Background

- The association of **immune checkpoint inhibitors (ICI)** with **chemotherapy (I-ChT)** has been shown to be more effective than chemotherapy (ChT) alone for patients with various solid tumours, thus becoming a standard treatment option in multiple settings (1).
- It remains to be determined whether a detrimental interaction between ChT-induced myelotoxicity (2) and ICI-immune-mediated cytopenias (3) occurs, with the potential for **I-ChT to elicit a worse hematologic toxicity profile than ChT alone**.
- In this sense, the aim of this systematic review and meta-analysis is to address this question.

Methods & Objectives

- The **primary objective** was to assess whether I-ChT compared to ChT alone increases the odds of **all-grade (G) anemia, neutropenia, febrile neutropenia (FN) and thrombocytopenia**.
- The **secondary objective** was to assess whether I-ChT compared to ChT alone increases the odds of the same cytopenias grouped by grades (**G1-2, G3-4, and G5**).
- A systematic review using MEDLINE, Cochrane, and conference proceedings (manual selection of studies presented at ASCO and ESMO annual congresses) up to 5 June 2020, with restriction to English language, was performed in accordance with PRISMA guidelines (4).
- All randomized clinical trials comparing I-ChT vs. ChT alone in patients with solid tumors, reporting hematologic toxicities, were selected.
- Subgroup analysis according to **class of ICI (anti-PD(L)1: pembrolizumab, durvalumab, atezolizumab; anti-CTLA4: ipilimumab)**, and a **sensitivity analysis excluding trials with a different number of cycles of ChT between arms** were done.
- Pooled odds ratios (pOR) with 95% confidence intervals (95% CI) were calculated using **random effect models**.
- Heterogeneity was assessed with the I² test (substantial heterogeneity whenever I²≥50%).
- Publication bias was ascertained by visual inspection of funnel plots.
- All reported p-values are two-sided, with significance set at p<0.05.

Results

- Following the retrieval of 10201 studies, **19 publications (14 testing an anti-PD(L)1-based I-ChT and 5 an anti-CTLA4-based I-ChT)** were included, with 5254 patients in the I-ChT group and 4316 patients in the ChT alone group (**Table 1**).
- Table 2** shows the pooled incidences per I-ChT and ChT alone groups of all-G anemia, neutropenia, FN, and thrombocytopenia.
- There was neither a significant increase in the odds of **all-G anemia (pOR=1.04; 95% CI=0.90-1.21)(Fig. A), neutropenia (pOR=1.01; 95% CI=0.87-1.16)(Fig. B), FN (pOR=1.24; 95% CI=0.97-1.58)(Fig. C), and thrombocytopenia (pOR=1.14; 95% CI=1.00-1.30)(Fig. D)(Table 2)**, nor by groups of G (data not shown).
- An **increment** in the odds of **all-G thrombocytopenia** was found with **anti-PD(L)1-based I-ChT vs. ChT alone (pOR=1.18; 95% CI=1.02-1.36; p=0.03)(Fig. D)**.
- Results were **similar** in the **sensitivity analysis** (all-G anemia pOR: 1.12 [95% CI, 0.95-1.31]; all-G neutropenia pOR: 1.03 [95% CI, 0.85-1.24]; all-G FN pOR: 1.20 [95% CI, 0.95-1.52]; all-G thrombocytopenia pOR: 1.17 [95% CI, 1.00-1.38] with anti-PD(L)1 subgroup pOR: 1.21 [95% CI, 1.02-1.44]).
- Symmetric funnel plots of hematologic endpoints indicates a **low risk of publication bias** (Figs. E-H).
