variance is as a statistical method.
Results: The results are under organization and analysis recently. It will be revealed during the AD/PD 2024 conference.
Conclusions: Caregivers burden may damage the health of caregivers and decrease the quality of care in patients with dementia. To understand the needs of caregivers in different types of dementia is essential. Strategies of dementia care should modify for different dementia cases.

DEVELOPMENT AND PSYCHOMETRIC EVALUATION OF FAMILY CAREGIVERS' HARDINESS SCALE: A SEQUENTIAL-EXPLORATORY MIXED-METHOD STUDY

POSTERS: K01.A. DEMENTIA AND COGNITIVE DYFUNCTION: CAREGIVER SUPPORT

Lida Hosseini[1], Hamid Sharif Nia[2], Mansoureh Ashghali Farahani[1]
[1]Iran university of medical science, Nursing And Midwifery School, Tehran, Iran, [2]Mazandaran University of Medical Sciences, School Of Nursing And Midwifery Amol, Amol, Iran

Aims: Caring for patients with Alzheimer's disease is a stressful situation.Caregivers need to have their hardiness empowered to provide proper and appropriate care to these older adults. Few studies have been conducted to assess the hardiness of caregivers of patients with AD. Presumably, one reason for this knowledge gap is the lack of a proper scale to evaluate hardiness in this group.This study was conducted to develop a reliable and valid Family Caregivers' Hardiness Scale (FCHS).
Methods: This study is a cross-sectional study with a sequential-exploratory mixedmethod approach. The concept of family caregivers' hardiness was clarified using deductive content analysis, and item pools were generated. In the psychometric step, the samples were 435 family caregivers with a mean age of 50.26 (SD ± 13.24). The data were gathered via an online form questionnaire. The items of the FCHS were evaluated using face and content validity. Then, the factor structure was determined and confirmed using exploratory factor analysis (EFA) and confirmatory factor analysis (CFA) followed by convergent and divergent validity, respectively. Finally, scale reliability, including stability, and internal consistency were evaluated.
Results: The finding revealed that FCHS consists of five factors, namely, "Religious Coping" (5 items), "Self-Management" (6 items), "Empathic Communication" (3 items), "Family Affective Commitment" (3 items), and "Purposeful Interaction" (4 items) that explained 58.72% of the total variance. The results of CFA showed a good model fit. Reliability showed acceptable internal consistency and stability.
Conclusions: The concept of hardiness in Iranian family caregivers is a multidimensional concept that is most focused on individual-cultural values, emotional family relationships, and social relationships. The designed scale also has acceptable validity and reliability features that can be used in future studies to measure this concept in family caregivers.

HARDINESS IN FAMILY CAREGIVERS DURING CARING FROM PERSONS WITH ALZHEIMER DISEASE: A DEDUCTIVE CONTENT ANALYSIS STUDY

POSTERS: K01.A. DEMENTIA AND COGNITIVE DYFUNCTION: CAREGIVER SUPPORT

Lida Hosseini[1], Hamid Sharif Nia[2], Mansoureh Ashghali Farahani[1]
[1]Iran university of medical science, Nursing And Midwifery School, Tehran, Iran, [2]Mazandaran University of Medical Sciences, School Of Nursing And Midwifery Amol, Amol, Iran

Aims: This study was designed to describe the experiences of family Caregivers' hardiness in caring for Alzheimer's Patients.
Methods: The deductive content analysis method was performed between April 2020 and February 2021 in one of the teaching hospitals in Iran. Fourteen family caregivers of Alzheimer's patients were selected using purposive and snowballing sampling and the data were collected by semi-structured interviews. After that, data were analyzed using Elo and Kingas steps.
Results: The results of this study showed that based on the experiences of family caregivers, the family caregivers' hardiness in caring for Alzheimer's patients is a feature of cognitive ability to deal with stressful care situations and consists of five dimensions of commitment, control, challenge, communication and culture with 22 generic categories that they were nested into this five dimension.
Conclusions: Family caregivers' hardiness is a trait related to the individual and environmental factors, and the prevailing social and cultural conditions affect the individual's perception and experience of hardship and threats, as well as his/her understanding of protective factors and how to use them. Therefore, hardiness should not be interpreted as a simple approach regardless of culture.

DEVELOPMENT AND VALIDATION OF CARE STRESS MANAGEMENT SCALE IN FAMILY CAREGIVERS FOR PEOPLE WITH ALZHEIMER: A SEQUENTIAL EXPLORATORY MIXED-METHOD STUDY

POSTERS: K01.A. DEMENTIA AND COGNITIVE DYFUNCTION: CAREGIVER SUPPORT

Lida Hosseini[1], Hamid Sharif Nia[2], Mansoureh Ashghali Farahani[1]
[1]Iran university of medical science, Nursing And Midwifery School, Tehran, Iran, [2]Mazandaran University of Medical Sciences, School Of Nursing And Midwifery Amol, Amol, Iran

Aims: Considering all the emotional and fnancial costs imposed on the families of Alzheimer's patients, stress from caring is an issue that cannot be ignored and plans need to be developed to help these caregivers to manage the care properly. The current study was designed to develop a valid and reliable care stress management scale for family caregivers of patients with Alzheimer's
Methods: This study is a methodological study with a sequential-exploratory mixed-method approach that was performed in two-phase: develop the caring stress management scale and evaluate the psychometric properties of the scale. In the frst phase, 14 semi-structured face-to-face interviews were performed with family caregivers of patients with Alzheimer's. The interviews were transcribed immediately and an item pool with 275 items was prepared. After removing the duplicate or overlapping code, the initial format of the caring stress management scale (CSMS) was designed. In the second step, the items of the CSMS were evaluated using face and content validity. After that, the construct validity was evaluated using exploratory factor analysis, confrmatory factor analysis, and convergent and divergent validity respectively. Finally, the reliability was assessed by stability and internal consistency. The sample size was 435 and data was gathered via an online form questionnaire.
Results: This study designed the CSMS with two factors including emotional-focused coping (4 items) and problemfocused coping (4 items) that explained 51.00% of the total variance. The results of the confrmatory factor analysis showed a good model ft. Furthermore, the internal consistency and stability of this scale were acceptable.
Conclusions: The results showed that the care stress management scale has two factors in Iranian family caregivers and it is valid and reliable and can be used by therapists and researchers.

EXPLORING THE IMPACT OF FAMILY SUPPORT GROUP CAREGIVING PROGRAM AT DEMENTIA CARE CENTERS ON FAMILY CAREGIVERS: A CASE STUDY OF A SOUTHERN REGIONAL HOSPITAL

POSTERS: K01.A. DEMENTIA AND COGNITIVE DYFUNCTION: CAREGIVER SUPPORT

Chia Hui Hsiao, Yuan-Han Yang
Kaohsiung Municipal Ta-Tung Hospital, Neurology, Kaohsiung, Taiwan

Aims: This study explores the impact of the Family Support Group Caregiving Program provided by dementia care centers on family caregivers. It aims to determine if the program positively affects aspects of family caregivers, such as caregiving burden, stress, knowledge, skills, attitudes, and quality of life.
Methods: The study used the 'SCZBI-12 Caregiver Burden Scale,' a structured questionnaire from a dementia care center at a regional hospital in the south. It involved 15 family caregivers who participated in six sessions of the Family Support Group Caregiving Program. To evaluate the program's impact on caregivers' well-being, pre- and post-program questionnaires were administered. The pre-test was conducted before the caregivers' first session at the center, while the post-test followed program completion. Data analysis was carried out using SPSS 22.0 software, including paired tests to compare pre- and post-program results.
Results: Statistical analysis of 15 valid samples revealed a significant decrease in caregiver burden following participation in the Family Support Group Caregiving Program at the dementia care center. The burden score dropped from 3.08 before the program to 2.24 after the program, showing a significant difference ($P < 0.001$). This represents a notable 27% reduction in burden. These findings underscore the program's effectiveness in reducing caregiver burden among family caregivers.
Conclusions: In summary, dementia care centers' Family Support Group Caregiving Program effectively reduces caregiver burden and stress, improves knowledge and skills, and enhances attitudes and overall quality of life for family caregivers. These programs equip caregivers with professional expertise, offer emotional and social support, and ultimately strengthen their caregiving abilities and well-being. Therefore, it is recommended that relevant organizations continue to offer and develop such programs to enhance dementia care and improve the lives of family caregivers.

CAREGIVING BURDEN FOR SPOUSES OF PATIENTS WITH COGNITIVE IMPAIRMENT: EFFECTS ON SERUM HOMOCYSTEINE LEVEL

POSTERS: K01.A. DEMENTIA AND COGNITIVE DYFUNCTION: CAREGIVER SUPPORT

Ho Young Jeong[1], Jeong Lan Kim[1,2], So Yeon Jeon[1,2]
[1]Chungnam National University Hospital, Department Of Psychiatry, Daejeon, Korea, Republic of, [2]Chungnam National University College of Medicine, Department Of Psychiatry, Daejeon, Korea, Republic of

Aims: Spousal caregivers (SCG) are predisposed to an elevated risk of cognitive decline and cardiovascular diseases. Identifying potential biomarkers for these adverse health outcomes is of utmost importance. Homocysteine is a promising biomarker associated with both cardiovascular diseases and dementia risk. This study aimed to scrutinize the correlation between caregiver burden and homocysteine levels in SCGs of individuals with cognitive impairment.
Methods: Between May 2020 and December 2022, clinical evaluations and blood tests were conducted on SCGs and care-recipients attending the Chungnam National University Geriatric Neuropsychiatric Clinic. The study encompassed a cohort of 98 spousal caregivers. Caregiver burden was quantified utilizing the Zarit Burden Interview, and blood assays were performed subsequent to overnight fasting.
Results: Linear regression analysis, controlling for variables such as age, sex, and care-recipient's clinical diagnosis, unveiled a significant positive correlation between spousal caregiver burden and homocysteine levels ($\beta = 0.280$, $t = 2.652$, $p = 0.010$). This positive correlation persisted ($p = 0.018$) even after adjusting vascular risk score and APOE ε4 positivity as covariates. Notably, even after the exclusion of SCGs caring for cognitively normal individuals (n = 8), the positive correlation remained significant ($p = 0.019$).
Conclusions: Our findings indicate that the caregiver burden in SCGs of patients with cognitive impairments might amplify homocysteine levels, potentially exacerbating the risk of cognitive decline or instigating cardiovascular diseases. Consequently, screening for homocysteine levels in spousal caregivers could be instrumental in initiating early interventions, mitigating negative health outcomes.

TEMPORAL RELATIONSHIPS IN DEMENTIA FAMILY DYADIC COMMUNICATION: SEQUENTIAL ANALYSIS

POSTERS: K01.A. DEMENTIA AND COGNITIVE DYFUNCTION: CAREGIVER SUPPORT

Sohyun Kim
University of Texas at Arlington, College Of Nursing And Health Innovation, Arlington, United States of America

Aims: This study examines the temporal relationships between antecedent family caregiver facilitative communication and subsequent care recipient communication during 75 in-home care video observations.
Methods: We conducted a secondary analysis using timed-window analysis of 5, 10, 15, 20, 25, and 30 seconds to examine the likelihood of relationships between dyadic communication patterns. We utilized 95% confidence intervals, p-values, and Yule's Q statistics.
Results: Care recipient engaging nonverbal communication was more likely to occur within all time windows after caregiver facilitative verbal and nonverbal communication (range: OR = 1.41 – 1.76, p < .001, Yule's Q = 0.170 – 0.274). Care recipient engaging verbal communication was more likely to occur within the 25- and 30-second windows after caregiver facilitative verbal communication (range: OR = 1.15 – 1.18, p = .027 – .039, Yule's Q = 0.069 – 0.082). Conversely, care recipient challenging verbal communication was less likely to occur within all time windows after caregiver facilitative verbal communication (range: OR = 0.73 – 0.83, p < .001 - .027, Yule's Q = -0.095 – -0.155). Care recipient neutral communication was less likely to occur within all time widows after caregiver facilitative verbal communication (range: OR = 0.70 – 0.80, p <.001 - = .036, Yule's Q = -0.114 – -0.178). Care recipient neutral communication was less likely to occur within all time widows except the 25-second window after caregiver facilitative nonverbal communication (range: OR = 0.68 – 0.85, p =.002 - .036, Yule's Q = -0.079 – -0.188).
Conclusions: Caregiver facilitative communication was associated with more likely subsequent care recipient engaging communication and less likely challenging and neutral communication. These findings will guide in educating family caregivers on engaging individuals living with dementia in their daily care.

THE LONG-TERM IMPACT OF ALZHEIMER'S DISEASE DIAGNOSTIC DISCLOSURE ON THE PSYCHOLOGICAL WELL-BEING OF INFORMAL CAREGIVERS: A PRELIMINARY STUDY

POSTERS: K01.A. DEMENTIA AND COGNITIVE DYFUNCTION: CAREGIVER SUPPORT

Claudio Singh Solorzano[1], Cristina Bonomini[2], Sandra Rosini[2], Michela Pievani[1], Cristina Festari[1]
[1]IRCCS Istituto Centro San Giovanni di Dio Fatebenefratelli, Laboratory Of Alzheimer's Neuroimaging And Epidemiology, Brescia, Italy, [2]IRCCS Istituto Centro San Giovanni di Dio Fatebenefratelli, Alzheimer Unit, Brescia, Italy

Aims: The disclosure of an Alzheimer's Disease (AD) diagnosis is an acute stress event for informal caregivers (iCGs). The present preliminary study explores the posttraumatic stress symptoms (PTSS) related to disclosure and their relationship with iCGs' psychological well-being.
Methods: The study included 39 iCGs (mean age=56) of mild-to-moderate AD patients. Participants completed the Impact of Events Scale (IES) retrospectively, considering the moment of AD disclosure, and filled out the Zarit Burden Interview (ZBI), State-Trait Anxiety Inventory (STAI-Y1-2), Beck Depression Inventory–II (BDI-II), and Revised Scale of Caregiving Self-efficacy (RSCSE). iCGs were classified as subclinical or mild-severe PTSS according to an IES cut-off of 26. Mann-Whitney U tests were used to compare subclinical vs. mild-severe PTSS groups on the above scales. Partial Spearman correlations were used to test the association between scales, controlling for the duration of the caregiving role (mean years=3).
Results: Compared to iCGS with subclinical PTSS (n=20), iCGs with mild-severe PTSS (n=19) reported higher levels of caregiver burden (ZBI: z=-2.853, *p*=0.004), anxiety (STAI-Y1: z=-2.815, *p*=0.005; STAI-Y2: z=-2.772, *p*=0.006), and depressive symptoms (BDI-II: z=-2.969, *p*=0.003) and lower levels of self-efficacy in controlling disturbing thought about their caring role (RSCSE-CUT subscale: z=-2.123, *p*=0.033). Moreover, higher levels of intrusive thoughts (IES-intrusion subscale) were associated with greater distress experience (ZBI: r=-0.460, *p*=0.004; STAI-Y1:r=0.340, *p*=0.037; BDI-II: r=0.494, *p*=0.002) and the presence of negative thoughts on their caregiving experience (RSCSE-CUT subscale: r=-0.328, *p*=0.044), while levels of avoidance (IES-intrusion subscale) were only associated with anxiety.
Conclusions: These findings suggest that disclosure of an AD diagnosis might be a traumatic experience for iCGs and may increase their vulnerability for subsequent poor mental health. Future research should deepen these findings and develop strategies to reduce the detrimental effects of the disclosure moment.

P1388 / #1774

Poster Topic: *Theme J: Psychiatric Symptoms in Neurodegenerative Diseases / J07. Animal Models*

ASSESSING THE COGNITIVE EFFECTS OF METHYLPHENIDATE IN A RAT MODEL OF SPORADIC ALZHEIMER'S DISEASE USING A HOME-CAGE-BASED APPROACH

POSTERS: J07. ANIMAL MODELS

Davor Virag[1], Jan Homolak[1,2], Ana Babić Perhoč[1], Ana Knezovic[1], Jelena Osmanovic Barilar[1], Melita Salkovic-Petrisic[1]
[1]University of Zagreb School of Medicine, Department Of Pharmacology And Croatian Institute For Brain Research, Zagreb, Croatia, [2]Medical Microbiology and Hygiene, Universitätsklinikum Tübingen, Interfaculty Institute Of Microbiology & Infection Medicine | cluster Of Excellence - Controlling Microbes To Fight Infection, Tübingen, Germany

Aims: Epidemiological and animal studies have highlighted an Attention Deficit Hyperactivity Disorder (ADHD)-like phenotype as a risk factor for later development of Alzheimer's disease (AD), with some smaller clinical studies in AD patients showing a potentially beneficial effect of methylphenidate (MPH) treatment. ADHD-related behavioural characteristics have been found in some AD animal models, such as the rat model of AD induced by intracerebroventricular streptozotocin (STZ). We aimed to investigate the effect of oral MPH on cognitive performance in this model.
Methods: Three-month old male Wistar rats (n=40) were injected intracerebroventricularly with citrate buffer (control/CTR) or STZ (3 mg/kg) split in two doses 48 hours apart after which MPH therapy was initiated daily in a dual-bottle dosage regimen (4 and 10 mg/kg) for 6 weeks to half of CTR and STZ groups. Cognitive ability was assessed in the classical Novel Object Recognition (NOR) test at 2, 4, and 6 weeks after STZ. Baseline and 6-week continuous measurement of cognitive performance was performed in an operant conditioning task using VlaDiSlav, a custom home cage apparatus.
Results: At 2 weeks, STZ demonstrated worse performance than CTR (NOR), but this deficit was ameliorated by MPH. No change in NOR were observed at 4 and 6 weeks between the groups. Learning curves in continuous testing using VlaDiSlav show a severely diminished learning rate in STZ group, however, STZ+MPH learning rate was similar to CTR values.
Conclusions: VlaDiSlav continuous measurement gives insight into the learning process suggesting that STZ induced a severe learning deficit that might be normalized by MPH treatment. These findings also highlight the benefits of supplementing conventional behavioural testing with continuously operating, automatised, programmable home cage-based devices.

DEMENTIA IDENTIFICATION AND CARE MANAGEMENT IN VALUE-BASED INSURANCE PROGRAM

POSTERS: K01.A. DEMENTIA AND COGNITIVE DYFUNCTION: CAREGIVER SUPPORT

Zaldy Tan, Nabeel Qureshi, Erica Spivack, Nancy Sicotte
Cedars-Sinai Medical Center, Neurology, Los Angeles, United States of America

Aims: To assess the impact of a dementia care program on a value-based Medicare population.
Methods: In a large multi-specialty medical group practice, we identified patients enrolled in a value-based insurance program (Medicare Advantage) using the EPIC electronic health record (EHR). Patients were eligible to enroll in a care coordination program if they had an ICD-10 diagnosis of ADRD in the EHR problem list and/or past medical history, or currently taking an FDA-approved medication for ADRD. A study-assigned nurse practitioner (NP) identified the patient's medical, behavioral, and psychosocial needs using the novel CEDARS-6 dementia care tool to formulate and share a care plan with the patient's primary care provider. To evaluate patient and caregiver health status, we assessed patient behavior (NPI-Q), caregiver stress [Modified Caregiver Strain Index (MCSI)], and caregiver depression (PHQ-9) at baseline and at one year.
Results: We enrolled 195 (33.1%) of eligible patients, with non-responders to the invitation accounting for the majority (75%) of non-enrollees. The average age of enrollees was 81.3 (SD=9.16), 64.6% were female, and 81.2% identified English as their primary language. At baseline, patients scored an average NPI-Q Severity score of 10.40 (6.87), and an average NPI-Q Distress score of 13.80 (10.54). Preliminary data show decreases of 1.4 and 1.1 in NPI-Q Severity and Distress scores, respectively ($p>0.05$). Caregivers scored an average PHQ-9 score of 5.65 (5.28) and MCSI score of 10.62 (7.01). Preliminary data show decreases of 0.8 and 1.2 in PHQ-9 and MCSI, respectively ($p>0.05$).
Conclusions: PLWD proactively enrolled in a dementia care program have high baseline rates of behavioral issues and their caregivers have elevated depression and stress scores. It is important to track the longitudinal effects of the CARES dementia program on these measures.

THE BDSC-MCI PROJECT: BEHAVIORAL FINDINGS OF AN ECOLOGICAL TEST OF SPATIAL NAVIGATION

POSTERS: K01.B. DEMENTIA AND COGNITIVE DYFUNCTION: MOBILE APPLICATIONS, SOCIAL NETWORKS

Davide Cammisuli, Gianluca Castelnuovo
Catholic University of the Sacred Heart, Department Of Psychology, Milan, Italy

Aims: Spatial abilities are involved in everyday tasks such as wayfinding and learning the layout of a new environment. Particularly, spatial orientation (SO) mainly relies on egocentric/body-oriented navigation, allocentric/world-related navigation and path integration. Behavioral reports of SO can be provided by wearable bodies with sensors able to detect posture and movement beyond physiological parameters, such as those developed by Comftech, the Howdy Senior, a class II medical device that processes and trasmits data to a devoted smarthphone application. In this research, we aimed to detect impaired SO in a sample of patients with MCI due to AD when compared with healthy older adults and individuals with subjective cognitive decline.
Methods: 25 healthy controls, 25 individuals with SCI, and 26 patients with MCI *due to* AD were tested by a naturalistic task (The Detour Navigation Test-modified version, DMT-mv) in an urban area of Milan (Italy). Thanks to the use of Howdy Senior device, gait parameters in the ecological task were recorded. Specifically, 'Time' (number of minutes to complete the pre-established route), 'Latitude', 'Longitude', 'Altitude', 'Speed' (estimated by an integrated accelerometer for calculating steps variability), and 'Direction' were recordered. Moreover, a GPX tracking of participants' body movements were registered, too. Anova with post-hoc tests was performed among groups on these measures.
Results: Patients with MCI due to AD showed significant differences on Time and Speed variables than the other groups ($p<0.001$). GPX tracking also demonstrated a lower adherence of the return walk, calculated as higher "wrong turns" and "moments of hesitation" of the DNT-mv.
Conclusions: Patients with MCI due to AD present with gait impairment when they are requested to lear new paths of a novel environement through a continuous and non-invasive monitoring device.

USING IOT TECHNOLOGY AND POSITIONING SYSTEM TO ASSIST IN THE CARE AND MONITORING OF THE DAYCARE CENTER FOR DEMENTIA

POSTERS: K01.B. DEMENTIA AND COGNITIVE DYFUNCTION: MOBILE APPLICATIONS, SOCIAL NETWORKS

Wen Chien Hsieh
Kaohsiung Municipal Ta-Tung Hospital, Soical Work, Kaohsiung, Taiwan

Aims: In order to respond to the needs of the dementia elderly and their families in the community, Kaohsiung Municipal Ta-Tung Hospital cooperated with the Kaohsiung City Government, social administration and education system to officially open the Full-Love Daycare center in 2016 which located in elementary school; although it has successfully model for Taiwan, till now it also faces difficulties after its operation dilemma: (1) Space dilemma(2) Difficulties in caring manpower.(3) Limited participation of family members.
Methods: Using the integrated long-term care system for internal(staff) and external(families) users, divided into positioning system, smart measurement, institution management and family services:(1) Intelligent positioning system for accurate positioning and safe moving .(2) Smart measurement: introduce IoT technology, use the Bluetooth function of the physiological measurement equipment, and automatically transmit to the hospital outpatient system, and the doctor.(3) Institutional management structure: Using color-based visual management, the system will pop up a reminder window.(4) Family service structure: this function is connected with LINE.
Results: The result included:
1. The number of get-lost dementia elders declined from 3-7 per year to 0. 2. The error rate of transcription of measurement records declined from 3.4% to 0% 3. The on-time completion rate and completeness rate of the assessment records are 100%. 4. Information import of staff satisfaction 100%. 5. The overall satisfaction of family members of integrated long-term care system is 100%.
Conclusions: Long-term care is the global care trend in the future, and the elderly with dementia are increasing year by year. How to make the elderly with dementia receive dignified care requires the dedication of health care institutions. Changes in technology can create an efficient and dignified care model, and can also reduce the burden on family members.

DOVE: AN APP TO REDUCE GETTING LOST INCIDENTS IN PEOPLE WITH COGNITIVE IMPAIRMENT, PART I

POSTERS: K01.B. DEMENTIA AND COGNITIVE DYFUNCTION: MOBILE APPLICATIONS, SOCIAL NETWORKS

Ming-Chyi Pai[1], Yang-Cheng Lin[2], Ray-Bing Chen[3], Chi-Hsiang Chu[4], Jing-Jy Wang[5], Cai-Ying Jhou[1], Chih-Han Chang[6], Wei-Pin Hong[1]
[1]Medical College and Hospital, National Cheng Kung University, Neurology (behavioral Neurology), Tainan, Taiwan, [2]National Chung Kung University, Industrial Design, Tainan, Taiwan, [3]National Chung Kung University, Department Of Statistics And Institute Of Data Science, Tainan, Taiwan, [4]Tunghai University, Department Of Statistics, Taichung, Taiwan, [5]National Chung Kung University, Nursing, Tainan, Taiwan, [6]National Chung Kung University, Biomedical Engineering, Tainan, Taiwan

Aims: As spatial navigation impairment is frequently seen in people with dementia, and may result in unexpected injury or life threatening conditions, we designed an APP called DOVE to reduce incidents of getting lost (GL) or missing.
Methods: People with cognitive impairment or their caregivers were encouraged to join the DOVE and install it on mobile, including mild cognitive impairment (MCI), Alzheimer dementia (AD), Lewy body dementia (LB) and other dementia. Demographic, clinical status, the scenarios of GL/missing, and the consequences were collected. We inquired previous incidents and requested the users to report each new incident.
Results: From 1 Feb 2023 to 13 Sep 2023, 488 incidents of GL or missing were uploaded to cloud databank. Among them, GL occurred more often in CDR 0.5 group (104 vs 75) while missing more often in CDR 1.0 group (235 vs 74). Before joining the DOVE, the average occurrence of GL or missing of the patients was 1.54 times. The figure dropped to 0.10 after they joined the DOVE. Based on the individuals who have never experienced GL/missing, people diagnosed having AD with CDR 1.0 or more have an increased risk of GL (OR 3.20) compared with those having non-AD and CDR 0.5.
Conclusions: The marked reduction in GL/missing after the users joined the DOVE may be thanks to more attention paid by caregivers. Most of the users, however, did not report through their mobile APP until been inquired by clinicians in the clinic. More efforts must be put on to improve active reporting. We will provide safety guide and education materials for the users in the future and the beneficial effect on newly diagnosed patients is expected to be promising.

EFFECTIVENESS OF WALKING PRESCRIPTION USING MOBILE HEALTH TECHNOLOGY FOR THE OLDER ADULTS WITH COGNITIVE IMPAIRMENT: A RANDOMIZED CONTROLLED STUDY

POSTERS: K01.B. DEMENTIA AND COGNITIVE DYFUNCTION: MOBILE APPLICATIONS, SOCIAL NETWORKS

Hee Jung Kim, Yun Jung Hwang, Jee Eun Park, Dong Young Lee
Seoul National University College of Medicine, Psychiatry, Seoul, Korea, Republic of

Aims: This study aims to verify the effectiveness and feasibility of walking prescription using mobile health (mHealth) technology for older adults with cognitive impairment.
Methods: Sixty older adults with mild cognitive impairment or mild dementia who visited the memory clinic were enrolled (76.1±5.4 years; female, 56.7%). They were randomly assigned into three groups: group A was prescribed the goal of daily steps based on their telemonitored activity using a smart band; group B only wore a smart band without a prescription; group C took a monthly education to encourage their walking. We investigated the changes in daily steps (primary outcome), cognitive function, physical status, and depressive symptoms from baseline to post-intervention (12-week) and to follow-up (24-week). We examined the linear mixed effect models with factors of group, time, and their interaction. Post-hoc analyses using paired t-tests were also conducted.
Results: For group A, there was a significant group x time interaction effect on daily steps both at 12-week and 24-week (β [SE] = 2205.88 [672.34], p = .001; β [SE] = 2194.63 [884.33], p = .015), whereas, group B showed increased numbers of steps only at 12-week but not at 24-week. Group C showed a continuous decrease in daily steps during the study period. Among the secondary outcomes, cognitive function measured by the Mini-Mental State Examination (MMSE) was significantly different according to groups and times. Groups C showed a significant decrease in cognitive function both at 12-week and 24-week, however, group A and B showed stationary MMSE scores during 24 weeks.
Conclusions: Our findings suggest that walking prescription using mHealth technology is effective for increasing physical activities and for maintaining cognitive health in older adults with cognitive impairment.

DEVELOPMENT OF A WEARABLE DEVICE AIMED AT CHANGING THE COGNITIVE FUNCTIONS OF OLDER ADULTS BY MASTICATORY BEHAVIOR CHANGE

POSTERS: K01.B. DEMENTIA AND COGNITIVE DYFUNCTION: MOBILE APPLICATIONS, SOCIAL NETWORKS

Ma. Therese Sta. Maria[1,2], Yoko Hasegawa[1], Yukina Miyazaki[3], Tatsuya Suzuki[3], Ryo Takehara[3], Shogo Yoshimura[1], Kazuhiro Hori[1], Yumie Ono[4], Kensuke Yamamura[5], Takahiro Ono[6]
[1]Niigata University Graduate School of Medical and Dental Sciences, Division Of Comprehensive Prosthodontics, Niigata, Japan, [2]Faculty of Dentistry, Manila Central University, Department Of Prosthodontics, Caloocan, Philippines, [3]Graduate School of Science and Technology, Meiji University, Electrical Engineering Program, Kawasaki, Japan, [4]Meiji University, Department Of Electronics And Bioinformatics, School Of Science And Technology,, Kawasaki, Japan, [5]Niigata University Graduate School of Medical and Dental Sciences, Division Of Oral Physiology, Niigata, Japan, [6]Osaka Dental College School of Dentistry, Department Of Geriatric Dentistry, Osaka, Japan

Aims: Although there have been various reports on the relation between cognitive function and mastication, the effect of the habit of chewing well on cognitive function is not yet clear. Therefore, to clarify whether cognitive function is affected by changes in masticatory behavior, we conducted a clinical trial on older adults and attempted to create an algorithm that effectively improves cognitive function.
Methods: We enrolled 50 healthy older adults, aged 65 years and over, who were randomly allocated into intervention and control groups. The intervention group used a chewing counter (biteScan®, SHARP) with an algorithm that promotes positive masticatory behavior change during each meal for one month, while the control group ate meals without a chewing counter. Cognitive function, masticatory behavior, and body composition were evaluated twice, once at the initial visit and once 30 days later. We evaluated whether changes in masticatory behavior affect cognitive function in older adults using two-way ANOVA and post hoc tests.
Results: In older adults, even if the number of chews increased significantly in the intervention group using the chewing counter compared to the control group, their body composition did not change. In addition, the intervention group of older adults also scored significantly higher than the control group in the memory task at the follow-up evaluation. Functional near-infrared spectroscopy (fNIRS) measured brain activity during a cognitive task and found increased cortical activity in the dorsolateral prefrontal cortex in the group using the chewing counter.
Conclusions: These results suggest that using a chewing counter that promotes positive masticatory behavior change may be an effective way to change mastication behavior and may alter cognitive functions related to memory.

Aims: Due to socio-demographic changes, the dementia prevalence is increasing. The current lack of treatments that can halt cognitive deterioration, highlights the importance of dementia prevention. The landmark FINGER study showed that a multidomain lifestyle intervention has significant cognitive benefits in non-demented elderly. The LETHE pilot trial is testing an updated FINGER intervention, that is delivered in parts through digital tools that were co-designed with an Advisory Board comprising individuals at risk for or living with cognitive impairment or dementia.
Methods: The LETHE pilot study is a 24-month randomized controlled feasibility study conducted in Austria, Finland, Italy, and Sweden. Participants (aged 60-77 years) at risk for dementia but without significant cognitive impairment are enrolled. Participants are randomized 1:1 to intervention and control group. Participants in the intervention group participate in tailored in-person and digital intervention activities in six lifestyle domains (physical activity, nutrition, cognitive activity, cardiovascular risk factors, social engagement, and relaxation). In contrast, participants in the control group have exclusively access to educational content related to the aforementioned domains. Both study groups are equipped with Fitbit smartwatches for passive data collection. The primary outcomes of the study are feasibility and change in risk of dementia.
Results: At this stage, all clinical sites completed recruitment. Overall, 315 people were invited to screening visits. Of these 159/315 (50.4%) met the eligibility criteria and attended baseline visits,

eventually 156 participants were randomized. For the intervention group, both digital and face-to-face intervention activities have already started. First study results are expected in 2025.

Conclusions: To make intervention programs accessible to the general population, digital tools are needed. The LETHE pilot study will therefore test the feasibility of a digitally supported lifestyle intervention for older people.

SOCIAL SUPPORT IN DEMENTIA: A VALIDITY AND RELIABILITY STUDY OF PERSONAL RESOURCE QUESTIONNAIRE-2000 INDONESIA VERSION (PRQ-2000 INA) IN PEOPLE WITH DEMENTIA

POSTERS: K01.B. DEMENTIA AND COGNITIVE DYFUNCTION: MOBILE APPLICATIONS, SOCIAL NETWORKS

Amelia Nur Vidyanti[1], Rizqa Nafiati[1], Galenisa Putri[1], Astuti Prodjohardjono[1], Christantie Effendy[2]
[1]Faculty of Medicine, Universitas Gadjah Mada, Department Of Neurology, Yogyakarta, Indonesia, [2]Faculty of Medicine, Universitas Gadjah Mada, Department Of Surgical Nursing, Yogyakarta, Indonesia

Aims: Social support may affect the clinical outcomes of people with dementia. However, the study investigating the relationship between social support and cognitive functioning in dementia is still lacking due to limited instrument to measure social support. The Personal Resource Questionnaire (PRQ2000) is an instrument used to assess perceived social support in a wide range of populations. We aimed to assess the validity and reliability of the PRQ2000 Indonesia version (PRQ2000-INA) in people with mild to moderate dementia.
Methods: This study was a cross-sectional study. We conducted forward-backward translation of the questionnaire. Confirmatory factor analysis (CFA) was used for the validity test. The reliability test was determined by using Cronbach's alpha value.
Results: The PRQ2000-INA has 15 questions which are divided into 3 factor dimensions of social supports. The results of CFA test from 75 respondents showed that all questions in each factor of PRQ2000-INA were valid and had an acceptable construct validity to measure social support. The Cronbach's alpha values for factor 1, factor 2, and factor 3 were 0.903, 0.918, and 0.940, respectively, indicating a reliable instrument.
Conclusions: In conclusion, PRQ2000-INA had a good validity and reliability to measure social support in people with mild to moderate dementia. Future study is needed to investigate the role of social support in cognitive functioning in people with dementia.

PROJECT EWA – AI METHODS FOR EARLY AD/PD SYMPTOM DETECTION AND THE USE OF MOBILE TECHNOLOGIES FOR SCREENING

POSTERS: K01.B. DEMENTIA AND COGNITIVE DYFUNCTION: MOBILE APPLICATIONS, SOCIAL NETWORKS

Alfred Zimmermann[1], Eugen Ružický[2], Matej Škorvánek[3], Zuzana Képešiová[2], Nataliia Zozuk[4], Milan Rusko[5], Marián Trnka[5], Richard Malaschitz[1]
[1]AXON PRO Ltd., Ewa - Early Warning Of Alzheimer, Bratislava, Slovak Republic, [2]Pan-European University, Faculty Of Informatics, Bratislava, Slovak Republic, [3]P. J. Safarik University, University Hospital L. Pasteur, Košice, Slovak Republic, [4]Constantine the Philosopher University, Faculty Of Informatics, Nitra, Slovak Republic, [5]Slovak Academy of Sciences, Department Of Informatics, Bratislava, Slovak Republic

Aims: The aim of the project was to investigate the detection of symptoms of neurodegenerative diseases, especially AD and PD, by analysing the speech of the test subject. The results of the research were used to develop a mobile application in which a person names simple objects and activities that he or she sees in 40 consecutive images and describes a more complex scene within a 90-second time limit. The speech is then evaluated using AI methods and the result is communicated to the user in the app. The app also includes the option to participate in a longer-term tracking and cognitive training program.
Methods: The research part of the project established a methodology for identifying appropriate words and their associated images and established inclusion and exclusion criteria for participation in the project. This was followed by the recruitment of people diagnosed with AD and PD and the healthy control, which was in total over 1700 participants. The own developed ASR method was used to convert speech into text. Different types of acoustic, lexical and semantic parameters were extracted from the speech utterances to be used as an input vector for classifier. Different AI methods were also investigated for suitability for this task. The resulting classification was done by combining the results from the 6 AI methods.
Results: The classification results in the speech classification into one of four groups - healthy, AD, PD, unspecified disease, with the achieved relevance at the level of 90% specificity, 85% sensitivity and 93% accuracy. An application for long-term training of cognitive functions was also developed.
Conclusions: The developed application can serve as an excellent, inexpensive and easily accessible tool for screening the population for AD and PD.

FAMILIARIZATION SESSION MAY INCREASE TREATMENT SENSITIVITY: DATA FROM THE DEEP & FREQUENT PHENOTYPING STUDY IN PRODROMAL ALZHEIMER'S DISEASE USING CANTAB

POSTERS: K01.C. DEMENTIA AND COGNITIVE DYFUNCTION: COGNITIVE TRAINING

John Bernstein[1], Emily Thorp[1], Nathan Cashdollar[1], Francesca Cormack[1], Jennifer Lawson[2], Vanessa Raymont[2], Simon Lovestone[3], James Rowe[4], Barbara Sahakian[5]
[1]Cambridge Cognition, N/a, Cambridge, United Kingdom, [2]University of Oxford, Psychiatry, Oxford, United Kingdom, [3]Johnson & Johnson, Research & Development, New Brunswick, United States of America, [4]University of Cambridge, Clinical Neurosciences, John Van Geest Centre For Brain Repair, Cambridge, United Kingdom, [5]University of Cambridge, Psychiatry, Cambridge, United Kingdom

Aims: Objectives: The Cambridge Automated Neuropsychological Assessment Battery (CANTAB) is a set of computerized cognitive tasks employed primarily in clinical trials. Prior work suggests that inclusion of a familiarization session (initial completion of a task prior to baseline assessment) may enhance treatment sensitivity by reducing the likelihood that increases in performance from baseline to follow-up testing sessions are due to practice/test familiarity. This study examined the utility of a familiarization session when employing commonly-administered CANTAB tasks in repeat testing designs.
Methods: Methods: Participants (n = 207, 57% male, mean age = 71.5) were individuals enrolled in a prodromal Alzheimer's Disease (AD) observational study. Participants completed measures examining reaction time (Reaction Time (RTI)), visual learning and memory (Paired Associates Learning (PAL)), working memory/executive functioning (Spatial Working Memory (SWM)) and sustained attention (Rapid Visual Processing (RVP)). Tests were completed at screening (familiarization), baseline (within one week of familiarization), 1-month, 2-month, 8-month and 10-month timepoints. Pearson correlation coefficients examined associations between subsequent time points for each task (e.g., familiarization vs. baseline, baseline vs. 1-month, etc.)
Results: Results: PAL and SWM performance at familiarization was only modestly correlated with performance at baseline (r = .45 and r = .44, respectively); however, correlations between subsequent time points for these tasks was moderate to strong (r ranges = .55 to .83 and .74 to .76, respectively), suggesting a potential benefit of familiarization session inclusion. RTI and RVP performance was strong across timepoints (r ranges = .84 to .89 and .70 to .93, respectively).
Conclusions: Conclusions: A familiarization session is useful in limiting practice effects on several CANTAB tasks, including the PAL and SWM. CANTAB tasks show good stability over a ten-month period and are suitable for longitudinal geriatric clinical trials.

THE BDSC-MCI PROJECT: IMPLEMENTATION OF A SPATIAL NAVIGATION VIRTUAL TRAINING IN INDIVIDUALS AT HIGH RISK OF DEVELOPING ALZHEIMER'S DISEASE

POSTERS: K01.C. DEMENTIA AND COGNITIVE DYFUNCTION: COGNITIVE TRAINING

Davide Cammisuli, Gianluca Castelnuovo
Catholic University of the Sacred Heart, Department Of Psychology, Milan, Italy

Aims: Spatial navigation (SN) impairment in Alzheimer's Disease (AD), such as disorientation or even getting lost, is often overshadowed by the most ascertained episodic memory defect. However, deficits in spatial orientation appear early in the course of AD, and we already provided evidence of a specific deficit of pure path integration in genetic risk carriers. In this study, we aimed at ameliorating spatial navigation (SN) performance in higher risk subgroups (amyloid-positive MCI patients and APOE-e4 carriers) by combined sessions of computer-based cognitive remediation and virtual reality.
Methods: Three amyloid-positive MCI patients and two individual carrying the APOE-ε4 allele underwent a combined intervention of computer-based (CB) sessions of spatial memory tasks by the Erica© software (Giunti, Florence, Italy) and VR navigation sessions by the NeuroVirtual 3D software in order to improve spatial memory for landmarks location and mental frame syncing for supporting spatial scenarios. The intervention will last one month for a total of 12 sessions (3 days a week, 50 minutes *per* session). In the CB spatial memory task, the patient has to memorize a certain number of target figures and their position within a grid of variable dimensions. For the encoding phase of the NeuroVirtual 3D task, participants are instructed to memorize the position of an object in a virtual city. Then, in the retrieval phase, participants have to indicate the position of the object from another start position. Participants were tested after and before the training by the Corsi learning suvra-span. Results were analyzed by a Wilcoxon non-parametric test.
Results: Participants improved on the Corsi learning suvra-span ($p<0.05$).
Conclusions: We estimate the impact of the present rehabilitation training in terms of SN amelioration in senior citizens at higher risk, with relevant implications for independent spatial orientation in everyday activities.

Aims: Age-related cognitive decline increases the need for cognitive interventions. Cognitive training is considered an effective non pharmacological intervention. Transfer of training gains to untrained tasks is a key indicator for the effectiveness of cognitive training. The underlying brain mechanisms need to be further investigated. We assessed functional connectivity determinants of transfer of training gains.
Methods: 181 healthy older adults (mean age:68 years) underwent a 4-week cognitive training across 3 sites. The control group consisted of 54 older adults. To evaluate transfer and training effects, participants underwent a neuropsychological assessment before and after the training. A second follow-up assessment was applied 12 weeks after the training. The training group was divided in subjects who had and who didn´t have successful transfer. We used composite scores representing working memory, memory and executive functions to assess transfer and training effects. Baseline resting-state functional magnetic resonance imaging was used to investigate functional connectivity of brain networks. We extracted brain resting state networks using Independent Component Analysis(ICA).
Results: We observed successful transfer of cognitive training gains in most of the participants. Our results demonstrated spatially restricted effects ($p < .01$ uncorrected) for the association of transfer of gains with the resting-state connectivity of brain networks.
Conclusions: Transfer of training gains in aging is possible. A strong association between transfer of gains and resting-state functional connectivity of networks was not identified.

WALKING PATTERNS, EQUILIBRIUM, COGNITIVE FUNCTION, AND INCIDENTS OF FALLS AMONG PARKINSON'S DISEASE PATIENTS IN NIGERIA

POSTERS: K01.C. DEMENTIA AND COGNITIVE DYFUNCTION: COGNITIVE TRAINING

Temitope Farombi[1], Olufisayo Elugbadebo[2], Rufus Akinyemi[3], Adesola Ogunniyi[4]
[1]University of Ibadan, Chief Tony Anenih Geriatric Center, Ibadan, Nigeria, [2]University of Ibadan, Geriatric Psychiatry, Ibadan, Nigeria, [3]University of Ibadan, Institute Of Medical Research And Training, Ibadan, Nigeria, [4]University of Ibadan, Department Of Medicine, Ibadan, Nigeria

Aims: Background: Falls in Parkinson's disease (PD) patients were thought to result from failure of motor mechanism in the central nervous system. Recent studies showed possibke association between cognitive dysfunction, gait abnormality and fall in PD Patients. However, it is not clear if ti is an independent risk factor or if its effect on falls is associated with gait abnormality. We studied this possible association between cognitive impairment and fall rate in PD patients.
Methods: Materials and Methods: This descriptive study was conducted among PD patients at the University College Hospital, Ibadna. Diagnosed PD were assessed for risk factors and frequency of falls using Tinneti gait and balance test, Hoehn and Yahr severity scale, Unified Parkinson's Disease Rating Scale (UPDRS). Timed-Up and Go tests and modified Community Screening Instrument for Dementia (CSI'D').
Results: Seventy-eight PDs were screened using the above tools. Of these patients, 40.3% experienced falls since the onset of the disease, with 74.1% having > 2 fall episodes in the last one year. Disease duration was significantly longer in the fallers (p= 0.001), with significant difference in Tinetti Balance (p= 0.004), Hoehn and Yahr (p=0.001), UPDRS (p=0.001), Geriatric Depression Scale (p=0.050) and CSID score when compared to non- fallers (p=0.034). Daily life disabilty was the only independent predictor of fall after a multivariate logistic regression was modelled.
Conclusions: Conclusion: PD patients with cognitive impairment fell more when compared with cognitively intact PD patients. However, daily life disabilty was the only significant factor associated with fall in PD Patients. Improving cognition might not improve the fasll rate

Aims: Roche Rater Academy (RRA) is a grass roots wide initiative that aims to improve scientific validity of clinical study endpoints in trials whilst increasing site productivity and improving rater training quality to ultimately improve the regulatory rigor of clinical trial submissions whilst supporting sites to upskill and diversify their qualified site raters.
Methods: A novel methodology was developed to select, calibrate, train and certify site rater's key for clinical endpoint data. The methodology is a holistic solution with fit for purpose training pathways designed to reduce site burden in tailored training to match rater's experience and enable upskilling of site raters reflective of their community. The solution embeds site feedback in an iterative approach to increase productivity by accelerating site start-up through a novel site centric approach to rater training, which removes previous bottlenecks in site activation and enrollment.
Results: With this innovative methodology we aim to improve Clinical Outcome Assessments data quality through gold standard rater training and certification pathways. RRA reduces site burden by tailored training to match rater's experience and accelerate study start up by removing bottlenecks in rater qualification. This will also develop a library of eCOA trainings which are more diverse in real clinical cases. The pilot study has been launched in AD and this model is scalable across indications in Neurodegenerative, Neuromuscular & Neuroimmunology trials.
Conclusions: The RRA is a novel approach to training and certifying site raters, which reduces rater related start up timelines by ∼25% and burden on study teams while enabling sites to upskill and diversify their site raters.

ENHANCING COGNITIVE SKILLS IN HEALTHY INDIVIDUALS THROUGH FIDGET SPINNERS: AN INTERVENTIONAL STUDY

POSTERS: K01.C. DEMENTIA AND COGNITIVE DYFUNCTION: COGNITIVE TRAINING

Yogesh Kumar, Ratandeep Biswas, Ruchi Rani
All India Institute of Medical Sciences Patna, Physiology, patna, India

Aims: 1) Assess the cognitive impact of consistent fidget spinner use. 2) Measure improvements in diverse cognitive functions. 3) Explore sustained effects after usage. 4) Investigate correlations with baseline cognitive abilities.
Methods: In this study, a cohort of 30 individuals characterized by good health was meticulously chosen. After establishing baseline scores through an array of cognitive function assessments, these participants underwent these evaluations both before and after a specific intervention – the daily utilization of fidget spinners – over a span of 9 days within three weeks. Following this intervention phase, a conclusive assessment was conducted. Subsequently, a follow-up evaluation was executed three weeks after discontinuation of fidget spinner usage.
Results: Significant enhancements were noted in scores of the digit symbol matching test, picture pairs test, multiple object track test, and fast choice test, both progressively over the study period and after the implementation of the fidget spinner intervention. Conversely, the matrix reasoning, fast reactions, and paced serial addition tests displayed nominal alterations. Importantly, a sustained effect was manifest in the follow-up scores, highlighting the persistence of these improvements in comparison to the baseline and end-assessment values.
Conclusions: While discernible changes were not observed in fluid intelligence and response speed, the practice of using fidget spinners elicited a consistent amelioration in processing speed, visual episodic memory, working memory, visuospatial attention, and inhibitory control. This phenomenon might be attributed to the demand for enhanced hand-eye coordination, allocation of attentional resources, and a reduction in spontaneous thought wandering imposed by fidget spinner usage. The findings underscore the potential benefits of regular fidget spinner engagement in augmenting diverse cognitive domains, thus holding promise for a wide spectrum of individuals.

IMPROVING HUMAN MEMORY THROUGH VOLITIONAL CONTROL OF HIPPOCAMPAL THETA OSCILLATIONS

POSTERS: K01.C. DEMENTIA AND COGNITIVE DYFUNCTION: COGNITIVE TRAINING

Vandana Prasad[1,2], Kramay Patel[2,3], Chaim Katz[2,4], Taufik Valiante[1,2,5]
[1]University of Toronto, Electrical And Computer Engineering, TORONTO, Canada, [2]Krembil Brain Institute, Toronto Western Hospital, TORONTO, Canada, [3]University of Toronto, Faculty Of Medicine, TORONTO, Canada, [4]University of Calgary, Faculty Of Medicine, Calgary, Canada, [5]University of Toronto, Division Of Neurosurgery, Toronto, Canada

Aims: Neurofeedback is a technique that allows individuals to control brain oscillations with incredible specificity and precision volitionally. Theta oscillations (3–8 Hz) are modulated during the encoding and retrieval of memories. We want to know if memory can be improved through neurofeedback up-regulation of theta oscillations. We will explore this question by increasing the power of hippocampal theta through neurofeedback before presenting a visual stimulus and determine if this improves the recollection of that stimulus.
Methods: Six individuals with drug-resistant epilepsy undergoing intracranial recordings were presented with a neurofeedback task designed to upregulate and downregulate theta rhythms. The study included recognition and associative memory components and presented visual stimuli following successful up-or-down-regulation of theta rhythms. The downregulation trials served as a control condition. After a brief distraction task, a combination of previously shown and new stimuli was presented and tested for recognition and associative memory performance.
Results: Preliminary results demonstrate the successful modulation of theta oscillations, as evidenced by observed theta power changes and reduced task completion times across consecutive trials. However, we did not observe a significant improvement in memory performance. Notably, these theta oscillation changes were localized to the electrode site used for neurofeedback training. Given the well-established fact that memory processes involve a distributed network of brain regions, this localized effect may explain the absence of consistent memory enhancement. Nevertheless, our findings offer initial evidence supporting the feasibility of volitionally enhancing hippocampal theta oscillations.
Conclusions: The present study provides evidence that individuals can volitionally control the amplitude of their hippocampal theta oscillation, modulated during human memory encoding and retrieval. These data thus represent critical first steps in understanding how neurofeedback could enhance memory formation and the possible development of novel neuroprosthetics.

FACTORS INFLUENCING THE SUCCESS OF SMARTWATCH BASED INTERVENTIONS IN PATIENTS WITH MCI OR DEMENTIA IN A CONTROLLED ENVIRONMENT

POSTERS: K01.D. DEMENTIA AND COGNITIVE DYFUNCTION: SUPPORT DEVICES & MONITORING

Doreen Goerss[1,2], Stefanie Köhler[2], Eleonora Rong[1], Gerald Bieber[3], Stefan Teipel[1]
[1]Rostock University Medical Center, Department Of Psychosomatic Medicine, Rostock, Germany, [2]DZNE, Clinical Dementia Research, Rostock, Germany, [3]Fraunhofer, Igd, Rostock, Germany

Aims: Assistive technologies show promising features to support people with cognitive impairment in daily life. Direct interaction of people with cognitive impairment with smartwatches is little investigated. We examined which factors influence the success of smartwatch-delivered interventions.
Methods: We designed two tasks delivered by smartwatch: A) drinking water and B) circling bells on a worksheet. We created two modes of intervention-intensity affecting vibration, alarm sounds, text sizes and images. In case of failure, interventions were repeated up to three times. We observed n=40 patients' reactions to interventions remotely via cameras and rated success on a 5-step scale from 0 to 2. Patients were assigned (n=20/20) either to mode "regular" or mode "intensive". They answered questionnaires, underwent neuropsychological testing and were diagnosed with MCI (n=12) or dementia (n=28). We hypothesized that affinity for technology (ATI) and cognitive status (MMSE) would influence the success of the interventions. We also expected that intensive interventions would be more successful than regular interventions.
Results: The groups statistically did not differ with respect to mean age, MMSE or ATI. The intensive group was more successful than regular group; for each task and the global success score (mean 1.7 vs. 1.2, Welch t-test p=0.03). Sequential testing of linear regression models showed that "mode" significantly increases model fit: $H_{1\ age + sex + MMSE + ATI + mode}$ p=0.03 and adjusted R^2=21% vs. $H_{0\ age + sex + MMSE + ATI}$ p=0.31 and adjusted R^2=2,7%.
Conclusions: Tasks delivered from a smartwatch as intensive interventions are more likely to be solved by patients than regularly delivered ones. Intensity is more critical than the patient's baseline status with respect to cognition and technology-affinity.

MEASURING SOCIAL INTERACTION BETWEEN PATIENT AND CARER

POSTERS: K01.D. DEMENTIA AND COGNITIVE DYFUNCTION: SUPPORT DEVICES & MONITORING

Derek Hill[1,2], Kate Mcleish[3], Jeremy Roche[3], Wan-Tai Au-Yeung[4], Jeff Kaye[4]
[1]University College London, Biomedical Engineering, London, United Kingdom, [2]Panoramic Digital Health SASU, R&d, ST PIERRE DE CHARTREUSE, France, [3]Panoramic Digital Health, R&d, SAINT PIERRE DE CHARTREUSE, France, [4]Oregon Health & Science University, Oregon Center For Aging And Technology (orcatech), Portland, United States of America

Aims: To measure social interaction in people with AD/PD using Digital Health Technologies.
Methods: This wearable platform comprises a *sensor bracelet* and *environment beacons* that can measure a patient's social interaction with a carer as well as sleep and activities. Environmental beacons are placed where the patient spends most of their time (eg: bedroom, living room, kitchen, bathroom). They contain environment sensors (temperautre, light level, noise level) and transmit these values over Bluetooth at 1.2Hz. The bracelet contains sensors (accelerometer, gyroscope, magnetometer, pressure sensor), listens to the beacon transmissions, and labels the bracelet sensor values with the signal strength of each beacon and the values of the environment sensors. The combined data is analyzed to calculate outputs including sleep time, daytime activity levels, and the location of the wearer through out the day. When no beacons are visible, the wearer is determined to be away from their home. Where a patient and carer both wear a bracelet, their relative location is derived to calculate measures of social interaction eg: how much time per day the patient is in the same room as their carer, in the same house but different room, either away from home or both away from home. Battery life between charging is 2 weeks..
Results: Example sensor output is shown in Fig 1 and summarised in Fig 2. Social interaction data can be associated with the raw data or activity level data for more fine grain analysis. Environment sensor values can control for impact of eg: room temperature on measurements.

Figure 1: Raw data view for participant A, combining Accelerometer data and RSSI from Bluetooth beacons

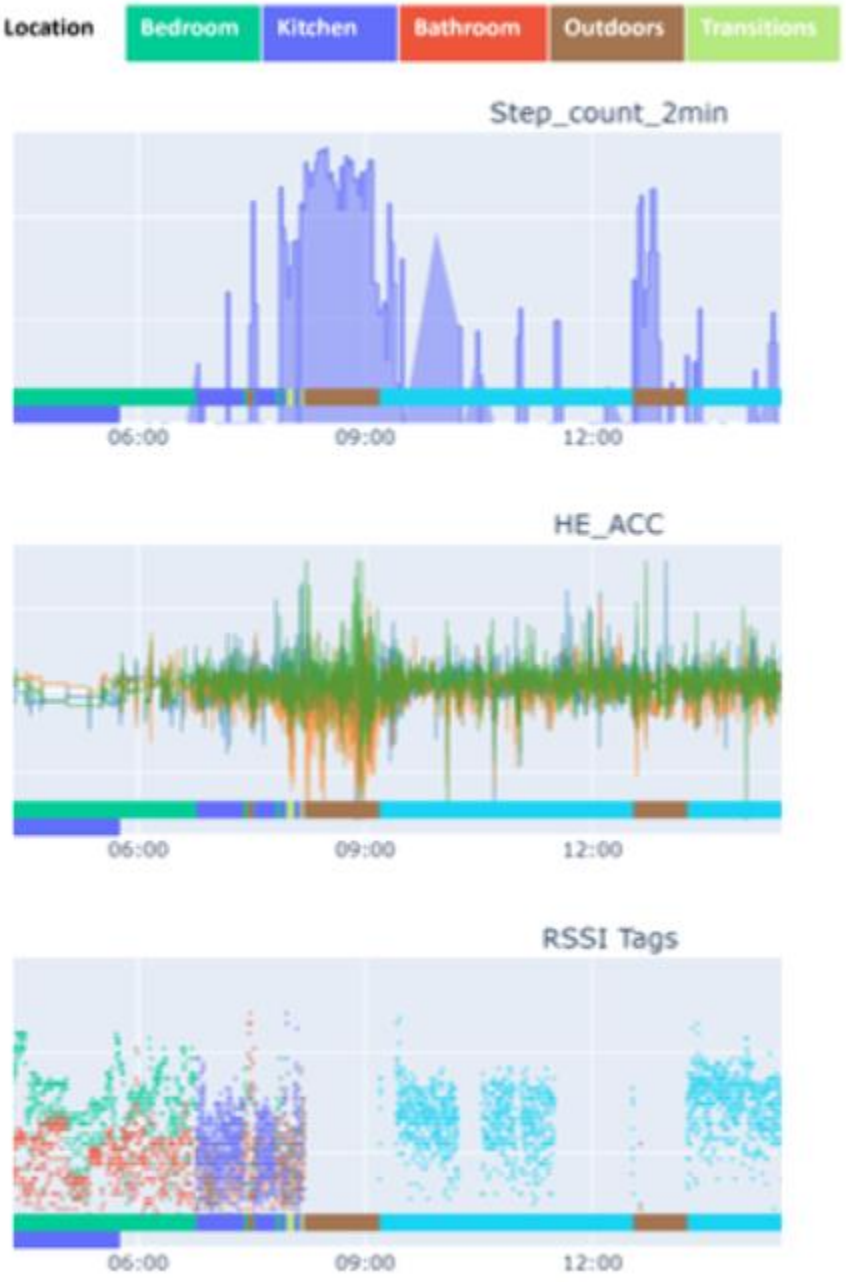

Figure 2: Time two participants, A and B, are together by hour (below) and daily summary (right)

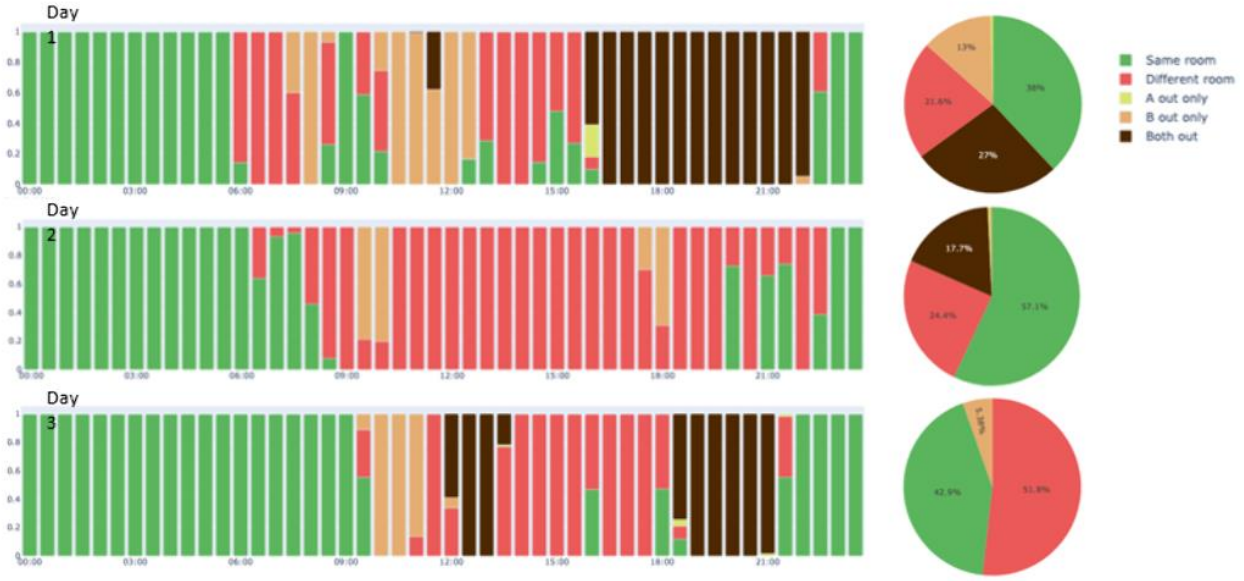

Conclusions: We presented a wearable platform to measure social interaction as well as activites and behaviours to provide more detailed assessment of functioning of AD/PD patients in the home setting.

Aims: Automated speech recording via telephone using a chatbot technology and AI-driven speech analysis would enable resource-saving cognitive assessment for people with cognitive decline. To extract reliable digital speech biomarkers through a chatbot it needs to be adapted to the users' needs. Here, we implemented a user centered design approach to evaluate usability of a phone-based chatbot system for automated speech assessments for people with prodromal or preclinical Alzheimer's disease (AD).
Methods: Within the study PROSPECT-AD, participants of ongoing national cohort studies are automatically called for six times every three months by our chatbot "Mili". To date, 189 participants have been recruited out of 300 planned cases through September 2023. Each call consists of three cognitive tasks (Wordlist, Semantic Verbal Fluency, Story Telling). We applied a six-stage usability check for Mili. For deeper insights regarding the chatbot's usability, we conducted semi-structured interviews (n=22).
Results: To date, Mili has completed 356 assessments. The SUS revealed a good usability for Mili (n=140, Age: Ø=72.6, SD=6.6, SUS: 69.3/100, SD=22.2). Interviewees perceived the Wordlist without visual input as challenging. However, some wished for variety in the tasks. Additionally, two participants reported frustration as they did not have a positive event to report (Story Telling). Some interviewees preferred a more human like chatbot, while others perceived Mili as a human being. All interviewees wished for feedback regarding their performance.
Conclusions: Our results revealed a high usability and feasibility of the automated phone calls by Mili. Socially intelligent chatbots may be able to address emotional strain during cognitive assessments. Furthermore, based on our usability data, we would aim for an adequate feedback system for the participants regarding their cognitive performance.

A COMPUTER SIMULATION MODEL TO PREDICT COGNITIVE IMPAIRMENT

POSTERS: K01.D. DEMENTIA AND COGNITIVE DYFUNCTION: SUPPORT DEVICES & MONITORING

Lewis Mehl-Madrona[1], Barbara Mainguy[2]
[1]Northern Light Acadia Hospital, Psychiatric Residency, Bangor, United States of America, [2]University of Maine, Intermedia, Orono, United States of America

Aims: Modifiable factors related to cognitive impairment and neurocognitive disorders (and their avoidance) are well recognized.
Methods: We designed a system's dynamics computer simulation model to predict the onset of cognitive impairment given data across the person's entire life. The model allows for studying multiple, interacting variables and an interactive patient and family motivational tool. The simulation model aims to portray the time course for a person to develop cognitive impairment and to progress to major neurocognitive disorder. It incorporated the role of exercise, genetic load, age, quality of diet, presence of diabetes and level of hemoglobin A1C, ongoing levels of cognitive stimulation, presence or absence of micronutrients, presence or absence of other co-morbidities, overall general health index, levels of smoking and other substance use, and family history. The model is based upon available data on individual risk factors with extrapolated interaction relationships. It was built with data on the life course of 14 individuals, adjusting parameters to make correct predictions for all people. Then we entered the data from another 18 people to determine how accurate the model would be with new individuals for whom it had not been developed. We defined success as a prediction of onset within 10% of the actual date and a prediction of the slope of the trend within 20%.
Results: We had 11 successes. We then modeled an additional 18 people, asking them what they would be willing to change to alter their predictions. We then re-ran the model using the changed variables to show what difference altering these factors could make. Thirteen indicated willingness.
Conclusions: Interaction with computer simulation models can provide tools of persuasion to overcome difficulties inherent in people changing their modifiable risk factors.

EARLY DETECTION OF MILD COGNITIVE IMPAIRMENT USING AN EYE-TRACKING TECHNOLOGY

POSTERS: K01.D. DEMENTIA AND COGNITIVE DYFUNCTION: SUPPORT DEVICES & MONITORING

Shin Teshirogi[1,2], Yuki Ito[1,3], Sho Yamamoto[1,2], Mizuki Katsuhisa[1,3], Yuya Ikegawa[1,3], Shuko Takeda[1,3]
[1]Osaka Psychiatric Research Cente, Osaka Psychiatric Medical Center, Hirakata, Japan, [2]Geriatric and General Medicine, Osaka University Graduate School Of Medicine, Suita City, Osaka Prefecture, Japan, [3]Department of Clinical Gene Therapy, Graduate School Of Medicine, Suita, Japan

Aims: The literature suggests that an early diagnosis and timely intervention can be effective for preventing dementia. Neuropsychological tests are commonly used to detect cognitive impairment; however, they are not sufficiently simple and rapid enough for use as routine screening tools in clinical settings. We previously reported a newly developed eye-tracking-based cognitive assessment (ETCA) tool (Oyama et al., *Scientific Reports* 2019) and demonstrated that ETCA scores are highly correlated with MMSE scores and show high diagnostic performance for dementia. In this study, we examined the ETCA's performance and utility in subjects with MCI and in cognitively normal individuals.
Methods: We assessed 94 participants using both the ETCA and traditional neuropsychological tests, including the MMSE, ACE-III, and RBMT, on the same day. The participants' mean age was 61.0 (SD 13.1), with a range of 40 to 91 (62 women and 32 men).
Results: The participants had relatively high scores on the neuropsychological tests, with mean values of 28.3 (SD 2.2) for the MMSE, 90.6 (SD 0.8) for the ACE-III, and 19.2 (SD 4.5) for the RBMT. Their ETCA scores were significantly correlated with the MMSE ($r = 0.443$), ACE-III ($r = 0.607$), and RBMT ($r = 0.595$) scores ($p < 0.0001$, Pearson). In subjects with an MMSE score of 24 or higher (the $27 \leq$ MMSE subgroup), the ETCA score showed statistically significant correlations with their ACE-III ($r = 0.556$) and RBMT ($r = 0.565$) scores, ($p < 0.0001$, Pearson).
Conclusions: The ETCA was able to detect a slight decline in the cognitive function in subjects with relatively preserved cognitive performance. The ECTA may provide a new platform for a sensitive detection of MCI or dementia.

USING ELECTROENCEPHALOGRAPHY TO GRADE DEMENTIA SEVERITY

POSTERS: K01.D. DEMENTIA AND COGNITIVE DYFUNCTION: SUPPORT DEVICES & MONITORING

Chang-Yu Chen[1], Tzu-Chao Lin[2,3], Yuan-Han Yang[1,3,4,5]
[1]Kaohsiung Medical University, Post-baccalaureate Medicine, Kaohsiung City, Taiwan, [2]Kaohsiung Municipal Siaogang Hospital, Department Of Neurology, Kaohsiung City, Taiwan, [3]Kaohsiung Medical University, Neuroscience Research Center, Kaohsiung City, Taiwan, [4]Kaohsiung Municipal Ta-Tung Hospital, Department Of Neurology, Kaohsiung City, Taiwan, [5]Kaohsiung Municipal Ta-Tung Hospital, Memory & Aging Center, Kaohsiung City, Taiwan

Aims: Current treatments and researches have raised the importance of biological approaches to early stage of Alzheimer's dementia (AD) for better therapeutic outcome. Electroencephalography (EEG) is regarded as a functional evaluation for AD, but the relationships between EEG and dementia with various stages were not well defined. In this study, we will compute EEG to dementia severities to provide more clinical applications.
Methods: A longitudinal study to recruit clinically diagnosed AD patients by NINCDS-ADRDA criteria with EEG performed every 6 months and the annual neuropsychological assessments including clinical dementiarating (CDR), cognitive ability screening instrument (CASI), and neuropsychiatric inventory (NPI) has conducted. Severity of dementia was regarded as global CDR. EEG contained 19 electrodes to receive 8 different frequency brain waveforms has been used to extract significant features with XGBoost (eXtreme Gradient Boosting) for computing.
Results: In total, 404 AD patients with CDR0.5=102, very mild stage, CDR1=234, mild stage, CDR2=63, moderate stage, and CDR3=5, severe stage have been recruited into statistical analysis. EEG's 152 features of a patient were extracted to compute the associations among dementia severity through XGBoost. For identifying CDR=0.5, compared to other stages, this proposed method can make a successful prediction of accuracy and precision up to 81.48% and 72.73%, respectively.
Conclusions: We have successfully identified very mild dementia using EEG waveforms and CDR score in XGBoost model with the accuracy and precision of 81.48% and 72.73%. The extracted critical features in brain waves could be selected as key parameters to identify dementia patient at the early stage in the future clinical applications.

NURSE SCREENING FOR VISION AND HEARING LOSS IN OLDER ADULTS WITH DEMENTIA LIVING LONG-TERM CARE

POSTERS: K01.E. DEMENTIA AND COGNITIVE DYFUNCTION: QUALITY OF LIFE

Fiona Höbler[1], Walter Wittich[2], Katherine Mcgilton[1,3]
[1]KITE Research Institute, Toronto Rehabilitation Institute – University Health Network, Research, Toronto, Canada, [2]Université de Montréal, École D'optométrie, Montréal, Canada, [3]University of Toronto, Lawrence S. Bloomberg Faculty Of Nursing, Toronto, Canada

Aims: Sensory impairments, including vision and hearing loss, become increasingly prevalent with older age, and are most prevalent among adults with dementia. In the long-term care (LTC) setting, combined vision, hearing, and cognitive impairment has been found in 30% of residents and is associated with expressive and receptive communication difficulties, and can negatively impact a resident's quality of care. We aimed at assessing the sensibility of sensory screening tools and strategies that could be used by nurses in LTC to detect vision and hearing loss in residents with dementia.
Methods: Environmental scans were first conducted with sensory specialists and LTC nurses to identify tools and strategies currently in use with older adults who have dementia. The results of these scans informed the selection of hearing and vision screening measures which were trialed by nurses and evaluated for their sensibility of use with residents in the LTC setting.
Results: Nurses expressed the need for timely and standardized screening for the early detection of sensory loss and the appropriate provision of interventions to maximize residents' quality of life. The most sensible screening tools, as evaluated by nurses, included otoscopic examination, vision and hearing history questionnaires, a test of pure-tone audiometry, as well as finger counting and hand motion measures.
Conclusions: These findings indicate that education on and implementation of sensory screening are feasible and acceptable to nurses caring for residents who have dementia. The timely identification and treatment of sensory loss in LTC residents living with dementia can support communication, help prevent social isolation, and thus enhance residents' quality of life.

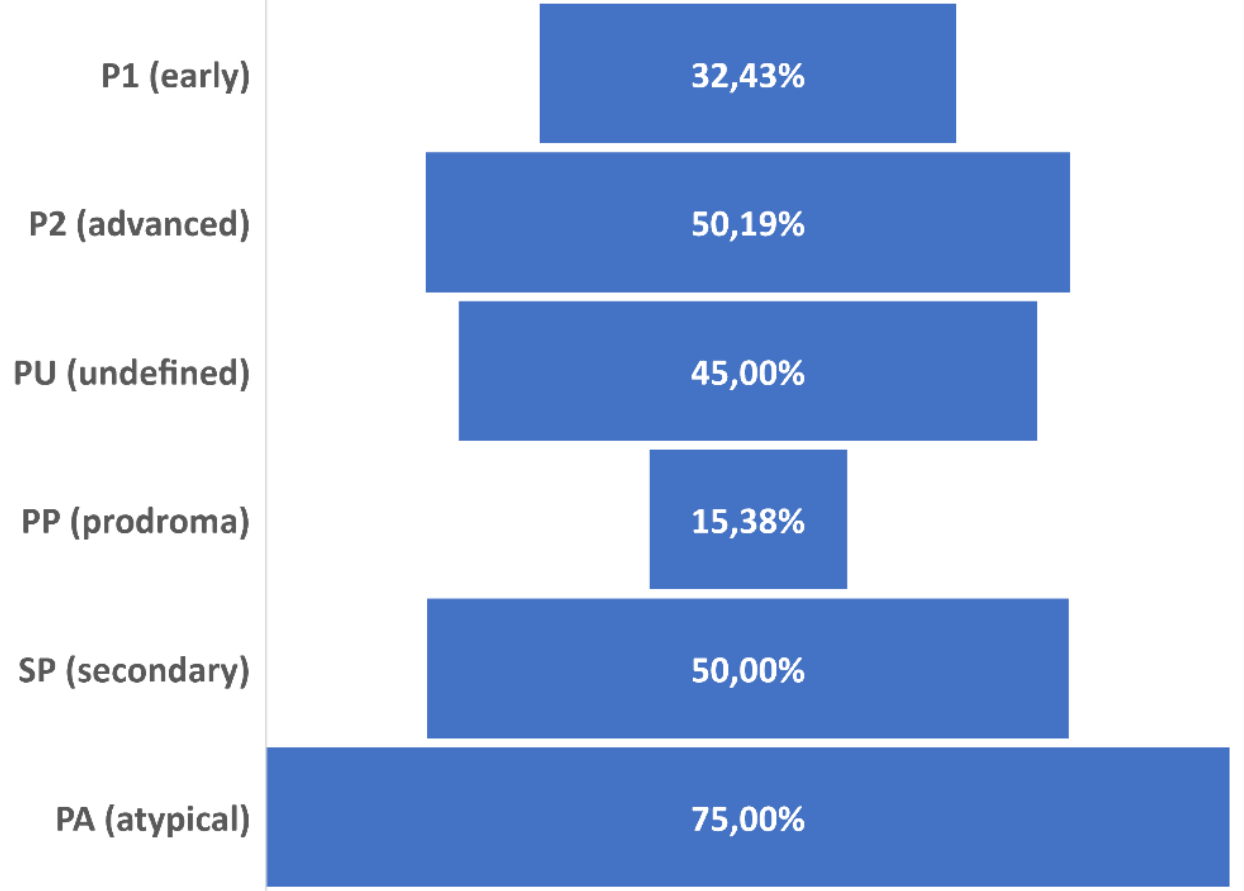
VHI-10 AND COGNITIVE DYSFUNCTION - RELATIONSHIP AND APPROPRIATENESS OF USE IN PATIENTS WITH PARKINSON'S DISEASE

POSTERS: K01.E. DEMENTIA AND COGNITIVE DYFUNCTION: QUALITY OF LIFE

Diana Khasanova[1], Ildar Khasanov[2], Zuleykha Zalyalova[1]
[1]Republican Centre for Movement Disorders, Republican Centre For Movement Disorders, Kazan, Russian Federation, [2]LLC Brainphone, Llc Brainphone, Kazan, Russian Federation

Aims: The aim of the study was to assess the impact of cognitive impairment on the possibility of using Voice Handicap Index - 10 scale (VHI-10) as a tool for voice disorders evaluation in Parkinson's disease patients. The work was carried out within the framework of BRAINPHONE project for voice assessment with artificial intelligence (AI). Data was collected in the form of a continuous sample manner in the period from December 2022 to May 2023 in the Centre for Movement Disorders, Kazan, Tatarstan Republic.
Methods: Patients were selected in continuous sampling mannerd. All patients underwent cognitive testing using MOCA test and the VHI-10 scale. All patients were stratified into 5 groups: P1 - patients with 1-2 stages (Hoehn&Yahr), P2 - patients with 3-5 stages (Hoehn&Yahr), PA - patients with parkinsonism-plus syndroms, PU - patients with parkinsonism that cannot be classified on the first visit into one of the groups, PP - patients without obvious motor parkinsonian signs, but meet the criteria of prodromal Parkinson's disease according to MDS Prodromal PD Calculator. All patients were assessed by 2 experienced parkinsonologists.
Results: The study involved 433 subjects with Parkinson's disease, subjective speech impairment reported 46% of respondents (Figure
1).



197 subjects completed both the MOCA test and the VHI-10. Parameters stratified by group are presented in Table 1.

Group	Age (y)	PD duration (y)	MDS-UPDRS	MOCA	Sum_VHI-10	MOCA-VHI-10 correlation coeff.
P1	64.14	3.18	29.14	23.35	8.17	0.05
P2	69.73	6.45	46.26	20.27	12.71	-0.15
PA	67.50	3.9	42.11	15.00	12.67	-0.62
PU	60.64	3.73	31.11	21.64	14.27	0.46
PP	61.95	0.52	12.85	23.57	4.17	0.03
Total	66.49	5.3	40.38	21.31	10.49	-0.15

Conclusions: The relationship between cognitive status and speech impairment assessment is not statistically significant.

Aims: Progression of Alzheimer's disease (AD) leads to a decline in the ability to perform activities of daily living (ADL) and increased dependence on caregiver support. The objective of this study is to assess changes in ADL among US Veterans with AD in the Veterans Affairs Healthcare System (VAHS).
Methods: Veterans with an AD clinical note in fiscal years 2010-2019 and a test result from Mini Mental State Examination (MMSE) or Montreal Cognitive Assessment (MoCA) were included in the study. Severity of AD was classified into 5 levels. Three scales used to assess ADL in the VAHS and a general linear model was used to evaluate association of AD severity with ADL measures.
Results: The overall study population included 36,164 Veterans with MMSE/MoCA and ADL scores. 6,514 Veterans were assessed using the 6-pt Basic ADL (Bas-ADL) scale, 17,297 Veterans were assessed using the 8-pt Instrumental ADL (Ins-ADL) scale, and 31,198 Veterans were assessed using the 18-pt Independence ADL (Ind-ADL) scale. The mean(SD) Bas-ADL score for Veterans with an MMSE/MoCA score within the Normal, MCI, Mild AD, Moderate AD, and Severe AD range were 4.6(2.0), 4.4(2.1), 4.2(2.2), 3.5(2.4), and 3.6(2.4), respectively. Ins-ADL and Ind-ADL scores showed similar trends. Analysis showed that increasing severity was associated with ADL scores across all 3 ADL scales ($p<0.0001$).
Conclusions: The decline of independence assessed by three ADL scales utilized in the VAHS are associated with progression of AD severity

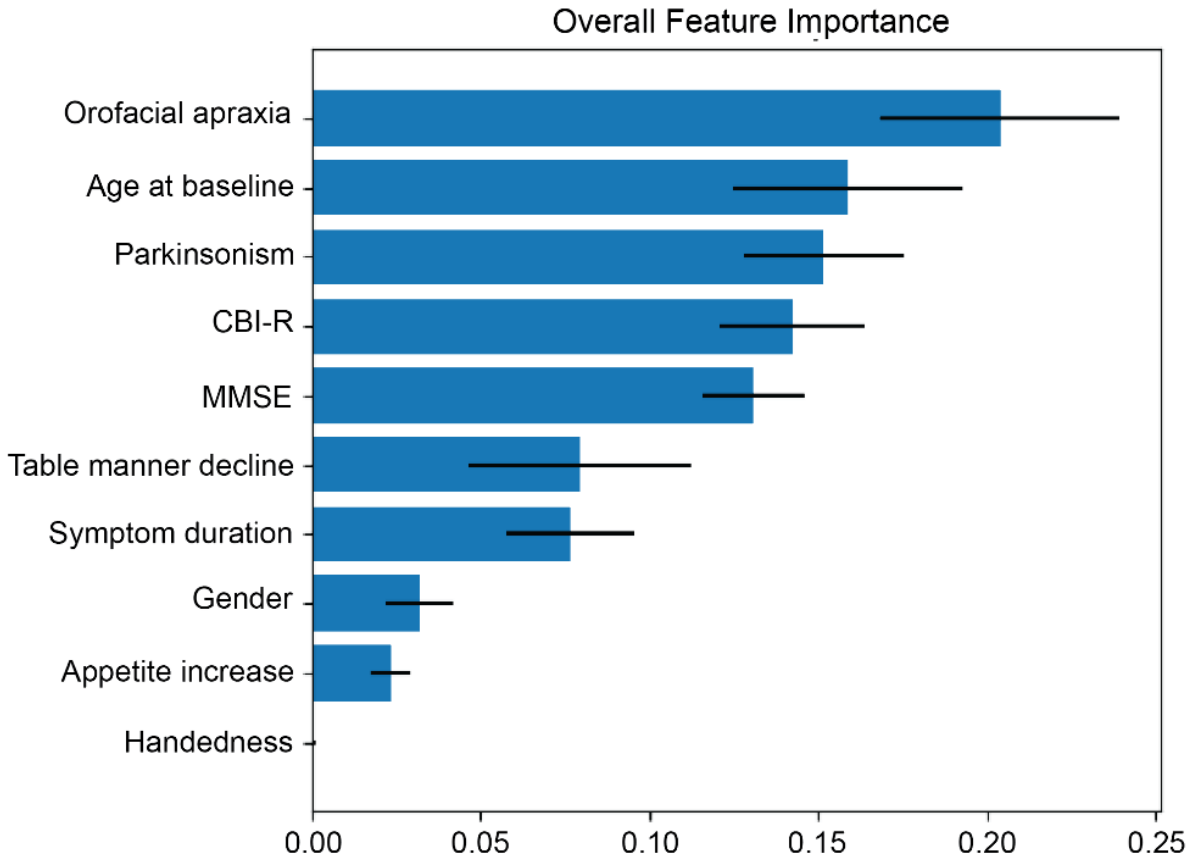
RISK OF DYSPHAGIA IN PRIMARY PROGRESSIVE APHASIA: DEMOGRAPHIC, CLINICAL, BEHAVIOURAL AND NEUROANATOMICAL FEATURES

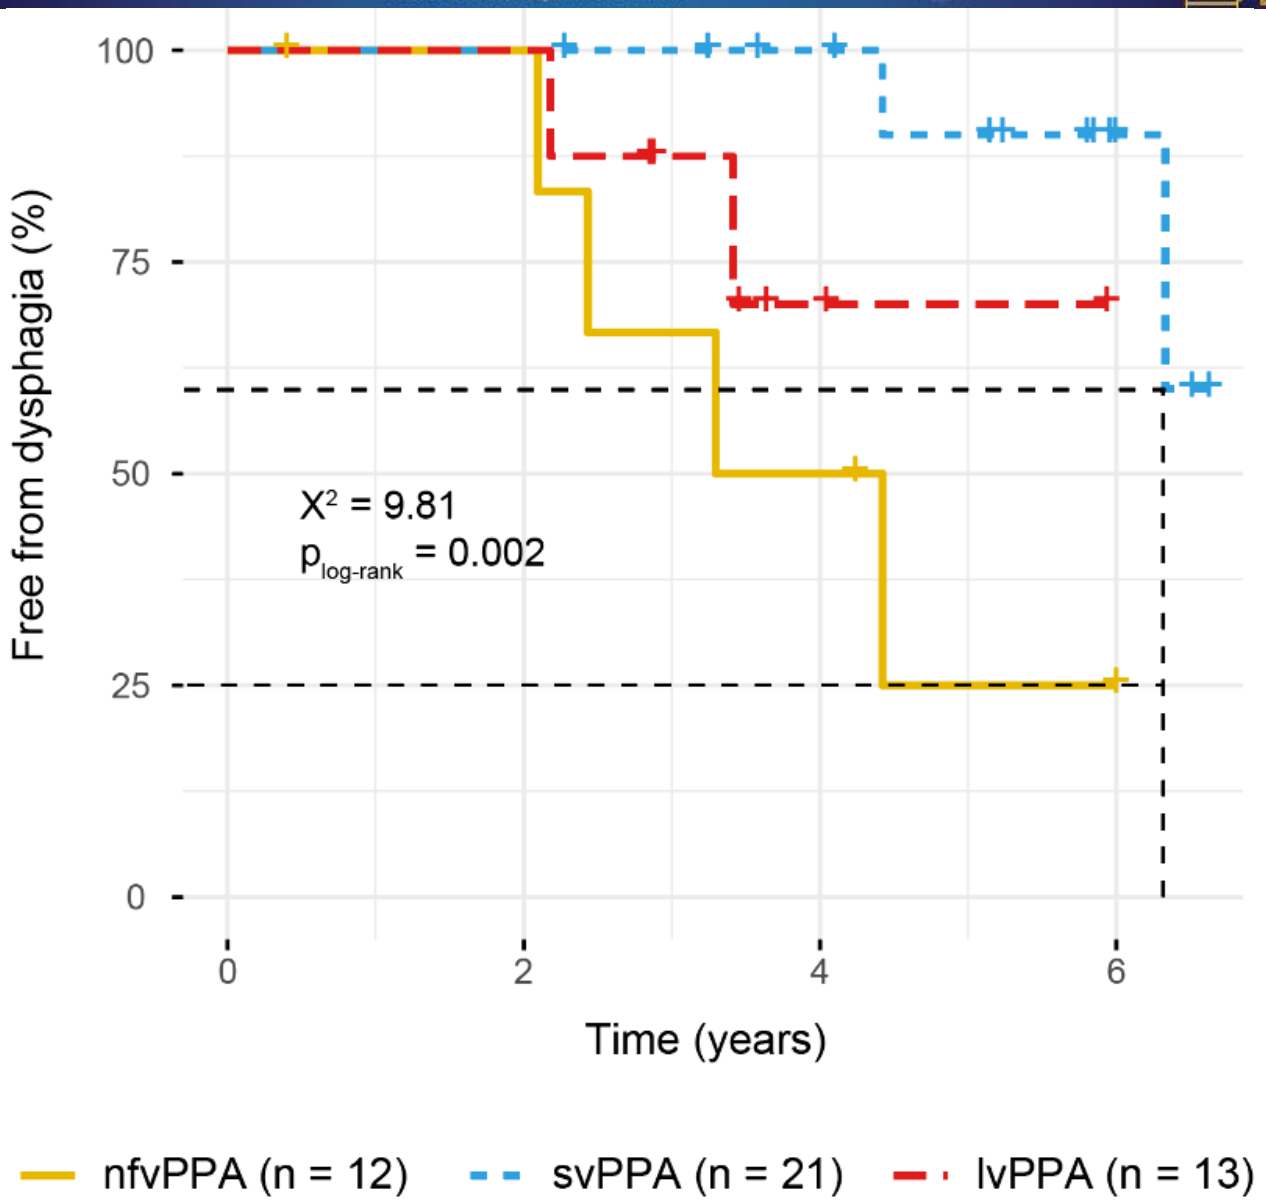
POSTERS: K01.E. DEMENTIA AND COGNITIVE DYFUNCTION: QUALITY OF LIFE

Salvatore Mazzeo[1,2], Eoin Mulroy[1], Jessica Jiang[1], Jeremy Johnson[1], Chris Hardy[1], Michael Lassi[3], Jonathan Rohrer[1], Jason Warren[1], Anna Volkmer[4]
[1]University College London, Dementia Research Centre, Department Of Neurodegenerative Disease, Ucl Queen Square Institute Of Neurology, London, United Kingdom, [2]University of Florence, Department Of Neuroscience, Psychology, Drug Research And Child Health, Firenze, Italy, [3]Scuola Superiore Sant'Anna, The Biorobotics Institute And Department Of Excellence In Robotics And Ai, Pisa, Italy, [4]University College London, Department Of Psychology & Language Sciences, London, United Kingdom

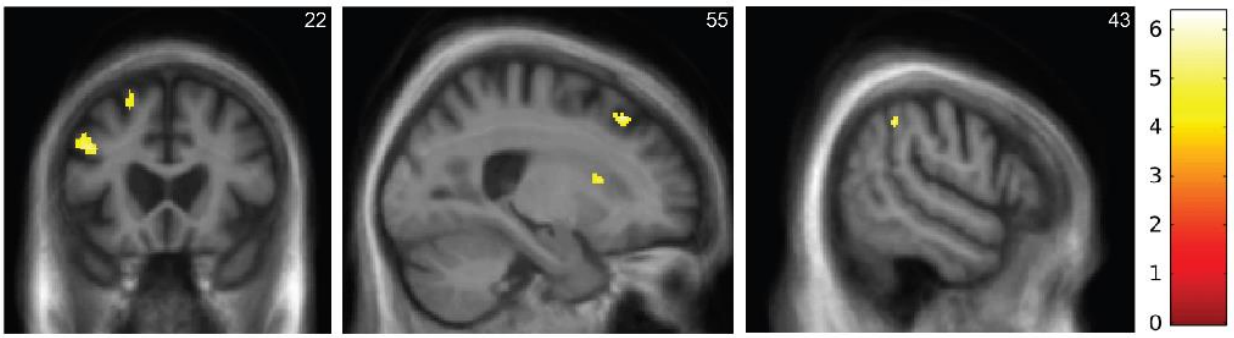
Aims: To investigate the clinical, neuropsychological, and neuroanatomical features associated with dysphagia in patients with primary progressive aphasia (PPA).
Methods: A cohort of 56 PPA patients were enrolled in this study, including 21 non-fluent/agrammatic variant PPA (nfvPPA), 22 semantic variant PPA (svPPA), and 13 logopenic variant PPA (lvPPA) cases. The presence of dysphagia at baseline or development of dysphagia during follow-up was recorded. Demographic, clinical, and behavioural data were used as candidate input features to train a random forest machine learning model. Brain MRI scans were processed using Voxel-Based Morphometry (VBM) to assess neuroanatomical associations.
Results: Dysphagia at baseline was more prevalent in nfvPPA (ten patients, 43%) compared to svPPA (one patient, 5%) and lvPPA (0%). The machine learning model revealed a hierarchy of features that accurately predicted dysphagia in the nfvPPA group, with the most important being orofacial apraxia, followed by age, presence of parkinsonism, Cambridge Behavioural Inventory Revised (CBI-R), minimental-state examination (MMSE) score, decline in table manners, and symptom duration (Figure 1).



During follow-up, dysphagia developed in eight (17%) of initially non-dysphagic PPA patients, with nfvPPA showing a significantly higher proportion. Eight patients were on modified diets or had behavioural strategies in place at follow-up. Cox's regression analysis revealed lower MMSE scores, the presence of orofacial apraxia, and higher CBI-R scores as predictors of dysphagia (Figure 2).



Neuroanatomically, dysphagia in nfvPPA was associated with regional grey matter atrophy in the left middle frontal gyrus, right superior frontal gyrus, right supramarginal gyrus, and right caudate (Figure 3).



Conclusions: This is the first study that identified demographic, clinical, behavioural, and neuroanatomical features associated with dysphagia in nfvPPA. These results provide valuable insights into identifying PPA patients at risk of dysphagia.

SEXUALITY IN ALZHEIMER'S DISEASE

POSTERS: K01.E. DEMENTIA AND COGNITIVE DYFUNCTION: QUALITY OF LIFE

Miguel Pão Trigo, Beatriz Calado Araújo, Bruno Da Luz, Joana Cavaco Rodrigues, Joaquim Sá Couto, Marco Mota Oliveira
Centro Hospitalar Universitário do Algarve, Departamento De Psiquiatria E Saúde Mental, Faro, Portugal

Aims: This abstract explores the intricate and often overlooked aspect of sexuality within the context of Alzheimer's disease. Our primary objectives were to investigate how Alzheimer's disease affects sexual behaviors, perceptions, and relationships among individuals with the condition and their caregivers. We aimed to shed light on the challenges and considerations in addressing the sexual needs and concerns of this vulnerable population.
Methods: We conducted a comprehensive literature review regarding sexuality in Alzheimer's disease. The research was carried out through the PubMed database.
Results: Our findings reveal that Alzheimer's disease can significantly impact an individual's sexuality, leading to changes in desire, inhibition, and the ability to engage in sexual activities. Caregivers often struggle with balancing their loved one's needs for intimacy while ensuring their safety and dignity. Misunderstandings, stigma, and a lack of appropriate guidance compound the challenges associated with addressing sexuality in Alzheimer's disease.
Conclusions: This review highlights the critical need for a comprehensive and compassionate approach to addressing sexuality in the context of Alzheimer's disease. The findings underscore the importance of healthcare professionals, caregivers, and support systems being well-informed and trained to navigate these sensitive issues with empathy and respect. Developing guidelines, resources, and support networks can help individuals with Alzheimer's disease and their caregivers navigate the complexities of sexuality while preserving their dignity and quality of life. Ultimately, recognizing and addressing the sexual aspects of Alzheimer's disease is integral to providing holistic care and improving the overall well-being of those affected by this condition.

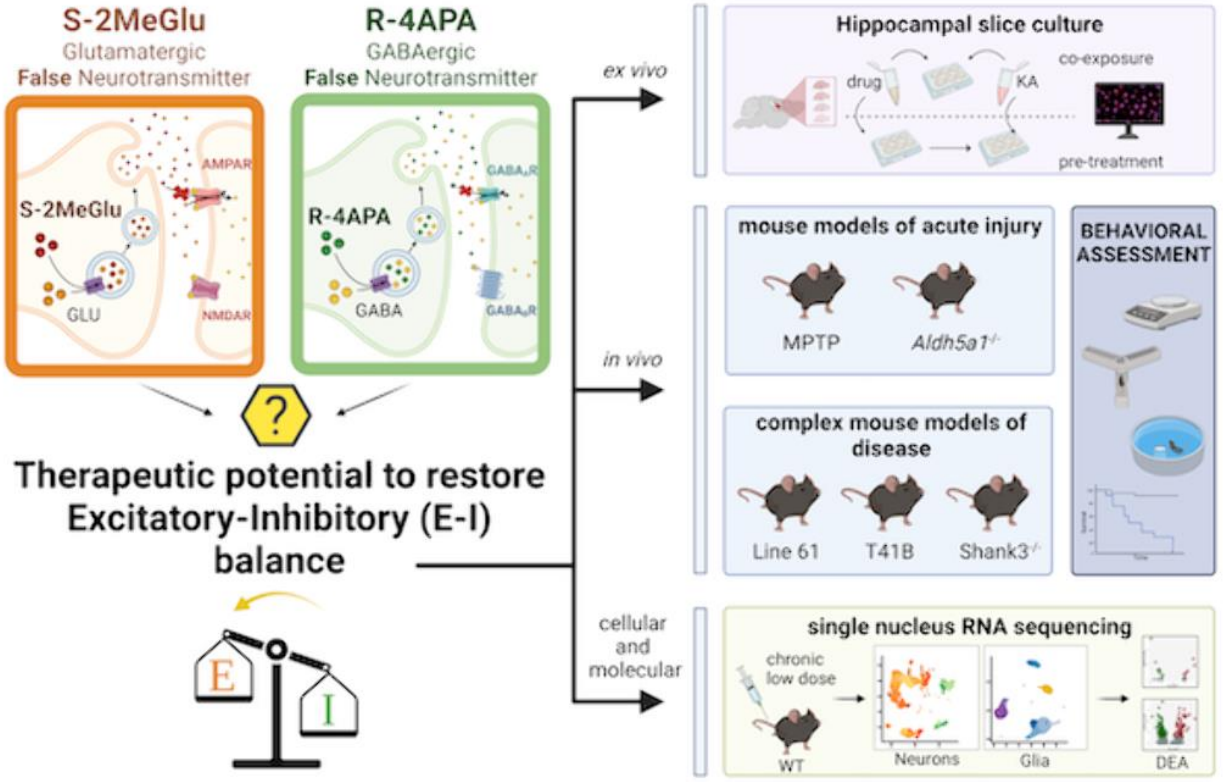
REBALANCING THE BRAIN: THE THERAPEUTIC POTENTIAL OF FALSE NEUROTRANSMITTERS IN EXCITATORY-INHIBITORY IMBALANCE

POSTERS: K01.E. DEMENTIA AND COGNITIVE DYFUNCTION: QUALITY OF LIFE

Amalia Perna[1], Jing Zhao[1], Chandresh Gajera[1], Marcus Shonemann[1], Nay Saw[2], Mehrdad Shamloo[2], Thomas Montine[1]
[1]Stanford University, Pathology, Stanford, United States of America, [2]Stanford University, Behavioral And Functional Neuroscience Laboratory (bfnl), Palo Alto, United States of America

Aims: Excitatory-inhibitory (E-I) imbalance has been proposed to underlie many brain diseases including some forms of seizure, neurodegeneration, and behavioral disorders. Multiple drug development programs pursue novel agents that interact with specific glutamatergic or GABAergic receptors with the goal of E-I rebalancing. However, targeting specific receptors has potential limitations including dozens of potential targets with highly adaptable expression. We took an innovative approach and created the first false neurotransmitters, molecules handled like an endogenous neurotransmitter but upon synaptic release have no or very limited ability to engage receptors.
Methods: We tested the activity of the excitatory (S-2-methyglutamate or S-2MeGlu) and inhibitory (R-4-aminopentanoate or R-4APA) false neurotransmitters in a variety of *ex vivo* and *in vivo* mouse models of brain diseases hypothesized to derive in part from E-I imbalance. We extended our analysis to transcriptomic changes induced by chronic exposure to low-dose false neurotransmitters.



Results: Chronic exposure of mice to R-4APA broadly altered neuronal and glial transcriptomes in mouse cerebral cortex, including increased expression of immediate early genes in excitatory neurons that was the focused transcriptional impact of S- 2MeGlu. R-4APA improved motor performance in α-synuclein and Aβ overexpressing mice but also worsened some behaviors in Shank3$^{-/-}$ mice and raised safety concerns in the context of hyperexcitability and enhanced anxiety. S-2MeGlu was neuroprotective from kainic acid toxicity in hippocampal slice cultures, extended lifespan in a mouse model of severe epilepsy (Aldh5a1$^{-/-}$), and improved motor performance in two different models of Parkinson's disease as well as spatial working memory in Aβ overexpressing mice without raising toxicity concerns.
Conclusions: Our data encourage further investigation of S-2MeGlu as a potential therapeutic agent to protect neurons from hyperexcitation and to alleviate some motor and cognitive deficits in neurodegenerative diseases.

SEXAGE: WHAT IS THE IMPACT OF STEREOTYPES REGARDING SEXUALITY OLDER PEOPLE ON SEXUAL HEALTH?

POSTERS: K01.E. DEMENTIA AND COGNITIVE DYFUNCTION: QUALITY OF LIFE

Cassandra Quin, Anne-Julie Vaillant-Ciszewicz, Laura Lantermino, Olivier Guérin
CHU DE NICE, Geriatrics, NICE, France

Aims: Scientific literature highlights the importance of sexuality for older people but also reveals the numerous barriers linked to its expression. In addition, the sexuality of older people faces several preconceived ideas that would have an impact on quality of life and sexual health. The consequences of these stereotypes on the sexual and psychological functioning of older people remain little studied to date. It should be noted that no study specifically explores the impact of sexual stereotypes on the sexuality of older people by considering place of life as a variable. **Main objectives:** Measure the impact of stereotypes towards sexuality on the sexual health of elderly people in nursing homes and at home. **Secondary objective:** Identify the specific needs of older people regarding sexuality in nursing homes and at home.
Methods: The exploratory study concerns people aged over 65 residing in nursing homes and at home. The data collect will begin in October 2023 after obtaining approval from a research ethics committee. A survey questionnaire developed by a psychologist trained in sexology and validated by a committee of experts will be distributed online via the Microsoft Forms platform.
Results: The study's hypotheses assume that the sexual needs of older people differ depending on where they live. In addition, it is expected to observe a greater impact of stereotypes on sexual health in nursing homes than at home.
Conclusions: It seems essential to integrate the sexological dimension into the care pathway and the life plan of institutionalized and at-home elderly people. The benefits of a satisfying sex life on quality of life are documented in the scientific literature. Thus, improving support for older people in terms of sexual health would improve their overall health.

DIABETES MANAGEMENT IN PEOPLE LIVING WITH DEMENTIA

POSTERS: K01.E. DEMENTIA AND COGNITIVE DYFUNCTION: QUALITY OF LIFE

Km Saif-Ur-Rahman
University of Galway, College Of Medicine, Nursing, And Health Sciences, Galway, Ireland

Aims: Dementia and diabetes are highly prevalent among the older society in Japan. People living with dementia (PLWD) often face hurdles in managing diabetes. This study explored the perspectives of healthcare providers in Japan regarding diabetes management in PLWD.
Methods: We conducted a qualitative study using in-depth interviews as a data collection method. A total of 15 physicians and nurses were interviewed. A qualitative content analysis of the codes was performed to generate the themes.
Results: The major themes focused on the management of medications/therapeutic regimen, difficulties of continuing health care, emotional aspects of PLWD for adherence to lifestyle modification, and varying direction and degree of family support for diabetes care.
Conclusions: PLWD in Japan face challenges in medication management, food restriction, and lifestyle modification. Policies to engage home visit care workers in medication management, consideration of the emotional aspect of PLWD, and utilisation of social support might help in the proper management of diabetes in PLWD.

HOME-BASED FAMILY CAREGIVER-DELIVERED MUSIC AND READING INTERVENTIONS FOR PEOPLE LIVING WITH DEMENTIA: AN INTERNATIONAL RANDOMISED CONTROLLED TRIAL (HOMESIDE TRIAL).

POSTERS: K01.F. DEMENTIA AND COGNITIVE DYFUNCTION: BEHAVIORAL & PSYCHIATRIC SYMPTOMS

Felicity Baker[1], Jeanette Tamplin[1], Anna Bukowska[2], Thomas Wosch[3], Karette Stensaeth[4], Ming Hsu[5], Helen Odell Miller[5]
[1]University of Melbourne, Music Therapy, Melbourne, Australia, [2]Institute of Applied Sciences, University of Physical Education, Music Therapy, Krakow, Poland, [3]Institute for Applied Social Sciences, Music Therapy Lab, Wurzberg, Germany, [4]Norwegian Academy of Music, Music Therapy, Oslo, Norway, [5]Anglia Ruskin University, Music Therapy, Cambridge, United Kingdom

Aims: To evaluate the impact of music interventions on dementia symptom management when provided by family caregivers trained in music use.
Methods: We implemented a superiority, single-masked RCT to evaluate if caregiver-delivered music was superior to usual care (UC) on reducing BPSD measured by the Neuropsychiatric Inventory-Questionnaire (NPI-Q). PwD (NPI-Q score >6) and their caregiver were randomly allocated to caregiver-delivered music, reading (active control), or UC. Caregivers received three online protocolised music or reading training sessions delivered and were recommended to provide minimum twice weekly over 90-days. The NPI-Q severity assessment of PwD was completed online by masked assessors at baseline, 90- (primary) and 180-days post-randomisation and analysed on an intention-to-treat basis using a likelihood-based longitudinal data analysis model. Secondary outcomes included: cognition (Mini-Mental State Examination), depression (Montgomery Asberg Depression Rating Scale),quality of life (Quality of Life-Alzheimer's Disease).
Results: Between 27th November 2019 and 7th July 2022, we randomised 432 eligible of 805 screened dyads (music n=143, reading n=144, UC n=145). There was no statistical or clinically important difference in the change from baseline BPSD between caregiver-delivered music (-0·15, 95% CI -1·41 to 1·10, p=0·81) or reading (-1·12, 95% CI -2·38 to 0·14, p=0·082) and UC alone at 90-days. Pre-specified subgroup analyses were performed for NPI-Q at 90- and 180-days post-randomisation. Compared with UC, PwD with moderate to severe cognitive impairment with a mixed diagnosis tended to be more responsive to music at 90-days. Short-term and rest-of-the day effects showed that longer durations of music use led to better outcomes. No related adverse events occurred.
Conclusions: Music interventions delivered by trained caregivers do not decrease enduring BPSD symptoms. Subgroup analyses suggest that people with some dementia types (vascular dementia) may be more responsive than others (Alzheimer's Disease).

TRAUMATIC BRAIN INJURY AND NEURODEGENERATIVE CHANGES

POSTERS: K01.F. DEMENTIA AND COGNITIVE DYFUNCTION: BEHAVIORAL & PSYCHIATRIC SYMPTOMS

Cheryl Cottrol
Yale University school of Medicine Greenwich Hospital, Psychiatry, Old Greenwich, United States of America

Aims: This case report is an 18 month retrospective study of a 27 year old white female graduate student who experienced a traumatic brain inury (TBI) secondary to a motor vehcle accident in March 2022. Serial descriptions of her brain imaging and cognitive testing are described and are consistnt with long term cognitive impairment. Impllications of TBI as a potential cause of dementia are discussed
Methods: Record review of hospital, inpatient and outpatient charts Serial assessments of brain imaging studies including 1) initial MRI brain immediately after TBI; 2) MRI with Neuroquant sequencing 1 month after TBI; 3) SPECT imaging 3 months after TBI 4) Repeat MRI one year after TBI Standardized Neuropsychiatric testing using Evox Neuroscience to assess brain processing speed, memory, attention, concentration, impulsivity as well as questions to assess level of Depression, Anxiety and Post Traumatic Stress Disorder
Results: Initial MRI: small subarachnoid hemorrhage MRI with neuroquant analysis: abnormally low hippocampal volumes for age and bilateral thalami and basal ganglia atrophy and left parietal lobe atrophy SPECT scan showed mild hypo perfusion of the right parietal region MRI 1 year after TBI: foci of microhemorrhage in frontal lobes representing sequaelae of prior sheer axonal injury; 2 punctate foci of susceptibility related to signal loss within the subcortical white matter of the left paramedian precentral gyrus and the paramedian right frontal lobes Electrophysiological cognitive testing : difficulty with speed of processing, memory, attention as well as high scores for Depression, Anxiety and PTSD
Conclusions: 27 year old graduate student who sustained a traumatic brain injury 18 months ago, continues to have structural, cognitive and psychiatric changes consistent with cognitive decline. .Mechanisms contributing to this process are discussed.

THE ASSOCIATION OF NUTRITIONAL STATUS AND REGIONAL BRAIN BLOOD PERFUSION WITH NEUROPSYCHIATRIC SYMPTOM AND ITS SUBTYPES IN ALZHEIMER'S DISEASE CONTINUUM: A PROSPECTIVE COHORT STUDY

POSTERS: K01.F. DEMENTIA AND COGNITIVE DYFUNCTION: BEHAVIORAL & PSYCHIATRIC SYMPTOMS

Jiwei Jiang, Wenyi Li, Jun Xu
Beijing Tiantan Hospital, Capital Medical University, Neurology, Beijing, China

Aims: To investigate the associations between baseline and long-term nutritional status and the regional cerebral perfusion with subsequent changes in neuropsychiatric symptoms (NPS) and its subtypes in patients with Alzheimer's disease (AD) continuum.
Methods: Totally, 435 participants {374 aMCI and AD (285 with NPS, 89 without NPS) and 61 HCs} were included from May 1, 2021 and April 30, 2023. Neuropsychiatric Inventory (NPI) and Mini-Nutritional Assessment (MNA) were used to evaluate the presence and severity of NPS and its 12 subtypes and nutritional status, respctively. Regional cerebral perfusion was evaluated by the corrected cerebral blood flow (cCBF) from the 7-delay pCASL. GLMMs were used to examine the association of baseline and longitudinal nutritional status and cCBF with the changes in the general or specific domain NPI scores after adjustment.
Results: During the (8.79±4.11) months follow-up, patients at risk or presence of malnutrition at baseline were significantly associated with subsequent increase in the NPI scores of general NPS (β=3.825, P=0.020), depression (β=0.841, P=0.004), apathy (β=0.702, P=0.048) and appetite/eating disturbances (β=0.639, P=0.002). Baseline increasing cCBF values of left putamen (β=0.135, P=0.001) and right ventral tegmental area (VTA) (β=0.069, P<0.001) were associated with subsequent deterioration of apathy, while baseline increasing cCBF values of left hypothalamus (β=0.062, P<0.001) and right VTA (β=0.028, P=0.016) were associated with deterioration of appetite/eating disturbances. The longitudinal decrease of MNA score was significantly associated with the increase NPI score of general NPS (β=-0.685, P=0.013), depression (β=-0.147, P=0.003), anxiety (β=-0.126, P=0.009), apathy (β=-0.149, P=0.012) and appetite/eating disturbances (β=-0.116, P=0.001).
Conclusions: Baseline and long-term poor nutritional status, and baseline hyperperfusion in dietary nutrition-related brain areas (putamen, VTA, and hypothalamus) can independently predict the deterioration of NPS and its sub-types in patients with AD continuum.

Aims: Falls are the most common mechanism of injury faced by millions of older adults and those with neurodegenerative diseases (NDs) each year and are often linked to accelerated decrease in quality of life. However, there are large gaps in literature and little research on fall related cognitive and neuropsychiatric symptoms. We hypothesized that experiencing falls will significantly increase the presence and severity of neuropsychiatric symptoms and lead to cognitive decline.
Methods: We used data from the Ontario Neurodegenerative Disease Research Initiative dataset (ONDRI) on 482 individuals in five ND types. Neuropsychiatric (NPI) measures were used to compare the frequency of 12 symptoms and their severity between patients with and without falls in the past 12 months and between different ND types. We also compared cognition between fallers and non-fallers longitudinally using six different cognitive assessments.
Results: For our p-value cut-off of <0.01, comparing those who experienced falls in the last year (n=169; mean-age=68.3±9; 36%Female), to those who had no falls (n=314; mean-age=68.7±7; 32%Female), there was significantly higher: total NPI severity (w=22497, p-value = 0.0061), frequency of anxiety (X2(df=1)=13.68; p-value=0.00026); anxiety severity (X2(df=3)=15.1; p-value=0.002); and partner anxiety-related distress (X2(df=3)=19.9; p-value=0.0005). Number of falls in past year had a highly significant (p <0.001) affect on six cognitive assessments both for the first visit and combining longitudianlly for two timepoints. The interaction between specific disease and presence of any fall significantly affected four different cognitive tests, including longitudinal combination of visits.
Conclusions: Anxiety frequency, severity and distress were significantly higher in patients with neurodegenerative disease who fell compared to those without falls. Fall number and the interaction between fall and specific disease impacted cognition, as seen through six different assessments and accounting for longitudinal changes.

ARE GLOBAL MEASURES OF GAIT AND COGNITION ASSOCIATED WITH SPATIAL NAVIGATION WHILE WALKING IN PATIENTS WITH MILD COGNITIVE IMPAIRMENT (MCI)?

POSTERS: K01.F. DEMENTIA AND COGNITIVE DYFUNCTION: BEHAVIORAL & PSYCHIATRIC SYMPTOMS

Magnus Lindh-Rengifo[1], Sofie Fors[2], Sebastian Palmqvist[3,4], Erik Stomrud[3,4], Oskar Hansson[3,4], Maria Nilsson[1,3,4]
[1]Lund University, Department Of Health Sciences, Faculty Of Medicine, Lund, Sweden, [2]Skåne University Hospital, Lund, Rehabilitation Medicine, Lund, Sweden, [3]Lund University, Clinical Memory Research Unit, Malmö, Sweden, [4]Skåne University Hospital, Memory Clinic, Malmö, Sweden

Aims: The primary aim was to investigate how a global measure of gait as well as cognitive functioning are associated with spatial navigation while walking in patients with mild cognitive impairment (MCI). Moreover, executive/attentional cognitive functioning was also considered.
Methods: This cross-sectional study included 209 patients with MCI; their mean (SD) age was 72.4 (7.3) years and 86 (41%) were women. Spatial navigation was assessed by using the total time of completing the Floor Maze Test (FMT), i.e., the dependent variable in linear regression analyses. A global measure of gait (i.e., gait speed) was assessed by using an electronic walkway. Global cognitive functioning was assessed by using the Mini-Mental State Examination (MMSE, 0-30 points). Executive/attentional cognitive functioning was assessed by using a composite score from z-scores of three cognitive tests (i.e., Trail making Test A and B as well as the Symbol Digits Modalities Test). Multivariate analyses were adjusted for age and sex.
Results: Decreased gait speed was significantly associated (standardized β=-0.214, $p<0.003$) with an increased total time of the FMT, i.e., when controlling for age and sex. Global cognitive functioning was not associated ($p=0.098$) with FMT, whereas executive/attentional functioning showed a statistically significant association with FMT time (β=-0.291, $p<0.001$). When including both gait speed and executive/attentional functioning in the same model (controlled for age and sex), a higher gait speed (β=-0.154, $p<0.027$) and better executive/attentional cognitive functioning (β=-0.291, $p<0.001$) were independently associated with a decreased time to complete the FMT.
Conclusions: The findings suggest both gait speed and executive/attentional cognitive functioning might be pertinent factors to consider if assessing or addressing spatial navigation while walking in patients with MCI.

Centre, Bergamo, Italy, [14]Department of Psychiatry, Charité-universitätsmedizin Berlin, Campus Benjamin Franklin, Berlin, Germany, [15]Aristotle University of Thessaloniki (AUTh), Greek Association Of Alzheimer's Disease And Related Disorders (gaadrd), Thessaloniki, Makedonia, Hellas. 1st Department Of Neurology, School Of Medicine, Macedonia, Greece

Aims: People with dementia present a high prevalence of comorbidities. We aimed to identify the prevalence of multimorbidity (I.e., ≥2 comorbidities) and specific comorbidities in the subgroup of people with severe behavioral and psychological symptoms of dementia (BPSD).
Methods: All data was analyzed at baseline and the three-year follow-up of people with severe BPSD (NPI ≥32) included in the European multicenter cohort ReCAGE (Respectful Caring for the Agitated Elderly).
Results: Of 508 people with dementia and BPSD, 54.9%% were female, with a mean age of 78 ± 7.93 years. The mean NPI score was 52.44 points, with the domains of apathy/indifference (85.4%), agitation/aggression (83.1%), depression/dysphoria (81.7%), and irritability/lability (80.9%) being the BPSD most frequently present. Multimorbidity was frequent in this population (90.6%), with hypertension (52.2%), dyslipidemia (17.5%), and diabetes (17.1%) being the most prevalent comorbidities documented. Comorbidities such as heart failure (2%), coronary artery disease (7.3%), osteoarthritis (4.8%), osteoporosis (4.8%), stroke (2.9%), carotid arteriosclerosis (2.8%), chronic kidney disease (2.4%), and chronic pulmonary obstructive disease (2.4%) had a lower prevalence than that observed in the general population. No comorbidity had a higher prevalence than expected for a population of the same age.
Conclusions: In people with severe BPSD, multimorbidity is very frequent. Conversely, the overall

prevalence of some comorbidities was lower than expected. Severe BPSD may undermine adequate diagnosis and management of comorbidities in people with dementia. Future studies should evaluate the reasons for this disparity.

BRAIN CONNECTIVITY AND METACOGNITION IN INDIVIDUALS WITH SUBJECTIVE COGNITIVE DECLINE (COSCODE PROJECT): BASELINE COHORT FEATURES

POSTERS: K01.F. DEMENTIA AND COGNITIVE DYFUNCTION: BEHAVIORAL & PSYCHIATRIC SYMPTOMS

Federica Ribaldi[1,2], Christian Chicherio[3], Chen Wang[1], Matthias Kliegel[4], Giovanni Frisoni[1]
[1]Geneva Memory Center, Department Of Rehabilitation And Geriatrics, Geneve, Switzerland, [2]University of Geneve, Laboratory Of Neuroimaging Of Aging (lanvie), Geneve, Switzerland, [3]Geneva University Hospitals, Geneva Memory Center, Department Of Rehabilitation And Geriatrics, Geneva, Switzerland, [4]University of Geneva, Laboratoire Du Vieillissement Cognitif, Geneva, Switzerland

Aims: Subjective Cognitive Decline (SCD) refers to the self-perceived decline in cognitive functions in the absence of objective evidence. The COSCODE project aims to identify SCD subjects who are at a high risk of cognitive decline. In this abstract, we present the baseline characteristics of the study participants.
Methods: A total of 441 participants were enrolled, comprising 105 volunteers, 109 individuals with SCD, 172 with Mild Cognitive Impairment (MCI), and 55 with dementia. Differences in demographics, clinical, and biomarker features were analyzed using the Kruskal-Wallis test for continuous variables and the chi-square test for categorical variables.
Results: SCD individuals were averagely older (65.7±9.3) than volunteers (60.9±8.1) but younger than MCI (70.8±8.3) and dementia (75.1±5.0,$p<0.001$). SCD (71%) and volunteers (77%) exhibited a high proportion of females. SCD and volunteers had a higher level of education compared to MCI and dementia ($p<0.001$). Additionally, SCD and MCI individuals reported higher levels of depression and anxiety than volunteers (<0.05). Notably, 21% of SCD individuals were carriers of the APOE ε4 allele. SCD participants showed a greater impairment in activities of daily living compared to volunteers ($p<0.05$) but less than MCI and dementia ($p<0.001$). SCD participants had higher cognitive complaints than volunteers, but lower than MCI and dementia ($p<0.005$). When assessing the difference between self and informant complaints, SCD individuals showed hyperawareness (self>informant) compared to MCI (self=informant) and dementia (self<informant,$p<0.05$). Moreover, SCD individuals reported higher levels of fatigue and stress compared to volunteers ($p<0.05$).
Conclusions: These findings shed light on the distinctive features of individuals with SCD, emphasizing their unique demographic, psychological, and clinical features. These insights contribute to a better understanding of SCD and its potential implications for dementia risk profiling and for the development of intervention strategies.

RESTING-STATE BRAIN ACTIVITY IN THE LEFT SUPRAMARGINAL GYRUS IN BETA BAND REFLECTS COGNITIVE DECLINE

POSTERS: K01.F. DEMENTIA AND COGNITIVE DYFUNCTION: BEHAVIORAL & PSYCHIATRIC SYMPTOMS

Yoshihito Shigihara[1], Hideyuki Hoshi[1], Momoko Kobayashi[2], Yoko Hirata[3], Kesuke Fukasawa[4], Sayuri Ichikawa[4]
[1]Hokuto Hospital, Precision Medicine Centre, Obihiro, Japan, [2]Kumagaya General Hospital, Precision Medicine Centre, Kumagaya, Japan, [3]Kumagaya General Hospital, Neurosurgery, Kumagaya, Japan, [4]Kumagaya General Hospital, Clinical Laboratory, Kumagaya, Japan

Aims: To identify the most responsible cortical regions for cognitive impairment in individuals who visited memory clinic.
Methods: We retrospectively obtained the resting-state magnetoencephalography data, neuropsychological assessment scores [Mini-mental state examination (MMSE) and frontal assessment battery (FAB)], and clinical diagnosis from 310 individuals. Resting-state cortical activities were estimated from magnetoencephalography data in terms of oscillatory intensities and they were compared with the neuropsychological assessment scores and between clinical groups.
Results: The oscillatory intensities (i.e., resting-state brain activity) in the widely distributed regions were associated with the MMSE and FAB scores from theta to high gamma bands. Negative correlations in the left frontal regions in alpha band and positive correlations in the left supramarginal gyrus in beta band were commonly found with the MMSE and FAB scores. The oscillatory intensities were significantly different between healthy individuals and patients with mild cognitive impartment, and between healthy individuals and patients with dementia, in multiple regions and frequency bands. Decreased oscillatory intensities in the left supramarginal gyrus in the beta and low gamma bands were commonly observed in the two comparisons. Taken together, decreased oscillatory intensities in beta band were common fingerprints along with progression of cognitive impairments.
Conclusions: Previous studies showed the low frequency oscillatory intensities in the caudal regions were corresponding with the pathology of Alzheimer's diseases. However, our finding demonstrated that high frequency (beta) oscillatory intensities in the caudal-dorsal region (i.e., supramarginal gyrus) were associated with cognitive impairments. This suggests the mismatching between the level of cognitive impairment and underling pathology. It implies that treating cognitive symptoms should be considered separately from treating pathology.

FACIAL EMOTION RECOGNITION IN OLDER ADULTS WITH COGNITIVE COMPLAINTS

POSTERS: K01.F. DEMENTIA AND COGNITIVE DYFUNCTION: BEHAVIORAL & PSYCHIATRIC SYMPTOMS

Yongsoo Shim, Dongwon Yang
The Catholic University of Korea, Neurology, Seoul, Korea, Republic of

Aims: Facial emotion recognition deficits impact daily life, particularly in Alzheimer's patients. We aimed to assess these deficits in three groups: subjective cognitive decline (SCD), mild cognitive impairment (MCI), and mild Alzheimer's dementia (AD).
Methods: We used the Korean version of the Florida Facial Affect Battery (K-FAB) on 72 SCD, 76 MCI, and 76 mild AD subjects. The Mini-Mental State Examination (MMSE) was utilized to gauge overall cognitive status, while the Seoul Neuropsychological Screening Battery (SNSB) was employed to evaluate performance in five cognitive domains: attention, language, visuospatial abilities, memory, and frontal executive functions.
Results: showed that FAB subtest 1(facial identity discrimination) and subtest 2(facial affect discrimination) did not yield significant differences among the three groups. However, FAB subtest 3(facial affect naming), subtest 4(facial affect selection), and subtest 5(facial affect matching) exhibited notable differences across the three groups (p=0.001, 0.003, and 0.004, respectively), particularly in the recognition of angry and fearful emotions among the 5 target emotions (happy, sad, anger, fear, neutral). Specifically, the *post-hoc* comparison revealed a decline in the recognition of the 'angry' emotion in FAB subtest 5 as individuals progressed from SCD through MCI to mild AD. Additionally, the FAB tests exhibited correlations with age and education according to Pearson's correlation analysis. After controlling for age and education through partial correlation analysis, it was revealed that MMSE and frontal executive function were associated with FAB tests (in FAB subtest 5, r=0.507, p<0.001 and r=-0.288, p=0.026, respectively).
Conclusions: Emotion recognition deficits worsened from SCD to MCI to mild AD, especially for negative emotions. Complex tasks like matching, selection, and naming showed greater deficits, with a connection to cognitive impairment, especially frontal executive dysfunction.

DISENTANGLING THE EFFECTS OF BEHAVIORAL SYMPTOMS ON SPECIFIC COGNITIVE FUNCTIONS IN PARKINSON'S DISEASE

POSTERS: K01.F. DEMENTIA AND COGNITIVE DYFUNCTION: BEHAVIORAL & PSYCHIATRIC SYMPTOMS

Scott Sperling
Cleveland Clinic, Center For Neurological Restoration, Department Of Neurology, Cleveland, United States of America

Aims: Disentangling the effects of behavioral symptoms on specific cognitive abilities in patients with Parkinson's disease (PD) is important to diagnostic accuracy, treatment, and clinical research.
Methods: We used linear regression to examine if the Beck Depression Inventory (BDI-II), Apathy Scale (AS), and/or Beck Anxiety Inventory (BAI) predicted discrete neuropsychological abilities in patients with PD, controlling for age, gender, and disease duration. Variables that were significantly associated with cognition on univariate analysis were entered into a multiple regression.
Results: Patients were on average 65.2(SD=8.93) years old with 8.6(SD=5.3) years disease duration. Their mean MoCA score was 21.2(SD=6.8). The mean BDI-II 9.9(SD=7.3), AS 11.4(SD=7.5), and BAI 11.6(SD=8.4) scores were subclinical. The BAI (p=.047), BDI-II (p<.001), and AS (p<.001) predicted HVLT-R delayed recall, but not HVLT-R or BVMT-R encoding or WMS-IV Logical Memory I or II scores. On univariate analyses, the BDI-II and AS predicted WAIS-IV Digits Forward, Trails A, Trails B-A, Stroop Interference, and JLO scores. Examined together, only AS contributed significantly to HVLT-R delayed recall $F(5,102) = 5.6$, p=.002, R^2=.22, (AS: p<.001); WAIS-IV Digits Forward $F(5,103) = 4.13$, p=.002, R^2=.17 (AS: p=.006); Trails A $F(5,105) = 8.9$, p<.001, R^2=.3 (AS: p<.001); Trails B-A $F(5,103) = 6.09$, p<.001 (AS: p=.032); Stroop Interference $F(5,93) = 3.61$, p=.005, R^2=.16 (AS: p=.025); and JLO $F(5,91) = 4.13$, p=.002, R^2=.19 (AS: p=.018) scores. AS also predicted Stroop Color Naming (p<.001), whereas BDI-II predicted Stroop Word Reading (p=.011), oral SDMT (p=.039), BVMT-R delayed recall (p<.001), and BNT-short (p=.032) scores.
Conclusions: Depression, anxiety, and apathy do not equivalently contribute to cognitive deficits across or within neuropsychological domains. Subclinical depressive symptoms have a broad effect on cognition, though comorbid symptoms of apathy are more significantly associated with cross-domain cognitive dysfunction.

TECHNIQUES DERIVED FROM EMDR (EYE MOVEMENT DESENSITIZATION AND REPROCESSING) THERAPY FOR TREATING POST TRAUMATIC DISORDERS IN FRENCH NURSING HOME.

POSTERS: K01.F. DEMENTIA AND COGNITIVE DYFUNCTION: BEHAVIORAL & PSYCHIATRIC SYMPTOMS

Anne-Julie Vaillant-Ciszewicz, Olivier Guérin, Laura Lantermino, Fanny Lecerf, Aurélie Pinguet, Ines Occeli, Mélanie Jeannin, Cassandra Quin, André Quaderi
CHU DE NICE, Geriatrics, NICE, France

Aims: The scientific literature highlights the existence of various forms of Post-Traumatic Stress Disorder (PTSD, DSM5) in the elderly (Lapp et al, 2011; Maccarrone et al, 2021). However, there is little empirical data to date regarding the potential link between traumatic flashbacks, cognitive impairments, and psycho-behavioral disorders (Delrue, 2017).
Methods: The provided text describes a research method conducted by Master's students in Integrative Clinical Psychology and Aging at the University of Côte d'Azur (FRANCE). They were supervised by senior gerontopsychologists trained in EMDR therapy and implemented an adapted EMDR protocol for the elderly, mainly in Nursing home. Before implementing the protocol, the students conducted thorough patient histories, etiological investigations, and a differential diagnosis of PTSD (Post-Traumatic Stress Disorder, DSM5). The protocol spanned 3 to 8 weeks, involving multiple adapted EMDR therapy sessions for selected elderly individuals. The potential effects of this approach were evaluated using the neuropsychiatric inventory (NPI).
Results: A non-significant clinical effect of the adapted EMDR protocol is noted in the short term for all participants with behavior disorders (anxiety, agitation) on the NPI-ES, as well as clinical signs suggestive of Post-Traumatic Stress Disorder (PTSD, DSM-5). However, the results of the present study are not generalizable due to its heterogeneity and small sample size (sample of women in institutions, 74-96 years old, MMSE less than 10/30, presence of type II traumatic events).
Conclusions: EMDR therapy adapted for elderly could be a component of the non-pharmacological treatment for old post-traumatic stress disorders. These results should be considered with caution. Indeed, the study deserves to be reproduced in a standardized manner on a more representative sample of the population to draw conclusions. Adapted EMDR remains an interesting and innovative avenue in psychology of aging.

Medical Affairs Neurology, Nutley, United States of America, [5]Eisai, Inc., Us Heor & Rwe, Nutley, United States of America, [6]Prevent Alzheimer's Disease 2020, Inc. (PAD 20/20), Brain Watch Coalition, Rockville, United States of America, [7]OptumCare, Behavioral Health, Phoenix, United States of America, [8]Optum Behavioral Health, Clinical Policy And Quality, Portland, United States of America, [9]University of Southern California, The Center For Improving Chronic Illness Care, Los Angeles, United States of America

Aims: Timely identification of mild cognitive impairment (MCI) is key to early intervention and potential treatment with novel monoclonal antibodies. Primary care providers (PCPs) play a critical role in detecting early signs of MCI yet detection rates by PCPs as low as 6-15% have been reported. Here, we use electronic health record (EHR) data to build MCI risk prediction models, which could yield a rapid, adaptable, and low-cost tool for PCPs to detect potential MCI.
Methods: This retrospective case control study used EHR data to identify individuals ≥40 years old. The MCI cohort had ≥1 diagnosis record with an ICD-10-CM diagnosis code G31.84 (MCI cohort) with the first record as the index date. The non-MCI cohort had no diagnoses, medications, or mentions of MCI, dementia, or other cognitive disorders. Potential MCI risk factors were identified from the published literature, including sociodemographic characteristics, comorbidities, and medication use. Prediction models based on risk factors for discriminating between MCI and non-MCI will be constructed using machine-learning algorithms.
Results: A preliminary MCI cohort of 20,865 individuals has been identified with mean age 71.1 years, 59.1% female, 83.7% Caucasian, 10.7% African American, and 3.6% Hispanic. The final MCI and non-MCI cohorts will be compared to identify the significant MCI predictors and modeled for MCI risk prediction as described above.
Conclusions: Because our goal is an adaptable MCI risk prediction tool and inclusion of strong predictors is essential, results from the EHR data analysis will be complemented by an insurance claims data analysis to better discriminate between MCI and non-MCI individuals and, ultimately, to develop a triage tool for PCP use.

DETECTING MEANINGFUL CHANGES IN MINI-MENTAL STATE EXAMINATION SCORES IN LEWY BODY, PARKINSON'S, AND FRONTOTEMPORAL DEMENTIA

POSTERS: K01.G. DEMENTIA AND COGNITIVE DYFUNCTION: OTHER

Tamar Abzhandadze[1,2], Minh Tuan Hoang[2], Minjia Mo[2], Hong Xu[2], Maria Eriksdotter[2], Sara Ptacek[2]
[1]Sahlgrenska University Hospital, Department Of Occupational Therapy, Gothenburg, Sweden, [2]Division of Clinical Geriatrics, Department Of Neurobiology, Care Sciences And Society (nvs), Karolinska Institutet, STOCKHOLM, Sweden

Aims: To interpret changes in Mini Mental State Examination (MMSE) scores, we must establish two psychometric properties: the Minimal Detectable Change (MDC) and the Minimal Clinically Important Difference (MCID). Remarkably, these values remain unexplored in individuals with Dementia with Lewy Bodies (LBD), Parkinson's Disease Dementia (PDD), and Frontotemporal Dementia (FTD). Hence, we have aimed to establish the MDC and the MCID of the MMSE in individuals with LBD, PDD, or FTD.
Methods: In this registry-based study, we will utilize Swedish dementia population data from the world's largest clinical register of dementia, SveDem. The study period will comprise baseline registrations from 2007 to 2020. We will include adult individuals with LBD, PDD, or FTD, with baseline and 12-month follow-up MMSE data. The MDC will be calculated as the upper limit of a 95% confidence interval of the standard error of the MMSE mean. The MCID will be determined using a distribution method where 0.2 standard deviations of the baseline MMSE score represent the MCID. Additionally, an anchor method will be utilized.
Results: The study sample consists of 5,579 individuals: 2,308 with LBD, 1,564 with PDD, and 1,707 with FTD. The analysis of MDC and MCID values is ongoing in the total sample, as well as stratified based on individual diagnoses.
Conclusions: Finding the MDC and MCID values of MMSE in rare dementia diagnoses will enable us to place all other cognitive decline measures into context. We can assess changes in cognitive function over time and determine the accuracy of the MMSE in identifying these changes. The results can also be used for planning and evaluating interventions.

ASSESSING MORTALITY RISK AMONG INDIVIDUALS WITH DEMENTIA AFTER ADMISSION TO NURSING HOME, CONSIDERING UNDERLYING NURSINGCARE FACTORS: A COHORT FROM THE SWEDISH REGISTRY FOR COGNITIVE/DEMENTIA DISORDERS

POSTERS: K01.G. DEMENTIA AND COGNITIVE DYFUNCTION: OTHER

Madeleine Åkerman[1], Hong Xu[2], Marie Tyrrell[3], Dorota Religa[2], Maria Eriksdotter[2]
[1]Karolinska Institutet, Neurobiology, Care Sciences And Society, Stockholm, Sweden, [2]Division of Clinical Geriatrics, Department Of Neurobiology, Care Sciences And Society (nvs), Karolinska Institutet, STOCKHOLM, Sweden, [3]Sophiahemmet University, Department Of Nursing Science, Stockholm, Sweden

Aims: Background: Prior studies have identified factors impacting the survival of individuals with dementia in nursing homes. However, research focusing on the comparison of mortality risk among specific nursing home populations in relation to nursing care factors and different dementia diagnoses is limited. **Objective:** To compare the associations between nursing care factors and dementia disorders and their impact on mortality in a nursing home dementia population.
Methods: A cohort of 6,192 individuals from the nursing home population in the Swedish Registry for Cognitive/Dementia Disorders (SveDem) who were followed up between 2010 and 2022 were included in the study. The study outcome was all-cause death. The association between gender, age, BMI, activity level (eating, walking, bowel/bladder function, bathing), risk assessments and preventive measurements (risk for falls, ulcers, malnutrition, poor oral health), medication, restraints, and person-centred care (life story, physical environment adjustments, interaction strategies, offered activities) were examined using cox-proportional hazard models with 95% confidence intervals (CI).
Results: Individuals were followed-up for a median of 3.1 years (IQR 1.8-4.8), a total of 3737 deaths occurred with 167.89 (CI 162.59-173.36) deaths/1,000 person-years. Age, reduced walking ability, bowel/bladder function, help with bathing, no drug review within 12 months, higher number of medications, use of restraints, lack of risk assessments and preventive measurements and person-centred care were associated with increased mortality risk. Individuals with Vascular dementia or Parkinson's disease dementia had higher mortality risk and those with Frontotemporal dementia lower mortality risk, compared to those with Alzheimer's disease.
Conclusions: Our study highlights important knowledge about how nursing care factors affect mortality in nursing homes for people with dementia, which can contribute to improved dementia care in nursing homes and thus increased quality of life.

DOWN SYNDROME - BASQUE ALZHEIMER INITIATIVE (DS-BAI): INTRODUCTION OF A NEW HEALTH PLAN AND DISCOVERY COHORT FOR MULTIMODAL BIOMARKERS

POSTERS: K01.G. DEMENTIA AND COGNITIVE DYFUNCTION: OTHER

Miren Altuna[1,2], Ainara Estanga[2], Jon Saldias[2], Marta Cañada[2], Adolfo Garrido[3], Maitane Echeverria[3], Maria Botella[2], Maite García-Sebastián[2]
[1]Osakidetza, Organización Sanitaria Integrada (OSI) Debabarrena, Spain, Neurology, Euskadi, Spain, [2]Cita-Alzheimer Foundation, Neurology, Donostia-San Sebastián, Spain, [3]Donostia University Hospital, Clinical Laboratory, Donostia-San Sebastián, Spain

Aims: Creation of a specific health and care plan, as well as a multimodal biomarkers research cohort, for adults with Down syndrome (DS) residing in the Basque Country.
Methods: Longitudinal Population-Based Observational Study. Recruitment of adults with Down syndrome (DS) and neurological-neuropsychological assessment adapted to the level of intellectual disability. Syndromic diagnosis in relation to cognitive and etiological status in symptomatic or asymptomatic Alzheimer's disease (AD). Option to complete the study through brain magnetic resonance imaging, blood analysis, and lumbar puncture. In parallel, a training program is provided for healthcare professionals, social and healthcare workers, and caregivers on the promotion of the health of this community
Results: During the first 9 months, 106 adults with Down syndrome (more than 10% of the target population) were recruited, with an average age of 46.3 years (25-65), and 46.2% were women. 35.3% were symptomatic for Alzheimer's disease (AD), and prior to their visit, less than 5.7% had been diagnosed. It has been shown that the risk of epilepsy increases in the symptomatic phase of AD (32% in dementia vs. 4% in asymptomatic individuals), and the prevalence of obstructive sleep apnea syndrome is over 70% in the population, with an underdiagnosis rate exceeding 80%. In turn, 53.5% of them benefited from treatment adjustment during the visit. Additionally, 62.3% had access to blood analysis, 49.1% to magnetic resonance imaging, and 34.1% to lumbar puncture for clinical and/or research purposes.
Conclusions: Symptomatic AD is underdiagnosed and undertreated in the adult population with DS. Specific health plans not only allow for the improvement of healthcare for adults with DS but also empower them to become central agents in clinical and translational research. The collective response is highly satisfactory.

Aims: Patients with Alzheimer's disease (AD), Parkinson's disease (PD) and related disorders in remote regions have limited access to specialized healthcare. Although telemedicine use was increased during the pandemic, the perceptions of patients', caregivers' and healthcare professionals (HPs) remain unclear, and evidence from Greece is scant. The aim of this study was to describe our 2-year experience from a newly designed tertiary telemedicine program for patients with AD, PD and related disorders in Greece.
Methods: Individuals with cognitive and movement disorders in the Health Centers of the Aegean islands were examined via videoconferencing in the "Outpatient Clinic for Memory, Dementia and PD through the National Telemedicine Network", during 03/2021-03/2023, by specialized neurologists, psychiatrists and neuropsychologists from Aiginition University Hospital. Surveys, including 10 questions [ranging from 0 (not at all) to 4 (extremely) on 5-point Likert scale] on satisfaction, and recommendations for improvement were anonymously filled by patients, caregivers and HPs being present during the remote examination.
Results: 119 (68 first, 51 follow-up) telemedicine visits were totally conducted. We received 64 questionnaires (25 patients, 18 caregivers, 21 HPs). Most participants were satisfied (3 or 4 on the survey scale) with all telemedicine aspects, including comfort (patients:84%, caregivers:94%, healthcare professionals:90%), access to specialized care (92%,100%,100%), number of transportations (92%,89%,95%), adequate follow-up (92%,83%,86%), future selection of telemedicine (100%,100%,95%), perceived reliable medical assessment (100%,94%,90%), effective information delivery (96%,100%,86%), health improvement (96%,94%,76%), cost (92%,94%,100%), and general satisfaction (100%,100%,95%). Commonest recommendations were the need for more frequent visits and raising the awareness of the service.
Conclusions: Telemedicine for AD, PD and related diseases in the Aegean islands is feasible, with high satisfaction rates among most participants, highlighting its significance for equal care especially in remote areas.

TESTAMENTARY CAPACITY ASSESSMENT TOOL (TCAT): AN UPDATE REPORT

POSTERS: K01.G. DEMENTIA AND COGNITIVE DYFUNCTION: OTHER

Panagiota Voskou[1], Athanasios Douzenis[2], Alexandra Economou[1,3], Sokratis Papageorgiou[1]
[1]University of Athens, 1st Neurology D., Athens, Greece, [2]University of Athens, 2nd Psychiatry D., Chaidari, Greece, [3]University of Athens, Psychology, Athens, Greece

Aims: The present study reviews all studies about TCAT and its use in clinical settings, as well as its validation in different cultures. TCAT is a recently developed, short instrument (15 minutes are required for its administration), with good psychometric properties, specialized for the assessment of testamentary capacity (TC) in dementia. It assesses memory, perception of financial parameters and judgment. It evaluates cognitive functions not measured by other traditional tools, such as social cognition and it does not require the use of collateral information regarding financial parameters.
Methods: Pubmed database as well as unpublished data have been used.
Results: For now, there are no other specialized TC assessment instruments with measured psychometric properties in the scientific literature. Unpublished data about amnestic mild cognitive impairment (aMCI) performance in TCAT shows no difference of aMCI in comparison to healthy adults at any part of the tool. Another unpublished data has studied the correlation between the three parts of TCAT and the expert opinion regarding TC in patients with dementia. It has concluded that the Part C of financial parameters demonstrates the highest relevance with the expert opinion. Validation and standardization of the TCAT in Greek population is under study. The preliminary results show that age, and not educational level or gender, may predict the performance in TCAT. Validation and normative data of the TCAT in an Italian population of 323 healthy adults is provided in a recent published study showing that it is useful as an adjuvant instrument for TC assessment in the elderly.
Conclusions: While TCAT is a useful tool, more studies are needed in different cultures, both in healthy adults and cognitively impaired adults, for its standardized use in forensic and clinical settings.

[1]IRCCS Centro San Giovanni di Dio Fatebenefratelli, Laboratory Alzheimer's Neuroimaging And Epidemiology, Brescia, BS, Italy, [2]IRCCS Centro San Giovanni di Dio Fatebenefratelli, Laboratory Alzheimer's Neuroimaging And Epidemiology, Laboratory Of Biological Psychiatry, Brescia, BS, Italy, [3]IRCCS Centro San Giovanni di Dio Fatebenefratelli, Molecular Markers Laboratory And Clinical Trial Service, Brescia, Italy, [4]IRCCS Centro San Giovanni di Dio Fatebenefratelli, Brescia, BS, Italy, Service Of Statistics, Brescia, Italy, [5]Università "G. d'Annunzio" di Chieti-Pescara, Laboratory Of Phytochemistry And Chemistry Of Natural Products, Department Of Pharmacy, Chieti, Italy, [6]University Hospitals and University of Geneva, University Hospitals And University, Genève, Switzerland

Aims: *Citrus*-derived phytochemicals influence several biological mechanisms associated with cognitive decline, including neuronal damage, oxidative stress and inflammation. Here, we present the preliminary results of a 36-week treatment with *citrus* peel extract in older adults with subjective cognitive decline (SCD) (ClinicalTrials.gov identifier: NCT04744922).
Methods: Eighty SCD were enrolled and randomly assigned to receive active treatment (400 mg *citrus* peel extract standardized in content of auraptene - 0.1 mg - and naringenin – 3 mg) or placebo in a 1:1 ratio. Cognitive outcomes included changes in global cognition (Repeatable Battery for the Assessment of Neuropsychological Status, RBANS), verbal memory (California Verbal Learning Test, CVLT), attention, executive and visuospatial functions, and subjective memory concerns (Multifactorial Memory Questionnaire, MMQ). Biological outcomes included biomarkers indicative of neuronal damage, oxidative stress, and inflammation. The statistical analysis was performed using the intention-to-treat approach by generalized linear mixed models. Associations of cognitive outcomes with biological measures was tested using Spearman correlation analysis.
Results: At baseline, cognitve and biological measures were similar between groups. A significant effect of time, but not time*treatment interaction, was found on the RBANS ($p<.001$), the CVLT ($p<.001$) and the MMQ (Satisfaction $p<.001$, Ability $p<.001$ and Strategies $p=.026$). In the treatment group, but not placebo, improved global cognition, verbal memory, and better memory satisfaction were significantly correlated with inflammatory mediators (i.e. MCP-1, IP10, MPI1-μ, IL-8, TNFR-2, $0.38 < |rho| < 0.52$, $p < 0.044$).
Conclusions: The finding that both treatment and placebo groups improved in global cognition, verbal memory and metamemory might indicate a placebo-effect. However, correlation analysis suggests that cognitive benefit may be underlined by a modulation of neuroinflammation in subjects treated with *citrus* phytochemicals.

COMMUNITY-BASED PHYSICIAN ATTITUDES TOWARD THE DIAGNOSIS AND TREATMENT OF EARLY ALZHEIMER'S DISEASE IN THE UNITED STATES

POSTERS: K01.G. DEMENTIA AND COGNITIVE DYFUNCTION: OTHER

Timothy Juday[1], Ashley Holub[2], Soeren Mattke[3], Keith Betts[4], Sophie Kitchen[2], Amyn Malik[2], Richard Batrla[5], Feride Frech[1], Ara Khachaturian[6]
[1]Eisai Inc., Us Medical Affairs, Nutley, United States of America, [2]Analysis Group, Rwe, Boston, United States of America, [3]University Of Southern California, Cesr, Los Angeles, United States of America, [4]Analysis Group, Healthcare Economics And Outcomes Research, Los Angeles, United States of America, [5]Eisai, Inc., U.s. Medical Affairs Neurology, Nutley, United States of America, [6]Prevent Alzheimer's Disease 2020, Inc. (PAD 20/20), Brain Watch Coalition, Rockville, United States of America

Aims: The two early symptomatic stages of Alzheimer's disease (AD) are mild cognitive impairment (MCI) and mild AD. With the advent of new medical therapies, it is important to understand the patient journey from the perspective of physicians in a community-based setting, where most patients are seen. This study examines physician attitudes toward diagnosis, referral, and treatment of early AD among community-based primary care physicians (PCPs) and neurologists in the US.
Methods: This physician survey collected data on the care of early AD drawing participants from a verified physician panel with broad representation from 41 US states. Community-based PCPs and neurologists in practice for 3 years or longer who have cared for at least 15 early AD patients in the past year were asked to complete a 20-minute survey about their experiences managing early AD patients, including selection of tests, decision to refer and treatments. Descriptive statistics for all study endpoints will be generated during the analysis phase.
Results: This study includes 301 physicians (176 PCPs and 125 neurologists). Target recruitment is 334 physicians. Mean years in practice was 19.7 for PCPs and 18.5 for neurologists. Mean early AD patients seen in prior year by PCPs was 192 and by neurologists 237. The vast majority of physicians (PCPs=86%, neurologists=94%) was from urban or suburban settings, though PCPs had more rural representation. Most physicians were male and white (78% and 54% of PCPs and 72% and 61% of neurologists, respectively). Physician recruitment is ongoing.
Conclusions: Results from this survey are intended to understand physician attitudes and challenges in caring for early AD patients in community-based settings and help inform the patient journey on more localized levels, particularly in underserved populations.

IMPACT OF DELAYED DEMENTIA DIAGNOSISON HEALTHCARE UTILIZATION DURING INITIAL HOSPITALIZATION BEHAVIORAL AND PSYCHOLOGICAL SYMPTOMS OF DEMENTIA

POSTERS: K01.F. DEMENTIA AND COGNITIVE DYFUNCTION: BEHAVIORAL & PSYCHIATRIC SYMPTOMS

Szu-Nian Yang[1,2], Chen-Han Chueh[3], Chien-Liang Liu[4,5], Yi-Wen Tsai[3]
[1]Armed Forces Taoyuan General Hospital, Department Of Psychiatry, Taoyuan, Taiwan, [2]Jen-Teh Junior College of Medicine, Nursing and Management, Department Of Oral Hygiene, Miaoli, Taiwan, [3]National Yang Ming Chiao Tung University, Institute Of Health And Welfare Policy, Taipei, Taiwan, [4]Taipei City Hospital Heping-Fuyou Branch, Department Of Neurology, Taipei, Taiwan, [5]Taipei City Hospital, Dementia Center, Taipei, Taiwan

Aims: Psychiatric hospitalization due to behavioral and psychological symptoms of dementia (BPSD) signifies the presence of profound emotional, perceptual, and behavioral disturbances in individuals with dementia which are also common in other psychiatric disorders, and thus potentially resulting in underrecognition or misdiagnosis of dementia as it progresses. We aimed to investigate the correlation between the timing of dementia diagnosis and the utilization of healthcare services during the first episode of hospitalization for BPSD.
Methods: We retrospectively examined whether early diagnosis of dementia affected healthcare management at the first psychiatric hospitalization between 2005 and 2015 due to BPSD in 1,972 elderly patients using National Health Insurance claims data in Taiwan. Patients were classified into the early diagnosis group and delayed diagnosis group based on the time of the diagnosis of dementia before index admission. To counteract potential confounding, a doubly robust estimation approach was employed, encompassing both the inverse probability of treatment weighting (IPTW) and outcome regressions. The outcomes were chemical restraints, physical restraints, and healthcare utilization.
Results: Among the 1,972 patients, 89.6% had an early diagnosis, and 10.4% had a delayed dementia diagnosis. The delayed dementia diagnosis group was younger and had less comorbidity. After IPTW, the delayed diagnosis group received more chemical and physical restraints. The length of hospitalization in the delayed diagnosis group was 8 days longer than in the early diagnosis group. The delayed diagnosis group had significantly higher total expenses by NT$27,344 and total drug expenses by NT$1,912 than the early diagnosis group.
Conclusions: These findings underscored the imperative of dementia monitoring, particularly for younger elderly and those with less comorbidity.

CHANGES IN DEMENTIA TREATMENT PATTERNS ASSOCIATED WITH NATIONAL POLICY IN KOREA: MULTICENTER, RETROSPECTIVE CAPTAIN STUDY

POSTERS: K01.G. DEMENTIA AND COGNITIVE DYFUNCTION: OTHER

Junhong Lee[1], Jinran Kim[2], Yoona Lee[2]
[1]National Health Insurance Service Ilsan Hospital, Neurology, Goyang-si, Korea, Republic of, [2]Eisai Korea Inc., Marketing, Seoul, Korea, Republic of

Aims: South Korea has actively addressed combating dementia since 2008, expanding mandatory long-term care insurance (LTCI) for dementia patients in 2014. This study aimed to investigate changes in treatment patterns for Alzheimer's disease (AD) between July 2011 and June 2017 which spanned the 2014 revision.
Methods: This multicenter, retrospective, observational study of patients with newly diagnosed AD analyzed electronic medical records from 17 general hospitals across Korea. Based on their time of AD diagnosis, subjects were categorized into Cohort 1 (1 July 2011 to 30 June 2014) and Cohort 2 (1 July 2014 to 30 June 2017).
Results: Subjects (N=3,997) divided into Cohorts 1 (n=1,998) and 2 (n=1,999). Cohort 1 subjects were significantly older (P<0.0001) and had a lower number of comorbidities (P=0.002) compared with Cohort 2. Mean Mini-Mental State Examination (MMSE) scores in Cohorts 1 and 2 at the time of AD diagnosis or start of initial treatment were 16.87 and 17.09, respectively (P=0.2790). At 1 year, mean MMSE scores in Cohorts 1 and 2 increased to 17.89 and 17.43, respectively (P=0.1524). Donepezil was the most frequently administered medication overall (75.01%), with comparable rates between cohorts. Discontinuation and switch treatment rates were significantly lower (49.72% *vs.* 58.01%; P<0.0001), and mean duration of initial treatment significantly longer, in Cohort 2 *vs.* 1.
Conclusions: Comparison of cohorts before and after revision of the national LTCI system for dementia patients found no significant difference in mean MMSE scores (time of AD diagnosis or start of initial treatment). The reduction in the proportion of patients who discontinued or changed their initial treatment, and the significant increase in mean duration of treatment, are attributed to revision of the LTCI policy which enabled increased patient access to long-term care.

DEMENTIA AND SMOKING

POSTERS: K01.G. DEMENTIA AND COGNITIVE DYFUNCTION: OTHER

Anna Bezdenezhnykh
FSBEI HE Prof. V.F. Voino-Yasenetsky KrasSMU MOH Russia, Department Of Nervous Diseases With A Pe-course, Krasnoyarsk, Russian Federation

Aims: Recently nicotine consumption has been suggested to be protective against AD neuropathology via activation of nicotinic acetylcholine receptors (nAChR). The aim is to review interactions between smoking and cognitive decline.
Methods: Literature review of the relevant articles.
Results: Case-controlled and cohort studies with a tobacco industry affiliation demonstrated a significantly decreased risk for AD, while those with no tobacco industry affiliation showed a significantly increased risk for AD (Cataldo JK et al, 2010). Novadays it is clear that smoking increases the risk of cognitive impairments. Smokers have increased risk of dementia about 30%, risk of AD - 59-78% and risk of VD -35-78% comparing to non-smokers. 4.7 million (14%) cases of AD is connected with smoking. Compared to continual smokers, long-term quitters and never smokers had decreased risk of overall dementia (hazard ratio, HR 0.86 95% CI, confidence interval 0.75–0.99 and HR: 0.81; 95% CI: 0.71–0.91, respectively). Both long-term quitters (HR: 0.68; 95% CI: 0.48–0.96) and never smokers (HR: 0.71; 95% CI: 0.54–0.95) had decreased risk of vascular dementia compared to continual smokers (Choi, D., Choi, S. and Park, S.M., 2018). In a combined group of active and former-smokers, Tyas et al. found that smokers with 27–41 (OR = 2.55; 95% CI = 1.22–5.58), and 41–56 (OR = 2.92; 95% CI = 1.37–6.53) pack years, had significantly greater risk of AD compared to those with < 27 pack-years; however, those with > 56 pack years showed no statistically significant increased risk for AD (OR = 1.37; 95% CI = 0.53–3.44), which was attributed to a strong survivor bias.
Conclusions: Smoking is essential risk factor of dementia. Harm reduction principles can be applied to those patients who can not quit smoking immediately.

360° TURN TEST (SINGLE AND DUAL TASK) - PATIENTS WITH MILD COGNITIVE IMPAIRMENT VS. COGNITIVELY HEALTHY INDIVIDUALS.

POSTERS: K01.G. DEMENTIA AND COGNITIVE DYFUNCTION: OTHER

Magnus Lindh-Rengifo[1], Sebastian Palmqvist[2,3], Erik Stomrud[2,3], Oskar Hansson[2,3], Maria Nilsson[1,2,3]
[1]Lund University, Department Of Health Sciences, Faculty Of Medicine, Lund, Sweden, [2]Lund University, Clinical Memory Research Unit, Malmö, Sweden, [3]Skåne University Hospital, Memory Clinic, Malmö, Sweden

Aims: To better understand potential motor differences, this study aimed to investigate turn duration (a 360° turn in standing, i.e., as a single task and while dual tasking) in patients with mild cognitive impairment (MCI) and cognitively healthy older persons.
Methods: This cross-sectional study included 420 individuals. Patients with MCI (n=140) had a mean age (SD) of 74.2 years (4.9), 37% were women. Cognitively healthy (n=280) had a mean age (SD) of 77.7 years (5.2), 62.5% were women. The assessment of turning 360° in standing included two turns (i.e., both directions), which were timed by using a digital stopwatch (seconds). Turning was initially assessed as a single task and thereafter while dual tasking (continuous subtraction of 3, starting from 99). The Mann-Whitney U test was used for group comparisons. Turn duration (single and dual tasking, respectively) was also used as the dependent variable in linear regression analyses where sample was used as an independent variable (controlled for age and sex).
Results: Patients with MCI had an increased turn duration as compared to cognitively healthy older persons, both when assessed as a single task ($p<0.001$) and while dual tasking ($p<0.001$). In linear regression analyses (controlled for age and sex), having MCI was associated with an increased time to perform a 360-turn both as a single task (B 1.20, 95% CI 0.83-1.57, $p<0.001$) and while dual tasking (3.05, 2.10-3.99, $p<0.001$).
Conclusions: From a clinical perspective, the Turn 360° test might be a relevant and easy test to implement. Although our findings suggest that patients with MCI perform a 360° turn slower than those who are cognitively healthy, the clinical relevance of this assessment needs to be confirmed in future longitudinal studies.

REVERSIBLE SPLENIAL LESION SYNDROME IN METABOLIC ENCEPHALOPATHY CAUSED BY HYPERNATREMIA

POSTERS: K01.G. DEMENTIA AND COGNITIVE DYFUNCTION: OTHER

Won Tae Yoon
Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Neurology, SEOUL, Korea, Republic of

Aims: A wide variety of clinical conditions may involve the splenium of the corpus callosum on magnetic resonance imaging. But, reversible focal lesions in splenium of the corpus callosum (SCC) or reversible splenial lesion syndrome are extremely rare and little known about their pathophysiology. Our aim is to report unusual case of a woman who manifested reversible isolated splenial lesion in metabolic encephalopathy caused by hypernatremia and rapid improvement with correction of electrolyte imbalance.
Methods: Single case report and description of clinical characteristics.
Results: A 39-year-old female visited Emergency room with poor oral intake and fever. When coming to Emergency room, she had 39.1℃ fever and had stuporous mental status. After an extensive workout to exclude acute neurological disorders including ischemic, demyelinating disease and CNS infection, a clinical diagnosis of metabolic encephalopathy caused by hypernatremia. Initial magnetic resonance imaging (MRI) of the brain showed an isolated lesion in the SCC characterized by high signal intensity on FLAIR sequence and diffusion weighted imaging (DWI) showed restricted diffusion. There was no enhancement following Gadolinium administration. We administered ICU management and correcting hypernatremia, and then splenial high signal lesion of corpus callosum resolved markedly within several days. We can conclude final diagnosis as reversible splenial lesion syndrome in metabolic syndrome caused by hypernatremia.
Conclusions: For now, we report for the first time a rare manifestation of metabolic encephalopathy caused by hypernatremia presenting reversible splenial lesion syndrome. Along with this case, if there are acute isolated SCC lesion in MRI, it should be considered underlying emergent metabolic encephalopathy including hypernatremia.

IMPACT OF TREATMENT DURATION AND ROUTE OF ADMINISTRATION OF DISEASE-MODIFYING ALZHEIMER'S TREATMENTS ON MEDICAL COSTS AND CAREGIVER BURDEN (20 WORDS MAX)

POSTERS: K01.G. DEMENTIA AND COGNITIVE DYFUNCTION: OTHER

Soeren Mattke, Tabasa Ozawa, Grigory Franguridi
University Of Southern California, Cesr, Los Angeles, United States of America

Aims: Several disease-modifying treatments for early-stage Alzheimer's disease (AD) are approved or in late-stage development. Their properties differ by route of administration, treatment frequency/duration and monitoring requirements. We analyze how these properties affect the treatments' value in terms of medical and social-care costs and caregiver burden.
Methods: We compare five treatments: three for intravenous infusion, including two for chronic use with infusions every two or four-weeks until progression to moderate dementia (mean 7.25 years), one for 52-week treatment with monthly infusions, one for chronic bi-weekly subcutaneous injection and one for oral daily administration. We assume all reduce progression by ~30% at the MCI stage, and a 25% ARIA risk in the first year with injectables agents, with monitoring requirements per US label. We used gross-value estimates of treatments from the published literature, administration costs and monitoring from Medicare rates, and caregiver burden from a survey of 28 clinical sites, inquiring about time use for visits and travel and proportion of patients accompanied.
Results: Table 1. Gross value and Value Reductions Per Treatment Modality

		st of burden of treatment administration and monitoring				
		Absolute and relative impact by modality				
	Gross lifetime value	iv biweekly	iv four-weekly	iv 52 weeks	subcutaneous four-weekly	oral
Cost offsets	$24,165	-$47,825(198%)	-$25,593(106%)	-$6,307(26%)	-$5,284(22%)	-$2,258(9%)
Caregiver benefit	$4,298	-$7,467(174%)	-$3,879(90%)	-$1,141(27%)	-$746(17%)	-$581(14%)

Conclusions: Burden of chronic intravenous treatments would exceed gross medical and social care cost savings and value of caregiver benefit. Subcutaneous and oral agents have lower and lowest burden, respectively. Subcutaneous and oral AD treatments that reduce clinic visits have greater potential to preserve the value of treatment benefit.

DELIRIUM INCIDENCE IN ALZHEIMER'S DISEASE AND DEMENTIA WITH LEWY BODIES BEFORE AND AFTER DEMENTIA DIAGNOSIS

POSTERS: K01.G. DEMENTIA AND COGNITIVE DYFUNCTION: OTHER

Kristin Eidsheim Sønnesyn[1], Kristoffer Haugarvoll[2], Dag Aarsland[3,4], Ragnhild Skogseth[1,5]
[1]Haraldsplass Deaconess Hospital, Neuro-sysmed, Department Of Internal Medicine, Bergen, Norway, [2]Haukeland University Hospital, Neuro-sysmed, Department Of Neurology, Bergen, Norway, [3]Institute of Psychology, Psychiatry & Neuroscience (IoPPN), King's College London, Department Of Old Age Psychiatry, London, United Kingdom, [4]Stavanger University Hospital, Centre For Age-related Medicine (sesam), Stavanger, Norway, [5]University of Bergen, Department Of Clinical Science, Bergen, Norway

Aims: Delirium is reported to be more common in Dementia with Lewy bodies (DLB) than in Alzheimer's disease (AD). Delirium is proposed to be one presentation of prodromal DLB, in addition to neuropsychiatric and mild-cognitive impairment onset. However, the frequency is unknown and symptoms of DLB resemble those of delirium. The aim was to analyze differences in incidence of delirium in DLB and AD patients before and after dementia diagnoses in a dementia cohort in Norway.
Methods: The Dementia Study of Western Norway included 247 persons with mild dementia (Mini Mental State Examination (MMSE) ≥ 20, Clinical Dementia Rating Scale (CDR) ≤1), who were followed annually until death. 181 subjects with DLB (n=75) and AD (n= 106) were included in this analysis. Delirium was retrospectively diagnosed through chart review assessing all available information in 732 acute or planned hospital admissions into psychiatric and somatic wards from 5 years before dementia diagnosis until death.
Results: Delirium was recorded in 221 (30,2 %) hospital admissions. 49 (65,3 %) DLB patients and 71 (67,0 %) AD patients had at least one delirium episode. There was a significant difference in the number of DLB patients with at least one delirium episode before diagnosis compared to the AD group (p.023), and the incidence rates of delirium after diagnosis were higher in DLB than AD, 20 versus 15 per 100 person-years respectively (p.033).
Conclusions: Delirium seems to be more common in DLB patients than in AD patients both before and after diagnosis. This holds true when delirium diagnoses are made by chart review by dementia specialists, thus reducing the risk of misinterpreting DLB symptoms as delirium. More studies are needed to establish the frequency and trajectory of delirium onset DLB.

EVALUATION AND TREATMENT OF DIZZINESS / IMBALANCE IN PATIENTS WITH VASCULAR DEMENTIA

POSTERS: K01.G. DEMENTIA AND COGNITIVE DYFUNCTION: OTHER

Ioseb Burduladze
Research Institute of Clinical Medicine (TODUA Clinic), Neurology, Tbilisi, Georgia

Aims: The prevalence of balance problems in people aged more than 70 years reaches 40-45%, and due to aging of world population, the number of patients is rapidly increasing, mainly in patients with Vascular Dementia (VD). The terms Imbalance cover a variety of symptoms regarding disorders of spatial orientation, such as the illusion vertigo or unsteadiness, which can affect objectively the ability to achieve a posture, stable gaze, and normal gait. The aim of this study was to recognize main signs of this problem and determine rapid support recommendations.
Methods: 30 patient wish VD, with acute dizziness, admitted to Neurological department, were investigated. The main symptoms was acute vertigo with fall (n=21) and acute vertigo with unsteadiness (n=9). After exclusion of cerebral stroke (CS) and other acute vascular pathologies, investigation of balance system was provided by vestibular Romberg test, Fukuda step test, vestibular ocular reflex (VOR) and Dix–Hallpike maneuver (DHM). In some cases (n=5), after the fast stabilization, video head impulse testing (VHIT) was done.
Results: In all patients, CS was not revealed. In 18 cases, reason of dizziness was bilateral vestibulopathy, in 5 cases, - benign paroxysmal positional vertigo, in 3 cases, - vestibular neuritis and in 4 cases, somatosensory loss. In all cases, VOR and DHM were effective for balance recovery as well as first medical support. After the acute period (24hr) vestibular rehabilitation (VR) exercises were more effective than DHM.
Conclusions: Dizziness/Imbalance in patients with VD (except of Stroke) can be treated with physical and pharmacological therapy to help improve symptoms and reduce risk for falls.

EFFICACY OF ROBOTIC GAIT TRAINING IN PARKINSONIAN PATIENTS USING THE END-EFFECTOR ROBOTICS

POSTERS: K02.B. MOVEMENT DISORDERS: MOTOR COORDINATION & EXERCISE

Seong-Yeol Kim[1,2], Da-Sol Kim[1,2], Gi-Wook Kim[1,2], Yu Hui Won[1,2], Sung-Hee Park[1,2], Jeong-Hwan Seo[1,2], Myoung-Hwan Ko[1,2]
[1]Jeonbuk National University Hospital, Department Of Physical Medicine And Rehabilitation, Jeonju, Korea, Republic of, [2]Jeonbuk National University Hospital, Research Institute Of Clinical Medicine - Biomedical Research Institute, Jeonju, Korea, Republic of

Aims: This research aims to determine the effectiveness of RAGT, specifically using the “Morning Walk®” end-effector gait robotic system, in enhancing both motor and non-motor manifestations in Parkinsonism patients.
Methods: We conducted a prospective randomized controlled trial at a single center. A total of 20 Parkinsonism patients were enlisted and divided randomly into RAGT (n=9) group and conventional physical therapy (CPT, n=11). The RAGT group utilized the "Morning Walk®" robotic system, while the CPT group underwent standard therapeutic exercises and manual therapy in 18 sessions over six weeks. Primary evaluations were based on the 2-minute walk test (2MWT) and the 10-meter walk test (10MWT). Secondary outcomes were assessed using tools like the Berg Balance Scale(BBS), Timed Up and Go (TUG) Test, MDS-UPDRS part I,II, and III, and the Non-Motor Symptoms Assessment Scale(NMSS), with assessments taken before and after the treatment sessions.
Results: The results showed a significant improvement in 2MWT in both the RAGT (E2-E1: 14.00±12.80 meter, p=0.007) and the CPT (E2-E1: 8.25±7.69 meter, p=0.019) while 10 MWT showed significant improvement only in the RAGT (E2-E1 -3.20±4.33 second, p=0.005). However, there were no significant differences in primary outcomes between the two groups. BBS (p=0.004) and TUG (p=0.042) showed significant improvement while MDS part II (p=0.010) and III (p=0.036) showed significant decrease only the RAGT. Both group showed significant decrease in MDS part I (p=0.035 in RAGT and p=0.044 in CPT). In non-motor symptom measurements, RAGT showed significant decrease in NMSS in total scale, anxiety, urinary, and gastrointestinal subscale (p=0.028, 0.043, 0.042, 0.039) whereas the CPT did not. There were no other significant differences between groups.
Conclusions: RAGT, especially when utilizing the 'Morning Walk®' system, presents a promising avenue for addressing both motor and non-motor symptoms in Parkinsonism.

Aims: Upper extremity skills and cognitive function in addition to balance and mobility are impaired in patients with Parkinson's disease (PwPD), which leads to difficulties in activities of daily living. Most intervention is focused on lower extremity treatment rather than upper extremity and cognitive functions. However, training that aims to improve upper extremity skills has the potential to both make it easier for patients to cope with activity limitations in daily life and improve their cognitive functions. The aim of this study is to investigate the effectiveness of task-oriented training applied to the upper extremity via videoconference on cognitive functions in PwPD.
Methods: Fourteen PwPD (aged between 45 and 70 years, Hoehn & Yahr stage I-III) were included in the study. All individuals received a treatment that included task-oriented training of the upper extremity via videoconference three days a week for six weeks. Task-oriented training of the upper extremity is a 1-hour exercise program consisting of 15 workstations. Cognitive status was evaluated with a Mini-Mental State Examination (MMSE) and Montreal Cognitive Assessment (MoCA).
Results: After rehabilitation, a statistically significant improvement was observed in terms of global cognitive status (MoCA, p=0.003 and MMSE, p=0.010).
Conclusions: This is the first study showing that task-oriented training of the upper extremity via videoconference improved cognitive functions. The training of the upper extremity via videoconference may be recommended as an effective option, especially for PwPD with barriers to reaching the clinic.

INVESTIGATING THE RELATIONSHIP BETWEEN UPPER EXTREMITY FUNCTION AND BALANCE AND FUNCTIONAL MOBILITY IN PATIENTS WITH PARKINSON'S DISEASE

POSTERS: K02.B. MOVEMENT DISORDERS: MOTOR COORDINATION & EXERCISE

Kader Eldemir[1], Sefa Eldemir[2], Fettah Saygili[3], Rezzak Yilmaz[4], Muhittin Cenk Akbostancı[4], Arzu Guclu-Gunduz[5]
[1]Ordu University, Department Of Physiotherapy And Rehabilitation, Ordu, Turkey, [2]Sivas Cumhuriyet University, Department Of Physiotherapy And Rehabilitation, Sivas, Turkey, [3]Aydın Adnan Menderes University, Department Of Physiotherapy And Rehabilitation, Aydın, Turkey, [4]Ankara University, Department Of Neurology And Ankara University Brain Research Center, Ankara, Turkey, [5]Gazi University, Department Of Physiotherapy And Rehabilitation, Ankara, Turkey

Aims: Functional disability in the upper extremity, loss of balance, and mobility limitation are common problems in patients with Parkinson's Disease (PwPD), and these problems significantly affect the quality of life of patients. This study's objective was to examine the relationship between upper extremity functions and balance and mobility for PwPD.
Methods: Twenty-two PwPD (aged 45–70 years, Hoehn & Yahr stage I-III) were recruited in this study. The Nine-Hole Peg Test (9-HPT) was used to evaluate upper extremity function. Balance and functional mobility were evaluated with the Berg Balance Scale (BBS), Functional Reach Test (FRT), and Timed Up and Go Test (TUG).
Results: The result of correlation analyses showed that both sides' of upper extremity functions were related to BBS, FRT, and TUG scores ($r = -0.640$ to 0.675, $p<0.05$).
Conclusions: These results indicate that PwPD with better functional skills in the upper extremities perform better in activities related to balance and functional mobility. In addition, these results point out that the upper extremity has an important role in developing strategies and creating protective reactions to maintain the position of the center of gravity on the support surface to maintain balance while standing or walking. Therefore, the physiotherapy program should include exercise stations aimed at improving functional skills in the upper extremity.

OPINIONS OF MCI/DEMENTIA PATIENTS AND THEIR FAMILY CAREGIVERS ABOUT UNDERGOING A DETAILED EVALUATION

POSTERS: K01.G. DEMENTIA AND COGNITIVE DYFUNCTION: OTHER

Aiko Osawa[1], Shinichiro Maeshima[2], Takako Yoshimura[3]
[1]National Center for Geriatrics and Gerontology, Department Of Rehabilitation Medicine, Obu, Japan, [2]National Center for Geriatrics and Gerontology, Education And Innovation Center, Obu, Japan, [3]Kyoto University of Advanced Science, Department Of Speech Pathology, Kyoto, Japan

Aims: In selecting treatment for dementia, a detailed neuropsychological background and ability to perform activities of daily living should be assessed to determine the individual patient's medical condition and daily living problems. However, necessary assessments are often not conducted due to the assumption by healthcare providers that "it is pitiful to conduct detailed assessments on people with dementia. Therefore, this study investigated the opinions of people with mild cognitive impairment (MCI) and dementia receiving non-pharmacological treatment and their family caregivers about undergoing detailed evaluations.
Methods: A questionnaire survey was conducted among people with31 MCI/dementia patients and 50 family caregivers undergoing Holistic physio-cognitive rehabilitation at the National Center for Geriatrics and Gerontology.
Results: 94% of the persons with MCI/dementia indicated that being evaluated was a good thing, 86% wanted to be evaluated, and 66% wanted a longer but more detailed evaluation. 29% were saddened to find out what they can't do and 89% were happy to find out what they can do. 96% of the family caregivers also answered that the evaluations were a good thing. 84% said that the evaluation was helpful, and 86% said that the evaluation was necessary to reduce the burden of caregiving, and more than 90% wanted to be present during the evaluation.
Conclusions: It was clear that both parties with MCI/dementia and family caregivers expect the correct evaluation of their medical conditions and appropriate treatment and care suggestions based on the evaluation, even if it takes time. It was considered that detailed evaluation and feedback of the results should be conducted based on such requests from the parties with dementia, and treatment should be selected based on these requests.

Aims: The aim of this study was to investigate the relationship between functional mobility and executive functions in patients with early and intermediated Parkinson's disease (PD).
Methods: Seventeen patients (7 females, 10 males) with PD were included in the study. The Modified Hoehn and Yahr Scale (MHYS) was used to evaluate disease severity, and the Unified Parkinson's Disease Rating Scale (UPDRS) was used to evaluate disability in PD. Functional mobility was assessed by the Timed and Up Go Test (TUG) under 3 conditions: TUG-single task; TUG-cognitive dual task (TUG-cog), TUG-manual dual task (TUG-man). The Montreal Cognitive Assessment (MoCA), the Trail Making Test (TMT), and the Stroop Test Çapa Version (STROOP) were used to evaluate executive functions.
Results: The median age of the participants was 60.0 years. The median total UPDRS score was 49.0. The relationship between functional mobility and executive functions was presented in Table 1. **Table 1.** The relationship between functional mobility and executive functions

	TUG-single task
	rho/p
MoCA	-0.518/0.033*
TMT-A	0.799/<0.001*
TMT-B	0.576/0.016*
STROOP-Experiment 1	0.645/0.005*
STROOP-Experiment 2	0.600/0.011*
STROOP-Experiment 3	0.620/0.008*

TUG: Timed and Up Go Test, TUG-cog: TUG-cognitive dual task, TUG-man: TUG-manual dual task, MoCA: Montreal Cognitive Assessment, TMT: Trail Making Test, STROOP: Stroop Test Çapa Version, rho:Spearman's correlation coefficient, *p<0.05.
Conclusions: There are strong relationships between TUG under single and dual task conditions and executive functions in patients with early and intermediated PD. As the

executive functions of patients are impaired, functional mobility may be negatively affected.

INTERRATER RELIABILITY OF HAND MOTOR FUNCTION: ASSESSMENT IN PARKINSON'S DISEASE: IMPACT OF CLINICIAN TRAINING

POSTERS: K02.C. MOVEMENT DISORDERS: SUPPORT DEVICES & MONITORING

Lorna Kenny[1], Zahra Azizi[1], Kevin Moore[1], John Barton[2], Salvatore Tedesco[2], Marco Sica[2], Colum Crowe[2], Suzanne Timmons[1]
[1]University College Cork, Centre For Gerontology And Rehabilitation, School Of Medicine, Cork, Ireland, [2]University College Cork, Tyndall Institute, Cork, Ireland

Aims: Parkinson's disease (PD) is a progressive neurodegenerative disorder characterised by motor and non-motor symptoms. Clinicians may vary in rating the severity of motor features. This study aims to determine the interrater reliability (IRR) of hand motor function assessment among expert clinicians and explore potential for improvement.
Methods: People with PD performed six standardized hand movements from the Movement Disorder Society's Unified Parkinson's Disease Rating Scale (MDS-UPDRS), while two cameras simultaneously recorded from the front and side. The severity of tremor and bradykinesia was rated independently by eight clinicians, using a visual analogue scale (VAS). We compared intraclass correlation coefficient (ICC) before and after a training/group calibration session, where four participant videos with high variance were reviewed, and the MDS-UPDRS rating instructions were discussed.
Results: In the first round, bradykinesia received higher mean severity scores than tremors in both hands. Poor agreement was observed for various hand movements, with best agreement found in resting tremors (right hand: ICC 0.66; 95% CI 0.50-0.82; left hand: ICC 0.66; CI 0.50-0.81). Postural tremor in the left hand had the least agreement (ICC 0.14; 95% CI 0.04-0.33), as did wrist pronation and supination in the right hand (ICC 0.34; 95% CI 0.19-0.56). In post-training assessments, agreements improved, especially in the right hand. Best agreement was observed for hand open close in the left hand (ICC 0.82, 95% CI 0.64-0.94) and resting tremor in the right hand (ICC 0.92, 95% CI 0.83-0.98). Least agreement was seen for kinetic tremor in the left hand (ICC 0.25, 95% CI 0.06-0.60) and HOC in the right hand (ICC 0.48, 95% CI 0.22-0.78).
Conclusions: Experienced clinicians vary in their rating of (video-recorded) PD motor features but this can be improved somewhat with training.

AUXILIARY DEVICES SITUATION IN PATIENTS WITH AMYOTROPHIC LATERAL SCLEROSIS IN THE REPUBLIC OF KAZAKHSTAN

POSTERS: K02.C. MOVEMENT DISORDERS: SUPPORT DEVICES & MONITORING

Larissa Kuanova
University Medical Center, Program Of Neurology, Astana, Kazakhstan

Aims: Assistive devices include medical devices designed to compensate the loss of function and improve daily life. The lack of analysis of the situation with auxiliary devices in Kazakhstan for patients with ALS and other motor neuron diseases significantly affects their duration and quality of life. The purpose of this study is to determine the need for assistive devices for patients with ALS living in Kazakhstan.
Methods: We conducted a questionnaire survey concerning the process of providing assistive devices among 65 patients with ALS registered in the social network "Life is beautiful". The social network unites patients living in the Republic of Kazakhstan with this diagnosis, receive advice on a wide range of issues, and morally support each other. The interview moderators were resident doctors of the first and second years of study. Diagnostic aspects and phenotypes of the disease were studied according to the extracts from medical records.
Results: According to the clinical spectrum of phenotypes, classical bulbar onset was noted in (17%), pseudobulbar paralysis (16%), progressive bulbar paralysis (20%), classical cervical onset (31,6%), "hanging arms", "hanging legs" syndromes (15, 4%). Depending on the phenotype, there is a need for the use of non-invasive pulmonary ventilation, a cough suppressant, orthoses, mobile devices, moving devices, communication devices.
Conclusions: The goal of preventive adaptation of assistive devices is to be one step ahead of the need for assistive devices, planning adaptations to functional limitations before they become pronounced. The results show that difficulties in obtaining and financing assistive devices are an unsolved problem among patients with ALS in the Republic of Kazakhstan. There is a need for an interdisciplinary approach to the provision of assistive devices and public financing.

EFFECTS OF LSVT-BIG THERAPY ON MOTOR FUNCTION AMONG PEOPLE LIVING WITH PARKINSON DISEASE: A 6-MONTHS FOLLOW-UP STUDY

POSTERS: K02.B. MOVEMENT DISORDERS: MOTOR COORDINATION & EXERCISE

Fariba Yadolahi[1], Najmeh Hosseini[2]
[1]KUMS, Rehabilitation, Kermanshah, Iran, [2]SBMU, Rehabilitation, Tehran, Iran

Aims: Parkinson's disease (PD) is a neurodegenerative disease with motor and non-motor symptoms affecting the lower limbs. Abnormal motor function is one of the reasons leading to restriction in independence and morbidity among them. LSVT-BIG therapy is an efficient model of exercise therapy that can be beneficial in improving mobility in people living with Parkinson's disease. Current literature focuses on conventional exercise training in this population. The purpose of this study was to investigate the effects and persistence of LSVT-BIG treatment versus conventional therapy on people living with Parkinson's disease.
Methods: Twenty-four participants with URPDS levels 2-3 randomized into LSVRT class (n=12) and conventional class (n=12). Both groups underwent 4 sessions of therapy in a week for two months. The blind examination was done using the 10 Meter Walk Test, Time Up and Go, Time Up and Down Stairs (TUDS), and 6 Minute Walk Test (6MWT). Test means were compared before intervention, at the end of treatment and after 6 months using repeated measures ANOVA with a Tukey correction, p value < .05.
Results: All participants completed the treatment sessions without adverse effects. After four weeks of treatment, the LSVT-BIG group showed statistically significant improvement in TUG ($p<0.05$) and TUDS ($p=0.001$), and 10MWT ($p<0.05$). The conventional group only showed statistically significant improvement in 6MWT ($p<0.05$). Significant improvements were noted after 6 months when comparing initial evaluation ($p<0.05$).
Conclusions: This study suggest that LSVT-BIG therapy is an effective intervention with long-term retention to improve motor function in individuals with Parkinson's disease. These findings need to be confirmed by appropriately-powered trials.

DEVELOPMENT OF A MOTOR FLUCTUATIONS PATIENT JOURNEY MAP FOR PEOPLE LIVING WITH PARKINSON'S DISEASE

POSTERS: K02.D. MOVEMENT DISORDERS: QUALITY OF LIFE

Nelson Lopes[1], Alberto Albanese[2], Ryan Case[1], Anat Amit[1], Shmuel Ben-Hamo[1]
[1]NeuroDerm.com, Clinical Development, Rehovot, Israel, [2]IRCCS Humanitas Research Hospital, Neurology, Milan, Italy

Aims: Develop a Motor Fluctuations Patient Journey Map (MFPJM) for people with Parkinson's disease (PwP) to describe the holistic experience from pre-diagnosis through long-term treatment, with a focus on motor fluctuations.
Methods: The MFPJM is in development based on in depth surveys with PwP (n=33), their care partners (n=40), and healthcare professionals with experience of treating Parkinson's disease (n=61) in the UK, Germany, France, and USA.
Results: Qualitative analysis supported five stages of the journey: onset & awareness, referral & diagnosis, early treatment, living with motor complications, and palliative care. PwP described experiencing subtle (often non-motor) symptoms long before they suspected PD. Across the 4 countries, PwP typically started their first treatment (often levodopa monotherapy) immediately following diagnosis. PwP described consistent symptom control for the first few years of treatment. After this 'honeymoon' phase, oral medications typically become less effective, and PwP/care-partners recalled noticing a more frequent re-emergence of motor and non-motor symptoms. However, 75% of PwP said they were not previously aware of the possibility of motor fluctuations until they developed them. While HCPs aim to minimize OFF time, treatment is centered around the patient's personal tolerance/comfort level with symptoms, side effects, and pill burden. PwP and care partners described the 'trial-and-error' process of frequently adjusting and optimizing the treatment plan as particularly frustrating. Eventually, as treatment options are no longer effective, PwP become dependent on their care partner or other support services for daily life and seek more advanced treatments.
Conclusions: The MFPJM is in development as a visual aid to enable service providers to identify unmet needs, potential gaps, and barriers in service provision, as well as identifying new opportunities for innovation.

ROLE OF PALLIATIVE CARE IN ADVANCED PARKINSON'S DISEASE - A PATIENT-CENTERED APPROACH

POSTERS: K02.D. MOVEMENT DISORDERS: QUALITY OF LIFE

Alexandra Armitage
Baylor Scott and White Health, Supportive Palliative Care, Temple, United States of America

Aims: Palliative care has a pivotal role in the management of advanced Parkinson's disease. Non-motor symptom management, caregiver support, the value of individualized medical decisions, and the holistic approach of an interdisciplinary team are explored.
Methods: A case study approach supported by the best evidence-based practice; this talk aims to highlight the multifaceted aspects of Palliative Care in advanced Parkinson's disease embracing the holistic philosophy of interdisciplinary collaboration.
Results: Advanced Parkinson's disease management extends beyond motor symptoms, with complex non-motor manifestations that often carry the greatest burden to both patient and caregiver. Managing these symptoms by a palliative care team can complement regular neurological care due to longer palliative appointment lengths, focus on symptoms management and holistic approach to care. Patients with Parkinson's disease exhibit diverse medical decisions influenced by their personal values, preferences, and goals. Therefore, engaging in explicit goals of care discussions, including advanced directives, becomes imperative to ensure that patient autonomy and wishes are upheld, even in the face of disease progression. Palliative care stands as an embodiment of holistic patient-centered care. Its interdisciplinary approach amalgamates medical expertise, nursing care, psychological support, and allied health interventions. This holistic philosophy caters to the physical, emotional, and spiritual needs of patients, ultimately enhancing their overall well-being and dignity.
Conclusions: By advocating for the integration of palliative care into the comprehensive management of advanced Parkinson's disease we propose a patient-centered approach. Bringing Palliative Care to the table empowers the neurological team to optimize the quality of life for patients living with advanced Parkinson's disease and their caregivers.

ASSOCIATION OF APATHY WITH CLINICAL MOTOR AND NON-MOTOR SYMPTOMS IN DE-NOVO PATIENTS WITH PARKINSON'S DISEASE

POSTERS: K02.D. MOVEMENT DISORDERS: QUALITY OF LIFE

Sun Ju Chung, Sungyang Jo, Jihyun Lee, Sangjin Lee
Asan Medical Center, Neurology, Seoul, Korea, Republic of

Aims: Apathy is a common non-motor symptom of Parkinson's disease (PD) that may associate with motor and other non-motor symptoms in PD patients. The clinical implication of apathy in early PD is still lacking. Therefore, we aimed to investigate the association of apathy with the motor and non-motor clinical features in patients with de-novo PD.
Methods: This study retrospectively investigated de-novo PD patients at Asan Medical Center from March 2021 to December 2022. We analyzed baseline demographics, severity of motor symptom assessed by Unified Parkinson's Disease Rating Scales (UPDRS) part III, apathy assessed by Apathy Evaluation Scale (AES), and quality of life assessed by The Parkinson's Disease Questionnaire (PDQ-39). Additionally, we investigated non-motor symptoms other than apathy using Non-Motor Symptoms Scale (NMSS), which includes 8 subscores (cardiovascular, sleep and fatigue, mood, problem, hallucination, attention and memory, gastrointestinal symptoms, urinary symptoms, and miscellaneous).
Results: Study subjects included 68 patients with de-novo PD, including 38 female (55.9%), with mean age of 64.7 ± 9.9 years. The mean severity of motor symptoms, assessed by UPDRS part III, was 22.4 ± 11.1 and mean AES was 44.8 ± 7.9. In the univariable linear regression analysis, the severity of motor symptoms was significantly associated with apathy (beta=0.469, $P < 0.001$). The severity of apathy was significantly associated with non-motor symptoms, assessed using NMSS, BDI, HADS, and PDQ-39. In the multivariable linear regression analysis, the severity of sleep symptoms was significantly associated with AES score (beta=2.999, $P = 0.008$).
Conclusions: Our study suggests that the severity of apathy is associated motor and non-motor symptoms in de-novo PD patients. Further researches are required to clarify the pathomechanisms of the correlation among apathy, sleep problem, and quality of life in de-novo PD patients.

PROGRESSION OF PARKINSON'S DISEASE IN ASIAN AND NATIVE HAWAIIAN AND PACIFIC ISLANDER PATIENTS

POSTERS: K02.D. MOVEMENT DISORDERS: QUALITY OF LIFE

Kirra Borrello[1,2], Shay Nakahira[1,2], Paul Fontana[1,3], Darrel Guittu[1], Chanel Hunter[1], Anson Lee[1,2], Julia Jahansooz[1,2], Edward Weldon Iv[1,2], Meliza Roman[4], Hyeong Jun Ahn[4], Jason Viereck[1,2], Enrique Carrazana[1,2], Kore Liow[1,2,4]
[1]Hawaii Pacific Neuroscience, Parkinson's And Movement Dis. Center & Center For Neuroscience Diversity, Honolulu, United States of America, [2]University of Hawaii, John A. Burns School Of Medicine, Honolulu, United States of America, [3]University of Michigan, Department Of Biopsychology, Ann Arbor, United States of America, [4]John A. Burns School of Medicine, University of Hawaii, Department Of Quantitative Health Science, Honolulu, United States of America

Aims: Parkinson's disease (PD) is a neurodegenerative disorder caused by dopaminergic cell death and is the second most common neurodegenerative disorder after Alzheimer's. However, a detailed exploration of PD in Asian, as well as Native Hawaiian and Pacific Islander populations (NHPI) has not been well documented. This study aimed to investigate the comorbidities and progression of PD severity among these understudied populations.
Methods: This retrospective study analyzed data from an outpatient neurological care facility between 2017-2022. ICD-10 codes were used to identify PD patients and data was collected through manual chart abstraction. Variables included demographics, date of diagnosis, and original and current Parkinson's medications and dosing. Severity of PD was measured by medication dosage amount and frequency using the Levodopa Equivalent Daily Dosage (LEDD). Descriptive statistics were calculated as appropriate. Additionally, Spearman's rank correlation test was used to identify the relationship between LEDD scores and PD duration.
Results: Overall, 262 patients (48.1% White, 36.6% Asian, 11.5% NHPI, 3.8% Other) were included for analysis. Aside from rates of dementia ($p=0.006$) and alcohol use ($p=0.017$), comorbidities did not vary significantly by race. Mean LEDD score also did not differ significantly by population, but Spearman's rank correlation identified a positive correlation between time from PD diagnosis and LEDD score among Asians ($p<0.001$) and NHPIs ($p<0.001$). Conversely, LEDD scores did not increase significantly among White patients even over a longer disease duration.
Conclusions: PD severity was found to be positively associated with PD duration in both Asians and NHPI. Further understanding of these race-specific differences is essential in managing patient expectations about the progression of their disease and planning interventions.

QUALITY OF LIFE IN PATIENTS WITH HUNTINGTON'S DISEASE: THE ROLE OF PATIENTS' AND CAREGIVERS ILLNESS PERCEPTIONS

POSTERS: K02.D. MOVEMENT DISORDERS: QUALITY OF LIFE

Ines Martin
Hospital Clinic de Barcelona, Psychiatry And Clinical Psychology, Barcelona, Spain

Aims: Huntington disease (HD) is a chronic, debilitating genetic disease that affects physical, emotional, cognitive, and social health. The progressive nature of the motor, cognitive, psychiatric, behavioral and functional symptoms of Huntington's disease can cause a deterioration in the perception of the quality of life of patients and their caregivers. Moreover, research suggests that chronically ill patients and their caregivers perceive illness differently, and that these differences have a negative impact on patients' quality of life (QoL). The aim of this study is describe the health-related quality of life in patients with Huntington's disease and caregivers, and assess whether illness perceptions of patients with Huntington's disease (HD) differ from those of their caregivers and affect their quality of life.
Methods: Descriptive cross-sectional study with comparison group of 22 patients with genetic testing for diagnosis and first-degree caregivers. We used the WHOQOL-BREF scale to assess quality of life. It evaluates four areas: physical health, psychological health, social relationships and environment.
Results: Statistically significant differences were found in the perception of quality of life and satisfaction with health status in the group of patients with Huntington's disease compared to the group of caregivers. The most affected areas of quality of life in patients were social relationships and the environment. Also, chronically ill patients and their caregivers perceived illness differently, and that these differences have a negative impact on patients' quality of life.
Conclusions: Due to the complexity of the signs and symptoms of Huntington's disease, the study of quality of life provides a comprehensive and valid evaluation of satisfaction with the state of health and well-being of patients and their caregivers.

A SMARTPHONE MONITORING TOOL FOR PARKINSON'S DISEASE AND DEMENTIA: NEU HEALTH PLATFORM

POSTERS: K02.C. MOVEMENT DISORDERS: SUPPORT DEVICES & MONITORING

Kinan Muhammed[1], Francis Chmiel[1], Siddharth Arora[2], Masud Husain[3,4], Michele Hu[3]
[1]Neuhealth Digital Limited, Neu Health, London, United Kingdom, [2]University of Oxford, Somerville College, Oxford, United Kingdom, [3]University of Oxford, Nuffield Department Of Clinical Neurosciences, Oxford, United Kingdom, [4]University of Oxford, Experimental Psychology, Oxford, United Kingdom

Aims: To develop an objective, multi-modal digital platform (Neu Health) aimed at improving the management of patients with Parkinson's disease (PD) and dementia by remotely and objectively capturing digital markers of motor, non-motor and cognitive decline using a smartphone app.
Methods: A software-based platform was built to utilise smartphone sensors that can remotely quantify symptoms associated with PD and dementia. Digital assessments included voice; balance; gait; finger tapping; reaction time; rest tremor; and postural tremor. Cognitive tests measured working memory, processing speed and executive function. 689 healthy controls and 1076 patients with either idiopathic PD or Alzheimer's disease completed the assessments. Clinical scores were also performed including Unified Parkinson's disease rating scale (UPDRS) and Addenbrookes cognitive assessment (ACE-III). Using smartphone derived features, heuristic analysis and random forest machine learning algorithms were developed to estimate clinical scores and predict risk of clinical outcomes.
Results: Individual features derived from smartphone motor tests significantly correlated with corresponding clinical questions from the UPDRS (r ranging from 0.11 to 0.51, $p<0.05$) and were sensitive to daily symptom fluctuations in PD. Digital cognitive tests also correlated with ACE-III ($r>0.52$, $p<0.05$). Smartphone features alone could estimate clinical scores, and future clinical outcomes including the risk of falls, freezing, cognitive decline and functional needs, were predictable 18 months in advance (AUC above 0.7 for all).
Conclusions: It is possible to estimate clinical scores and clinical risk outcomes using remote digital smartphone assessments. The development of a reliable digital platform that combines digital assessment and predictive capabilities could significantly improve the management of patients with neurodegenerative conditions. Future research is needed to evaluate the clinical and service impact of the platform.

TRAJECTORIES OF OUTCOMES IN NEUROLOGICAL CONDITIONS (TONIC): MOTOR NEURONE DISEASE & PARKINSON'S DISEASE

POSTERS: K02.D. MOVEMENT DISORDERS: QUALITY OF LIFE

Sulev Koks[1], Abigail Pfaff[1], Denise Howting[2], Lewis Singleton[2], Jack Price[2], Carolyn Young[3]
[1]Murdoch University, Centre Of Molecular Medicine And Innovative Therapeutics, Perth, Australia, [2]Perron Institute for Neurological and Translational Science, Perron Institute, Nedlands, Australia, [3]The University of Liverpool, Department Of Neurology, Liverpool, United Kingdom

Aims: Based on the Trajectories of Outcomes in Neurological Conditions (TONIC) from the Walton Centre, Liverpool, [https://www.finders-study.org/tonic] on MS and methodology MND, we are exploring trajectories of patient experience in Parkinson's disease in addition to MND. Both MND and PD are complex diseases where genetic predisposition and environmental factors interact. Our aim is to characterise the less well-understood non-motor symptoms of MND and PD, their influence on quality of life (QoL), seek new potential causative or modulating genetic variants and investigate any possible influence upon non-motor symptoms and translate findings into more comprehensive clinical care.
Methods: A longitudinal design with 6 to12 monthly administration of questionnaires of validated patient-reported outcome measures (PROMs) to people with MND and PD. These encompass domains such as physical functioning, dyspnoea, fatigue, sleep, pain, anxiety, apathy, depression, disability, quality of life, coping, hope, social withdrawal, self-efficacy, self-esteem, stigma, worry, clinical and community communication, and health-related costs.
Genomic analysis involving custom SNP panel, GWAS, WGS, and structural variants, STRs, transposable elements, and RNA sequencing may play a role in disease mechanism, age of onset, progression or phenotype. Recruitment of partners/domestic cohabiters as genetic controls.
Modelling PROMs and genetics to determine the genetic factors that influence the patients' well-being, QoL, and their perception of the disease.
Results: Recruitment is ongoing at present. We have recruited 28 MND participants with 16 controls, and 89 PD participants with 63 controls.
Conclusions: TONIC is a suitable protocol for the complex analysis of the Quality of Life of PD patients, The Combination of patients' reported Quality of Life outcomes with the genomic analysis would give us a unique opportunity to identify the genetic markers for the progression of PD.

NON-MOTOR SYMPTOMS IN PRODROMAL PARKINSON'S DISEASE ARE LINKED TO REDUCED QUALITY OF LIFE

POSTERS: K02.D. MOVEMENT DISORDERS: QUALITY OF LIFE

Sinah Röttgen[1,2], Marie-Sophie Lindner[2], Aline Seger[1], Johanna Kickartz[2], Kim-Lara Weiß[2], Christopher Doppler[1], Gereon Fink[1], Anja Ophey[3], Michael Sommerauer[2]
[1]Research Center Jülich, Institute For Neuroscience And Medicine, Cognitive Neuroscience, Jülich, Germany, [2]University Hospital Cologne, Neurology, Cologne, Germany, [3]University of Cologne, Medical Psychology | Neuropsychology & Gender Studies, Medical Faculty And University Hospital Cologne, Cologne, Germany

Aims: Background: Isolated REM sleep behavior disorder (iRBD) is the most specific prodromal marker of Parkinson's disease (PD), often accompanied by various non-motor symptoms. In PD, non-motor symptoms are strongly associated with reduced health-related quality of life (hrQoL). **Objectives:** To identify factors linked to poorer hrQoL in patients with iRBD and to compare their hrQoL to healthy control participants (HC) and patients with PD.
Methods: Methods: Sixty-two patients with iRBD (*age:* 66.44±6.14 years), 29 patients with PD (*age:* 67.21±7.23 years), and 19 HC (*age:* 67.57±8.16 years) were included. We administered the 36-Item Short Form Health Survey (SF-36) to assess hrQoL. Additionally, participants underwent a comprehensive clinical evaluation of non-motor symptoms.
Results: Results: The SF-36 total score was significantly lower in patients with iRBD (83.33±16.96) compared to HC (92.29±5.49, U = 390.00, Z = -2.218, p = .027, r = 0.246). Poorer hrQoL in patients with iRBD was linked to self-reported neuropsychiatric symptoms, sleep-wake disturbances, and a higher burden of autonomic symptoms (all r = -.25 to -.76, all p < .05). Multiple regression analysis revealed fatigue and depressive symptoms as significant independent determinants of poorer hrQoL in patients with iRBD (F (5.56) = 51.59, p < .001, adjusted R^2 = 0.81).
Conclusions: Conclusions: This study highlights the importance of non-motor symptoms for hrQoL in prodromal PD, irrespective of motor symptoms. Fatigue and depressive symptoms arise as the most relevant therapeutic targets in the prodromal stage of PD to optimize the patient's quality of life.

MOVEMENT ANALYSIS SYSTEM FOR EARLY RECOGNITION OF CIGNITIVE DECLINE

POSTERS: K02.E. MOVEMENT DISORDERS: BEHAVIORAL & PSYCHIATRIC SYMPTOMS

Gergely Hanczar[1], Bence Borbely[2], Agnes Chripko[2], Andras Horvath[3], Anita Kamondi[3]
[1]Cursor Insight, Head Of Research & Development, London, United Kingdom, [2]Cursor Insight, Research, London, United Kingdom, [3]National Institute of Mental Health, Neurology and Neurosurgery, Neurocognitive Research Center, Budapest, Hungary

Aims: Current early stage diagnostic methods for cognitive decline are not suitable for regular wide scale screening. The Hungarian National Institute of Mental Health, Neurology and Neurosurgery (NIMNN) has partnered with Cursor Insight Ltd. (CI), a deep tech company specialized in movement analysis solutions in order to develop an easy to use screening system based on fine motor movement analysis to make early recognition of cognitive decline accessible to the wider population.
Methods: Digital solution - Dynamic movement components are assessed for predictive power regarding different variants and stages of cognitive decline by implementing the digitized versions of the following tests on a tablet + digital pen setup: handwritten signature; writing down heard numbers; Trail Making Test (A); Benson Figure Copy; Archimedes spiral. Subject groups - 50 clinically tracked patients at various stages of cognitive decline and 50 age matched controls. Expressive features are extracted from fine motor movement dynamics based on anonymized clinical track records.
Results: Results from a pilot study [1] showed that dynamic features of fine motor movements can be used for proper early screening. The current work brought significant improvements to the pilot setup both in terms of usability and data quality and was utilized to discover new predictive fine motor dynamics features for cognitive decline. [1] https://doi.org/10.1016/j.imu.2022.101120
Conclusions: In a collaboration between clinical (NIMNN) and industrial (CI) partners, an easy to use screening system is proposed based on movement analysis that holds the promise of making early recognition of cognitive decline possible and accessible to the wider population.

AGE AND GENDER-RELATED DIFFERENCES OF NON-MOTOR SYMPTOMS IN PATIENTS WITH PD IN BULGARIA

POSTERS: K02.E. MOVEMENT DISORDERS: BEHAVIORAL & PSYCHIATRIC SYMPTOMS

Desislava Marinova[1,2], Yoanna Todorova[1,2], Maya Danovska-Mladenova[1,2]
[1]Medical University, Neurology, Pleven, Bulgaria, [2]University Multiprofile Hospital for Active Treatment (UMHAT) "Dr. Georgi Stranski", Neurology, Pleven, Bulgaria

Aims: To evaluate the incidence and age- and gender-related differences of non-motor symptoms (NMS) of patients with PD treated at UMHAT-Pleven.
Methods: A total of 73 patients with Parkinson's disease (44 men and 29 women) were included in this study. The average age was 66.41 (+/- 7.60). The variety of NMS were compiled into 15 main groups and a special questionnaire to encompass all of them was developed. Depression was assessed on the Hamilton scale and cognitive impairment on MMSE and ISAACS scale.
Results: All patients had at least one NMS, with the majority of them showing a combination of multiple NMS. For both groups, the most common NMS were: pain - 79.45%, followed by symptoms of the urinary and gastrointestinal systems - 73.98% each. Statistically significant gender-related differences were shown in the groups of sexual disorders ($\chi 2$= 6.57, Df=1, p= 0.0104) and skin symptoms ($\chi 2$= 6,70 Df=1, p=0.0096), which were more commonly encountered in men. Significant age-related difference was established among respiratory symptoms, as they were more prevalent in older PD patients (age over 71,44years.) (F=5.36, p=00235). Age-related correlation was documented with sensory symptoms as well, which were found primarily among men older than 70 years with incidence 70,31% (F=5,46, p=0.223).
Conclusions: All of our patients reported having NMS of PD, with their severity increasing with age and disease progression. The search for and establishment of dominant NMS is important for the implementation of additional treatment that will surely improve the quality of life of all patients, regardless of age and gender.

Aims: Neuropsychiatric symptoms play a central role in Parkinson's disease (PD) since they are related to a lower quality of life as much as motors symptoms. One of the neuropsychiatric symptoms often seen in PD is impulse control disorder (ICD) with a prevalence of 23%. However, the association of ICD and cognitive performance has been little studied from a longitudinal perspective. The main objective is to characterize cognitive trajectories in PD participants with ICD (PD-ICD) vs. PD participants without ICD (PD-no-ICD).
Methods: Parkinson's Progression Markers Initiative data of 1105 participants with idiopathic PD was analyzed over 4 years of follow-up on average. ICD assessment was based on the Questionnaire for Impulsive-Compulsive Disorders in Parkinson's Disease short version (QUIP-S) and neuropsychological assessment included Judgment of line orientation, Hopkins Verbal-Learning test, Letter-number sequencing test, lexical fluency, Modified Boston Naming test, Semantic fluency task, Symbol Digit Modalities test, Trail Making test and MoCa. Linear mixed-effects regressions were used to test the longitudinal effect of ICD (interaction between QUIP-S score and time) on each cognitive task. Age, sex, and years of education were considered as covariates.
Results: A higher QUIP-S score for PD participants was associated with a greater decline in the Symbol digit modalities test and the Trail making test part B over time. Also, a higher QUIP-S score for PD participants was associated with worst performance on Hopkins Verbal Learning Test-Revised immediate recall trial 2.
Conclusions: This study suggests that, in PD, the higher the ICDs symptoms, the higher the decline in processing speed, mental flexibility and attention over time. Future studies should also investigate brain morphology changes related to PD-ICD comorbidity and take in consideration PD treatment implications.

RISK DISCLOSURE IN PATIENTS WITH ISOLATED REM SLEEP BEHAVIOR DISORDER

POSTERS: K02.F. MOVEMENT DISORDERS: OTHER

Sinah Röttgen[1,2], Ramona Hartung[2], Annette Rogge[3], Eva Schaeffer[4], Michael Sommerauer[1,2]
[1]Research Center Jülich, Institute For Neuroscience And Medicine, Cognitive Neuroscience, Jülich, Germany, [2]University Hospital Cologne, Neurology, Cologne, Germany, [3]Paracelsus Nordseeklinik, Neurology, Helgoland, Germany, [4]Christian-Albrechts University, Neurology, Kiel, Germany

Aims: Isolated REM sleep behavior disorder (iRBD) is an early α-synucleinopathy associated with a high risk for phenoconversion to Parkinson's Disease (PD), dementia with Lewy bodies (DLB), or multiple system atrophy (MSA). Recently, a debate arose regarding the risk disclosure of these patients regarding the increased risk for phenoconversion to one of the α-synucleinopathies. Studies consulting movement disorders specialists are inconclusive as to whether and, if so, how risk disclosure should be performed in patients with iRBD. Patients with PD were mostly skeptical regarding early disclosure of risk due to the lack of disease-modifying treatment. However, patients with iRBD report that they would have liked to have received prognostic information. Our study aims to answer the question if *active* recruitment of patients with iRBD from the general population is ethically justifiable.
Methods: We designed a questionnaire to assess preferences on risk disclosure that has been dispatched to our growing Cologne iRBD cohort. Patients have been recruited via newspaper advertisements that were followed by thorough telephone screening and, if applicable, polysomnography. After polysomnography-confirmed iRBD diagnosis, patients were invited to our clinical consultation hour at the university hospital of Cologne where we perform yearly follow-ups.
Results: At present, no results are available yet. We anticipate revealing insights into our patients' experiences regarding risk disclosure, as well as preferences for managing risk education in the clinical setting.
Conclusions: This study is the first to retrospectively describe the views of affected individuals who have already been diagnosed with iRBD and were educated in this setting about their increased risk for phenoconversion. The results will provide valuable insights for the recruitment of further iRBD cohorts, which are essential to conduct therapeutic intervention studies.

NEUROLOGICAL EXAMINATION OF PATIENTS WITH PARKINSON'S DISEASE THROUGH TELEMEDICINE: A SYSTEMATIC REVIEW

POSTERS: K02.F. MOVEMENT DISORDERS: OTHER

Efthalia Angelopoulou[1], Evangelia Stanitsa[1], Stella Fragkiadaki[1], Dionysia Kontaxopoulou[1], Evangelia Smaragdaki[1], Kalliopi Vourou[1], John Papatriantafyllou[1], Dimosthenis Pavlou[2], Christos Koros[1], Leonidas Stefanis[1], Sokratis Papageorgiou[1]
[1]Eginition University Hospital, Neurology Department, Athens, Greece, [2]University of West Attica, School Of Topography And Geoinformatics, Athens, Greece

Aims: Individuals with Parkinson's disease (PD) living in remote and underserved areas have limited access to specialized healthcare, due to mobility issues, financial reasons, and long waiting lists. Despite the increasing use of telemedicine, the reliability of the video-based examination remains unclear. The aim of this systematic review is to examine which parts of remote neurological assessment are reliable in PD.
Methods: We performed a systematic search on MEDLINE database using as keywords: "Parkinson's disease", "neurological examination", "virtual", "telemedicine", "teleneurology", "videoconference", and "remote" in various combinations. Clinical studies (observational studies, clinical trials) published until 08/2023 were included.
Results: Among 439 relevant articles, 26 were included. Most parts of the video-based neurological examination in PD are feasible, even in the absence of a third party, including stance and gait –if an assistant device is not required-, bradykinesia, tremor, dystonia, some ocular mobility parts, coordination, and gross muscle power and sensation assessment. Technical issues (video quality, internet connection, camera placement) might affect bradykinesia and tremor evaluation, especially in mild cases, possibly due to their rhythmic nature. Rigidity, postural instability and deep tendon reflexes cannot be remotely performed unless a trained healthcare professional is present. A modified version of incomplete UPDRS-III and an equation lacking rigidity and pull testing items can reliably predict total UPDRS-III. MoCA, UPDRS-II,-IV, Timed "Up and Go", PDQ-39, and NMSQ can be reliably administered remotely, while the remote MDS-UPDRS-III requires further investigation.
Conclusions: Most parts of neurological examination can be reliably performed virtually in PD, except for rigidity and postural instability, while technical issues might affect the assessment of mild bradykinesia and tremor. The combined use of wearable devices may at least partially compensate for these challenges in the future.

WHAT WE KNOW ABOUT FOOD AND PARKINSON'S DISEASE: AN EVIDENCE-BASED EXPLORATION INTO NUTRITIONAL IMPACTS

POSTERS: K02.F. MOVEMENT DISORDERS: OTHER

Alexandra Armitage
Baylor Scott and White Health, Supportive Palliative Care, Temple, United States of America

Aims: The relationship between nutrition and Parkinson's Disease (PD) is complex yet significant, affecting patient outcomes and quality of life. This presentation offers an over-arching analysis of how various foods and dietary regimes influence PD symptoms and progression.
Methods: A review of existing medical literature was conducted. Findings were organized and synthesized into common themes according to specific food groups and dietary patterns.
Results: Certain foods offer notable benefits for PD patients. We explore beneficial foods which have been shown to have neuroprotective qualities and lower PD morbidity and mortality rates. Fruits and vegetables, especially those rich in flavonoids, can mitigate oxidative stress and neurodegeneration. A fiber-rich diet improves gut health and medication effectiveness, while coffee can lessen PD risk and improve motor skills. There is some evidence that moderate red wine consumption may reduce PD risk due to its polyphenols, while excessive alcohol is neurotoxic. Certain foods should be eaten with caution. Protein-rich foods can interfere with levodopa absorption, so timing protein intake around medication is crucial. Diary has been linked to both an increased risk of developing PD as well as poorer PD outcomes. Examining popular diets, the Mediterranean diet, low in dairy and animal proteins but rich in fresh produce, seems beneficial for PD patients. Both vegan and ketogenic diets have been shown to improve function in PD patients.
Conclusions: Nutritional choices play a pivotal role in PD management and should be considered an adjunct treatment. The presentation aims to arm healthcare providers and patients with actionable, evidence-based recommendations for managing PD through diet. By investing in a deeper understanding of the relationship between nutrition and PD, we open doors to improve symptom management and enhance the quality of life for affected individuals.

PARKINSONISM AS A MANIFESTATION OF STIFF-PERSON SYNDROME

POSTERS: K02.F. MOVEMENT DISORDERS: OTHER

Mohammad Golzarian, Mehri Salari
shahid beheshti university, Medicine School Of Shahid Beheshti University, tehran, Iran

Aims: We investigate the relationship between anti-amphiphysin antibody with parkinsonism and cortical ribbon sign by reporting 2 cases. Our case series expand the phenotypic spectrum of antiamphyphisin related disorders. We report 2 antiamphiphysin positive cases with parkinsonism. One of them manifested with cortical ribbon's sign beside parkinsonism which has not been reported yet.
Methods: We conducted a systematic review of papers in English indexed in PubMed with no time restriction reporting cases of positive antiamphyphisin. We used the following search terms, either as plain text or as MeSH terms: ("amphyphisin) AND ("parkinsonism" OR "parkinsonian disorder*) , "Autoimmune Diseases of the Nervous System" AND "amphiphysin" , ("stiff-man syndrome" OR "stiff-person syndrome") AND ("anti amphiphisin antibody") , "ribbon sign" AND "antiamphyphisin" , "cortical ribboning" AND "antiamphiphysin" , "cortical diffusion restriction" AND "amphiphysin" , "movement disorder*" AND "antiamphiphysin" , "movement disorder*" AND "neuronal antibod*" , ("parkinsonian disorder" OR "parkinsonism") AND ("neuronal antibod") and "antiamphyphisin". All results of the literature search were reviewed and relevant information was extracted and summarized. References of the included articles were also screened for eligible studies. Finally with duplication a total of 74 records were identified and assessed for eligibility, with 32 articles included in the review, some of these studies reviewed several cases retrospectively 1 additional article was identified via screening of references of articles, with 33 studies finally included in the review.
Results: We ruled out all of differential diagnosis of parkinsonism and cortical ribbon sign and realized that there might be a novel relationship between anti-amphyphisin antibody with parkinsonism and cortical ribbon sign.
Conclusions: Prkinsonism and cortical ribbon sign should be considered as new manifestations in the phenotypic spectrum of antiamphyphisin antibody-related disorders.

Aims: We aimed to investigate the relationship between baseline cerebrospinal fluid (CSF) glucocerebrosidase (GCase) activity and amyloid-beta 1-42 (Aβ42) with longitudinal cognitive decline in two large Dementia with Lewy bodies (DLB) and Parkinson's disease (PD) cohorts.
Methods: DLB (n=122) and PD (n=117) patients were included from the European-DLB Consortium (E-DLB) and the Norwegian ParkWest Study, respectively. CSF GCase activity was assessed using a validated assay and CSF Aβ42 levels were categorized as normal or abnormal based on local reference standards. Information on *GBA1* mutations and the *APOEε4* allele was collected. Patients were divided into tertiles according to baseline GCase activity. Cognitive decline was evaluated using a transformed Mini-Mental State Examination score in a linear mixed-effects model, with adjustments for potential confounders including age, sex, education, and *GBA1* and *APOEε4* status.
Results: Table 1 outlines the cohorts' baseline characteristics. Abnormal CSF Aβ42 levels at baseline predicted greater cognitive decline in DLB (95% CI -1.03; -1.16, p=0.03) but not in PD, a trend persisting after adjusting for demographics and genetic factors. However, this was not significant in PD patients. Conversely, reduced GCase activity at baseline predicted faster cognitive decline in PD patients (95% CI -0.06; -0.01, p=0.02), independent of demographic and genetic factors, but not in DLB patients.
Conclusions: Our study confirms that abnormal Aβ42 levels are associated with accelerated cognitive decline in DLB while decreased CSF GCase activity is associated with accelerated cognitive decline in newly diagnosed PD. These findings provide valuable insights into the clinical presentation and aberrant pathways involving Aβ and GCase in DLB and PD. Future studies with larger cohorts will be needed to compare the effect size of the two biomarkers in the diagnostic groups.

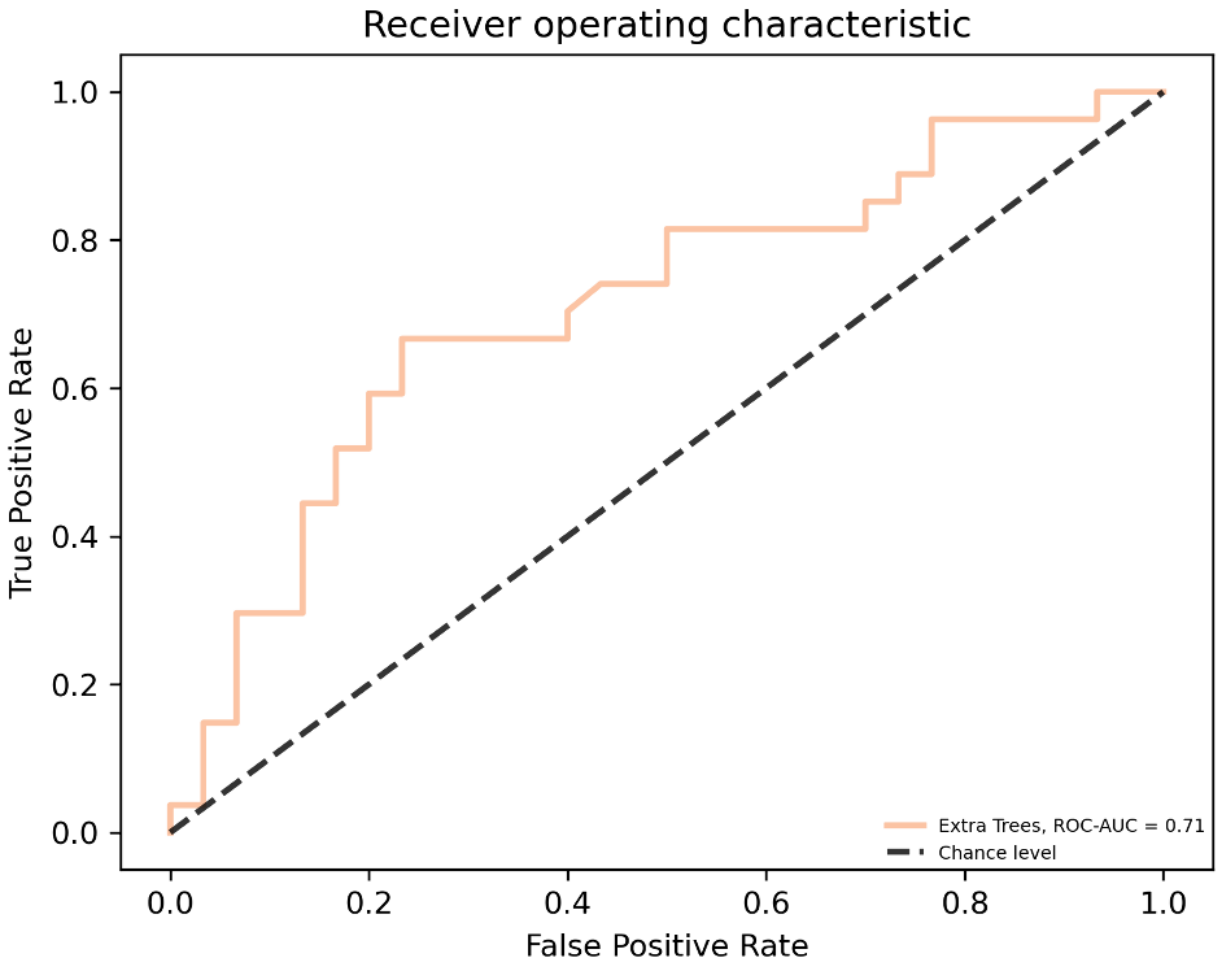
USING ACOUSTIC SPEECH BIOMARKERS TO DETECT ISOLATED REM SLEEP BEHAVIOR DISORDER

POSTERS: K02.E. MOVEMENT DISORDERS: BEHAVIORAL & PSYCHIATRIC SYMPTOMS

Johannes Tröger[1], Elisa Mallick[1], Sinah Röttgen[2,3], Ebru Baykara[1], Nicklas Linz[1], Tabea Thies[3], Michael Barbe[3], Michael Sommerauer[3]
[1]ki:elements, Research, Saarbrücken, Germany, [2]Research Center Jülich, Institute For Neuroscience And Medicine, Cognitive Neuroscience, Jülich, Germany, [3]University Hospital Cologne, Neurology, Cologne, Germany

Aims: Isolated REM sleep behavior disorder (iRBD) is an early alpha-synucleinopathy and can precede overt motor Parkinson's Disease (PD) for decades. Speech changes have proven to be a robust and sensitive indicator of motor-function and coordination impairment in PD. Recently automatic speech analysis has shown to be an early biomarker of incipient motor dysfunction in individuals with iRBD (Hlavnička et al., 2017). The goal of this research is to evaluate the feasibility of using speech biomarkers to automatically detect iRBD as compared to healthy controls (HC).
Methods: This feasibility research is based on German pilot data with 27 iRBD (4F, mean age = 61,43 ± 8,59) and 30 HC (10F, mean age = 64,67 ± 5,71) with recordings from maximum phonation of the vowel /a/ and fast syllable repetitions of the sequence /pataka/. From the recordings, acoustic features were extracted using the Dysarthria Analyser Software (DYSAN) (Hlavnicka, 2019). We normalized acoustic features for age and gender effects and subsequently trained extra trees machine learning classifiers using leave one out cross-validation and feature selection.
Results: The extra trees model was able to differentiate between iRBD and HC with an AUC of .71 (sensitivity and specificity both around .67). The receiver operating characteristics of all models evaluated can be seen in the figure
below.



Conclusions: The results show that acoustic speech biomarkers could be potentially utilized to screen for iRBD. Future research has to show whether this result persists in a study with a larger population and different languages. Results might impact future applications both in clinical trials as well as healthcare.

USER EXPERIENCE (UX) SUPPORT: SUCCESSFUL REMOTE ENGAGEMENT STRATEGY FOR INDIVIDUALS AT RISK FOR PARKINSON'S DISEASE IN PPMI

POSTERS: K02.F. MOVEMENT DISORDERS: OTHER

Lynell Lemon[1], Ken Marek[2], Kim Fabrizio[2], Craig Stanley[2], Bridget Mcmahon[1], Maggie Kuhl[3], Roseanne Dobkin[3]
[1]Institute for Neurodegenerative Disorders, Site Management Core, New Haven, United States of America, [2]Institute for Neurodegenerative Disorders, N/a, New Haven, United States of America, [3]The Michael J. Fox Foundation, Clinical Research, New York City, United States of America

Aims: Describe practices for progressive User Experience (UX) in a remote risk screening study. Discuss strategic use of technology to engage participants through a multi-step digital process. Illustrate the Parkinson's Progression Markers Initiative (PPMI) Smell Test (ST) Direct screening web-based portal design to sustain progressive UX and facilitate study compliance.
Methods: ST Direct engages individuals from the general population aged 60 and older without a PD diagnosis living in the US, Canada, and England. Participants are led to a web portal via QR code or URL and screened for eligibility; contact information is collected and consent is completed online. A smell test is mailed to participants to complete and submit test responses via web-based portal. At launch of study, moderate rates of attrition were observed related to technology and ease of use. The study team then created a vanity URL, added Help Desk phone line access, restructured web-portal features including device platform compatibility, simplified portal page format, and an option to return later. Enhanced communication practices included an adapted smell test instruction sheet and additional reminder emails to address incomplete tasks in the process.
Results: This multi-layer approach provides a reliable mechanism for engagement and progressive UX illustrated in conversion rates from eligible participants to registration at 36% (61,600), registration to consent 62% (38,070), consent to clinical questionnaire 69% (26,168), and smell test sent to submission of smell test data 62% (16,303).
Conclusions: Strategic use of technology and supportive UX throughout the study process may enable investigators to successfully engage and support interested participants, help maximize limited resources, and lead to more cost-effective and efficient clinical trial management of study participants as modes of UX and connection evolve among target populations.

WORSENING OF EXTRAPYRAMIDAL SYMPTOMS AFTER LIVER TANSPLANTATION IN A PATIENT WITH WILSON'S DISEASE

POSTERS: K02.F. MOVEMENT DISORDERS: OTHER

Iva Sarac[1], Helena Sarac[2], Fran Borovečki[2], Neven Henigsberg[1,3], Ida Ivek[4], Zdravko Krešić[5]
[1]University of Zagreb, Medical School, HR-Šalata 3, Zagreb, Croatia, Medical School, Zagreb, Croatia, [2]KBC Zagreb, Neurology, Zagreb, Croatia, [3]University of Zagreb, Schoool of Medicine, Psychiatry, Zagreb, Croatia, [4]KBC Zagreb, Internal Medicine, Zagreb, Croatia, [5]General Health Center East, General Practice, Zagreb, Croatia

Aims: Wilson's disease (WD) san genetic disorder which causes symptoms related to excess copper accumulation in various tissues, especially liver and brain. Patients may presented with symtpoms of acute liver failure, while other patients exhibited serious neurological symptoms. Liver transplantation (LT) is recommended only to WD patients with acute liver failure and severe severe neurological symptoms, particularly in patients resistant to pharmacological decoppering therapy. Neurological symptoms improved at a rate of 71.2% after the operation. Worse outcome was described in WD patients with neurological presentations, while reversal of symptoms in patients with persistent neurological involvement is less likely.
Methods: we present the case of 42-yrs old young male affected with WD with hepatic and neurological involvement, who underwent orthopic liver transplantation (OLT) in 2014 for acute liver failure. Clinical, neuroradiological, neuropsychological examination were performed before and after OLT
Results: During the early postoperative period, a worsening of extrapyramidal symptoms (EPS) and balance disturbances were observed. Further worsening of EPS was observed on subsequent control examinations. Control MRI scans (2015-2023) showed diffuse atrophy with pronounced atrophy of basal ganglia around copper deposits and cerebral peduncles.
Conclusions: Acute and then gradual worsening of brain MRI changes in the days after LT in a WD patient, in correlation with the clinical worsening of his EPS, was the most likely consequence of the massive release of copper into the circulation during the operation.

MEDICATION DEVIATIONS, CONTRAINDICATED MEDICATIONS, AND CLINICAL OUTCOMES IN HOSPITALIZED PATIENTS WITH PARKINSON'S DISEASE

POSTERS: K02.F. MOVEMENT DISORDERS: OTHER

Scott Sperling[1], Jeryl Ritzi Yu[1], Claire Sonneborn[1], Olivia Hogue[1], Debolina Ghosh[2], James Liao[1], Shannon Shaffer[1], Hubert Fernandez[1], Anne Brooks[3], Benjamin Walter[1]
[1]Cleveland Clinic, Center For Neurological Restoration, Department Of Neurology, Cleveland, United States of America, [2]Case Western Reserve, School Of Medicine, Cleveland, United States of America, [3]Parkinson's Foundation, Strategic Initiatives, Miami, United States of America

Aims: Up to 28% of people with Parkinson's disease (PD) are hospitalized each year. We examined the frequency of administered antidopaminergic medications and PD medication deviations between home and inpatient medication regimens, and their associated clinical outcomes, in patients with PD.
Methods: We examined the records of 492 patients with PD who had 725 hospital admissions during a 12-month period. We compared patients' home and inpatient medication administration records to establish the frequency of deviations in levodopa equivalent daily doses (LEDD), omissions of time-critical PD medications, substitutions of levodopa compounds, and administration of antidopaminergic medications. We used logistic regression to assess the relationships between these variables and clinical outcomes.
Results: LEDD deviations occurred in 68% of hospital admissions and 43% of hospital days. Levodopa formulation substitutions occurred in 19% of patients and 22% of patients missed at least one levodopa dose. An LEDD underdose was associated with 78% higher odds of 30-day readmission/death (OR 1.78, 95%CI 1.08-2.93, p=0.025) and every additional day with an underdose was associated with 14% higher odds of 90-day mortality (OR 1.14, 95% CI 1.05-1.24, p=.002). Antidopaminergic medications were administered during 10% of admissions and associated with 85% higher odds of 30-day readmission/death (OR 1.85, 95% CI 1.02-3.45, p=0.041) and over two-fold odds of 90-day mortality (OR 2.2, 95% CI 1.2-4.3, p=0.018). Length of stay (LOS) was associated with LEDD overdose (median 6.5 vs 4.1 days; p<0.001) and the administration of antidopaminergic medications (median 7.6 vs 3.8 days; p<0.0001).
Conclusions: Deviations between patients' home and inpatient medication regimens, and the administration of antidopaminergic medications, were common in hospitalized patients with PD and associated with greater risk of poor outcomes. Specialized PD education and intervention programs for inpatient providers are needed.

NEURAL CORRELATES OF BALANCE IN PARKINSON'S DISEASE: A SYSTEMATIC REVIEW

POSTERS: K02.F. MOVEMENT DISORDERS: OTHER

Patrick Tait[1], Lisa Graham[1], Rodrigo Vitorio[1], Emily Timm[2], Joanne O'Keefe[2], Tamlyn Watermeyer[3], Samuel Stuart[1], Rosie Morris[1,4,5]
[1]Northumbria University, Sports, Excersise And Rehabilliation, Newcastle upon Tyne, United Kingdom, [2]RUSH medical college, Department Of Anatomy & Cell Biology, Chicago, United States of America, [3]Northumbria University, Psychology, Newcastle upon Tyne, United Kingdom, [4]Northumbria Healthcare NHS Foundation Trust, Northumbria Nhs Foundation Trust, North Shields, United Kingdom, [5]Northumbria University, Sports, Exercise And Rehabilitation, Newcastle upon Tyne, United Kingdom

Aims: An increasing number of studies employ cortical brain-imaging techniques, such as functional near-infrared spectroscopy (fNIRS) and mobile electroencephalography (EEG). Similarly, behavioural studies have evaluated cognitive performance in relation to balance, in people with Parkinson's disease (PwPD). This review aims to provide a comprehensive overview of all studies that have assessed cognitive associations of balance in PwPD, and/or assessed cortical function, using fNIRS and/or EEG, in relation to standing tasks.
Methods: Scopus, PubMed, and ProQuest were searched between January 1980 and December 2022. Two authors (PT & LG) reviewed the search results independently, using pre-established selection criteria detailing the measurement technique, cohort, and balance task/device. I
Results: Behavioural studies generally demonstrate a positive association between cognitive function and performance on balance tasks. Only seven brain-imaging studies met the inclusion criteria, revealing distinct cortical activity in PwPD compared with healthy age-matched controls during standing tasks. PwPD exhibited higher levels of HbO^2 in the prefrontal cortex and greater inter-regional and inter-hemispheric connectivity. Additionally, PwPD with balance issues showed differences in cortical activation patterns, including lower mid-frontal and mid-cerebellar theta-band power, compared to PwPD without balance impairments. This suggests a compensatory mechanism that attempts to redress and ameliorate the postural control issues caused by subcortical dysfunction.
Conclusions: The limited number of studies and lack of standardisation regarding protocols, measurement devices, and data analysis make it challenging to draw concrete conclusions. A nuanced approach that considers all relevant variables regarding protocol and data analysis is recommended. Moreover, the integration of behavioural (cognitive) measures, in addition to objective balance measures, may be a valuable addition to mobile imaging studies.

NEUROINFLAMMATION AND -PATHOLOGY IN SARS-COV-2 INFECTED MACAQUES: GLIAL CELLS, NEURODEGENERATION AND PROTEIN AGGREGATION

POSTERS: L01A. NEUROPATHOLOGY OF COVID-19

Juliana Nieuwland[1], Erik Nutma[1], Mirjam Pikaart[1], Ella Zuiderwijk-Sick[1], Elga De Vries[2], Marieke Stammes[1], Jinte Middeldorp[1]
[1]Biomedical Primate Research Centre, Neurobiology & Aging, Rijswijk, Netherlands, [2]Amsterdam UMC, location VU, Medical Cell Biology And Immunology, Amsterdam, Netherlands

Aims: Infection with severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) results in respiratory symptoms, yet neurological symptoms are common as well, both in acute phase as well as months later in patients with post-COVID syndrome. With longitudinal PET scans using [^{18}F]DPA714, a tracer for 18 kDa translocator protein, we were able to visualize the onset and progression of inflammation in the brain following a SARS-CoV-2 infection in rhesus macaques. These results together with post-mortem immunostainings showed that more than 7 weeks after infection neuroinflammation is still ongoing in the brains of these animals. Similar results have now been observed in patients with post-COVID syndrome. To investigate how these long-term effects progress and cause further damage in the brain, macaques are infected with various SARS-CoV-2 variants for different time periods.
Methods: Nasal and throat swabs are obtained to detect viral presence and replication, and blood and cerebrospinal fluid for proteomic analyses. Brain tissue is collected for postmortem analyses.
Results: Preliminary data suggests functional and morphological glial cell changes in certain brain regions of SARS-CoV-2 infected monkeys, as well as changes in T cell numbers. In the substantia nigra a decline in the number of dopaminergic neurons is also demonstrated together with alpha synuclein pathology. Moreover, alpha- and phosphorylated synuclein aggregates are seen in the meninges and choroid plexus of infected animals.
Conclusions: Protein aggregation following viral infections has been observed in previous studies, however this research is the first to demonstrate protein aggregation together with neuron decline in the substantia nigra following a SARS-CoV-2 infection. This study provides information on the progression of the neuroinflammatory process and neuropathology and can help to understand mechanisms behind neurological symptoms during COVID-19 and post-COVID syndrome.

OBSERVATIONAL PILOT STUDY ON THE IMPACT OF TRANCRANIAL PULSED STIMULATION (TPS) ON PATIENTS WITH POST-COVID-19 NEUROLOGICAL INVOLVEMENT (LONG COVID).

POSTERS: L01C. NEUROLOGICAL MANIFESTATIONS OF COVID-19

Cristina Guijarro-Castro[1], Miguel Ángel Fernández Blázquez[2], Rubén Sebastián-González[1], Lucía Fernández-Arana[1], Javier Martín[3], Karin Freitag[4]
[1]Clínica DKF, Neuroscience Department, Madrid, Spain, [2]Universidad Autónoma de Madrid, Department Of Biological And Health Psychology, Madrid, Spain, [3]Clínica DKF, R&d Department, Madrid, Spain, [4]Clínica DKF, Rheumatology Department, Madrid, Spain

Aims: Trancranial pulsed stimulation (TPS) has been shown to improve cognitive performance in patients with mild cognitive impairment, and there are already studies with transcranial stimulation that have improved Neuro Long-Covid. With our study, we expect to confirm the usefulness of TPS on the "Neuro-Long Covid", since there is no specific treatment for this entity.
Methods: Observational, blinded, pilot study to verify the safety, usefulness for cognitive impairment in Neuro-LongCovid. This study recruit a total of **20 subjects** aged between 18 and 75 years, diagnosed with Neuro-LongCovid19. All subjects are randomized into either the intervention group or the sham TPS group in a 1:1 ratio. All patients will undergo MRI. The inclusion criteria are the persistence of self-reported cognitive impairment at least after 12 weeks of suffering from Covid19, manifestation of symptoms of Covid19, positive Sars-Cov2 PCR and full recovery from Covid-19 at the time of evaluation. Cognitive impairment are screened using the Montreal Cognitive Assessment (MoCA) test and a self-perception scale of cognitive complaints (EMQ). A neuropsychological evaluation are conducted for all patients, before and after treatment, investigating attention and executive functions (The Trail Making Test, The Symbol-Digit Modalities Test, the Stroop test). Also, we will asses attention (D2 test), episodic memory (Free and Selectively Facilitated Recall Test) and depressive symptomatology (BDI). We also perform evaluations using the Fatigue Severity Scale (FSS), Modified Fatigue Impact Scale (MFIS), and questionnaires PHQ9 (Patient Health Questionnaire-9) and EuroQoL-5D.
Results: Preliminary results will be presented at the congress
Conclusions: We propose an observational pilot study on the TPS impact as treatment on patients with post-Covid-19 neurological involvement (Long covid). This treatment is safe and without side effects.

EFFECTS OF VIRAL RNA MIMETIC LOXORIBIN ON NEURONAL-GLIA CO-CULTURES

POSTERS: L01C. NEUROLOGICAL MANIFESTATIONS OF COVID-19

Silvija Jankeviciute, Katryna Pampuscenko, Vilmante Borutaite
Lithuanian University of Health Sciences, Neuroscience Institute, Kaunas, Lithuania

Aims: Neurotropic viruses such as severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) can invade and harm the central nervous system (CNS). Studies show that neurological symptoms linked to SARS-CoV-2 are associated with immune-mediated mechanisms and inflammatory responses affecting the brain, potentially leading to neurotoxicity, and may contribute to neurodegenerative diseases. However, the exact mechanism of viruses induce neurotoxicity remains unclear. To get more insight into mechanisms of viral RNA-induced neurotoxicity, we treated primary rat neuronal-glial co-cultures with RNA-mimetic loxoribine (Lox), a selective Toll-like receptor 7 (TLR7) agonist. TLR7 is vital in recognizing single-stranded RNA viruses triggering immune responses crucial for host defense against viral infections.
Methods: In this study, co-cultures were incubated with 1-100 µg/ml Lox for 24-72 h. The viability, number of neuronal and microglia cells, and phagocytic activity were assessed by fluorescence microscopy.
Results: Our results show that Lox causes concentration-dependent loss of viable neurons without increasing neuronal apoptosis or necrosis. Selective elimination of microglia by treatment of cultures with L-leucine-methyl-ester (LME), prevented Lox-induced neuronal loss suggesting that Lox-induced neuronal loss is microglia-mediated. We found that Lox stimulates microglial proliferation and induces morphological changes such as increased average cell body area in co-cultures. Lox does not affect NO production but stimulates TNF-α production in cell co-cultures after 72h treatment. In microglial monocultures, Lox stimulates phagocytic activity of cells as measured by engulfment of fluorescently labelled latex beads by microglial cells.
Conclusions: In conclusion, our data suggest that viral RNA-mimetic Lox causes microglial activation leading to neuronal loss from mixed neuronal-glial cell cultures. This work was supported by the Research Council of Lithuania, Researcher Groups projects No S-MIP-23-98 (APNEVIR).

GENOTOXIC STRESS DRIVES NEUROLOGICAL AND COGNITIVE SEQUELAE OF VIRAL INFECTION IN A NOVEL MOUSE MODEL OF LONG COVID

POSTERS: L01C. NEUROLOGICAL MANIFESTATIONS OF COVID-19

Xinli Tian, Jiyu Li, Hongbo Zhang, Kelsea Keys, Jian Wang, Andrew Yurochko, Xiao-Hong Lu
LSU Health, Pharmacology, Toxicology, And Neuroscience, Shreveport, United States of America

Aims: There are growing concerns arise regarding whether SARS-CoV-2 infection or other emerging viral infections, especially those affecting the population on a pandemic scale, could instigate and propagate neurological and cognitive sequelae (PASC) with the possibility of progress to cognitive decline and neurodegenerative conditions. SARS-CoV-2 and other viral infections have been associated with genotoxic stress and cell senescence. COVID-19 induces molecular markers of brain aging, strongly correlated with cellular responses to DNA damage.These findings align with our earlier research, which found that persistent genotoxic stress is a prominent feature in Parkinson's disease (PD) and Huntington's disease (HD).
Methods: To facilitate the longitudinal study PASCs in vivo, we created a human ACE2 transgenic mouse model with full-length human ACE2 regulatory regions that faithfully recapitulated the structure, tissue distribution, and gene regulation of the human gene. A strategy was developed to model the immunopathology of SARS-CoV-2 infection with signature cytokine storm, ARDS, and characteristic gene expression profiling to facilitate the longitudinal analysis in an ABSL-2 facility.
Results: The mice manifested PASCs and many brain aging-like features, including brain genotoxic stress, cell senescence, autophagy dysfunction, proteotoxicity, long-lasting neuroinflammation, anosmia, and cognitive deficits. Importantly, we have both in vitro and in vivo, indicating that inhibiting genotoxic stress response can effectively lessen acute and PASC-like symptoms.
Conclusions: These results support the hypothesis that viral inflammation inflicted genotoxic stress accelerates brain aging to drive neurological and cognitive post-acute sequelae of SARS-CoV-2 Infection. Our study aims to advance a unique human ACE2 mouse model of PASC for investigating concurrent aging and neurodegenerative processes and will prove advantageous for the development of novel therapeutic strategies targeting aging pathways for preventing and treating PASC.

POST-COVID19 COGNITIVE DYSFUNCTION: CLINICAL FEATURES AND DETERMINING FACTORS IN A CASE SERIES

POSTERS: L01C. NEUROLOGICAL MANIFESTATIONS OF COVID-19

Antonio Palasi, Jesus Pizarro, Belen Gutierrez, Diana Liebana, Alejandro Ballvé, Olga Maisterra, Manuel Quintana, Paulo Gutiérrez-Rodríguez, Francesc Pujadas, Pilar Delgado
Hospital Universitari Vall d'Hebron, Unitat De Demències, Neurology Department, Barcelona, Spain

Aims: Long COVID (LC) encompasses a wide range of symptoms, with cognitive impairment (CI), fatigue and mood disorders being among the most commonly reported. Our objetives were first to describe the characteristics of the cognitive profile and the symptomatic spectrum associated with the CI in a series of LC patients. Also, an association between subjectively perceived cognitive impairment and objective neuropsychological examination scores was investigated.
Methods: Patients referred to our Dementia Unit between 2020-2022 affected by LC and CI after the COVID-19 infection were selected. Validated questionnaires were used to measure subjective cognitive complaints(MFE-30), fatigue (MFIS), and anxiety/depression symptoms (HADS). All CL symptoms were systematically collected and the patient was evaluated with a neuropsychological examination
Results: 39 patients were recruited for the study, with a predominance of women (66%), an average age of 56.7±10 and MMSE scores of 28.5 (26.3-29). In all patients the infection occurred before receiving the first dose of COVID-19 vaccine. The most common symptomatology associated with CI were fatigue (85.7%), respiratory symptoms (68%), pain (64.3%), and mood disorders (57%). The neuropsychological scores were on average within normal values. However, for attentional, executive (phonetic fluency and cognitive flexibility) and short-and long-term memory were at the low limit. Patients with dizziness were significantly associated with higher subjective CI and mood disorders scores, while those with brain fog with more severe fatigue. There was no association between subjective CI and neuropsychological scores.
Conclusions: CI in LC patients is commonly associated with a wide variety of symptoms. The neuropsychological profile, although within normal limits, could suggest greater impairment of attention, executive and memory functions. In our series, there was no association between the subjective perception of DC and the scores of the neuropsychological tests

TRANSCUTANEOUS VAGUS NERVE STIMULATION AS A TREATMENT FOR LONG COVID IN FEMALE PATIENTS: A PILOT STUDY

POSTERS: L01C. NEUROLOGICAL MANIFESTATIONS OF COVID-19

Amy Zheng, Benjamin Zhang, Niko Fullmer, Caroline Schnakers, Emily Rosario
Casa Colina Hospital and Centers for Healthcare, Casa Colina Research Institute, Pomona, United States of America

Aims: Long COVID, a post-viral illness affecting 10-30% of COVID-19 patients, presents a wide range of symptoms that persist for months, impacting multiple organs. This condition disproportionately affects female patients and those with pre-existing anxiety/depression, which are also more prevalent in females. The vagus nerve, an essential component of the parasympathetic nervous system, has been implicated in a variety of physiological and neuropsychological functions. In this pilot study, we aimed to explore the potential therapeutic effects of non-invasive transcutaneous vagus nerve stimulation (tVNS) on some of the most common long COVID symptoms.
Methods: 24 female long-haulers underwent 10 daily tVNS sessions remotely, lasting one hour each day. The primary outcome measure was cognition (NIH toolbox), with anxiety, depression, sleep, and fatigue as secondary outcome measures. Assessments occurred at three timepoints: pre-intervention, post-intervention, and 1-month follow-up.
Results: The study found significant pre- to post-intervention improvements with moderate to large effect sizes across all the domains, except for fatigue. Notably, when comparing one-month follow-up data with pre-intervention data, we observed significant improvements across all five domains, including fatigue.
Conclusions: Despite the encouraging results of this pilot study, further research is needed to confirm these findings, investigate the long-term effects of tVNS, and explore the underlying mechanisms responsible for the observed improvements. Moreover, future studies should consider larger samples and the use of control groups to validate the effectiveness of tVNS.

POST COVID NEUROLOGICAL SEQUELAE

POSTERS: L01C. NEUROLOGICAL MANIFESTATIONS OF COVID-19

Maria Roberta Vazzana[1], Antonia Nucera[2], Michela Papa[3]
[1]grande ospedale metropolitano, Urgency Medicine (mcae), reggio di calabria, Italy, [2]f. spaziani hospital, Urgency Medicine, frosinone, Italy, [3]moscati asl ce, General Medicine, aversa, Italy

Aims: Introduction:The World Health Organization declared the coronavirus a global health emergency because of its rapidly transmissible nature,increasing mortality rate.Long-term sequelae of SARS-Cov-2 infection have become increasingly recognized and need and huge effort to prevent and care.
Methods: We set up a 3 months follow-up of 160 patients,82 women and 78 men,admitted in the Emergency-Medicine-Covid from october 2020 to march 2021.The mean age was 60. Asthenia,fever,cough,myalgia,headache,anosmia,ageusia are the most common primary symptoms.
Results: All the patients performed blood-test,neuroimaging,respiratory and neurological assessment.We noticed a decrease in the laboratory findings inflammatory response.The Chest Ct showed that 70 patients had significant pulmonary fibrosis.80 patients had a neuropsychological conseguences associated with depression,sleep impairment,anxiety,loss of memory and concentration,ageusia,anosmia,headache and asthenia.Patients with pre-existent disease experiencied a worsening,especially those with cognitive decline.
Conclusions: Conclusion:Currently,as we are still experiencing the pandemic and its effects,it is too early to describe the full clinical picture of post-covid syndrome.We need for more long-term clinical follow-up data to prevent long-term sequelae and post-covid Neurological Syndromes.We need ongoing neurological cognitive and affective monitoring of all cases of Covid-19 to formulate relevant prevention and intervention strategies.Finally,the economic impact of this disorder,together with patient care,must be worked out in advance.

NEUROLOGICAL INVOLVENT IN COVID-19 INFECTION,DATA FROM A SMALL COMMUNITY HOSPITAL

POSTERS: L01E. CNS INVASION OF SARS-COV2

Maria Roberta Vazzana[1], Antonia Nucera[2], Michela Papa[3]
[1]grande ospedale metropolitano, Urgency Medicine (mcae), reggio di calabria, Italy, [2]f. spaziani hospital, Urgency Medicine, frosinone, Italy, [3]moscati asl ce, General Medicine, aversa, Italy

Aims: Introduction:A comprehensive review of the neurological disorders reported during the current COVID-19 pandemic demonstrates that infection affects the central nervous system,the peripheral nervous system and the muscle.
Methods: In this retrospective,observational study,we enrolled 748 patients,with laboratory confirmed diagnosis of severe acute respiratory syndrome from coronavirus infection.Data were collected from march to may 2020 and from october to april 2021and were estracted from electronic medical records.Neurological symptoms included central nervous system headache, dizziness,impaired consciousness,acute cerebrovascular disease,and epilepsy, peripheral nervous system symptoms ,hypogeusia,hyposmia,hypopsia,and neuralgia,and skeletal muscle injury.Data of all neurological symptoms were checked by a multidisciplinary team .
Results: Of 814 patients admitted to the Urgency Medicine ward 284 were severe and 530 were nonsevere patients.Severe patients were older,and showed less typical symptoms.633patients had neurologic manifestations hypoageusia,hyposmia,neuralgia,headache,29 patients had stroke,2 Myastenic syndrome,2 Guillaime Barre,1 encefhalitis.
Conclusions: Conclusion:The SARS-CoV-2 pandemic has implications for all areas of medicine.SARS-CoV-2 infection is associated with an increased incidence of neurological manifestations .Involvement of the nervous system carries a poor prognosis.The pathobiology of these neuroinvasive viruses is still incompletely known, and it is therefore important to explore the impact of CoV infections on the nervous system.

TITLE: "LONG COVID EXACERBATES VASCULAR DEMENTIA VIA ENDOTHELIAL INFLAMMATION"

POSTERS: L01D. COMORBIDITY OF NEURODEGENERATION WITH COVID-19

Grant Talkington[1], Gregory Bix[1], Saifudeen Ismael[2]
[1]Tulane University School of Medicine, New Orleans, LA 70112, United States., Clinical Neuroscience Research Center, Department Of Neurosurgery,, New Orleans, United States of America, [2]1. Clinical Neuroscience Research Center, Department of Neurosurgery, Tulane University School of Medicine, New Orleans, LA 70112, United States., Neuro Surgery, New Orleans, United States of America

Aims: Vascular dementia (VaD), the second most common cause of dementia, is characterized by cognitive decline due to reduced cerebral blood flow and blood brain barrier disruption. Current evidence demonstrates that not only are VaD patients at higher risk of severe COVID-19 illness and mortality, but also that pre-existing cognitive dysfunction/dementia is associated with increased COVID-19 incidence. Conversely, SARS-CoV-2 infection alone worsens dementia-related mild cognitive impairment (MCI) and increases risk of cognitive decline, supported by similar fMRI findings demonstrating hypoperfusion. Therefore, we hypothesize that both vascular dementia and long COVID bear a common vascular mechanism.
Methods: To investigate, we conducted a chronic-phase COVID-19 study utilizing an innovative non-transgenic mouse model with Mouse Adapted 10 (MA-10) strain of SARS-CoV-2 following surgical treatment with bilateral carotid artery stenosis (BCAS) to model VaD. We inoculated 12-week-old C57 mice intranasally with 1x10^4 PFU of MA-10 and followed them to 15 days post-infection. Bulk RNA sequencing on brain tissues and analysis with Ingenuity Pathway Analysis (IPA) was performed.
Results: Bulk RNA sequencing on brain tissues and analysis with Ingenuity Pathway Analysis (IPA) revealed substantial net alterations to several signaling pathways, potentially providing critical insights into the mechanisms underpinning acute and chronic COVID-19 morbidities. Our findings confirm a significant mechanistic interaction between VaD and long COVID, suggesting that existing therapies targeting VaD may also be effective in long COVID.
Conclusions: In conclusion, our study provides compelling evidence that vascular dementia and long COVID share a common pathophysiological basis, likely rooted in vascular dysfunction via endothelial inflammation.

IDENTIFICATION OF SARS-COV2 SUSCEPTIBLE AREAS IN HUMAN BRAIN: STUDY OF VIRAL ENTRY PROTEINS

POSTERS: L01E. CNS INVASION OF SARS-COV2

Tulika Gupta
Post Graduate Institute of Medical Education and Research, Anatomy, Chandigarh, India

Aims: The Coronavirus Disease 2019 (COVID-19) is caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) which mainly targets respiratory cells. Emerging clinical evidence suggests that neurological involvement is also an important aspect of the disease and the SARS-CoV2 can directly infect neurons and glia. SARS-CoV-2 entry into a target cell requires co-expression of ACE2 (angiotensin-converting enzyme-2) and TMPRSS2 (trans membrane serine protease-2). Relevant literature on human neurological tissue is sparse and mostly focused on the olfactory areas. Therefore, the present study was carried out to map the entire brain for co-expression of afore-mentioned viral entry proteins, along with determining the age-related changes in their expression pattern.
Methods: Methods: Brain tissues samples were collected from cerebral cortex, hippocampus, basal ganglia, thalamus, hypothalamus, brain stem and cerebellum; and were divided into two groups - up to 40 years (n=10) and above 40 years (n=10). Real time PCR and Immunohistochemistry analysis was performed to check the gene and protein expressions, respectively. Finally, immunofluorescence (IF) analysis for co-expression of proteins was done using confocal microscopy.
Results: Evaluation of ACE2 and TMPRSS2 gene expression using real-time PCR indicated their presence in all the regions of the brain studied. Similarly, the Immunohistochemistry using monoclonal antibodies against ACE2 and TMPRSS2, demonstrated their presence in all regions. Cellular location of both could be studied in detail. Further, co-expression of both the proteins was observed in different regions of the brain. Age related changes were most marked in the cerebellum.
Conclusions: The expression of both these viral entry receptors suggests that normal human brain is susceptibility to SARS-CoV-2, perhaps which could be related to the cognitive and neurological impairment that occur in patients.

PROJECTIONS FOR PREVALENCE OF DEMENTIA IN 18 GEOGRAPHICALLY DISPERSED EUROPEAN COUNTRIES AND IMPACT OF PREVENTION STRATEGIES: A MARKOV MODELLING STUDY

POSTERS: L01F. EPIDEMIOLOGY OF COVID-19 IN PATIENTS WITH NEURODEGENERATIVE DISEASES

Sara Ahmadi-Abhari[1], Piotr Bandosz[2], Martin Shipley[3], Eric Brunner[3], Mika Kivimaki[3], Abbas Dehghan[1]
[1]Imperial College London, Department Of Epidemiology And Biostatistics, London, United Kingdom, [2]Medical University of Gdansk, Department Of Preventive Medicine And Education, Gdansk, Poland, [3]University College London, Department Of Epidemiology And Public Health, London, United Kingdom

Aims: Accurate projections for dementia prevalence, and estimating the impact of public-health prevention strategies, require statistical-modelling to integrate dynamic calendar-trends in incidence of cardiovascular-disease, dementia, and mortality, and incorporate the period effect of COVID-19 deaths.
Methods: Markov models were developed for Austria, Belgium, Czech Republic, Denmark, Estonia, France, Germany, Greece, Hungary, Italy, Netherlands, Poland, Portugal, Slovenia, Spain, Sweden, Switzerland, and the United Kingdom. Input data were derived from official statistics for population numbers and mortality rates, including COVID-19 deaths over 2020-2022, and from the Survey for Health, Ageing and Retirement in Europe for prevalence estimates, transition-probabilities, and calendar-trends.
Results: Among 289-Million population aged 35+, the pandemic, over 2020-2022, is estimated to have resulted in loss of 16.8M (95% Uncertainty-Interval 12.0M-21.8M) person-years of life (PYL), with 12.6M directly attributable to COVID-19 deaths, including loss of 13.2M PYL free of dementia. Estimated 9·5M (95% UI 8·7M-10·3M) persons lived with dementia in 2019 rising to 10·8M by 2035, thereafter declining to 9·7M by 2050 under continuation of previous trends, accounting for COVID-19 deaths. Demographic changes due to excess COVID-19 deaths do not have a remarkable impact on future projections for dementia prevalence. The highest age-standardised prevalence was observed in Spain and Italy, and lowest in Switzerland, Sweden, and Denmark among the studied countries. If intensified public-health efforts further shift the downward trends in dementia incidence to parallel those achieved for cardiovascular-disease, there will be 1·8M fewer cases of dementia by 2050 and19·7M fewer PYL lived with dementia.
Conclusions: Dementia prevalence is likely to rise for a decade, driven by population ageing. To reduce number of dementiapatients by a fifth, prevention strategies need to be as effective as those have been for cardiovascular-disease.

IMPACT OF THE COVID-19 PANDEMIC ON MORTALITY AND LOSS TO FOLLOW-UP AMONG PATIENTS WITH DEMENTIA.

POSTERS: L01F. EPIDEMIOLOGY OF COVID-19 IN PATIENTS WITH NEURODEGENERATIVE DISEASES

Hojin Choi[1], Hyuk Sung Kwon[2], Seung Hyun Kim[3], Kee Hyung Park[4]
[1]Hanyang University College of Medicine, Guri Hospital, Neurology, Guri, Korea, Republic of, [2]College of Medicine, Hanyang University, Neurology, Guri, Korea, Republic of, [3]College of Medicine, Hanyang University, Neurology, Seoul, Korea, Republic of, [4]College of Medicine, Gachon University Gil Medical Center, Incheon, Korea, Neurology, Incheon, Korea, Republic of

Aims: The coronavirus disease 2019 (COVID-19) pandemic, which began to escalate rapidly in South Korea in February 2020, has profoundly impacted healthcare, especially for vulnerable groups such as patients with dementia. We examined changes in mortality and loss to follow-up in patients with dementia using data from the Korean National Health Insurance Services research database.
Methods: Patients with dementia who visited a medical institution with a recorded dementia-related diagnostic code including Alzheimer's disease and received anti-dementia medication between February 2018 and January 2020 were included in this study. We divided the participants into two cohorts: those newly diagnosed with dementia between February 2018 and January 2019 (n = 62,631) and those diagnosed between February 2019 and January 2020 (n = 54,494). We then followed their records for a year, until January 2020 and January 2021.
Results: There was a significant increase in follow-up loss among patients newly diagnosed with dementia during the COVID-19 outbreak; the rate rose from 42.04% in 2019 to 45.89% in 2020. Conversely, we observed no significant change in mortality rates before and after the onset of the pandemic in February 2020. Female sex, younger age, fewer comorbidities, diagnosis of dementia at the Department of Neurology or Psychiatry, and high income were associated with decreased follow-up loss and mortality. Living in metropolitan areas was associated with a decreased follow-up loss.
Conclusions: This study highlights the importance of providing extra attention to dementia patients, particularly in pandemic situations, given their increased risk of losing follow-up.

Aims: To compare the receipt of dementia diagnosis and drugs between pre-, during and post-COVID-19 pandemic periods.
Methods: This observational study employed data of persons with dementia (PWD) registered in the Swedish registry for cognitive/dementia disorders - SveDem (2019-2022). Time of dementia diagnosis was divided into: pre- (2019-Jan-01 - 2020-Feb-29), during (2020-Mar-01 - 2020-Dec-31) and post-COVID-19 pandemic (2021-Jan-01 - 2022-May-01). Outcomes included the basic diagnostic work-up, as is recommended by the Swedish Board of Health and Welfare, individual diagnostic tests and the use of drugs.
Results: There were 19,813 PWD selected for analysis: the pre-pandemic period (n = 8335, 42.1%), during pandemic period (n = 4149, 20.9%) and the post-pandemic period (n = 7329, 37.0%). More than 50% of PWD were living alone at dementia diagnosis in three periods. Compared to the pre-pandemic group, the during pandemic group was less likely to receive lumbar puncture (OR 0.89, 95% CI 0.80 – 0.99), neuropsychological assessment (OR 0.81, 95% CI 0.73 – 0.91), but more likely to get occupational therapy assessment (OR 1.11, 95% CI 1.03 – 1.20). The post-pandemic group had higher likelihood of receiving the basic diagnostic work-up (OR 1.14, 95% CI 1.01 – 1.29), blood analysis (OR 1.88, 95% CI 1.44 – 2.49), CT – MRI (OR 1.22, 95% CI 1.01 – 1.48) and occupational therapy assessment (OR 1.13, 95% CI 1.04 – 1.22). The use of cholinesterase inhibitors and memantine was not different between these periods.
Conclusions: Compared to the pre-pandemic period, chances of receiving the basic diagnostic work-up, blood analysis and CT-MRI were not different during the pandemic, but higher in the post-pandemic period. The prescription of anti-dementia drugs was not different between periods.
