A Rare Case of Non–Hodgkin’s Lymphoma of the Appendix
Case Report

- 61 year old woman
- History of gastrointestinal NHL of the stomach 2006, R-CHOP to complete remission
- Eight years later reported 6 month history dull RIF pain, flu like symptoms
- Routine blood panel unremarkable
- Raised LDH levels at 236 units/l (120-220 IU/l)
- Elevated beta2 microglobulins were elevated at 5.7mg/l (1.2-2.4 mg/l)
- Anti TTG negative
- Staging CT PET demonstrated increased fluorodeoxyglucose (FDG) uptake at the appendix (SUV max 31) and mild uptake at fundus of stomach
Axial (A) and coronal (B) images from PET CT. Markedly abnormal FDG activity (SUV max 31) within the appendix and caecum.
Investigations

- Gastroscopy normal
- Colonoscopy revealed abnormal swelling of the ileocecal valve
- Biopsies normal
- Discussed at MDM
- Decision made to proceed to appendectomy
Diffuse Large B Cell of the Appendix. The appendix wall showed a transmural infiltrate (A) of intermediate to large atypical cells (B). The neoplastic cells were positive for CD45 and CD20, while CD3 and CD5 highlighted a background population of T cells, confirming a Diffuse Large B Cell lymphoma (C). The neoplastic cells stained with BCL6, consistent with germinal centre B-cell like cells (D). MIB1 demonstrated a proliferation index of 85% (C).
Diagnosis and Treatment

- Relapsed diffuse large B cell, germinal centre subtype, NHL
- Subsequent bone marrow biopsy showed one intratrabecular lymphoid aggregate with increased reticulin suspicious for involvement

- Treated with salvage RICE (Rituximab, Ifosfamide, Carboplatin, Etoposide) chemotherapy followed by autologous bone marrow transplant
- End of treatment day 100 CT PET showed a complete remission (CR)

- At her most recent follow up 9 months after CR, there was no evidence of recurrence
Axial (A) and coronal (B) images from PET CT. No evidence of FDG abnormality in PET CT post treatment.
Extranodal NHL

- One third of all NHLs
- GIT most common site (4-20% primary NHLs)
- Stomach and small bowel
- Median age of GIT NHLs 55yrs

- Incidence of primary appendiceal lymphomas estimated at 0.015% (Rao 1991)
- RIF pain, fever, vomiting – suggestive of acute appendicitis
- Can be non-specific – delays diagnosis

- Reaching the diagnosis radiologically prior to surgery is challenging
- Diagnosis often made post op

- Clinical awareness and suspicion is crucial in achieving the correct diagnosis and initiating treatment
## Literature Review

</table>
Management

- No clear guidelines
- Successfully treated with appendectomy, + limited right hemicolecotomy
- Adjunctive therapy depends on the stage of the disease and the histopathology
- Our patient treated with salvage RICE chemotherapy followed by autologous bone marrow transplant due to her suspicious bone marrow biopsy
Summary

- Rare

- Clinical awareness and suspicion is crucial in achieving the correct diagnosis and initiating treatment
