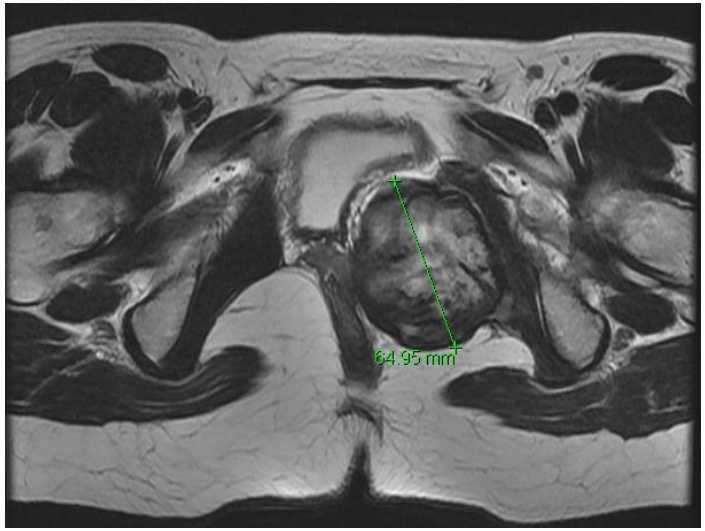
DIAGNOSIS



2.1. Biopsy

A biopsy confirming DF diagnosis is mandatory and a definitive histology should be awaited before undertaking any further treatment steps. In most cases, diagnosis of DF can be made on core needle biopsies using 14G or 16G systems; an excisional biopsy is not needed. Given the rarity of this disease, a diagnosis of DF has to be confirmed by an expert soft tissue pathologist.

Management of desmoid tumors: A nationwide survey of labeled reference center networks in France

- From 2010 to 2013, the expert pathologists of FSG confirmed the diagnosis of DT in 861 pts
- 445 pts initially diagnosed outside the referral centers, were reviewed
- Prior to the review, DT was diagnosed in 389/545 cases (71·3%)
- 156/545 cases (28·7%) had another diagnosis
- The most common misdiagnoses were:

- sarcoma in 35/156 cases (22·4%)
- GIST in 26/156 cases (16·6%)
- nodular fasciitis 20/156 cases (12·8%)
- leiomyoma 6/156 cases (3·8%)

ABSTRACT

Purpose. Surgery is still the standard treatment for desmoid-type fibromatosis (DF). Recently, the Institut Gustave Roussy (IGR), Villejuif, France, reported a series of patients treated with a front-line conservative approach (no surgery and no radiotherapy). The disease remained stable in more than half of patients. This study was designed to evaluate this approach on the natural history of the disease in a larger series of patients.

Methods. A total of 142 patients presenting to the IGR or Istituto Nazionale Tumori (INT), Milan, Italy, were initially treated using a front-line deliberately conservative policy. Their progression-free survival (PFS) was observed and a multivariate analysis was performed for major clinical variables.

Results. Seventy-four patients presented with primary tumor, 68 with recurrence. Eighty-three patients received a "wait & see" policy (W&S), whereas 59 were initially offered medical therapy (MT), mainly hormonal therapy and chemotherapy. A family history of sporadic colorectal cancer was present in 8% of patients. The 5-year PFS was 49.9% for the W&S group and 58.6% for the medically treated patients ($P = 0.3196$). Similar results emerged for primary and recurrent DF. Multivariate analysis identified no clinical variables as independent predictors of PFS. In the event of progression, all patients were subsequently managed safely.

Conclusions. A conservative policy could be a safe approach to primary and recurrent DF, which could avoid unnecessary morbidity from surgery and/or radiation therapy. Half of patients had medium-term stable disease after W&S or MT. A multidisciplinary, stepwise approach should be prospectively tested in DF.

Data were presented at the Connective Tissue Oncology Society (CTOS) 14th Annual Meeting, London, UK, November 14–17, 2008.

Desmoid-type fibromatosis (DF) is a clonal fibroblastic proliferation marked by an infiltrative growth and an inability to metastasize.[1,2] For decades, standard treatment has been complete macroscopic surgical resection. However, sizable rates of local recurrences have been reported (range 20–60% at 5 years in major retrospective studies).[3–6] Given the unpredictable outcome of the disease and the lack of metastatic potential, the aggressiveness of surgery has evolved over time. Currently, it differs from that of soft tissue sarcomas.[4–8] In fact, until 1998 the standard treatment for DF consisted of primary resection with wide margins, possibly with radiotherapy when negative margins could not be achieved or surgery would have resulted in major functional or cosmetic defects.[9] Later, function-preserving surgery was advocated for DF, with particular emphasis on limiting unnecessary morbidity.[4–6] A "wait & see" (W&S) policy alone was first proposed for recurrent but stable lesions.[10] An initial period of observation also was considered for unresectable primary tumors.[11] Furthermore, DF may respond to chemotherapy or other systemic treatments

Evaluation of management of desmoid tumours associated with familial adenomatous polyposis in Dutch patients

MH Nieuwenhuis*[,1], EM Mathus-Vliegen[2], CG Baeten[3], FM Nagengast[4], J van der Bijl[5], AD van Dalsen[6], JH Kleibeuker[7], E Dekker[2], AM Langers[8], J Vecht[9], FT Peters[7], R van Dam[3], WG van Gemert[3], WN Stuifbergen[10], WR Schouten[11], H Gelderblom[12] and HFA Vasen[1,8]

BACKGROUND: The optimal treatment of desmoid tumours is controversial. We evaluated desmoid management in Dutch familial adenomatous polyposis (FAP) patients.

METHODS: Seventy-eight FAP patients with desmoids were identified from the Dutch Polyposis Registry. Data on desmoid morphology, management, and outcome were analysed retrospectively. Progression-free survival (PFS) rates and final outcome were compared for surgical *vs* non-surgical treatment, for intra-abdominal and extra-abdominal desmoids separately. Also, pharmacological treatment was evaluated for all desmoids.

RESULTS: Median follow-up was 8 years. For intra-abdominal desmoids ($n = 62$), PFS rates at 10 years of follow-up were comparable after surgical and non-surgical treatment (33% and 49%, respectively, $P = 0.163$). None of these desmoids could be removed entirely. Eventually, one fifth died from desmoid disease. Most extra-abdominal and abdominal wall desmoids were treated surgically with a PFS rate of 63% and no deaths from desmoid disease. Comparison between NSAID and anti-estrogen treatment showed comparable outcomes. Four of the 10 patients who received chemotherapy had stabilisation of tumour growth, all after doxorubicin combination therapy.

CONCLUSION: For intra-abdominal desmoids, a conservative approach and surgery showed comparable outcomes. For extra-abdominal and abdominal wall desmoids, surgery seemed appropriate. Different pharmacological therapies showed comparable outcomes. If chemotherapy was given for progressively growing intra-abdominal desmoids, most favourable outcomes occurred after combinations including doxorubicin.

Medical options

- Non-steroidal anti-inflammatory drugs (Sulindac, Meloxicam…)

  COX-2 partially regulates proliferation because of beta-catenin stabilization in AF. COX-blocking agents results in reduced proliferation.

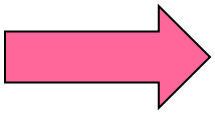
- Hormone therapy (Tamoxifen, Toremifene, Gn-RH analogues)

  Antiestrogen treatment could be mediated by estrogen receptor (ER) beta (Deyrup AT et al. Cancer. 2006)

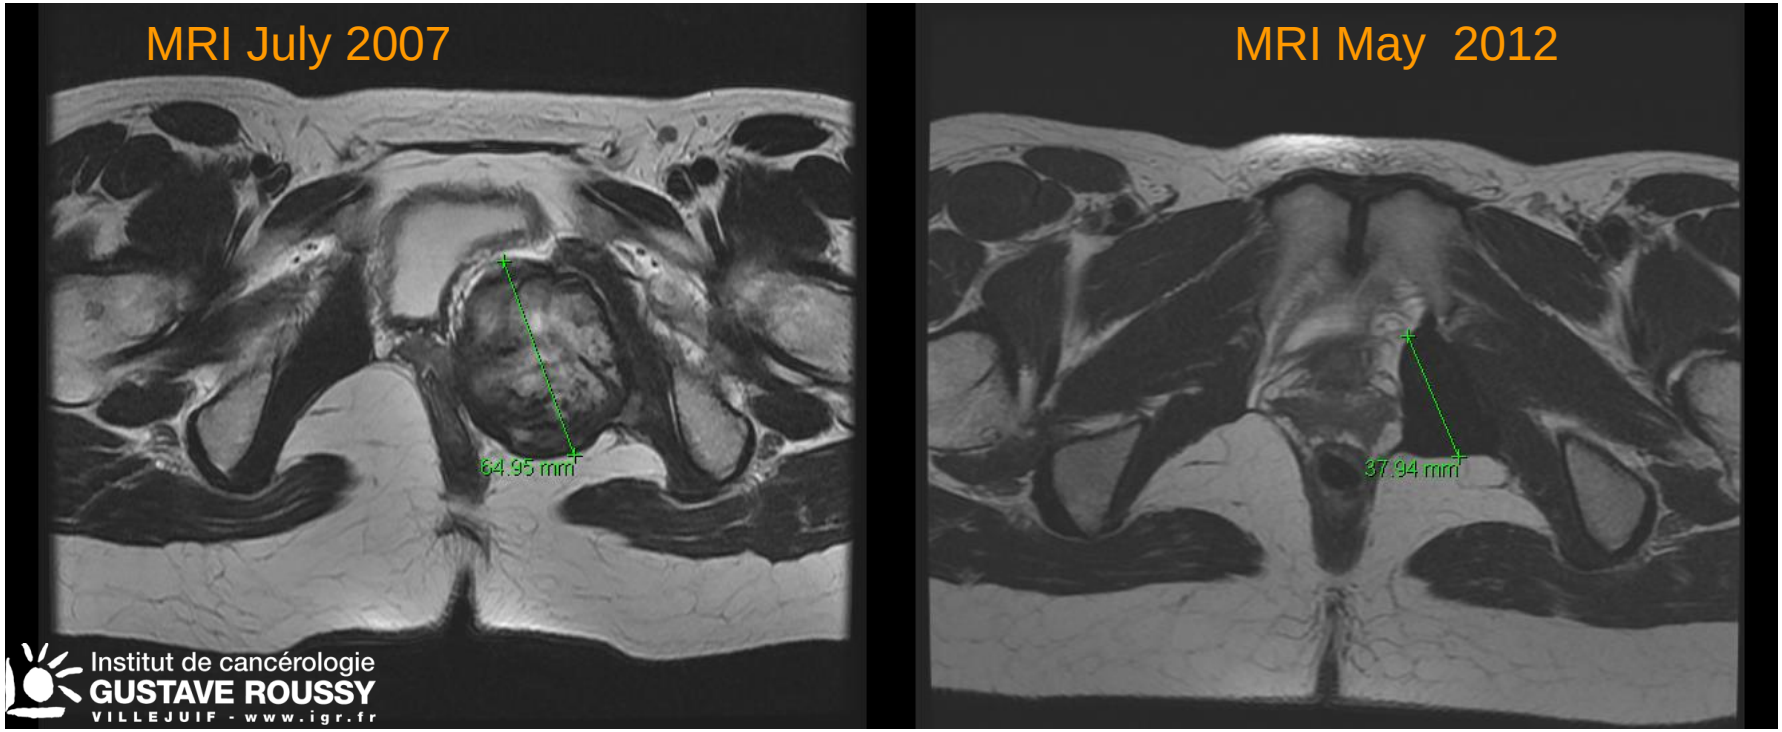
- Tyrosine kinase inhibitors

- Interferon

- Chemotherapy (single or multiple agents):
  - Vinca alkaloid (Vinblastine or Vinorelbine) + MTX
  - Anthracycline alone or in association (Doxo, liposomal Doxo, Doxo + Dacarbazine)



No randomized trial



34 years old female: post partum
Percutaneous biopsy: Desmoid
Tamoxifen and agonist LHRH: 18 months

- The surgery would have been mutilating
- The radiation source of sequelae in this young patient

ABSTRACT

Background: Desmoid tumours are rare neoplasms characterised by clonal proliferation of myofibroblasts that do not metastasise, but often exhibit an infiltrative pattern and functional impairment. When desmoids arise in the intestinal mesentery, surgical resection is seldom possible without life-altering loss of intestinal function.
Methods: Retrospective review of the clinical management of 52 consecutive patients treated for desmoids of the intestinal mesentery from January 2001 to August 2006. A multidisciplinary treatment plan was developed based on primary disease extent, tumour behaviour and resectability. Patients with stable but unresectable disease were observed without treatment. Patients with resectable disease underwent surgery, and patients with unresectable progressing disease received chemotherapy, most commonly liposomal doxorubicin, followed by surgery if chemotherapy rendered the disease resectable.
Results: At a median follow-up of 50.0 months (range 4.6–212), 50 patients (96%) have either no recurrence or radiographically stable disease. No patient requires total parenteral nutrition.
Conclusion: These data indicate that the extent of disease, tumour behaviour and resectability are the important factors when defining a treatment plan for mesenteric desmoid tumours. A multidisciplinary approach of surgery combined with chemotherapy is an effective and function-sparing strategy for managing this disease.

1. Background and aims

Desmoid tumours, also known as desmoid fibromatoses, are uncommon soft tissue neoplasms. Although they do not metastasise, desmoids often exhibit an infiltrative pattern of spread in an abundant collagen matrix, giving them a dense, fibrotic character.[1] As a result, these tumours can produce local tissue destruction leading to significant morbidity and

Surgery versus radiation therapy for patients with aggressive fibromatosis or desmoid tumors
A comparative review of 22 articles

1983 1998	Surgery + RT			RT alone
Local Control rate	Margins			
	-	+	overall	
	94%	75%	75%	78%

- RT alone or S + RT results in significantly better local control than S alone
- When radiotherapy is expected feasable and necessary, why to operate the patient if RT alone seems equivalent to S+RT??

Conclusions

- Aggressive treatments that take their indications from retrospective studies should be re evaluated in the light of new data

- Observation alone could be considered for primary tumors
  - In case of diagnosis certitude (biopsy)
  - located such that progression would not cause significant morbidity
  - Surgery is not the best treatment of pain

- In cases of RECIST progression, treatment is tailored according to age, gender, location, symptoms…in specialized team
